"This solution discloses an entirely different purpose in calling the fish, namely the desire of every fisherman, that the fish will swim into his trap, net, or weir. Thus the text becomes meaningful if we imagine the fisherman reciting, or better singing, the text, while he places his trap in the river and waits for his catch. In this case the 'house' would actually turn out to be a metaphor for a weir, and the description of it as an attractive house simply serves the purpose of trapping the fish. The concluding section, according to which the fish, by entering the 'house,' will be safe from the birds of prey, is of course ambiguous. If the fish hurries into the weir, it will indeed escape the birds, but be caught by the fisherman instead.

" Considering this, we must conclude that the interpretation of Nanše as a protector of the

fish … is to be revised. To all appearances Nanše, just because the fish belong to her, is the protector and helper of the fisherman, or maybe a fisherman herself."

Samuel Noah Kramer (1897- 1990) was one of the world's leading Assyriologists and a world-renowned expert in Sumerian history and Sumerian language. The title of this essay is "Sumer: The Home of the First Aquarium?" with a question mark because Kramer published a book in 1981 titled "History Begins at Sumer, Thirty-Nine Firsts in Recorded History" in which he includes the invention of the aquarium as one of the firsts. However, Kramer does not comment on Civil's or Thomsen's interpretations but simply takes the literal point of view that the poem describes an unnamed individual who provided food and housing for fishes, which he held in high esteem. So, which of these three expert's interpretation should we adopt?

The Civil and Thomsen versions both rely upon assumptions. In the case of Civil he assumes that the author is a god or goddess (he suggests Nanše, a water and fishing goddess) and that Nanše is protecting the fish in her charge. However, there is nothing in the text that refers to any deity as the author. Although Nanše is mentioned it is in the third person, so she cannot be the author. Thomsen's assumption is a real jump as she suggests that all the protection mentioned in the text is nothing more than a series of fish traps, just the opposite of what the text relates. What is left then is Kramer's interpretation, which is to take the text at its face value, sans conjectures that require a leap of faith and which cannot be proven. Considering the fact that Kramer's reputation far exceeds that of the other two, this text then is a record of the first aquarium and, perforce, the first aquarist.

"THE FROG DOES NOT DRINK UP THE POND IN WHICH IT LIVES"—INCAN PROVERB

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Post, March 22, 2016)

In Andean belief, Titicaca is the birthplace of the sun. In addition, it's the largest lake in South America and the highest navigable body of water in the world. The lake is located at the northern end of the Altiplano basin high in the Andes on the border of Peru and Bolivia. The western part of the lake lies within the Puno Region of Peru, and the eastern side is located in the Bolivian La Paz Department. Although the region is considered in the tropics, Titicaca's cold water sends a chill through the body upon touch. The cold sources and winds over the lake give it an average surface temperature of 50 to 57 °F. In the winter (June – September), mixing occurs with the deeper waters, which are always between 50 to 52 °F.

Lake Titicaca is home to more than 530 aquatic species, about 90% of them being endemic. This region has given rise to complexes of endemic cyprinodontids, totaling perhaps 43 species, largely in the genus *Orestias*.

The islands in Lake Titicaca may be mistaken for natural ones, but rather are rafts woven of totora reeds. The rafts are littered with houses for the

Aymara women prepare a meal of freshly caught killifish on a floating reed island in Lake Titicaca. (David Wallace, The Arizona Republic.)

indigenous people, the Aymara, who live on the water and rely upon the lake's fish to survive. Their ancestors lived in the region for many centuries before becoming a subject people of the Inca in the late 15th or early 16th century, and later of the Spanish in the 16th century. The Aymara eat their karachi - their name for the Orestias species - like potato chips; fried to a crisp they crunch just like them. At lunchtime, these fish fill ceramic bowls that are passed around to everyone who lives on their floating island.

The Aymara face a problem familiar to those in other parts of the world: invasive species have fundamentally changed the balance of Lake Titicaca. Unfortunately, habitat destruction, pollution from mining, and introduced species has led to major declines. The umanto, *O. cuvieri*, the world's largest killifish at 10.6 inches, is probably extinct. The Peruvian government has listed 6 other *Orestias* species as Critically Endangered and another 13 as Vulnerable. Here, the invader is the rainbow trout.

This three million-year-old lake has changed dramatically in the last century, changes that were predicted by an 1872 British expedition. These explorers described 20 unique fish: one species of catfish and 19 Orestias. Their report concluded that since all of the fish were small, the lake was unproductive. However, Samuel Garman, an ichthyologist well-known to killifish aquarists, described the lake four years later (in A. Agassiz and S.W. Garman, "Exploration of Lake Titicaca," *Bull. Mus. Comp. Zool*., 3, 276-278) as an opportunity. He wrote: "A more inviting opportunity for a grand experiment in fish-culture can hardly be imagined than is offered here in the extensive sheet of pure water with its numerous mountain streams, complete isolation, abundance of vegetation, and vast number of animals."

Fast forward now to 1935, some 63 years after the expedition, when Peruvian and Bolivian officials met and decided that they should consider introducing supplemental fish to the lake they shared. They felt the karachi were not a sufficient food source to sustain the local population. The United States Bureau of Fisheries (the United States Commission of Fish and Fisheries was created in 1871 to investigate, promote, and preserve the fisheries of the United States; in 1903, it was reorganized as the United States Bureau of Fisheries which operated until 1940) was asked to conduct a study of Titicaca, and Milton C. James, the Assistant Chief of Fish Culture, was assigned the task. Sigh! The lake would never be the same.

A subsistence fisherman navigates his boat while fishing in Lake Titicaca in March. The many dozens of native karachi he catches in his nets in one day of fishing will feed his family for an entire week. (David Wallace, The Arizona Republic.)

A trout farm is seen in the middle of Lake Titicaca. North American trout were introduced into Lake Titicaca in the 1930s and have had a negative effect on the native killifish. (David Wallace, The Arizona Republic.)

After only a month of research, James decided upon a number of species that could be suitable for the South American great lake. The rainbow trout is one of the most widely introduced of fishes and may be regarded as global in its present distribution although, in the tropics it is only established at altitudes above about 4,000 feet. The first introductions of rainbow trout were for sporting purposes but its adoption for aquaculture led to an accelerated spread in the 1950's. Furthermore, although introduced for angling, many host countries subsequently expanded the distribution of the species for culture. It is now one of the main species cultured in temperate zones and at higher altitudes in the tropics.

The first round of transplants - lake trout fingerlings - arrived at the lake from North America in 1938. Compared with the tiny karachi, trout were a substantial source of protein swimming through the lake's waters. It was intended that the trout would stimulate a commercial fishery and add an additional food source for the people of the region. However, trout became the top predator in the lake. Suddenly many karachi were consumed by larger fish and the ones that weren't eaten had to compete with trout for food. Ironically, some 30 years later, Michigan was on the receiving end of fish importation when it introduced Pacific salmon to the Great Lakes. The exotic salmon there have crowded out native species and caused their populations to plummet.

In Lake Titicaca, the trout (trucha as they are called here) explosion transformed local fishing practices. Rainbow trout have been the most successful of all North American trout introduced to Lake Titicaca. They are now caught by hook,

farmed, sold in local markets and served in restaurants in Puno alongside the local staples of quinoa, potatoes, llama, guinea pig, trout and kingfish. The kingfish, *Basilicthys bonariensis* (but locally called pejerrey), is another invasive fish. They are even more voracious hunters than trout, and their arrival in 1955 caused a decline in trout numbers. Today, trout are most commonly cultivated in floating farms on the lake.

The rainbow trout is one of the nest widely introduced of fishes and may be regarded as global in its present distribution although, in the tropics it is only established at altitudes above about 4,000 feet. First introductions of rainbow trout were for sporting purposes but its adoption for aquaculture led to an accelerated spread in the 1950's. Furthermore, although introduced for angling, many host countries subsequently expanded the distribution of the species for aquaculture. It is now one of the main species cultured in temperate zones and at higher altitudes in the tropics.

Rainbow trout have been implicated in the disappearance or decline of many small native species, through either predation or competition. They have, together with the pejerrey, been responsible for some decline in Lake Titicaca of stocks of *Orestias* and in the parasitic catfish species of *Trichomycterus*. As mentioned, *O. cuvieri* has disappeared since the introduction, and *O. pentlandii*, *Trichomycterus rivulatus* and *T. dispar* have been considerably reduced in abundance.

A trout farm in the middle of Lake Titicaca in March. Dead trout are visible, killed by choppy water in the pens. Trout, first introduced from Michigan in the 1930s, and have had a negative impact on the native killifish in Lake Titicaca. (David Wallace, The Arizona Republic.)

THE CARP FIASCO

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Post, March 22, 2016)

The law of unintended consequences, often cited but rarely defined, is that the actions of people - and especially that of government - always have effects that are unanticipated or unintended. Economists and other social scientists have heeded its power for centuries; for just as long, however, governments have largely ignored it. This was not the first blunder committed by our U.S. Fish Commissioners. Arriving in the United States during the mid-1800s, the increasing waves of immigrants could scarcely believe that this vast new land had no carp. It had been a cultivated food source, garden element and symbol of strength and courage in Asia for over 4,000 years, and similarly esteemed in Europe for nearly 2,000. Inspired by the European model (whereby the Austrian princes of Schwarzenberg maintained 20,000 acres of carp ponds), scattered entrepreneurs here began to import the prized fish, hoping to provide a familiar and profitable food staple to the rapidly growing nation. Julius A. Poppe was one of the most successful, expanding a stock of five common carp imported from Germany in 1872 into a thriving California farm by 1876. Fielding orders from throughout the country, he actively began to lobby for the national cultivation of the hearty fish:

"There ought to be one person in every county who would raise choice carp as stock fish to sell to others to fatten for their own tables. It would be a cheap but sumptuous food and at the same time very convenient, as they are ready to be eaten at all times of the year."

In the Commission's 1872-73 report, commissioner Spencer Baird noted:

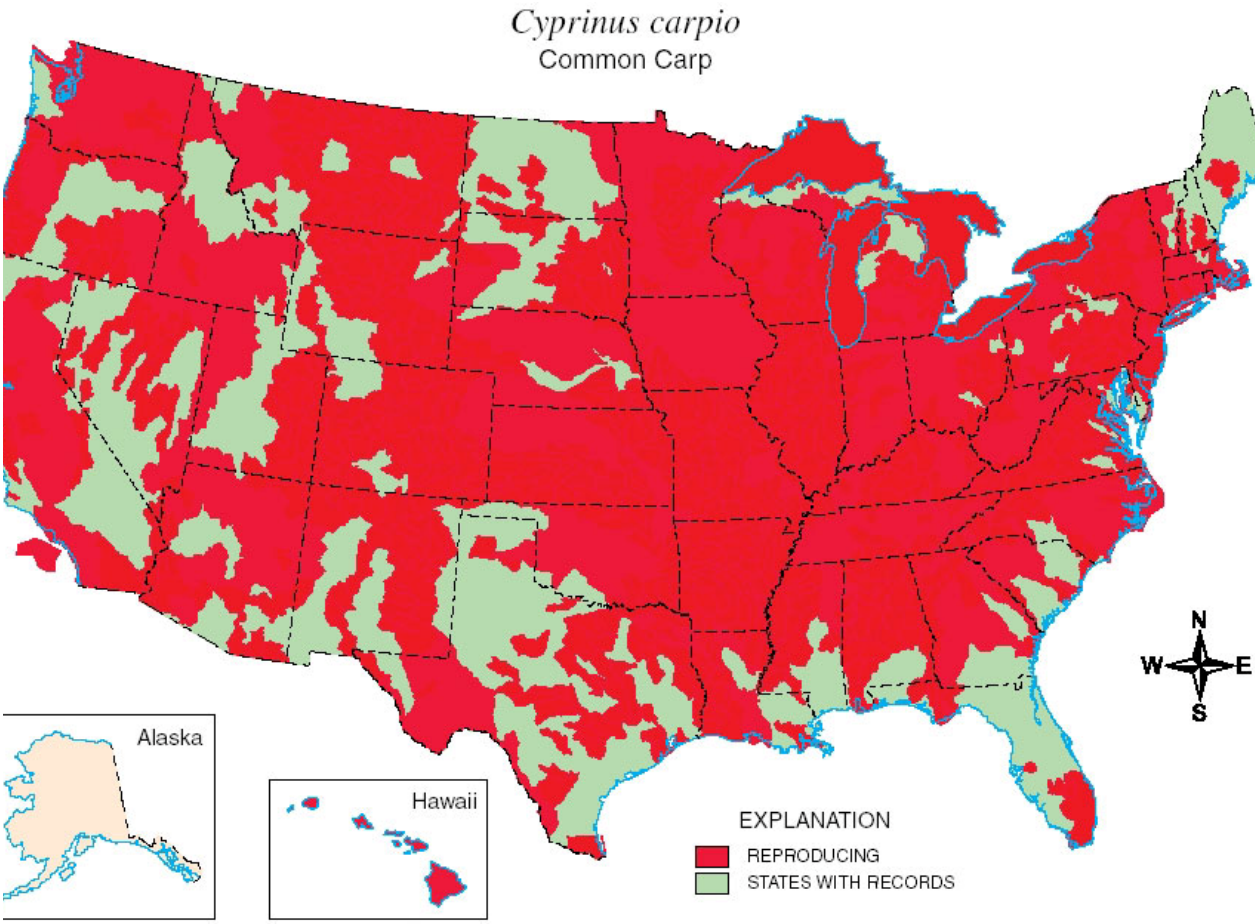
"Sufficient attention has not been paid in the United States to the introduction of the European carp as a food fish, and yet it is quite

The common Carp. This enormous freshwater fish is considered vulnerable to extinction in the wild, and yet it's also listed as one of the worst invasive species in the world. This contradiction is human-caused: It has been domesticated as a fish stock and has, either accidentally or illegally, been introduced to ponds and lakes on almost every continent in the world. The damage carp do to their new homes is extensive.

These fish were swarming in the O'shaugnessy Reservoir at the Columbus Zoo. A dad had brought a loaf of white bread, and his kids had a blast feeding these huge fish. They watched intently, thinking they were just another part of the zoo spectacle, not realizing that these fish don't live in a tank.

safe to say that there is no other species that promises so great a return in limited waters. It has the pre-eminent advantage over such fish as the black bass, trout, grayling, &c., that it is a vegetable feeder, and, although not disdaining animal matters, can thrive very well on aquatic vegetation alone. On this account it can be kept in tanks, small ponds, &c., and a very much larger weight obtained, without expense, than in the case of the other kinds indicated. It is on this account that its culture has been continued for centuries. It is also a mistake to compare the flesh with that of the ordinary cyprinidae of the United States, such as suckers, chubs, and the like, the flesh of the genuine carp (Cyprinus carpio) being firm, flaky, and in some varieties almost equal to the European trout."

Thus the U.S. Commission of Fish and Fisheries began an intensive effort of carp cultivation in 1877. In the late 1870's, Hugo Mulertt was appointed Assistant Commissioner of Fishes for the District of Southern Ohio and the surrounding area. It turned out that the area around Cincinnati was ideal for the cultivation of fishes and in a short while it became the leading producer of German carp. Subsequent efforts by state Fish Commissions had also introduced the carp to many area waters and by 1883, the fish's remark-



States color coded green represent those from which the species has been recorded at least once from natural waters within state borders. States color coded red are where there is evidence of natural reproduction in the wild. Once a nonindigenous fish establishes a reproducing population, it may persist indefinitely, becoming a permanent addition to the fauna.

able ability to live and reproduce in most every water condition allowed it to quickly infiltrate others.

By the turn of the century, the introduction of the carp was such a "success" that both public agencies and sportsmen had come to regard the fish as a nuisance. While tons of free-swimming carp were being harvested from area waters, they were not comparable in taste to either the selectively bred pool-cultivated carp of Europe or to the native game species and thus were useless as a food source. People had rushed into the venture without knowledge of the procedures involved. They ate carp during the spring spawning season, when the flesh was of poor quality. It was cooked incorrectly, without the European techniques that rendered it palatable. (I often wonder what Mulertt thought of his involvement in the carp affair.)

Their habit of eating by slurping up tidbits on the bottom of a river or pond and spitting out detritus made the water turbid. Such native predator fish as the pike had difficulty seeing prey through the haze. In feeding, carp dislodged or damaged aquatic vegetation, a food source for some waterfowl and shelter for other fishes. They could cause riverbank erosion in scouring for food. Sportsmen suspected that they were crowding out more desirable fish. By the turn of the century, the carp's reputation was in tatters.

"Some years ago the cries went up all over Michigan that the German carp be planted in our rivers," wrote the August 24, 1899 Benton Harbor Daily Palladium. "Now that we have them the lovers of game fish are wishing they could be exterminated, for it is said that they are destroying the spawn of our best river fish, and that they themselves are scarcely fit to eat. Carp are depopulating the Kalamazoo River of its best fish."

Conceding to the fish's permanence, carp removal programs began in the 1950s. None, however, were successful. Ironically, the greatest present promise for carp control hearkens back more than a century, when carp was intended to become a great renewable food source. A steady, or hopefully increasing, market for carp and carp products could today provide the prolonged check

Grass Carp (*Ctenopharyngodon idella*).

Black Carp (Mylopharyngodon piceus).

Bighead Carp (*Hypophthalmichthys nobilis*).

upon their population that State removal programs have been unable to due to limited resources.

Unfortunately, we now have another carp problem. Asian carp - there are many types but usually only the grass (*Ctenopharyngodon idella*), black (*Mylopharyngodon piceus*), silver (*Hypophthalmichthys molitrix*), and bighead carp (*Hypophthalmichthys nobilis*) are meant by the term - were introduced into Southern fish farm ponds in the 1970s and quickly spread across the United States. Asian carp are fast-growing, aggressive and adaptable fish that are outcompeting native fish species for food and habitat in much of the mid-section of the United States. They are now on the verge of invading the Great Lakes.----

ADDENDUM
(Lingua in maxillam or "tongue in cheek")

There are other ways to solve the carp problem, although it would involve digging large holes in city neighborhoods and filling them with water. For example, a wide sinkhole in East Detroit was the result of a utility job done years ago by the energy company DTE Energy, according to Gregory Eno, a spokesman for the Detroit Water and Sewerage Department. Left unrepaired for nearly four years it has recently been turned into a fishing pond. Neighbors were tired of dealing with the hole, so they decided to turn it into something they could enjoy. They've added blue gills, goldfish and also carp. "We like our fish, but honestly we'd like the road fixed," they said.

DTE Energy told ABC News,

"While we are still investigating how the damage occurred on Hull Street, we are working collaboratively with the city to make sure the road is repaired and safe for the residents who live in the area". As for the water in the hole, it's from a leak that the Detroit Water and Sewerage Department is currently trying to track down. "We're not sure about the source of the leak, but we are currently investigating that," Eno said. "Our goal is to get it rectified, get the water shut off and the hole drained within 24 to 48 hours."

After the water is drained, what happens to the hole is up to DTE Energy, Eno said. He added that the department has reached out to those individuals who put the fish into the hole and that they are hoping they will take the fish out there. If not, the department may work with Animal Control to "safely remove the fish and relocate them to another habitat," he said. One couldn't write a better fiction story than this true one!

THE ANCIENT FISHPONDS OF HAWAII

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, April 2, 2016)

The building of fishponds in Hawaii cannot be dated precisely but ancient chants and legends indicate ponds existed in Hawaii as far back as the 14th century. In mythology, the builder of the first Hawaiian fishpond is Ku-ula-kai, "Ku of the abundance of the sea," a member of the Ku family of gods. As told in stories, Ku-ula-kai built the fishpond at Kaiwiopele in Hana on Maui. Ancient Hawaiian fishponds were noted in the 1826 journal of William Ellis, the naturalist on James Cook's third voyage (1776–1779):

"They [the Hawaiians] have numerous small lakes and ponds, frequently artificial, wherein they breed fish of various kinds, and in tolerable abundance."

The Moi or Pacific Threadfin (*Polydactylus sexfilis*) is known as the most desired fish in Hawaii. In the ancient Hawaiian days, this fish was the fish for kings where only the royalty were allowed to eat this fish, commoners caught eating the fish faced severe punishment. The fish were such an important thing to the ancient Hawaiians that they would build ponds to farm these fish and help the population grow making sure this fish would never go extinct.

The Moi (*Polydactylus sexfilis*).

A makaha or sluice gate.

Each pond had a set of sluices or gates that controlled the seawater flow and the fish available in the pond for harvesting. A grate of vertical wooden sticks built into the pond walls allowed small fish to enter from the open sea and prevented larger fish from leaving. The grate aided water circulation, fish harvesting and stocking, and silt removal. The gate was a natural location for animal or human poachers as fish swarming the entrance during high tides were easy targets. A guardhouse built on top of the fishpond wall next to the gate was where the guard stayed while guarding against poachers and attending to pond maintenance. As payment for his labor and vigilance, he was allowed to eat fish from the pond not reserved for the ruling chief. The Moli'i pond

A Moli'i sluice gate.

had five such sluices, and three of them were still in place in 1972 when the pond was listed on the National Register of Historic Places listings in Oahu. This system of harvesting ocean catch was unique to Hawaii, and does not exist within other areas of ancient Polynesia.

Moli'i, Huilua, Kahaluu and He‘eia, are the only four original Hawaiian fishponds remaining on Oahu among the 100 or so that once existed on the island. Moli’i is the only one still operational and commercially successful. It encompasses 125 acres and fish cultivated in the pond - Tilapia, Mullet and Moi - are sold to local markets. Hawaiian fishponds are unique and feature advanced forms of aquaculture found nowhere else in the world. The techniques of herding or trapping adult fish with rocks in shallow tidal areas is found elsewhere but the six styles of Hawaiian fishponds, especially the large walled ponds, were technologically advanced and efficient, as their purpose was to cultivate pua or baby fish to maturity.

The 4,000 feet wall which partitions the Moli'i pond from Kaneohe Bay dates back to the earliest Hawaiian settlement of the land, and is traditionally attributed to the Menehune of Hawaiian mythology. The Menehune are said to be a people, sometimes described as dwarfs in size, who live in the deep forests and hidden valleys of the Hawaiian Islands, far from the eyes of normal humans. were said to be superb craftspeople. Legends say that the Menehune built temples, fishponds, roads, canoes, and houses. Some of these structures that Hawaiian folklore attributed to the

The Moli'i fishpond showing present-day commercial operations.

Aerial view of the He'eia fishpond.

Menehune still exist. The craftsmanship applied in constructing the wall is similar to brickwork, in that the gaps and crevices between the stacked stones are plugged with coral and smaller rocks.

The He'eia Fishpond is a walled (kuapā) style fishpond enclosing 88 acres of brackish water. The kuapā is built on the Malauka`a fringing reef that extends from the shoreline surrounding the pond out into Kāne`ohe Bay. Built approximately 600-800 years ago by the residents of the area, the wall is possibly the longest in the island chain measuring about 1.3 miles (7,000 feet) long and forms a complete circle around the pond. This is unique as most other fishpond walls are either straight lines or half circles connecting one point of shoreline to another.

The puka or hole in the He'eia Fishpond before reconstruction.

The Pani ka Puka campaign workers lined up ready to start the job.

The wall is composed of two separate volcanic rock walls parallel to one another on the outer edges and the 8 foot area between them is filled up with mostly coral and in some places rock and dirt. This compact style of wall slows water flow, allows the pond to maintain a base water level even at the lowest tides, and forces more water to the sluice gates. He'eia Fishpond has six sluice gates – three along the seaward edge that regulate salt water input and three along He`eia stream that regulates fresh water input. It is unknown who commissioned He'eia Fishpond to be built but it likely required thousands of residents to pass and stack rocks and coral for approximately two to three years to complete the massive wall.

Pani ka Puka was a campaign to raise the $100,000 needed for the repairs as well as mobilize hundreds of volunteers in the community to

Dec. 3, 2014 Pani ka Puka Blessing Ceremony.

The completed wall with the hole repaired.

assist with the physical labor needed to fix the wall by the end of 2015. On December 12, 2015 between 7:30am and 12:30pm, nearly 2,000 people from across the street, across our island chain and even across the Pacific joined the effort to turn a vision and dream into reality. The 50-year old puka (= "hole") in He'eia Fishpond is a puka no more. The human chain line spanning 2,000 feet moved several tons of coral and rock and the final sluice gate, the latter without it ever touching the ground. This feat and outpouring of community strength on behalf of fishpond restoration has not been seen in Hawaii in over 200 years.

Putting the final touches on the sluice gate.

The finished sluice gate and guardhouse.

The He'eia Fishpond looking towards the land.

THE MYSTERY OF LADY PEN'S FISH

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, May 4, 2016)

The following entry made by Samuel Pepys in his diary on May 28, 1665 is well known among aquarium hobby historians:

"Thence home and to see my Lady Pen, where my wife and I were shown a fine rarity: of fishes kept in a glass of water, that will live so for ever; and finely marked they are, being foreign."

The "Lady Pen," it should be noted, was Margaret Penn (1622-1682), the mother of William Penn of Pennsylvania.

Aquarists have tried to pin down the fish in question, the first being William Alford Lloyd in 1876 and, much later, Cristopher Coates. Lloyd stated:

"The Chinese kept gold and silver carp for amusement long before they were introduced into Europe during the second half of the seventeenth century. It was probably some such fish as these which are alluded to by Pepys in his Diary (quoted as a motto to this pamphlet), and doubtless vegetation grew, and was encouraged to grow, in the glass and porcelain vessels in which these household pets were kept, and so constituted them in some measure as "Aquaria."

Coates, on the other hand, suggested that the fish in question was the Paradise fish, *Macropodus opercularus* and his is the view most commonly accepted. In their 1968 book, "The Goldfish," Hervey and Hems write:

"It is unlikely that these fish were goldfish, and Dr. C. W. Coates, of the New York Zoological Society, has expressed what he calls the 'educated guess' that the fish were Paradise Fish (*Macropodus opercularis*), which is finely marked in the sense that the word 'finely' would be used by a seventeenth-century writer, and which by reason of its supplementary breathing organ, would be able to live for a very long time in a small container. Certainly, at this time, goldfish were not generally known in England; for Willughby (1635-72), old Izaak Walton (1593-1683), and others do not mention them, especially, they are not mentioned by John Ray (1627-1705) in his *Synopsis Methodica Piscium*, posthumously published in 1710."

However, I would like to play Devil's Advocate and suggest a different approach to the question. We know four things from Pepys' entry:
1. The fish were foreign, i.e., not native to England;
2. There was more than one fish in the glass;
3. The fish were finely marked;
4. The fish could live in a glass of water "forever."

Let us now see which of these requirements better fits Lloyd's assessment and which better fits that of Coates.

With regard to Number 1, Hervey and Hems argue that there is no evidence that the goldfish had arrived in England at or prior to this time, placing their importation to England in the early years of

Samuel Pepys (1633-1703).

the eighteenth century or perhaps in the late seventeenth century, i.e., sometime between 1692 and 1705. The Paradise fish - one of the first ornamental fishes available to western aquarium keepers - was imported much later, in 1869, to France by Pierre Carbonnier in Paris. Hervey and Hems are in error when they state that goldfish were first imported into the Netherlands in 1753 or 1754, as I have shown in the 4th edition of my "The Toy Fish" that the Jesuit, Martinus Martini, brought 10 goldfish to Holland in 1653.

I mention this because Margaret Jasper ("Lady Pen") was the daughter of John (Jan Baptiste) and Alet Jasper. The Jaspers were wealthy Protestants in County Clair (Ireland), London and The Netherlands. Records reflect that the Jaspers traveled often between Ireland and England, maintaining homes in both countries. Margaret first married Nicasius Van der Shure, a Dutchman and a merchant from Rotterdam in the Netherlands based in County Clare. He was killed in the 1641 Irish uprising, Margaret then inheriting all of his land.

Both her father and her first husband were Dutch and it is known that she spoke Dutch as well. In London, Margaret Jasper Van der Shure, known as "the gay widow," married Capt. William Penn, who later became Admiral William Penn, in London on June 6, 1643 and brought to this marriage Irish lands valued at more than 8000 pounds. This was the very same year Martini brought the goldfish to the Netherlands. Through relatives in Holland, she could easily have received some goldfish, either from this importation, offspring from this importation or from later exportations to the Netherlands. It should be noted that Penn himself had important naval and military connections with Holland.

With regard to Numbers 2 and 3, male Paradise fish are fairly combative, harassing and attacking each other and so cannot be kept together, especially in tight quarters. Thus if Pepys saw Paradise fish then he saw only females, otherwise he would have commented on the male's impressive finnage and coloration. However, although their markings are less impressive than that of the males they do have pointed fins, at least faint vertical bars and some color. Pepys, however, comments on none of these. He uses the adverb "finely" to describe the markings of the fish but among the many meanings of this word are included "beautifully," "elegantly" and "extremely well." In other words, since it can be used to say that something is very good or impressive, the markings of goldfish can also be described in this manner. Note that in red goldfish the red scales are edged in yellow, forming very fine lines that can be vertical, horizontal or even diagonal, depending upon the light. This effect can also be observed in goldfish of lesser or different pigmentation.

With regard to Number 4, glass is from the Old English glæs which means glass or a glass vessel and Pepys' reference to glass was to the latter and not to what we consider a drinking glass today. He comments that the fish will live forever in such a container, but Pepys knew nothing about the fish in question so this bit of Pepysian hyperbole can only be explained if Pepys had been informed that the fish had been kept successfully in her household for some time before his visit.

Sir William Penn (1621-1670).

Coates - surprisingly - jumped to the conclusion that the only fish that could be kept in small quarters for long times is the Paradise fish, a fish that did not arrive in Europe until 217 years later. An anemone kept in an unaerated, unfiltered small glass jar by Sir John Graham Dalyell and several others to whom it was passed on, survived for 59 years, a much more difficult feat considering that an anemone is a marine animal.

The water must be changed in all small containers that are without filtration or aeration regardless of whether the fish kept are air-breathers or not, since a buildup of rotting food, algae or feces are health risks to the fish and the resultant cloudiness of the water detracts from seeing them, destroying the usefulness of the aquarium as an ornamentation. An example of such present-day water changes with air breathing fishes is bettas kept in small containers, whose owners change their water on a regular basis. It also should be noted that water changes do not require anything but common sense; if the water becomes cloudy, the average person will change it without any further ado. Whether a fish survives in such quarters or not depends upon the care its owner gives it, not whether it breathes atmospheric air or not.

However, just keeping a fish alive in a small container under these circumstances must have appeared as something short of a miracle in 1665, as the only such previous recorded event was that due to Jeanne Rondelet, who had kept a fish alive in the mid-1500s in a glass of water for three years, something I doubt Pepys was familiar with. There being no reason why Lady Penn's success would not continue, it is not surprising that Pepys declared her fish would live forever. In any event, if the water is changed, goldfish (or even Jeanne Rondelet's unknown fish) could, in the Pepysian sense, also live forever.

Upon reflection it can be seen that, save for the fact that the fish were foreign and that there were more than one in the glass container, Pepys' diary entry really provides no information at all as to their identification. There are many definitions for the adverb "finely" and the statement that the fish "…will live so for ever…" if true at all is as true for goldfish (or almost any other fish) as it is for the Paradise fish.

Lloyd's conjecture in 1876 that Lady Penn's fish were goldfish lost favor over the years when no evidence was unearthed to show that the goldfish had been introduced into England prior to 1655. That, and Coates' fanciful conclusion that a fish could only "live so forever" in a small glass container if it were an air breather, have been refuted in this essay.

In matters like these I tend towards the use of Ockham's razor, which states that among competing hypotheses, the one with the fewest assumptions should be selected. Although I have previously (in "The Toy Fish") raised some questions about the identification of Pepys fish being the Paradise fish, I now favor the view of William Alford Lloyd much more favorably.

When the 1641 Irish Rebellion commenced, Margaret Jasper Van der Schuren inherited all of his land. She immediately fled on to London leaving all her holdings unattended. During her absence these holdings were Confiscated and Margaret never received compensation. Later, William Penn served in the Commonwealth Navy during the English Civil War and was rewarded by Oliver Cromwell with estates in Shanagarry and Clonakilty in County Cork, Ireland. The lands were seized from Irish Catholics in retaliation for the failed Rebellion. This ruin in Shanagarry is one of those estates.

ADDENDUM I: SAMUEL PEPYS

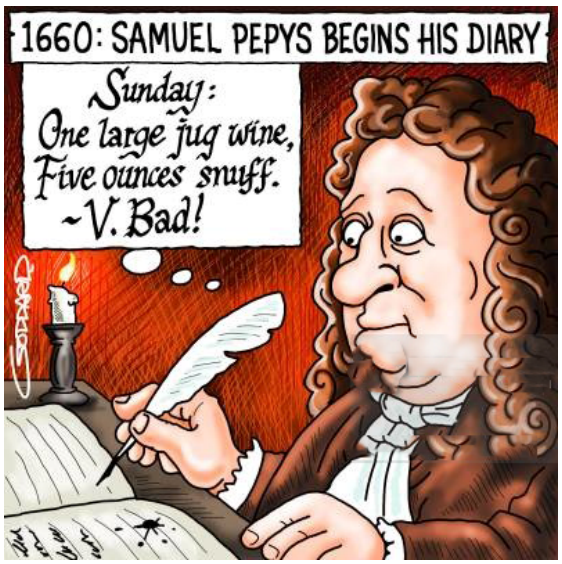
A key source for the adult life of Penn is the Diary of his next door neighbor, Samuel Pepys. Pepys (1633-1703), was an English naval administrator and Member of Parliament who is most famous for the diary he kept for a decade while still a relatively young man. Although Pepys had no maritime experience, he rose by patronage, hard work, and his talent for administration to be the Chief Secretary to the Admiralty under both King Charles II and King James II. His influence and reforms at the Admiralty were important in the early professionalization of the Royal Navy.

Penn is a figure of considerable importance in British naval history. Later, as Lord High Admiral and General at Sea for Parliament he helped to draw up the first code of tactics provided for the navy. It was the base of the "Duke of York's Sailing and Fighting Instructions," which continued for long to supply the orthodox tactical creed of the navy. He was an early proponent of fighting in line ahead, so as to bring as much firepower as possible to bear. After his death, his son, William, accepted the grant of land in the American colonies in lieu of money owed by the Crown to his father, and he named the new colony Pennsylvania in his father's memory.

Unsurprisingly, Penn appears several times in Pepys diary. Sir William Penn and Pepys were much thrown together, and were alternately very friendly and very jealous of each other. Penn frequently annoyed Pepys, both by his interference in what the latter considered his peculiar province - the governance of his office, and by his want of official aptitude. Tidiness, method, and business habits were all essentials in Pepys's eyes, and there is no evidence that Sir William Penn was at home in these departments of practical work.

Some of the many instances of Pepys's ill-humor with Penn were evidently caused by jealousy. Penn wished the Commissioners to take rank in the office in accordance with their relative social positions. Pepys was determined that he alone should be master in his own office, so that he was constantly anxious to prevent Penn from taking precedence of him.

The Earl of Sandwich was an English Infantry officer who later became an Admiral, and was killed at the Battle of Solebay, first naval battle of the Third Anglo-Dutch War; he also was the first cousin of John Pepys, the father of Samuel Pepys. When Pepys first associated with Penn, he found him sociable but cunning, but when Sandwich's jealousy of Penn began to break into the open, it did also with his protégé, Pepys, and ever after the pages of his Diary were filled with vituperation respecting this very successful admiral. The following is a typical entry:



"To the office, where the falsenesse and impertinencies of Sir W. Pen would make a man mad to think of." [April 5, 1666]

But he is referenced perhaps most vividly when we read of Penn's empting of a chamber pot, the stench of which drove Pepys off the roof of his house where, for relaxation, Pepys had installed a railing:

"At night home and up to the leads [roof]; but were, contrary to expectation, driven down again with a stinke by Sir W. Pen's emptying of a shitten pot in their house of office close by; which doth trouble me, for fear it do hereafter annoy me." [April 30, 1665]

Pepys describes his first meeting with Margaret Penn thusly:

"At noon dined at home and after dinner my wife and I to Sir W Pen's to see his lady, the first time, who was well looked, fat short old Dutch woman, but one that hath been heretofore pretty handsome, and is now very discreet and I believe hath more wit than her husband. Here we stayed talking a good while and very well please I was with the old woman at first visit." [August, 1664]

Note: Old for a woman at that time meant any age past twenty-five. Lady Penn was probably two or three years past forty.

Two years later, Pepys had changed his view of Lady Pen:

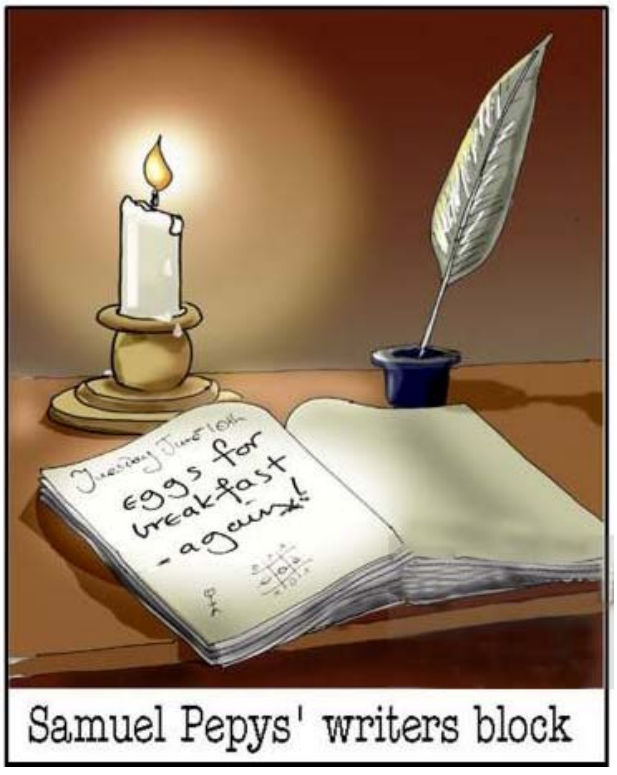
"At noon dined at home and so to my office again, and taking a turne in the garden my Lady Pen comes to me and takes me into her house…with whom I, notwithstanding all my resolution to follow business close this afternoon, did stay talking and playing the foole almost all the afternoon, and there saw two or three foolish sorry pictures of her doing, but very ridiculous compared to what my wife do. She grows mighty homely and looks old." [April 12, 1666]

Although plainly dressed the Penn newlyweds still had a capacity for high spirits. (Admiral) Penn was described by Pepys as one whose pranks included "drinking the susceptible into a stupor, singing bawdy songs and supping at midnight off bread-and-butter on the roof." Pepys found Penn "a very merry fellow" [October 9, 1660] with a wife with a similar approach to life.

Margaret has been describes as a "merry widow" and even in later age she had not lost her carefree proclivities. Pepys described one of Margaret's pranks :

"So home, vexed, and going to my Lady Batten's, there found a great many women with her, in her chamber merry, my Lady Pen and her daughter, among others; where my Lady Pen flung me down upon the bed, and herself and others, one after another, upon me, and very merry we were, and thence I home and called my wife with my Lady Pen to supper, and very merry as I could be, being vexed as I was. So home to bed" [April 12, 1665].

Two years later, however, Pepys' view of Penn and his wife changed significantly because of a notorious gossip, another neighbor and friend. Mrs. Turner was the wife of Thomas Turner, a minor official in the Navy Office. Twenty years before, when Turner was a petty naval officer, they had been intimates of Sir William's. Mrs. Turner was a middle-aged, talkative, disappointed woman, inquisitive about happenings in the Navy Building



where she, too, lived. In 1644 she had been a close (and persistent) neighbor of the Penns when, newly married, they lived in Great Tower Street in two rooms "one over another." Twenty years later, she held a strong grudge against Sir William and Lady Penn, mainly for benefits forgotten and for Sir William's success. Her gossip was constant and colored and malicious. Endlessly, she picked up trifles to the discredit of the Penns and unfortunately, Pepys listened to her.

"Then we fell to talk of Sir W. Pen, and his family and rise. She [Mrs. Turner] says that he was a pityfull [fellow] when she first knew them; that his lady was one of the sourest, dirty women, that ever she saw… she brought my Lady, who then was a dirty slattern, with her stockings hanging about her heels, so that afterwards the people of the whole Hill did say that Mrs. Turner had made Mrs. Pen a gentlewoman… and that in short his rise hath been his giving of large bribes…" [May 21, 1667]

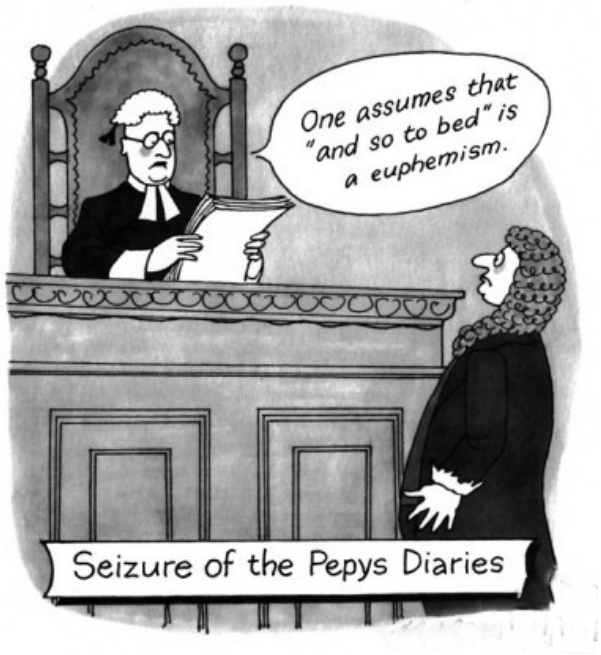
Pepys set down Mrs. Turner's talk as all true, facts and feeling. "Upon the whole, she told me stories enough to con-firm me that he [Sir William] is the most false fellow that ever was born of woman, and that so she thinks and knows him to be."

However, Pepys was accustomed to set down unfavorable opinions (formed on the spur of the moment) of persons to whim he was attached. Doubtless Pepys, while educating himself for the efficient discharge of his duties, learned much from Penn and it is certainly a blot in his character that he showed so little appreciation in his writings of their eminent position as practical seamen who had seen much hard fighting and occupied prominent positions in their profession. He may, however, have shown them more consideration in real life. It is evident that the strong words used in the Diary were only the hot expressions of passing feelings which were not followed by unfriendly action. There is every reason to believe that Pepys remained a cordial friend of Penn to the last, and this is corroborated by the evidence of the sincere friendship of the admiral's son - William Penn, the Quaker - for Pepys.

Pepys' philandering's are legendary and his diary was written in a shorthand that could not easily be read by a casual browser. There are, however, some passages of a secretive nature where, for reasons of concealment or because his passion deserves a special language, he resorted to a private code involving words based on Spanish, French and Italian. In this account Deborah "Deb" Willet (1650–1678) was a young maid employed by Pepys and his wife:

"...and he being gone, I called Deb. to take pen, ink, and paper and write down what things come into my head for my wife to do in order to her going into the country, and the girl, writing not so well as she would do, cried, and her mistress construed it to be sullenness and so was angry, and I seemed angry with her too; but going to bed, she undressed me, and there I did give her good advice and beso la [kissed her], ella [she] weeping still; and yo [I] did take her, the first time in my life, sobra mi genu [on to my knee] and did poner mi mano sub her jupes [put my hand up her skirts] and toca su [touch her] thigh, which did hazer [give] me great pleasure; and so did no more, but besando-la [kissing her] went to my bed." [March 31, 1668]

The things one gets involved in when studying the history of the aquarium hobby!



ADDENDUM II:
MARTINO MARTINI

Martino Martini (whose Chinese name was Jitai Wei Kuang-guo) was born in 1614 in Trento, Italy. After finishing high school studies in Trento in 1631, he entered the Austrian province of the Society of Jesus, from where he was sent to study classical letters and philosophy at the Roman College, Rome (1634-37). However his interest was more in astronomy and mathematics which he studied under the great Athanasius Kircher. Kircher was a 17th-century German Jesuit scholar and polymath who published around 40 major works, most notably in the fields of comparative religion, geology and medicine. Kircher has been compared to Leonardo da Vinci for his enormous range of interests, and has been honored with the title "Master of a Hundred Arts." Martini's request to be sent as a missionary to China had already been granted by Superior General of the Jesuits. Already on his way to China, he did his theological studies in Portugal (1637-39) where he was ordained as a priest in 1639 in Lisbon.

Martini embarked in 1640 and arrived in Macao in 1642. He began to study the Chinese but in the following year he crossed the border and took up residence in Hangzhou, which was his home port for some time. From there he crossed throughout the different provinces of the empire to gather scientific information, particularly on the geography of the Chinese empire. Along the way he visited Beijing and the Great Wall

When the Manchus invaded China in 1644 and seized Beijing and all of the whole empire, leading to the fall of the Ming dynasty, Martini ran into great danger. However, he was protected by lower officials who believed in the science and wisdom of the Jesuit. He did not hesitate to sometimes intervene with military and civil authorities to save lives.

In 1650 the superior of the mission sent Father Martini to Rome in order to explain and defend the missionary approach encultured of China Jesuits. Chinese customs that are not contrary to the Christian faith were respected and even encouraged by the missionaries, but that was not the view in Europe, especially by the Franciscans and Dominicans.

The travel was long and dangerous. The route passed through the Philippines on the way to Amsterdam where he arrived on August 31, 1653. In Amsterdam, Antwerp, Vienna and Munich he met with printers and prepared the edition of three important books including his famous *Novus Atlas Sinensis China*. He finally arrived in Rome in the spring of 1655.

In Rome, Martini delivered a lengthy memorandum prepared by the Chinese Jesuit missionaries, detailing and justifying their missionary approach. The discussions and debates lasted five months, following which the Propaganda Fide issued a decree in favor of the Jesuits in March 23, 1656.

In 1658, Martini was back in China. The trip lasted nearly two years as he was captured by pirates and a ransom had to be paid for his release. Only four of the ten young Jesuits who accompanied him arrived safely. Back in Hangzhou he resumed his pastoral work among the new Christians in the region. From 1659 to 1661, he built a triple nave

Martino Martini (1614-1661)

church, the current Cathedral of the Immaculate Conception of Hangzhou. Soon after, on June 6, 1661, Martini died of cholera in Hangzhou at the age of 47.

His great work, the *Novus Atlas Sinensis China* (1654), was published in French translation, without maps, under the title of *Description Géographique de l'Empire de la Chine traduite d'un autheur Chinois par le père Martini* (1655). It is remarkable for its precision and its positive assessments of Chinese society.

The following is an excerpt from Martini's *Description Géographique de l'Empire de la Chine*:

"La montagne de Cinking est proche de Ghanghoa, où il y a un lac, qui, pour n'estre pas des plus grands, ne laisse pas d'occuper deux cens arpens de terre; il est fameux & renomme pour les petits poissons dorez qui s'y peschent, que les Chinois ont nomme pour cet effet Kinyu, car la peau brille, pour estre en quelque façon entretaillée de lignes d'or: tout le dos est comme parsemé de poudre d'or: ils ne font point plus longs que le doigt, ils ont une queue à trois pointes, quelques fois à deux, par fois elle est simple & un peu large; ils font curieux à voir : ceux de la Chine en sont beaucoup d'estat, les nourrissent avec beaucoup de soin dans leurs maisons & dans leurs jardins de plaisance, en des vaissaux qui font faits tout exprès; les grands Seigneurs leur donnent quelques fois à manger de leur main, se joüent souvent avec eux, come si ces poissons connoissoient leur maistres, & qu'ils voulussent resmoigner le plaisir & le divertissement qu'ils reçoivent, lors qu'ils sont honorez de leur presence: un de ces petits poissons vaut bien par fois deux ou trois escus d'or, fur tout, lors qu'ils ont toutes les bonnes marques que les Chinois desirent."

Dropping this into Google Translate produces a lot of garbage since this is old French with spellings and words not found in current dictionaries. One example: Every beginning student of French learns first the word for "to be," which is être. In Martini's book it is estat. Also, Martini refers in this excerpt to acres (arpens) but it is French acres he has in mind and one French acre is about 50% larger than one of ours. In any event, my translation of the above follows:

"The mountain of Cinking is near Changhoa, where there is a lake, which, although not being the greatest, occupies three hundred acres of land. It is famous and renowned for the small golden fish within it, and because their skin shines between lines edged in gold, the Chinese have named this effect Kinyu. The whole back is like strewn with gold dust and they are no longer than a finger. They have a tail with three points, sometimes two, sometimes it is simpler and a little large; they are curious to see. The Chinese make much of their existence and feed them with great care in their houses and in their pleasure gardens, in vessels that are made just for this purpose. The great Lords give them some time to eat from their hands and often play with them as if the fish knew their masters, and they show that they like the pleasure and diversion they receive, when they honor their presence. When they have all the right markings that the Chinese desire, one of these small fish is worth two or three gold crowns."

This is probably the first reference to the Kinyu (also known as Chin-yü; in Japan it is Kingyo) or common goldfish in a Western publication in addition to providing an explanation of the name. Martini does not indicate that the locals bred these fish found in the lake but he does mention that the more prized (because of their markings) were kept by the Chinese in their houses and in their garden pools.

HUGO MULERTT AND THE TALKING GOLDFISH

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, April 23, 2016)

In aquarium hobby history, some events are important but not interesting; others are unimportant but are interesting. This is one of the latter. The following is from the 1883 edition of "The Goldfish and its Systematic Culture With a View to Profit," by Hugo Mulertt:

"The goldfish, we are told, like many other things, originated in China, though, so far as this is concerned, its history is involved in much obscurity. The first mention we find of it is in the "Arabian Nights' Entertainments," in the story of the Fisherman and the Genii, a story, which like those accompanying it, is of Persian origin."

This story was repeated an interview with Mulertt that appeared in The Brooklyn Daily Eagle on December 16, 1894.

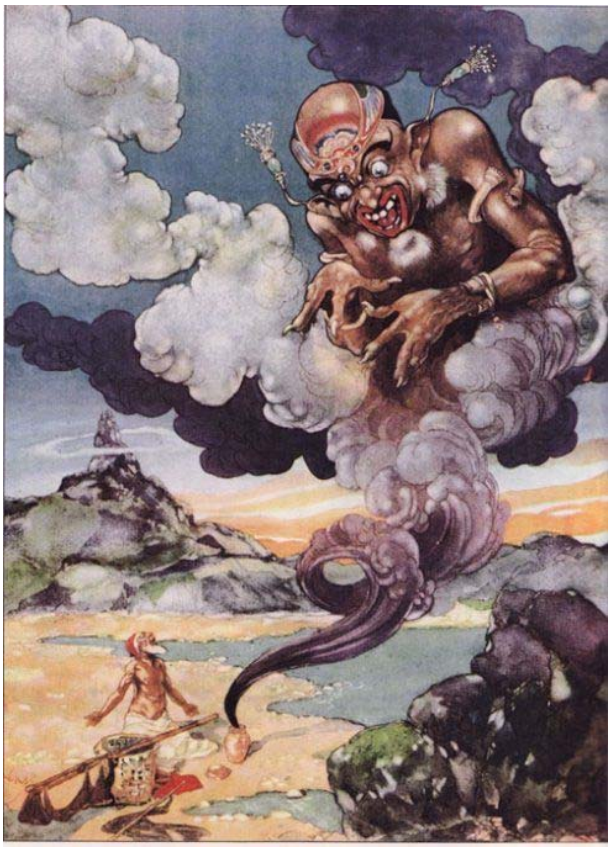
I never did follow up this claim - nor did anyone else that I can remember - until recently when I recalled that "The Arabian Nights' Entertainment or Thousand and One Nights" is a collection of about four hundred old oriental stories, chiefly from Persia, India, and Arabia, none of which had I had previously associated with goldfish.

"The Fisherman and the Jinni" [Genie] tells the story of a fisherman whose nets retrieve a yellow vase from the sea. When he opened it,

"…there came forth from the jar a smoke which spired heavenwards into aether (whereat he again marvelled with mighty marvel), and which trailed along earth's surface till presently, having reached its full height, the thick vapour condensed, and became an Ifrit [an Arabian genie or jinne], huge of bulk, whose crest touched the clouds while his feet were on the ground. His head was as a dome, his hands tike pitchforks, his legs long as masts and his mouth big as a cave ; his teeth were like large stones, his nostrils ewers, his eyes two lamps and his look was fierce and lowering."

The Ifrit, who has been trapped for hundreds of years had decided to kill the man who rescues him. The fisherman tricks the Ifrit into returning to the vase:

"He began by asking the Ifrit, 'Hast thou indeed resolved to kill me?' and, receiving for all answer, 'Even so,' he cried, 'Now in the Most Great Name, graven on the seal-ring of Sulayman the Son of David (peace be with the holy twain!), and I question thee on a certain matter wilt thou give me a true answer?' The Ifrit replied 'Yea;' but, hearing mention of the Most Great Name, his wits were troubled and he said with trembling, 'Ask and be brief.' Quoth the Fisherman, 'How didst thou fit into this vase which would not hold thy hand; no, nor even thy foot, and how came it to be large enough to



The fisherman confronting the Ifrit.

contain the whole of thee? 'Replied the Ifrit, 'What! dost not believe that I was all there?' and the Fisherman rejoined, 'Nay! I will never believe it until I see thee inside with my own eyes.'"

Then the Ifrit began to change himself into smoke, which, as before, spread over the sea and the shore, and which, then collecting itself together, began to go back into the vase slowly and evenly till there was nothing left outside. Then a voice came from the vase which said to the fisherman, **"Well, unbelieving fisherman, here I am in the vase; do you believe me now?"** The fisherman instead of answering took the lid of lead and shut it down quickly on the vase.

The fisherman then tells him the story of "The Wazier and the Sage Duban," and after the story, the Ifrit promises to reward the fisherman, and indeed shows him a magic lake full of strange fish:

"The Ifrit burst into laughter and stalked away, saying to the Fisherman, 'Follow me' and the man paced after him at a safe distance (for he was not assured of escape) till they had passed round the suburbs of the city. Thence they struck into the uncultivated grounds, and crossing them descended into a broad wilderness, and lo in the midst of it stood a mountain-tarn. The Ifrit waded in to the middle and again cried, Follow me and when this was done he took his stand in the centre and bade the man cast his net and catch his fish. The Fisherman looked into the water and was much astonished to see therein vari-coloured fishes, white and red, blue and yellow; however he cast his net and, hauling it in, saw that he had netted four fishes, one of each colour. Thereat he rejoiced greatly and more when the Ifrit said to him, 'Carry these to the Sultan and set them in his presence; then he will give thee what shall make thee a wealthy man; and now accept my excuse, for by Allah at this time I wot none other way of benefiting thee, inasmuch I have lain in this sea eighteen hundred years and have not seen the face of the world save within this hour. But I would not have thee fish here save once a day.'"

When he brings the fish to the King he is much pleased with their colors and orders his cook to prepare the fish. The fisherman receives four hundred dinars. When the slave-girl puts the fish in a frying-pan, a fissure appears in the wall and a beautiful lady appears. She reminds the fish to remember the agreement, they assure her and then the fish turn black as charcoal.

"…as regards the cookmaid, she took the fish and cleansed them and set them in the frying-pan, basting them with oil till one side was dressed. Then she turned them over and, behold, the kitchen wall clave asunder, and therefrom came a young lady, fair of form, oval of face, perfect in grace, with eyelids which Kohl-lines [eye shadow]enchase, Her dress was a silken head-kerchief fringed and tasseled with blue; a large ring hung from either ear; a pair of bracelets adorned her

The young lady thrusting her rattan rod into the frying pan containing the fishes.

wrists; rings with bezels of priceless gems were on her fingers ; and she hent in hand a long rod of rattan-cane which she thrust into the frying-pan, saying, 'O fish! O fish! be ye constant to your covenant?' When the cook-maiden saw this apparition she swooned away. The young lady repeated her words a second time and a third time, and at last the. fishes raised their heads from the pan, and saying in articulate speech 'Yes! Yes!' began with one voice to recite 'Come back and so will I! Keep faith and so will I! And if ye fain forsake; I'll requite till quits we cry!'

"After this the young lady upset the frying-pan and went forth by the way she came in and the kitchen wall closed upon her. When the cook-maiden recovered from her fainting-fit, she saw the four fishes charred black as charcoal…"

The King is amazed and orders the fisherman to bring new fish, which he does. A second time the lady appears. Consulting the fisherman as to where he got the fish, the King goes to the lake. Even the oldest inhabitants said that there wasn't such a lake as there was now and the King swears to find the truth of this mystery. After a long walk he finds a palace built of stone plated with iron. He enters the palace but can't find anyone. Then he hears a lament and goes to its source. He finds a man stuck in stone from his middle downwards who tells him his story.

The prince's wife had given him a sleeping potion each night and then left him to visit her lover. One night, the prince does not drink the potion and secretly follows his wife. When he encounters her lover, a black slave, he attempts to kill him but only wounds him. In order to punish him,

The prince secretly follows his wife and finds her in the bed of her lover

his wife, who actually is a powerful sorceress, turns his kingdom into a lake and the citizens of the four faiths, Muslem, Christian, Jew and Zoroastrian she turned into fishes: Muslems white, Zoroastrians red, Christians blue, and the Jews yellow (the woman who talked to the fishes in the Sultan's kitchen was, of course, the sorceress Queen). Next she turns the prince's lower half into stone and, as he cannot move, punishes him by lashing him with a whip every day.

Hearing this tale, the king kills the black slave and forces the wife to lift the spell. The Prince is restored to his former self, the fish are turned back into people, the King cuts the Queen into two with his sword and the fisherman is rewarded.

Mulertt seemed to have assumed that the Arabian Nights' Entertainments were true instances of actual occurrences, rather than a collection of folklore. In any event, he should have read the compete Fisherman's Tale before claiming that the fish were goldfish. He was careless in thinking that the fish were of all four colors at the same time - thus confusing them perhaps with calico goldfish - and he missed the explanation of just what the fish were. In Mulertt's time in Cincinnati, the city had numerous breweries. Perhaps he wrote the preface to "The Goldfish and its Systematic Culture With a View to Profit" while spending too long a time at one of its many Biergartens. Schande über Sie Hugo!

NOTES:

1. Genii is the plural form of genie and jinn is the plural form of jinni. Mulertt was a little confused about this.
2. I prefer the Richard F. Burton unabridged and unexpurgated English translation of the Arabian Nights Entertainment, the full title being, "A plain and literal translation of the Arabian Nights entertainments, now entitled the book of the Thousand Nights and a Night with introduction explanatory notes on the manners and customs of moslem men and a terminal essay upon the history of the Nights," printed by the Burton Club for private subscribers only, Vol. 1, 1885). Burton did his translation because he was dissatisfied with the translation available at the time. The following were his reasons:

"Our century of translations, popular and vernacular, from (Professor Antoine) Galland's delightful abbreviation and adapta-tion (A.D. 1704), in no wise represent the eastern original. The best and latest, the Rev. Mr. Foster's, which is diffuse and verbose, and Mr. G. Moir Busseys, which is a re-correction, abound in gallicisms of style and idiom ; and one and all degrade a chef- d'oeuvre of the highest anthropological and ethnographical interest and importance to a mere fairy-book, a nice present for little boys."

A Japanese artist's interpretation of the Arabian Nights fishes.

JEANNE RONDELET

by Albert J. Klee, Ph.D.
(Aquarium Hobby Historical Society of America, Facebook Files, May 4, 2016)

Ah, it all seemed so simple! Over the years my statement in *The Toy Fish* that Rondelet had claimed that his wife, Jeanne, had kept a fish alive in a glass of water for three years has often been repeated and copied. I knew that they were married in 1538 so if I could find out when she died I could narrow down the time interval in which she kept the fish.

There are three main early sources for biographical information about Rondelet's wife: **1.** "Gulielmi Rondeletii Vita, mors, et epitaphiae," in Joubert, Laurent, *Operum Latinorum, tomus primus* (Lyon, 1579), Lib. IX, pp. 185–192; 2 [in Latin], **2.** Planchon, Jules Emile, "Rondelet et Ses Disciples," Boehm & Fils, Éditeurs du Montpellier Médical, Place de l'Observatoire, 1866 [in French] and **3.** Kingsley, Charles, "Rondelet, The Huguenot Naturalist," a lecture given at Cambridge in 1869 [in English]. I found the first and third to be the most helpful as this essay is concerned with Madame Rondelet, and not so much with her husband.

Rondelet got his doctorate in 1537, and next year fell in love with and married a beautiful young girl - Jeanne Sandre - who seems to have been as poor as he. The newly-married Rondelet determined to apply for employment and to Venice he would have gone, leaving his bride behind, had he not been stayed by one of those angels who sometimes walk the earth in women's shape. Jeanne Sandre had an elder sister, Catharine, who had brought her up. She was married to a wealthy man, but she had no children of her own. For four years she and her good husband had let the Rondelets lodge with them, and now she was a widow, and to part with them was more than she could bear.

She carried Rondelet off from the students who were seeing him safe out of the city, brought him back, settled on him the same day half her fortune, and soon after settled on him the whole, on the sole condition that she should live with him and her sister. For years afterwards she watched over the pretty young wife and her two girls and three boys and over Rondelet himself, who, immersed in books and experi-ments, was utterly careless about money, and was to them all a mother - advising, guiding, managing, and regarded by Rondelet with genuine gratitude as his guardian angel.

The 1550s were Rondelet's palmy days. He had a villa outside the city where may be seen the rem-

Guillaume Rondelet (1507-1566), known also as Rondeletus (Rondeletius).

nants of the great tanks, fed with water brought through earthen pipes from the Fountain of Albe, wherein he kept the fish whose habits he observed. But trouble was coming. In 1559 he lost his sister-in-law, to whom he owed all his fortunes and watched over him and his wife like a mother, then in 1560 he lost Jeanne under most painful of circumstances - she died in a few days of a hemorrhagic inflammation - and then his best -beloved daughter. Jeanne had been married to Rondelet for 23 years and had borne him five children (Rondelet and his wife had three sons and two daughters but only the daughters survived). Conservatively speaking, the years 1538-1557 would have been the interval in which she keep her fish but a more likely interval would be 1540-1550. A reasonable point estimate, therefore, would be 1545.

My next quest was to pin down the original source for Rondelet's assertion that his wife kept a fish for three years. I vaguely recalled that it was Jim Atz but, not having his material conveniently at hand, I Googled the phrase. I came up with two hits that boggled the imagination and almost gave me a cardiac arrest!

The following appeared in *Littell's Living Age*, No. 716, pg. 419, - 13 February, 1858. The magazine essentially reprinted articles from other magazines and this one came from *Blackwood's Magazine* and was titled, "Hunger and Thirst"; as was common in those days, the article had no author's name:

"Rondelet kept a fish three years without food, and Rudolphi [Karl Asmund Rudolphi - (1771-1832) - was a Swedish-born naturalist, who is credited with being the "father of helminthology"] a *Proteus anguineus* five years! ...and with regard to the fish, some doubts may be entertained whether it did not find worms and larvae in the water."

The following was titled "A philosophical essay declaring the probable causes whence stones are produced in the greater world from which occasion is taken to search into the origin of all bodies, discovering them to proceed from water and seeds: being a prodromus [i.e., a forerunner or precursor] to a medicinal tract concerning the causes and cure of the stone in the kidneys and bladders of men." It was written by Dr. Thomas Sherley and printed in London in 1672 for privately for William Cademan.

Sherley (1638-1678) was a physician and the essay describes the origin and supposed causes of the formation of stones in the earth and in living things. Sherley sets forth and develops at length the thesis that all stones and metals have seeds from which they grow, as in the two other kingdoms of nature like botany and animals. The seed is invisible, but is often present in vapors that rise from the center of the earth. His ideas are based upon ancient traditions, principally Aristotlian philosophy.

Laurent Joubert (1529-1582). Joubert was a student of Guillaume Rondelet.

"Animals also are nourished by water; some immediately, others mediately. Immediately, from meer water, as Salmon, Sturgeon, and several other sorts of Fish, in whose stomacks no food, that I know of, was ever yet found. And to confirm this; Rondeletius {French physician and naturalist, Guillaume Rondelet (1507-1566)} [an Author of good credit] affirms, that his Wife kept a Fish in a large glass, and fed it with nothing but water [so long] till it grew so big, that it could no longer be contained in the glass; which they were forced to break to get it out."

Note: The Latin form of Guillaume Rondelet is Gulielmus Rondeletius. I should also mention that the Latin form of Jeanne Rondolet is Ioanna Rondeletius.

The thing that immediately struck me was that one article claimed that it was Rondelet who kept the fish and the other that it was his wife. If Rondelet kept the fish then he would get the credit for being the first Stage II aquarist and Lady Margaret Penn would be the first woman aquarist of record. However, the *Littell's Living Age* article was published - anonymously - 313 years later than our point estimate. - and the Philosophical Essay was published 127 years later and written by a highly educated man. Thus I decided in favor of Jeanne Rondelet being the one who kept the fish.

Both accounts, however, mention as fact that the fish were not fed during the entire three years. This was something new and I searched and found the Atz reference I was originally looking for. It turned out to be an article Jim had written for *Natural History* in early 1949 (Atz, James W., "The Myth of the Balanced Aquarium," *Natural History*, pp. 72-77 and 96, February 1949). In it he stated: "According to Boyle, Guillaume Rondelet, a Renaissance student of aquatic life who died in 1566, once claimed that his wife had kept a fish alive in a glass of water for three years." Atz, for some reason, did not say anything about the fish not being given any food during its stay in the glass but, as it turned out, Boyle did.

The Boyle in question was Robert Boyle (1627-1691), a British chemist and natural philosopher, best known as the discoverer of Boyle's Law. Boyle's Law is one of the laws in physics that concern the behavior of gases,, i.e., the relationship between the volume of a gas and its pressure at a constant temperature. When a gas is under pressure it takes up less space; the higher the pressure, the smaller the volume. The Law states that pressure is inversely proportional to the volume.

The problem was that the complete works of Robert Boyle takes up six volumes (Volume I

Jules Émile Planchon (1823-1888).

contains 1,073 pages!) and Atz did not indicate in which of these works the Rondelet quote could be found. However, after some Internet dredging I finally found it.

In *The Sceptical Chymist* (published in London in 1661), Boyle attacks the Aristotelian theory of the four elements (earth, air, fire, and water) and also the three principles (salt, sulfur, and mercury) proposed by Paracelsus. Instead, he developed the concept of primary particles which by coalition produce corpuscles. According to this concept, different substances result from the number, position, and motion of the primary matter - conceptually the simplest of all possible accounts. According to this view, all natural phenomena were explained not by Aristotelian elements and qualities (the remnants of a biological mode of construal), but by the motion and organization of primary particles.

My copy of *The Skeptical Chymist* was published by J.M. Dent & Sons in London and in New York by E.P. Dutton & Co. and on pages 214-215 we find:

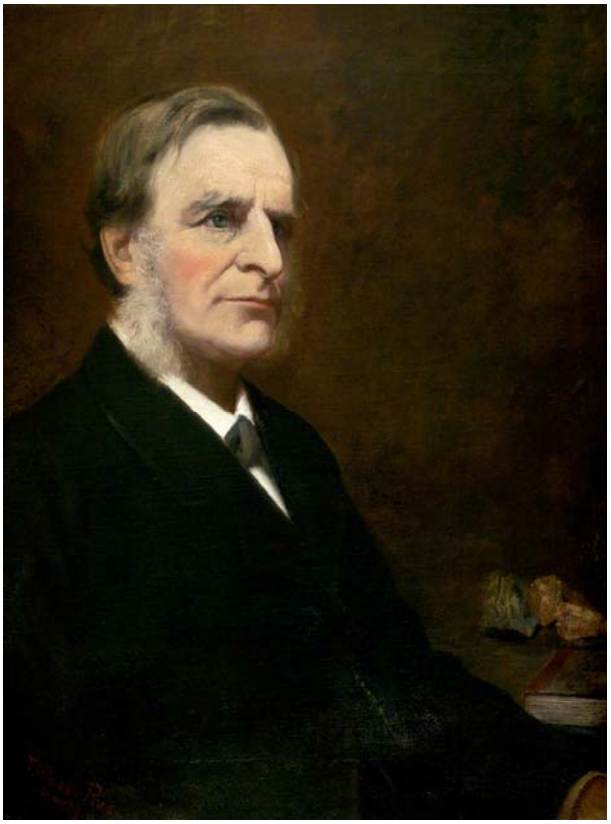
"And, these last arguments may be confirmed by the experiment I have often had occasion to mention, concerning the mint I produced out of water. And partly by an observation of *Rondoletius* concerning the growth of animals also, nourished but by water, which I remembered not to mention, when I discoursed to you about the production of things out of water. This diligent writer then, in his instructive book of fishes, affirms that his wife kept a fish in a glass of water without any other food for three years; in which space it was constantly augmented, till at last it could not come out of the place, at which it was put in, and at length was too big for the glass itself, though that were of a large capacity."

The original source then is Rondelet's *Libri de piscibus marinis in quibus verae piscium effigies expressae sunt*, published in 1554. The following is from Book I, Chapter XII which describes the nourishment of fishes:

"In Gallia Narbonensi curiosi quidam in vasis vitreis aqua plenis diu nutriunt, certumque est quo purior suerit aqua,eo diutius vitam producere, celeriter aute interire, si quid aliud praeter aquam vt panem, aut aliud quippiam solidioris alimenti in vas coniecerint. Hoc modo suauissima coniux mea tres annos piscem domi aluit, sicque educatus in eam corporis molem accreuit, vt tandem nec vas eum capere, nec qua ingressus fuerat, eadem exire potuerit."

The English translation follows:

"In the province of Narbonne, some of the curious [keep fish] in glass jars of water for a long time, adding no bread or any other solid



Charles Kingsley (1819-1875).

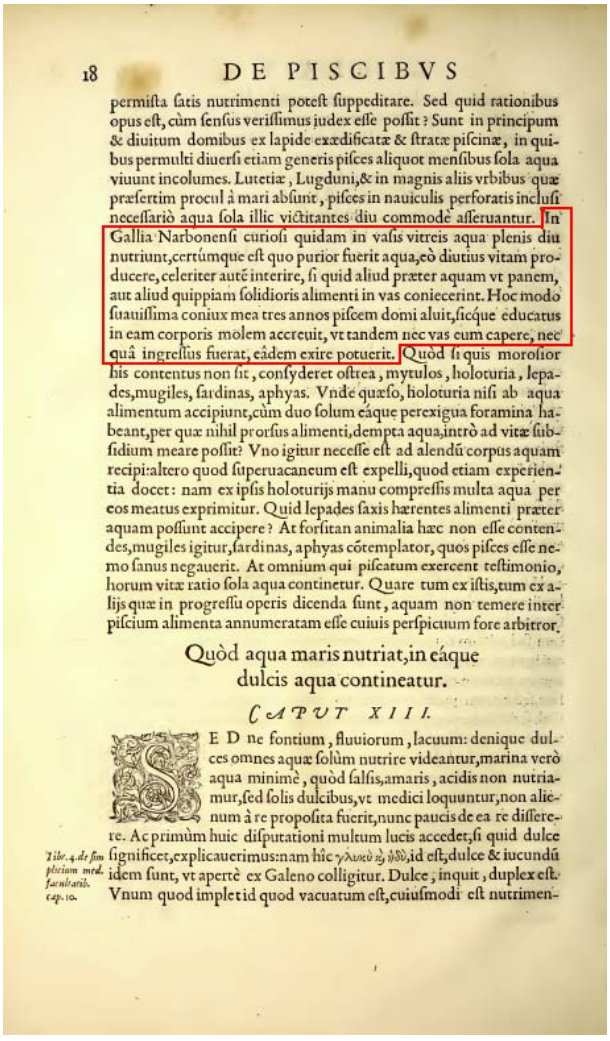
Robert William Boyle (1627-1691).

food to the water, since the longer the food lasts, the faster the fish die. In this way my sweet wife kept a fish at home for three years; she reared it so well that finally it was too large for the jar and could not leave through the opening through which it had been introduced."

Notes:
(1) Narbonne presently is a commune in southern France about 528 miles from Paris. French communes are roughly equivalent to townships or incorporated municipalities in the United States. However, they may be a city of 2.2 million inhabitants like Paris, a town of 10,000 people, or just a 10-person hamlet.
(2) Rondelet loved his wife very much. Here he describes Jeanne as his "sweet wife; in his will, he refers to her as "my dear wife."

Thus we now know that Jeanne Rondelet kept a fish in a large glass vessel ("glass" at that time did not mean a drinking glass) of water without any food given to it by her for three years, after which it had grown too large for the container and too large to be able to remove it through the opening through which it was originally inserted. Whether the glass had to be broken to release the fish is not clear, but the inference is there. As to how a fish could survive that long without food and in addition, grow, is a mystery. One possibility is that it ate insects that inadvertently fell into the opening of the jar. If consumed immediately, the water would have remained unpolluted. Since Rondelet did not name any particular person in Narbonne, Jeanne Rondelet remains as the first person of record to keep a fish alive in a glass container.

So ends my journey to learn more about Jeanne Rondelet and her fish. I enjoyed the trip while it lasted!



18 DE PISCIBVS

permista satis nutrimenti potest suppeditare. Sed quid rationibus opus est, cùm sensus verissimus iudex esse possit? Sunt in principum & diuitum domibus ex lapide exædificatæ & stratæ piscinæ, in quibus permulti diuersi etiam generis pisces aliquot mensibus sola aqua viuunt incolumes. Lutetiæ, Lugduni, & in magnis aliis vrbibus quæ præsertim procul à mari absunt, pisces in nauiculis perforatis inclusi necessariò aqua sola illic victitantes diu commodè asseruantur. In Gallia Narbonensi curiosi quidam in vasis vitreis aqua plenis diu nutriunt, certúmque est quo purior fuerit aqua, eò diutius vitam producere, celeriter autẽ interire, si quid aliud præter aquam vt panem, aut aliud quippiam solidioris alimenti in vas coniecerint. Hoc modo suauissima coniux mea tres annos piscem domi aluit, sicque educatus in eam corporis molem accreuit, vt tandem nec vas eum capere, nec quâ ingressus fuerat, eâdem exire potuerit. Quòd si quis morosior his contentus non sit, consyderet ostrea, mytulos, holoturia, lepades, mugiles, sardinas, aphyas. Vnde quæso, holoturia nisi ab aqua alimentum accipiunt, cùm duo solum eáque perexigua foramina habeant, per quæ nihil prorsus alimenti, dempta aqua, intrò ad vitæ subsidium meare possit? Vno igitur necesse est ad alendũ corpus aquam recipi: altero quod superuacaneum est expelli, quod etiam experientia docet: nam ex ipsis holoturijs manu compressis multa aqua per eos meatus exprimitur. Quid lepades saxis hærentes alimenti præter aquam possunt accipere? At forsitan animalia hæc non esse contendes, mugiles igitur, sardinas, aphyas cõtemplator, quos pisces esse nemo sanus negauerit. At omnium qui piscatum exercent testimonio, horum vitæ ratio sola aqua continetur. Quare tum ex istis, tum ex alijs quæ in progressu operis dicenda sunt, aquam non temere inter piscium alimenta annumeratam esse cuiuis perspicuum fore arbitror.

Quòd aqua maris nutriat, in eáque dulcis aqua contineatur.

CAPVT XIII.

SED ne fontium, fluuiorum, lacuum: denique dulces omnes aquæ solùm nutrire videantur, marina verò aqua minimè, quòd salsis, amaris, acidis non nutriamur, sed solis dulcibus, vt medici loquuntur, non alienum à re proposita fuerit, nunc paucis de ea re disserere. Ac primùm huic disputationi multum lucis accedet, si quid dulce significet, explicauerimus: nam hîc γλυκὺ καὶ ἡδὺ, id est, dulce & iucundũ idem sunt, vt apertè ex Galeno colligitur. Dulce, inquit, duplex est. Vnum quod implet id quod vacuatum est, cuiusmodi est nutrimen-

The Missing William Alford Lloyd Manuscript

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, June 4, 2016)

After Robert Warington demonstrated the principle of the balanced freshwater aquarium in 1850, the next step was to do the same for the marine aquarium. The problem was that keeping higher order aquatic plants in freshwater was a whole lot easier than keeping higher order aquatic plants in seawater, the higher order aquatic plants in the latter being mostly the large red (*Rhodosperma*) and green (*Chlorosperma*) algae.

In the freshwater aquarium, one of the problems was the *conferva* (plural *confervae*), meaning at the time any simple filamentous green algae. (Many *confervae* are now usually placed in the genus *Tribonema. Confervae* are present in seawater as well.) Under certain lighting conditions these would rapidly cover the higher order plants and the balance would be destroyed. The following are extracts from Warington's work on the freshwater aquarium (Warington, 1852):

While the slimy snail, finding its proper nutriment in the decomposing vege-table matter and minute confervoid growth, prevents their accumulation by removing them, and by its vital powers converts what would otherwise act as a poison into a rich and fruitful nutriment, again to constitute a pabulum for the vegetable growth, while it also acts the important part of a purveyor to its finny neighbours.

At present I am attempting the same kind of arrangement with a confined portion of sea water, employing some of the green sea weeds as the vegetable members of the circle, and the common winkle or whelk to represent the water snails.

The following is an example of problems with confervae in the marine tank (Hughes, 1875):

The silky greenish-black filamentous confervas (*Spirulina* and *Oscillatoria*) spring up with marvelous rapidity in hot months, covering rock work, glass, and shingle, and proving most difficult intruders to dislodge. In fact they cannot he thoroughly exterminated without a regular scouring process, invol-ving much time and trouble. Mr. Lloyd says that conferva, like fire, "is a good servant but a bad master." Its growth may be checked by the absence of light, and by rubbing the sides of the Tank, and the glass front, with a spade -shaped cleanser, covered with folds of lamp-cotton…

In his article demonstrating the proof of principle for the marine aquarium, Warington stated (Warington 1853):

My first object was to ascertain the kind of sea-weed boat fitted, under ordinary circumstances, for keeping the water clear and sweet, and in a sufficiently oxygenated state to sustain ani-mal life. And here opinions were at variance, for one naturalist friend whom I consulted, advised me to employ the Rhodosperms; another stated that it was impossible to make the red weeds answer the

Green hair algae, a *conferva*, growing on *Anacharis* plant leaves.
(Source: Aquariumbasics.com.)

purpose, as he had tried them, and strongly recom-mended the olive or brown-coloured Algae; while, again, others thought that I should be more successful with those which had in theory first suggested themselves to my own mind, namely the Chlorosperms. After making numerous unsuccessful experiments with both the brown and red varieties of Algae, I was fully convinced that, under ordinary circumstances, the green weeds were the best suited for the purpose.

In this way Warington managed to keep blennies, gobies and sculpins, as well as invertebrates. In the following year Gosse reported on his experiences with Rhodosperms (Gosse, 1854):

The Rhodosperms, or Red Sea-weeds, must be the test of success in any attempts to cultivate the marine Algae, and this for several reasons; such as their superior; the great number of their species; their delicacy of habit; and their organic rank in the class. The Chlorosperms, or Green Sea-weeds, have been mastered; and the central tanks in the Zoological Society's Aquarium afford interesting and easily accessible examples of the successful treatment of these. Here the visitor sees a profuse growth of *Ulva, Enteromorpha*, and *Conferva* covering the slate ends of the tanks with their abundant vegetation, all of which has grown since last summer; and an object of exquisite beauty is presented by a large stone completely concealed by a crop of the lovely *Bryopsis plumosa*, which has overspread its surface with luxuriant fronds growing so densely as to remind us of a bank of moss, though greatly excelling it in elegance, and affording shelter to myriads of tiny *Entomostraca*, that play in its foliage like clouds of moving dust. Hitherto, however, the Rhodosperms have resisted domestic culture, refusing, like the eagle, to propagate in captivity. [Gosse refers here to Bryon's, "The prison'd eagle will not pair."]

After describing his experiences, Gosse concluded**:**

The facts above recorded are sufficient to show that there is nothing in the nature of the Rhodosperms to prevent their being cultivated in confinement, with a facility far superior to that which attends the culture of multitudes of terrestrial plants that reward the skill and perseverance of the horticulturist.

A four-page manuscript written by William Alford Lloyd entitled "Observations on Mr. Gosse's paper pp. 488–91," was recently found by Fernando E. Vega at the National Agricultural Library (NAL), Beltsville, Maryland, USA. Dr. Vega is a research entomologist at the NAL.

The manuscript, written on pages embossed on the left upper corner with "Zoologische Gesellschaft Hamburg," was tipped-in in a volume of the *Annals and magazine of Natural History*, on the last page of an article by Philip Henry Gosse (1854), "On the growth of sea-weeds," and provides interesting insights into Lloyd's thoughts about Gosse's work. The manuscript was written twelve years after Gosse's paper was published, when Lloyd was Director of the Hamburg Aquarium (1862–1868), a position he had secured with the help of the Heinrich Adolph Meyer (1822–1899), whose name is mentioned in the manuscript. An examination of the *Annals and magazine of Natural History* at the NAL also revealed that volumes 3–8 (third series, 1859–1861) were stamped "H. Adolph Meyer" on the title-page.

A Rhodosperm, *Delesseria decipiens*.

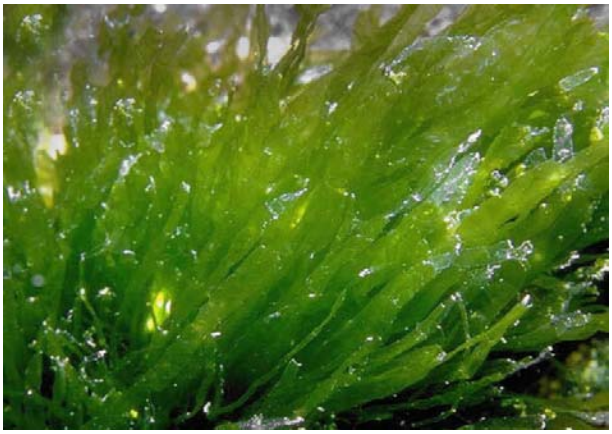
Thus, the volume containing the manuscript originally belonged to Meyer and was acquired in 1895 by the NAL (the volumes were also stamped "August 26 1895").

Lloyd's manuscript took exception to some of Gosse's 1854 statements:

Observations on Mr. Gosse's paper pp. 488–91. These notices were written by Gosse when he kept Aquaria at 58 Huntingdon St., Islington, London, 12 years ago. His tanks consisted of several vessels of varying shape & materials placed in windows of an ordinary dwelling-room at the top of the house, and it will be perceived that April was the time when the notes were written. But, during the next & the following hot summers (1855 & 1856) most of the Rhodosperms described were spoiled by being grown over with *confervæ* & other parasitic plants, so that the character of the red plants was quite obliterated by the effects of excessive light, while another tank standing in the same room between the windows, & therefore not exposed to direct illumination, was not so visited by *conferva*, & the plants in it remained tolerably free from parasites & preserved their normal colours. The same thing has been experienced in the Hamburg Aqm. where Rhodosperms in tanks under the full light of skylights have become grown over, while others in complete or partial darkness have continued clean. As to the central tanks in the Regent's Park Aquarium, referred to here by Gosse, & elsewhere, ("Aquarium" 2nd ed: p. 277–8 1856) as affording examples of successful Alga growing, time has shown that they have done nothing of the kind, for they, too, after a period, succumbed to their great enemy – Light – & are now no longer existing. It has been said that the red algae growing in Dr. Meyer's cellar in Hamburg contradicts this theory about light, but it doesn't, on the contrary, it harmonizes with it. Certain plants grow there, certainly, & are free from *conferva* but then the room has the coolness & subdued illumination of a cellar, while the Hamburg Aquarium, obtaining its light from skylights, has in it more of the circumstances of a hot-house than a cellar. Of course, there are varying degrees of light, & this amount of illumination, combined with a low and equable temperature has been well hit in Dr. Meyer's case. Absolute darkness may not be required, but even much greater darkness than Dr. Meyer possesses may be employed with advantage. Let him still further decrease his illumination & increase the motion of the water, & a still greater success will result. Mr. Gosse is much out of his reckoning in saying that the Chlorosperms "have been mastered." Certainly *Ulva, Enteromorpha, Cladophora, Bryopsis*, & a few others have been grown in tanks by Gosse, & in Regent's Park, in Paris, Hamburg, & elsewhere, but only by chance, & Gosse has himself often told me that neither he nor anyone else could with certainty grow them twice running, & that the cause of failure was unknown. My experience coincides with this, & therefore there has been nothing "mastered," but I can with certainty cultivate many Rhodosperms.

W. A. Lloyd Oct. 25th 1866 p.s. Oct. 27th 1866.

I have further to reason that not only did Gosse's red algæ, referred to in his paper, became in time disfigured by *conferva* but the seawater itself became opaquely green in consequence of the appearance of millions of



A Chlorosperm, Enteromorpha intestinalis.

locomotive plants, which Gosse, thought were spores, but which Dr. Cohn of Breslau [the Dr. Cohn Lloyd refers to here is Ferdinand Julius Cohn (1828-1898), a German biologist and one of the founders of modern bacteriology and microbiology] **has since determined to be a separate algæ *Chlamydomonas marina*. I remember calling on Gosse one hot day in July 1856, when he was fastening the Times newspaper round his tank to keep out the light, & he was in a state of wild despair & mentally tearing his hair with vexation, because as he said, he wrote instructions for the public to keep Aquaria, & he could not keep his own – either plants or animals!**

At the time Lloyd wrote this manuscript, he had been Supervisor of the Hamburg Aquarium for four years and perhaps was much too busy supervising the installation of the tanks and circulating system, and planning to make the Hamburg aquarium the largest and most modern in Europe, to follow it up by its publication. However, I think the real reason was that Lloyd and Gosse were close friends and Lloyd might have delayed publication for fear of alienating him. Lloyd often presented Gosse with the rarer specimens his marine collectors sent, which were either new to him or to science.

Their friendship was cemented when Lloyd in the autumn of 1858 he came across a strange worm-like anemone and discovered it to be a new species. Before submitting a monograph about its discovery he sent Gosse a specimen and Gosse asked if he would allow him to call it *Cerianthus Lloydii*. Gosse explained that the priority of discovery must go to Lloyd enterprise, and that it would also give him the opportunity of mentioning Lloyd's commercial undertakings. By this time Lloyd's practical ability, obtained by the necessity of keeping both his marine animal and seaweed stock alive and well, was now being widely recognized. Gosse, for example, often sought Lloyd's advice on the affect light and temperature had upon the aquarium. Lloyd's friendship with Gosse was mentioned by Gosse's son, Edmund (Gosse 1890): **"The late Mr. W. Alford Lloyd, whose affectionate devotion to my father deserves the warmest recognition…"**

After Lloyd took over as Aquarium Manager of the Crystal Palace Marine Aquarium in 1869, he authored the *Official Hand-Book to the Marine Aquarium of the Crystal Palace Aquarium Company (Limited*). The following are Lloyd's comments, written in 1873 (Lloyd, 1876):

…but with the exception of the knowledge taught by Warington and Gosse, namely, that a few of the red algae can be grown in captivity in darkness or in much shade, or by the interposition of coloured media, the means of systematically cultivating seaweeds of my kind—whether green, red, or brown—is as yet hardly known to us,* and especially with regard to the green ones, as *Ulva, Enteromorpha*, and *Porphyra*. By chance, indeed, sometimes one here and there (and even difficult kinds occasionally, as *Delesseria, Laminaria*, and others) may be

Philp Henry Gosse (1810-1888), taken in 1863.

grown more or less well; but as the reason is unknown, a repetition of success can seldom be obtained…

*** Since this passage was written, however, several of the red algæ have grown luxuriantly in this aquarium, chiefly in the dark corners of the north and south rooms. The species are *Phyllophora, Gymnogongrus Griffithsiea, Polyides rotundus, Iridia edulis, Chondrus crispus, Gelidium corneum, Rytiphlaea pinastroides, Corallina offcinalis*, and several others. (April 1873.)**

In this way, Lloyd said what had to be said without alienating his friend. In an article published a few years later, Lloyd admitted, somewhat plaintively (Lloyd, 1876),

This leads me to say that at present we do not know how to grow the higher marine algæ, the red, the brown, or even the green kinds, at will. Sometimes I succeed, but always by chance, not knowing why.

PROBLEMS IN AQUARIUM HOBBY HISTORY RESEARCH

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, June 18, 2016)

From time to time, I have discussed some of the problems I have encountered in doing research on the history of the aquarium hobby. A recent one involved trying to pin down an original reference. It started with the following statement by William Alford Lloyd in his "Hand-Book to the Marine Aquarium," published in 1876:

"Mr. Ward had, however, before 1849, made seawater by artificial means, and had grown marine plants in it."

I was interested in finding the original source for this statement and the first information I found was in Shirley Hibberd's "The Book of the Fresh-Water Aquarium or Practical instructions on the Formulation, Stocking, and Management in All Seasons, of Collections of River Animals and Plants," published in 1869: "With this opinion I quite concur, and it is agreeable to have to associate Mr. Ward's name with the subject before us, for he was one of the early pioneers, and at a meeting of the British Association at Oxford, 1849, communicated an account of his success in growing marine algae in artificial sea-water." I was surprised and somewhat amused that Hibberd chose to place this information in his "Book of the Fresh-Water Aquarium" instead of his "Book of the Marine Aquarium." In any event, the British Association that Hibberd referred to was the British Association for the Advancement of Science so I consulted their Annual Report for that year but was unable to find any mention of Ward mentioning artificial seawater.

I suspected that Hibberd had the wrong date so with A set of key words and phrases I did a Google search and came up with two relevant hits, one in "The Gardener's Chronicle and Agricultural Gazette," p. 524, London, July 31, 1847" and the other in "The Floricultural Cabinet, Florist's Magazine," p. 236, London, September, 1847. Since the reports did not differ, I am reprinting the entry as found in the Chronicle:

BRITISH ASSOCIATION.

Friday, June 25.- Section D.- Mr. WARD made some remarks on the results of his plan of growing plants in closed glass cases. He stated that the most perfect success had attended this plan, in bringing plants to this country from tropical climates. Where it had not succeeded it arose from the ignorance or of those who superintended it. In some instances the cases had been covered with tarpauling, thus preventing the access of light to the plants. Frequently they had not enough soil to grow in, or had not sufficient water. Unless the plants were placed as much as possible in their natural condition they would not do well in these cases, any more than any where else. Mr. Ward drew attention to the opportunity these cases afforded to the poor, in thickly populated towns, of cultivating a taste for natural objects. He read an letter from an artisan, who stated that growing

Nathaniel Bagshaw Ward (1791-1868).

plants in these cases had afforded him the most agreeable source of relaxation after his day's labour. Mr. Ward also stated, that not only could land-plants, and the higher forms of vegetation be grown in these cases, but that the various forms of marine Algae had been cultivated in artificial salt water.

Ah! This solved the problem (or so I thought at the time). It was the 1847 meeting of the British Association, not the 1849 one as Hibberd had it. Now all I has to do was to obtain a copy of the 1847 Annual Report and to find Ward's comments. Now these reports contain about 800 pages and one would go blind trying to go through each page to find a particular item. What I typically do, therefore, is to scan the document and OCR (Optical Character Recognition) it. The process starts with a pdf file (the 1847 Report in this case and the 1849 Report I first examined) where each page is an image and ends with each page containing text, which is searchable. The OCR process is lengthy and takes about a half hour to complete so I find something else to do while the program is doing its magic. Unfortunately, no matter what words I searched for - Ward, artificial, salt water, etc., Ward's comments just weren't in the Report. Furthermore, in both the Chronicle and the Floricultural Cabinet, Ward's paper was followed by a reference to one given by Charles Daubeny on the results of his experi-

The Wardian case was a portable airtight greenhouse developed by Nathaniel Bagshaw to protect live plant material during transportation overseas.

ments on the growth of plants in closed glass cases. This paper was not found in the Annual Report either.

I decided to find out what Stephen H. Ward, Ward's son, had to say so I read his paper titled "On Wardian Cases for Plants, and Their Applications," the substance of a lecture delivered at the Royal Institution on March 17, 1854. In this paper the following note appeared in the appendix:

At the Meeting of the British Association at Oxford, in 1847, Mr. Ward called attention to the fact, that all the lower marine algae might be grown in these cases by means of salt-water artificially prepared."—Athenaeum, July 3rd, 1847.

Like the Gardener's Chronicle, the Athenaeum was large, in newspaper style, set up in three columns and had much more detail than was in the Association's Annual Report. The Association did not include the smaller, less important communications its Annual Report, whereas independent journals like the Chronicle, Floricultural Cabinet and Athenaeum did. Ward's report, however, read quite differently in the Athenaeum (No. 1027, p. 715, July 3, 1847) from that in the Chronicle and the Floricultural Cabinet:

FRIDAY

Mr. WARD made a communication on the subject of Growing Plants in Closed Cases. Ilia object was to give the results of a long experience of his plan, as well as to point out some errors with regard to the use of these cases. Time had enabled him to mature his plan, and to try it with every form of plant; and he might say that, whether for transpor-tation from one climate to another, or for growing plants under circumstances where they could not be exposed to the atmosphere, it was perfectly success-ful. Palms had been transported from the tropics in these cases; and roses had blossomed in them ex posed to a southern aspect in London. In order to secure the proper growth of plants in these cases, they should hare moisture, be planted properly in soil, and exposed to the light if these conditions were not attended to, the cases would fail. Some-times, in voyages, they were covered over with boards or tarpauling—and the plants, not having light, were of course destroyed. Mr. Ward read some letters, showing that this plan of growing plants in closed cases might be made to contribute to the comforts of the poor in large towns, as the cases may be made at a small expense, and supplied with plants all the year round. He also called attention to the fact that all the lower

A large Wardian Case build against a window, which was very fashionable.

marine Algae might be grown in these cases by means of salt water artificially prepared.

Note that these reports were written by reporters who worked for - or were paid by - the periodicals in which the reports appeared (in the case of the reports in the Chronicle and the Floricultural Cabinet, it is almost certain that they were written by the same reporter). Periodicals need to publish information as soon as possible and the associations involved published their information annually. Furthermore, the associations of the day did not publish everything so reporters would attend meetings of the individual sections of the associations where many of the exchanges were not published by the parent associations except for their official transactions. Thus, a reporter for a botanical magazine would be sure to attend the meeting of the Botany Section of the British Association for the Advancement of Science where he would take notes of informal discussions and exchanges he thought might be of interest to his readers, Ward's comments being an example. Different reporters, of course, would produce reports of the same exchanges that would agree roughly but look quite different.

The last line of the reports above highlights a discrepancy between the Athenaeum version and the other two, the former stating that "all the lower marine Algae *might* be grown in these cases by means of salt water artificially prepared," and the latter stating that "the various forms of marine Algae *had been* cultivated in artificial salt water." The difference between "might be" and "had been" is significant. If the former, then Ward had not actually kept marine algae in artificial seawater, and even if it is the latter, Ward did not claim that he had been the one who did. The best that can be said is that Ward was the first on record to evince an interest in using artificial seawater in the marine aquarium.

Although, I solved my original problem, I discovered a much bigger one on the way!

Pteridomania or "Fern Fever" - made possible by the Wardian Case - was a fad that swept through England during the 19th century. Ordinary people not only started to mail-order exotic ferns to grow at home, but they set out in search of the perfect specimen.

HAND-BOOK TO THE MARINE AQUARIUM

June 23, 1873, by William Alford Lloyd

(Aquarium Hobby Historical Society of America, Facebook Files, June 10, 2016.)

In 1854 the Crystal Palace, a cast-iron and plate -glass structure originally built in Hyde Park, London, to house the Great Exhibition of 1851, moved from its temporary site in Hyde Park to its more permanent location at Sydenham, an affluent south London suburb of large villas. It had only been on the site for twelve years when in 1866 it experienced the first of a number of fires, which destroyed the North Transept. The fire left a large desolate area which had become a charred eyesore. There were insufficient funds to reconstruct the north end and it was not until 1870 that a plan was put before the directors to construct a marine aquarium. The directors saw its potential and the derelict site was opened as a salt water aquarium on August 22, 1871. It consisted of a building of one story high, measuring altogether about 400, feet long and 70 feet wide. There were 100,000 gallons of seawater, of which 80,000 gallons were below the floor of the saloon, and 20,000 gallons in the tanks where the animals were shown. These tanks were sixty in number, and varied in capacity from forty to 4000 gallons each. Thirty-eight of the tanks were for the public exhibition of creatures and their associated plants, and were contained in a saloon and two smaller rooms, but the remaining twenty-two tanks, for the storage of surplus animals, were in a gallery (behind the large show tanks), and were not shown to the public. All the public tanks were fitted with plate glass, varying in thickness from three eighths of an inch to one inch. The water for the tanks was brought by train from the sea at Brighton, and briefly the aquarium was the largest of its type in the world.

The Crystal Palace after its move to Sydenham Hill in 1854

What made the Crystal Palace Aquarium special was the fact that it was a marine and not a freshwater exhibit. No one before had created a working marine aquarium of this scale and diversity. The Crystal Palace was lucky to secure the services of William Alford Lloyd, the leading aquarist of his day, who developed a system of continuous circulation of the water, which was kept in the dark as much as possible and at strictly governed temperatures. Machinery to achieve this was doubled up to ensure the continuous flow. Excavations of the reservoirs have also shown that downward slopes were built into the system. These were designed to increase the 'scouring' action of the water and make the system as natural as possible.

Although not a commercial success, the site was regarded throughout the aquarium world for its technical merit and innovation. Excavations have yielded samples of the vulcanite piping that the water ran through, which was quite cutting edge for its day but necessary, as seawater could not travel through metal conduit. Charles Darwin is said to have been a regular visitor. Unfortunately, the Aquarium's popularity soon waned and in the summer of 1878, the Crystal Palace Aquarium Company was unable to pay Lloyd's salary of £400 per annum, forcing him to look elsewhere for other work.

After Lloyd took over as Aquarium Manager of the Crystal Palace Marine Aquarium, he authored the *Official Hand-Book to the Marine Aquarium of the Crystal Palace Aquarium Company (Limited*). The Fourth Edition, published in 1876, has 134 pages, 31 pages of which contain a detailed definition of what an aquarium is, a history of the aquarium, he reason why aquaria in private houses have met with such little success, problems with some public aquaria, the history of experiments with marine vegetation, aeration of small and large tanks, the decoration of aquaria, the plan of the Marine Aquarium and a description of its tanks, the effects of light on the aquarium and its inhabitants, shipping marine animals, feeding the marine animals, oxygenation, temperature and the construction of the Marine Aquarium.

All this is fascination information and I wanted to archive it. However, my copy of the Hand-Book was digitized by the University of Chicago and the result was disastrous, to say the least, since alternate pages are so faint that they are barely readable, much less able to be scanned. As I was unable to find a better digitalization of this edition, I bit the bullet, copied the faint pages into Photoshop, darkened them and then re-scanned them. This helped but they still needed considerable editing and my eyes were bleary in the process. To avoid having others go through this, I present this introductory material for general use. *Any comments I may make on selective portions of the text will be enclosed in square brackets to distinguish them from Lloyd's text.* Some of Lloyd's paragraphs are lengthy and I have broken them up into smaller paragraphs to assist in their reading.

.

An Aquarium is an arrangement for the maintenance of living animals* under the following three conditions:—

1st. The water must not be changed, though it may receive addition from time to time of whatever it may lose, as, for instance, in fresh water by evaporation, or in such solid matters as are taken from it in the course of the formation of the shells and other hard parts of creatures existing in it.

2nd. The water must be not only kept in a pure and respirable condition by its absorption of atmospheric air at its surface, which absorption may or may not be increased by putting the water in motion in any convenient manner, but this purity must be assisted by the presence of vegeta-

tion growing in it and tending to decompose the poisonous carbonic acid gas evolved from the animals, such vegetation taking up the carbon of the gas into its own substance, and liberating the resulting oxygen for the use of the creatures.
3rd. The animals must not be lung-breathers, that is to say, they must be either such as the sea-anemones and corals, and some others which have the function of respiration diffused over their entire bodies; or, be such as the creatures above them (up to and ending with fishes), which are provided with gills during their whole period of existence. As lunged animals do not require the purifying processes just alluded to, an aquarium is not for their use, and they are therefore excluded from it; and this exclusion applies even to such aquatic animals as water-lizards, frogs, and salamanders in their adult states.

*The word "animals" throughout this Hand-Book is to be understood as a collective term for all creatures kept in aquaria.

[In William R. Hughes' 1874 paper, "On the Principles and Management of the Marine Aquarium," he comments: "Exception may be taken to the third of Mr. Lloyd's propositions because the admission or rejection of lung-breathers in no way interferes with the balance of the Aquarium, and it is, therefore, a mere matter of opinion." In this I agree.]

These conditions apply alike to marine and to fresh-water aquaria. It is not known how long the same water may be kept unchanged, with the necessary occasional additions referred to; but periods of ten years with no apparent detriment are frequently met with. The duration of life of animals in aquaria depends on their kind. Thus there are now in England many healthy sea-anemones which have been in aquaria for the last eighteen years; and some fishes, as pike and carp, for ten years; while other fishes, as cod and turbot, grow so quickly in captivity as soon to become inconveniently large; and there are some, chiefly belonging to the herring family, which, though capable of being safely transferred during journeys of a dozen hours in duration, usually die from some unknown causes (possibly one main cause being change of temperature) in a few minutes, or in an hour or two after being placed in an aquarium. But in the case of a large number of animals living naturally in rivers or near the shores of the sea rather than in the open ocean, but always more or less concealed by the water in which they exist, an aquarium presents absolutely the only mode by which they can be conveniently observed alive at all times.

Bearing in mind the three conditions here laid down, neither the "Vivaria" of the ancient Romans, nor modern sea- and fresh-water ponds, or receptacles of any kind, in which fishes and other creatures, for table or show purposes, were or are kept in captivity in water in communication with the sea or with flowing fresh water, in which the water is changed constantly or otherwise, can be termed "Aquaria" in the conventional sense to which it is now necessary to restrict the word.

[For present day purposes, this is too restrictive a definition of the word "aquarium."]

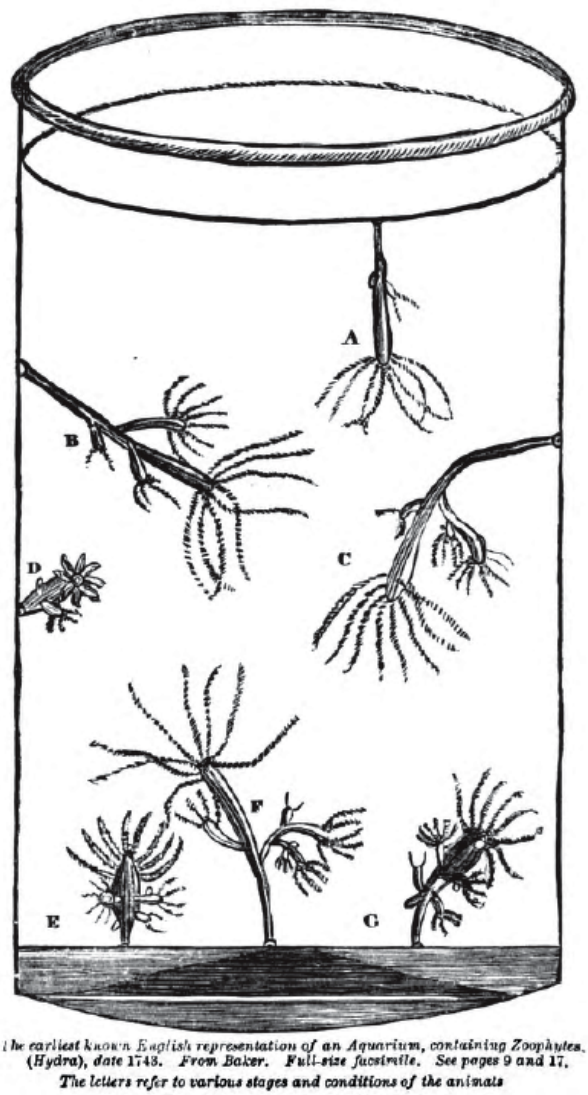
In China and Japan it is known that for many centuries dealers in living fresh-water fishes have observed that when a green silky filamentous plant or "weed "grows spontaneously under the influence of light in the vessels in which the fishes are kept, they are more healthy than in vessels in which such vegetation has not appeared; and thus, but empirically, the Chinese and Japanese have long since so far made aquaria. Still, as this result has not been arrived at by the exercise of reason, and by the intelligent application of known laws; and as the water was additionally kept pure by being constantly renewed, or changing it, this ancient people cannot be said to have invented "Aquaria." The Chinese kept gold and silver carp for amusement long before they were introduced into Europe during the second half of the seventeenth century. It was probably some such fish as these which are alluded to by Pepys

in his Diary (quoted as a motto to this pamphlet), and doubtless vegetation grew, and was encouraged to grow, in the glass and porcelain vessels in which these household pets were kept, and so constituted them in some measure as "Aquaria."

In the early editions of the late Mr. N. B. Ward's book "On the Growth of Plants in closely glazed Cases," there appeared a supplement where it is stated that in a German work on the microscope and on microscopic objects, by Martin Frobenius Ledermidler, in three volumes quarto, 1760, 1761, and 1762, there is a representation of an aquarium with plants and animals in it, and with visible bubbles of oxygen arising from the plants under the stimulus of light, the animals thereby being healthily maintained. This is a mistake, however, as in the plate referred to (No. 87, vol. ii.) [Note" See the accompanying image.] there are certainly plants and animals, but the appearance alluded to by Ward as a collection of air-bubbles is certainly caused by some minute organisms which are being lifted out by a glass tube for examination. In the descriptive text, pages 170 to 174, it is distinctly stated that the plants were merely put into the jar because certain animals were attached to them, but if it had been known that the water could have been preserved clear and unchanged by the chemical action of the vegetation, such a fact would naturally have been told as one of great interest.

About the middle of the last century much attention was given to a minute fresh-water zoophyte, the *Hydra,* and it became almost as much a fashion to keep it alive in glass jars, as it was a hundred years later to keep its larger marine relatives, the sea-anemones. In the books of Trembley in France, and of Baker in England, its mode of maintenance is described and figured; but nothing is said of employing vegetation to aerate the water without changing it. Yet, on carefully reading Baker's book—date 1745—there can be no doubt of his having unwittingly employed some self-grown low form of vegetation as a purifying agent, and that therefore be kept aquaria which did not need any change of water, had he been aware of the balancing principle. His interesting and somewhat rare volume shows this in several places.

Towards the close of the century, namely, in 1790, the late Sir John Graham Dalyell began to keep living marine animals for observation, in his house in Edinburgh, and continued this practice till his death, about 1850; but he changed the sea-water two or three times a week, though many of the animals lived for eight or ten years; and one



The earliest known English representation of an Aquarium, containing Zoophytes, (Hydra), date 1743. From Baker. Full-size facsimile. See pages 9 and 17. The letters refer to various stages and conditions of the animals

The Earliest known English representation of an aquarium containing zoophytes (hydra). From Henry Baker, "An Attempt towards a Natural History of the Polype," R. Dodsley, London, 1743.

sea-anemone (*Actinia mesembryanthemum*) taken by him from the sea in August 1828, is still alive and well. But Sir John knew nothing of employing plants to evolve oxygen, and thus to preserve a balance of life with unchanged water, though Dr. Joseph Priestley (1733—1804), the discoverer of oxygen gas, and the first observer of the fact that that gas is emitted by plants under the influence of light, and therefore the earliest enunciator of the main principle upon which the maintenance of aquaria depends, had published this discovery and observation. Ingenhousz also had shown that plants evolved this gas. Therefore, if Dalyell knew this, he did not apply the principle. Indeed, a reference to books of zoology for the whole of this period, and long before and after, shows that naturalists were in the habit of keeping aquatic animals without turning to account this self-supporting idea; even though in 1833 the late Professor Daubeny again showed how oxygen is given out by plants under the influence of light, and explained the exact manner in which it is done.

In 1840 Madame Power kept marine animals alive in Messina, and when, in 1860, a public aquarium was set up in Paris for the first time, she being then a resident in Paris, it was stated that she had invented aquaria; but this lady, by her own showing, knew nothing of the employment of plants in the manner stated, though she might have used them so, unconsciously, and derived benefit from them.

In 1837, and afterwards in 1842, Mr. Ward directed attention to the possibility of applying to the preservation of living animals a modification of the same plan that he employed for living plants in his “Wardian cases”; and in 1841 he set up in London a fresh-water aquarium, the water of which was maintained pure and unchanged, and the animals healthy, by the action of growing plants. This is the first recorded fresh-water aquarium on the compensating principle.

In 1842 the late Dr. George Johnston, of Berwick-on-Tweed, made a little marine arrangement consisting of six ounces of sea-water in a glass jar, in which animals and plants balanced each other, without any change of the fluid for a period of eight weeks, or perhaps longer; and he records the fact as demonstrating the dependence of the two organisms on each other. His object, however, was to prove the vegetable nature of a calcareous sea-weed, and not to show the possibility of maintaining an aquarium—that was merely incidental to his main purpose.

The very first recorded person who, endeavouring to keep marine animals far from the sea (in London), and feeling the difficulty of doing so, set about devising means to overcome it, was Mrs. Thynne, who (as recorded by Mr. Ward), in the spring of 1847, sent to the sea for weeds to place in water for her animals in town, in order to keep them in good condition. It will be seen that this lady did not do this by accident, while doing something else of more consequence to her, but introduced plants for a definite and avowed purpose, stated beforehand, and this was more than anyone else ever before her did with sea animals and sea-water.

[Regarding these comments on the work of Power, Johnson and Thynne, Lloyd did not consider that Power or Johnson kept an aquarium even though they maintained them using the balanced aquarium principle because it was incidental to the purpose of their work. Again, this was a restriction only applied by Lloyd.]

In the summer of 1849 the late Mr. Robert Warington, of London (with precisely the same intention and success as Mrs. Thynne with sea-water), began experiments with fresh-water aquaria, and in January 1852, he commenced applying the balancing principle to marine creatures, plants, and sea-water, and at the same time, Mr. P. H. Gosse, also in London, began his experiments with sea-water animals and plants.

[Here Lloyd seems to give Gosse and Warington equal credit for being the first to show the proof

of principle of the marine aquarium. Warington gets priority as a result of an interview that appeared in *Chamber's Edinburgh Journal* in 1852. Gosse followed up with an article published later that same year in the *Annals and Magazine of Natural History* and this was followed by Warington's article that appeared in 1853 in the *Annals*. However, Gosse's article contained nothing new (no fish were involved), whereas Warington's article was a tour de force and dealt with vertebrates as well as other marine animals. At this time they were not neck-to-neck as Lloyd implied; Warington was at least a half race track ahead.]

At about this period (1848-9) Dr. David S. Price successfully carried out some experiments on the equilibrium of vegetable and animal life in marine aquaria. Dr. E. Lankester kept small freshwater fishes and plants together on the balancing principle in 1849 and 1850, and so did at the same time Mr. (now Dr.) J. S. Bowerbank, at his house near London, where the late Mr. D. W. Mitchell, the then secretary to the Zoological Society of London, saw such an arrangement, which suggested to him the erection of a fish-house or aquarium in the Society's Gardens, Regent's Park.

This building, commenced in the summer of 1852, and opened to the public in May 1853, was the first public aquarium in England or anywhere,

An artist's rendition of the Marine Aquarium. The Aquarium was long and narrow (see layout on page 16). Here visitors are walking past Tanks 1 through 18a.

and still exists in nearly its original state, save in the diminution of light. Whatever may be its deficiencies consequent on being erected at a period when there was no experience available for guidance in its formation, it originated by far the greater part of the popular movement in the cultivation of aquaria in Britain and elsewhere, which prevailed as a kind of mania from 1854 to 1860, reaching its highest pitch in the last-named year, and then declined till it almost ceased to exist in its domestic aspect, in 1862.

During this period the taste for the subject was greatly fostered by a series of admirably illustrated works on British marine zoology from the pen and pencil of Mr. Gosse; and he was followed by many other writers, both of complete works and of magazine articles, and by many compilers of more or less merit; so that the date of the great bulk of aquarium literature generally is from 1853 to 1859. It was Mr. Gosse also who in 1854 greatly assisted inland aquarium keepers by showing that sea-water could be manufactured by adding its solid components to fresh water, and that animals would live and thrive in such a composition. Mr. Ward had, however, before 1849, made sea-water by artificial means, and had grown marine plants in it. [Actually, Ward had reported this at a meeting of the British Association for the Advancement of Science on June 25, 1847 (Hibberd is responsible for the 1849 date). The full text can be found in the *Athenaeum*, No. 1027, p. 715, July 3, 1847].

Such artificial sea-water answers very well: indeed the large aquaria at Hanover and Berlin have no other. Mr. Gosse records how several of the substances found in real sea-water, such as lime, iron, silica, and iodine, not introduced by him, were found in his artificial sea-water after a period of employment in aquaria; but it must be remembered that it is not possible to put a marine animal into artificial sea-water without some minute quantity of the real sea-water adhering to the creature, even if it has been previously long kept in artificial sea-water, and the very smallest quantity which thus finds admission may be enough to serve as a vehicle for the introduction and after-increase of the substances referred to, as well as of vegetation. Artificial sea-water has been made in London from distilled water, and the mixture afterwards boiled, and then closely stopped up in a glass jar strongly heated to destroy organic matters; but yet, on exposure to light for a few months, sea-weeds appeared in the jar without its having been unstopped.

The reason why aquaria in private houses have met with such small success may be found in the natural difficulty of the whole thing; in the general want of a knowledge of zoology among those attempting it; and in the difficulty of producing a sufficiently comprehensive and practical manual of instructions on the subject. General laws can only in such cases be stated, as it is not possible to give any definite rules, applicable under all circumstances, respecting the kind, sizes, and number of animals which may be permanently kept in a given quantity of water, inasmuch as the capability of the water for maintaining the animals in a private house (and even in a building specially made for aquarium purposes), is liable to continual change from various circumstances, among which temperature is a principal one, and regulation of light is another. Such capability is also greatly affected by the proportions of the vessel containing the water, for if the fluid is spread-out in shallow masses, its absorption of air by mere surface contact with it, and its consequent good condition is much greater than when it is piled up (so to speak) in tall masses with small surface area. It often has happened, therefore, that when an aquarium has been for some time in a flourishing condition, it has presented no manifest sign of containing as many animals as it can conveniently support in health, the temptation has arisen to add more creatures, perhaps some which are specially beautiful or interesting, and should there have been no appliance, in such cases, for any continuous aeration derived from constant motion (independently of passive contact of the water surface with air) to compensate for the new and excessive introductions, the collec-

tion has begun to show signs of being overcrowded. This may or may not be perceived; if not some animal, less hardy than its fellows, then dies, and is not immediately taken out; an increase of temperature perhaps takes place, the impurity from the dead animal (or perhaps from a morsel of uneaten and unremoved food) spreads quickly, then other creatures succumb, each death hastening the demise of the others, until in a few hours, especially in hot weather, the whole suddenly collapses, and becomes a dark and foul-smelling mass of corruption, the blacker and the worse in odour if the aquarium is marine. But such failures result from the wrong application of the principle, and not from the principle itself being wrong, the correctness of which is proved by the fact that if the water (whether sea- or fresh-water) which has been in an aquarium during such a mishap, be sufficiently exposed to the oxygen of the atmosphere, it will once more become transparent and pure.

It is not precisely correct to suppose that water is ever in a state of decomposition under such circumstances. Water is a chemical combination of two gases, oxygen and hydrogen, and it is an excessively difficult and slow process to separate them. Therefore it is only something contained in the water which decomposes, and if that something can be removed by the action of the free oxygen of the surrounding air, the water becomes again pure. Now, most decaying organic matters proceeding from animals and plants, singly or both together, can be so acted upon and removed; and if such matter can be thus taken away when it is present in such quantities as to make a highly putrescent mass, it is obvious that it can also be removed and got rid of in the same way, but as gradually as they come, when it emanates from healthy animals in a healthy aquarium, just as well as when in this imaginary case it has accumulated and become quickly poisonous. But the difficulty is to avoid giving the oxygen more work than it can thus gradually do, which object is attained by so limiting the animals that they will comfortably live within prescribed conditions, on the most unfavourable terms, and this applies both to aquaria with currents and many animals, and to aquaria without currents and with few animals; So to judge, however, needs more experience than the general public have been as yet found to possess; and before such experience has had time to be gained, the failures, and consequent discouragement, have been almost universal. “The balance of existence” between plants and animals in a streamless aquarium is never easy to maintain, and therefore amateurs have usually to choose between the meagreness of a tank with but very few and small animals in it, and one with so many that the destruction of the whole may be very quickly brought about by some small adverse circumstance; and there is frequently no choice between an aquarium with the water looking dull from an insufficiency of oxygen, a state caused by a want of the light indispensable to the development of vegetation, and one exposed to so much light that the water is rendered opaquely turbid and of a greenish-brown hue by the countless spores or seeds evolved from the plants. A stream of water in an aquarium, however, with the greater part of the water being in a separate vessel, the latter containing no animals and never exposed to light, while a smaller part of the water contains the animals, and is moderately illuminated, at once surmounts many difficulties, and is (so to speak) a fly-wheel which carries the whole machine of an aquarium over its “dead points.” But such an arrangement is expensive, and its working needs much attention. Attempts, however, were made to facilitate the maintenance of animals by increasing the surface and decreasing the depth of water in tanks, so as to give a large absorbing power to the field, and thus in a measure to compensate for the absence of motion. This was suggested by Mr. Gosse and by Mr. Warington, as before mentioned here, but it was found that scarcely any amateur would be content with keeping creatures of a certain kind and size, and in numbers suitable for such an arrangement, and in trying to keep more, failures took place, as has been described.

It was felt, too, that the light admitted to most receptacles used as aquaria was excessive, and led to an excessive growth of vegetation by rea-

son of an unnecessary amount of glass employed in their construction, and therefore the sides of such vessels were improved by being made opaque, and only one side was left of glass for convenience of observation. Quite early in the course of his experiments, Mr. Warington devised the form of tank which he named the "slope-back tank," from its resembling a box with its back receding upwards and backwards; this slope being placed towards a window, the light entered the tank from above, as in nature, and without undue shadow, and the creatures had also choice of various depths of water upon the shelving bank. This contrivance was afterwards much improved-upon by Mr. E. Edwards, of Menai, who converted the triangular space below the slope into a receptacle for water in a state of darkness, and containing no animals, but in contact with the water in the part of the tank where the animals lived; which arrangement, termed the "dark-water- chamber slope-back

Room I (see layout on page 16) containing tanks 28 to 36. A smaller room, H, containing tanks 19 to 27 was at the north end of the building.

tank," is perhaps the best existing form of tank without a current of water, as the fact of about half the whole quantity of fluid being in darkness tends much to retard the too rapid growth of some weeds, the spores or seeds of which ore disseminated in the water to such an extent as to make it opaque. This principle has been carefully recognized in the Crystal Palace aquarium, where about four-fifths of the water is kept in darkness, and only one-fifth in light. Dr. W. B. Carpenter, on April 18th, 1872, gave in the Crystal Palace a lecture entitled "Researches in the Deep Sea" (being an account of his personal experiences), and in course of it he bore testimony to the accuracy of the most essentially important principle employed in this aquarium in its direct imitation of the actual ocean, i.e. a great reserve is maintained to counteract the effects of light, as well as to be drawn upon for the adequate oxygenation of the show tanks where the animals are kept.

The larger the quantity of water, the greater will be the health of the animals kept in it; and this system enables the bulk of fluid to be very largely increased, but without correspondingly increasing the cost of construction and maintenance. Dr. Carpenter has also compared sea-water as found in the sea, to "a weak broth," in reference to the large quantity of decomposing organic matters it contains. Such matters would be very injurious in an aquarium, however harmless in the open sea—hence the value of depriving it of such substances by storing in a reservoir before using it. The dark-water-chamber tank of Mr. Edwards's for a time retarded the decline in the taste for domestic aquaria, but nothing could sustain it permanently while the public expected far more results than could possibly be attained by given means; those means being naturally very small under such limited conditions as were implied by little vessels containing animals in water often in a temperature and in light unnatural to them, and without the continual motion to which water in a state of nature, as in seas and rivers, is ever subject. Such motion was first pointed out as being desirable in aquaria, by E. W. H. Holdsworth.

In 1853, a public aquarium was opened for a few weeks in the Surrey Zoological Gardens, London; after which, another was formed in the Zoological Gardens of Dublin. Subsequently others were set up in public institutions in Belfast, Galway, Edinburgh, Scarborough, Weymouth, Vienna, the Crystal Palace, and in one or two other places; but the one in Dublin is note-worthy, as the late Dr. R. Ball, its manager, devised a method of keeping the sea-water in occasional motion by passing bubbles of air through it from a pair of bellows worked by visitors. This system, though of some small value in little arrangements, is of but very trifling worth in a series of great tanks, where it has been recently applied with much waste of steam power. In America there was an aquarium at Boston; and another formed a part of Barnum's Museum in New York. In all these the animals were sometimes in a series of tanks, sometimes in only one; but in every instance there was the same defect that usually characterizes private aquaria, namely, a stock of animals excessive in number and size, or wrong in kind, which dwindled at last to none at all. Combined with these drawbacks was the want of constant motion in the water (in the form of flowing streams, and not merely in the form of bubbles of air), with too much light and heat, developing too much vegetation.

About this time, Mr. Warington in some printed communications of his, termed an aquarium a "self-supporting arrangement"; but the application of such a phrase to any arrangement needing attention from without, such as the feeding of the animals, the removal of dead ones, the addition of water to compensate for evaporation, &c., is evidently erroneous. [Another quibble on the part of Lloyd.] It could only be correct in reference to such a thing as that which was set up some years ago, a couple of really self-supporting small aquaria, one sea-water and one fresh, consisting of two glass vessels, each of a quart capacity, which were filled with equal quantities of water and atmospheric air, and then hermetically sealed. No visible plants or animals were introduced, but

after a few weeks' exposure to light, both vegetation and creatures appeared, oxygen was evolved, and successive generations of plants and animals, humble in organization and minute in size, appeared, lived, and died for a series of years, with a rapidity which varied with the varying temperature and light of the seasons of the year. These arrangements were, so far as they went, perfect microcosms.

Up to about 1857 it was the practice to introduce oxygenating vegetation, generally the sea-weeds *Ulva* and *Enteromorpha* (sea-lettuce and sea-grass) growing on stones. Occasionally, possibly once in a thousand instances, these plants grew and flourished, but they almost always died; and some other plants, mainly the silk-weeds (*Conferva*), preceded by a microscopic growth of still lower organized plants (Diatomaceæ and Desmidiaceæ), grew up in their place. It then occurred to experimenters that the visible introduction of vegetation might advantageously be omitted altogether, leaving the *Conferva* to appear and grow by the action of light on the spores or seeds invisibly existing in water, as they grew ages before—in the fish receptacles of the Chinese and Japanese. This plan (which, in its immediate application to a London aquarium, was suggested by some vegetation which appeared in the drinking-glass of a bird-cage suspended in a window) was found to succeed much better than the former one, as the vegetation thus grown was healthy and vigorous, because it was the kind suited to the self-chosen conditions offered it, and gave off oxygen freely.

It is curious to think, therefore, that every person who at any period kept animals in water, which was left unchanged long enough and sufficiently exposed to light, must have obtained a vegetation which would render a change of water needless, if the observer had but know n it, as it really was known though not understood by the Orientals long periods ago. There can be no doubt but that Ledermüller, and Trembley, and Baker, and others, maintained their *Hydras* in good condition by the action of minute vegetation grown spontaneously on the inner surfaces of their glass jars; that Dalyell was similarly assisted without being aware of it; that Warington need not have introduced *Valisneria* or any other already visible plant in the vessel in which he made his first fresh-water experiments in 1849; that there was no occasion for him, in his early sea-water attempts in 1852 to successively experiment as to which of the three classes of sea-weed, the red, or brown, or green (Rhodosperma, Melanosperma, or Chlorosperma) were best adapted for this purpose.

So, too, Mrs. Thynne need not have sent from London to the ocean for sea-weeds to revivify the water for her flagging corals, even though she thus for the first time intelligently applied the purpose of the vegetation in a marine aquarium; for, had she but exposed the water long enough to light, seaweeds would inevitably have come, even in London, without their having been consciously put in—and they doubtlessly did come without being recognized, in her case. It was the same with Mr. Gosse, and with every other writer, who recommended the putting masses of grown-up or even young plants into tanks. Such vegetation is very elegant, often as much so, and as interesting, as the animals themselves, but with the exception of the knowledge taught by Warington and Gosse, namely, that a few of the red algae can be grown in captivity in darkness or in much shade, or by the interposition of coloured media, the means of systematically cultivating seaweeds of my kind—whether green, red, or brown—is as yet hardly known to us,* and especially with regard to the green ones, as *Ulva, Enteromorpha,* and *Porphyra.* By chance, indeed, sometimes one here and there (and even difficult kinds occasionally, as *Delesseria, Laminaria,* and others) may be grown more or less well; but as the reason is unknown, a repetition of success can seldom be obtained - and, in fact, so uncertain are these algae, and so easily are they killed from a slight disturbance of condition, that sometimes an alteration of position in a tank of even a few inches in extent, without the attachment or any other part being disturbed or injured, will cause a growing plant to die.

* Since this passage was written, however, several of the red algæ have grown luxuriantly in this aquarium, chiefly in the dark corners of the north and south rooms. The species are *Phyllophora, Gymnogongrus Griffithsiea, Polyides rotundus, Iridia edulis, Chondrus crispus, Gelidium corneum, Rytiphlaea pinastroides, Corallina officinalis*, and several others. (April 1870.)

It may be that some algae need the alternate exposure and submersion of tides, or the successive periods of rest and growth afforded by the cold and warmth of actual nature; or possibly some require tidal actions, or the influence of the rain they occasionally get when the tide is out. Be that as it may, it is certain that with our present knowledge, the putting into an aquarium of masses of already grown sea-weed, especially the green kinds, whether they be young or old, or attached to stones or not, or of any ready grown fresh-water plant, is not only very seldom attended with a successful result, but so much positive harm is done by the decomposition arising from their decay, that it is better to avoid them altogether, and to depend only upon that which gradually and naturally appears upon the rocks of the aquarium by the action of light, and which answers every chemical purpose. The amount of growth of such vegetation can always be precisely regulated by the amount of light given to it—indeed so vigorously does it flourish on places of its own choice, that its tendency is to increase too much when the light cannot be sufficiently diminished without making an aquarium too dark for objects in it to be distinctly seen—and in such cases some animals, as mollusks, the ormer (*Haliotis*), or fishes, as the grey mullet (*Mugil*) are employed to eat it down to the very small quantity required to decompose the carbonic acid gas of even the largest aquarium. If all the *necessary* vegetation of the Crystal Palace aquarium could be gathered together in one mass, it would, when deprived of its water, probably not weigh one ounce. This better mode of producing and keeping-up the vegetable element of the system, combined with the use of the new tank ("the dark chamber slope back") gave to domestic and public aquaria a new impulse; but only a temporary one, for the great want felt was *constant motion*, like that of nature, by which the water may be continually turned over and over, presenting successive and multitudinous surfaces to the surrounding atmosphere, and may by contact with it incessantly absorb the large quantities of oxygen necessary for the sufficiently rapid decomposition of organic matters given off by the animals, with sufficient rapidity to keep the aquarium clear of putrescence.

It will be seen by this, that motion in aquaria is merely the increase, frequently to an enormous extent, and of commensurate value, of the air-absorbing surfaces of the water. It then became more and more apparent that the oxygenation obtained by such motion should not be used merely as an auxiliary to the oxygen obtained from growing vegetation, combined with the surface absorption of oxygen effected by even motionless water, but that the *chief* means of aerating and purifying should be motion, or, in other words, the increase of air-absorbing surfaces, and that the plants should he used merely to do what motion will not do, that is, to decompose the carbonic acid gas. It was felt to be an error, and a fruitful source of failure, to so far stimulate the growth of plants with light, that dependence had to be placed in them for nearly all the oxygen needed for aquaria. Accordingly, early in the history of the subject, the writers of aquarium books, without seeing the matter quite as here stated recommended such aeration as could be got by occasionally drawing off some of the water into a separate vessel, and allowing it to drip back into the aquarium; or by forcibly injecting water through a small orifice with a hand syringe, so that a strong stream, mechanically entangling atmospheric air at the moment of its impinging on the surface of the water in the aquarium, should carry down into the latter great quantities of minute bubbles of air, so that the air being thus as it were, pulverized, is, by reason of its largely increased surface, in the fittest state to be easily absorbed by the water. In Ball's system, the air is driven into the tank at the bottom, and it *quickly* rises to the surface in huge

bubbles which effect but little service, and still less so because they rise in one straight column, and therefore are only of local benefit, but when driven down through the surface of the water, the bubbles ale so diffused everywhere, and are so very minute, that their smallness causes them to rise *slowly*, and thus time is afforded for the water to absorb as much as possible of the air in such bubbles.

In Mr. Gosse's book, ''The Aquarium," 1854, there is described and figured an arrangement termed "A fountain Aquarium,'' where water is pumped, or otherwise lifted, to a cistern above the aquarium, into which the stream runs and overflows the aquarium into another cistern below it, whence it is again periodically raised to the upper cistern. This plan, which is still a convenient one for small aquaria, is not only valuable in its aerating effects, but also by it the whole quantity of water can be largely increased, to the great benefit of the animals; and in the Regents Park aquarium, this system was adopted from the beginning. But when used for a large arrangement, the streams so produced, which depend on when the water is pumped up by manual power, are insufficient, or inconstant.

In 1859, Mr. George Hurwood, of Ipswich, contrived an arrangement whereby the pressure of a stream of fresh-water, such as exists in the pipes of waterworks of towns, or such as can be got from a high cistern already existing in a dwelling-house, may be employed to compress air, which compressed air in turn forces a current of sea-water into an aquarium; and this plan is perhaps the best that can be adopted for small aquaria where hand labour is undesirable, though the motion is of necessity intermittent unless the apparatus be in part doubled, and though, too, there is a small waste of power each time the air-vessel is charged. [The details of this pump can be found in my essay, "The Early History of Aquarium Aeration," in *Essays on Aquarium Hobby History*, p. 240.] This arrangement was adopted in several private aquaria in England, but afterwards on a much larger scale in the first public aquarium erected in Paris, in the Acclimatation Garden in 1859. This aquarium was very successful, the sea-water not being once changed during its thirteen years of existence, and in 1862 it stimulated the Zoological Society of Hamburg, then in the first year of its life, to have an aquarium in its gardens. This aquarium was opened in the spring of 1864. It is much larger and better than the one at Paris, and became speedily very popular and successful in every way, and is still the best, though not the largest, aquarium open on the Continent, thanks to the early influence of Dr. H. A. Meyer, Professor Mobius, and the late Baron Ernst von Merck. The sea-water is circulated partly by a water-pressure engine set in motion by the town waterworks, which drive a pair of water-pumps (instead of compressing air, as was done in Paris), and partly by a steam-engine which drives two other pumps.

The great pecuniary success of the Hamburg aquarium caused other public aquaria to be erected in various parts of the Continent, namely, in Hanover in 1866; in the Boulevard Montmartre, in Paris, in 1867; in the reserved Park of the Paris International Exhibition in the same year in two places; at Boulogne-sur-Mer in 1866; twice at Havre, in 1867 and 1869; in the Zoological Gardens of Brussels, in 1868; in the Flora Gardens of Cologne, in 1869; and in Berlin, in 1869. The money capital embarked in these Continental aquaria has amounted to about £180,000, but this large sum in the case of ten of them has not produced either scientific or commercial results in proportion to its amount. The chief cause of this failure may be traced to the neglect of one apparently small matter: this was a principle of aesthetics, the connection of which with the natural history scientific success of the entire project is not obvious at first sight, though it led gradually to the neglect of other principles, not merely of art, but of physics. As these two matters are subtly but intimately connected together, it will be of interest to explain how, thus:—the early experimenters, when they wished to introduce a plant (as *Valisneria*) into a fresh-water aquarium, embedded it among the sand and shingle forming the bottom, and then placed a somewhat heavy stone

or a few lighter ones over the root to hold it down more firmly and keep it in its place. For the same reason the first workers at marine aquaria, when they introduced sea-weeds, always procured them attached to stones, often of rather large size, which, therefore, became conspicuous features in aquaria; but it will he seen that they were essential to a stated purpose, however unnecessary it may have been to introduce plants at all in such a manner.

After a while it was found that such stones had a further use, since fishes liked to rub themselves against them, or to hide under their edges, or among their crevices; or worms crept beneath them, and sea-anemones clung to their welcome surfaces. This evidence of the use of such stones caused their increase in number and dimensions, till at length they were disposed in a somewhat decorative form, and built up as miniature columns and arches, or sometimes even as small cromlechs, that is to say, with two upright pieces supporting a third piece on their tops. This latter device was not in the best possible taste, as a cromlech is a mode of enclosing a space not needed beneath the surface of water; but so long as this grotto building was confined to the interior of tanks— where it incidentally afforded the creatures the shelter they needed, and supplied places on which vegetation might grow by the action of light—no great objection could be urged against it, even if sometimes the form of such grottoes was fantastic rather than fanciful. Still less could anything he said to their prejudice when occasionally some unassuming rock-work in fresh-water aquaria was carried above the surface of the water, and used for the growth of ferns and other plants overshadowing the water below.

But the thing did not stop here, for in an evil hour someone proposed to construct an entire aquarium like one big grotto, and accordingly two public aquaria, one in Hanover, and one in the Boulevard Montmartre, Paris, were so made, and in such manner that not only was there rock-work inside the tanks, where it was of course essential to the use and comfort of the creatures, but there was rock-work outside the tanks also, projecting from walls, suspended from ceilings and rising from floors; in which places it was improper and most objectionable, because unnecessary for the use and comfort of visitors, and in fact, tending to their discomfort by reason of the sharp and ragged edges and surfaces it presented, and the dirt it harboured. Still, the public admired, and could neither perceive nor he induced to understand that a thing, which only serves to gratify inartistically educated eyes, is not merely valueless, but is actually wrong - wrong because devoid of purpose. However, the new fashion was approved, and every Continental aquarium made after that period (1866) was constructed on this erroneous principle. Perhaps none of them have been seen and admired by so large a number of persons of all nations as the two, one fresh-water and one marine, in the International Exhibition of Paris in 1867; although both were utter failures in every way, and one of them (the marine one) displayed the crowning absurdity of making the ceiling of the aquarium the transparent base of a tank over the spectator’s head, in addition to having its side -walls composed, and properly, of glass forming the fronts of tanks. But it was not generally remarked that no good zoological result proceeded from such puerilities, and the materials of this Paris Exhibition aquaria were in fact re-erected in Brussels in the following year, where of course no better scientific result ensued. In the first Havre aquarium, set up in 1867, the rock-work building was modified into an imitation of the Cave of Fingal in Scotland, and it is almost needless to say that as an exhibition of living aquatic animals (the sole purpose for which an aquarium is intended) it was very poor. The same may be said of the second Havre aquarium, one-half of the interior of which is apparently constructed to imitate the Israelitish passage of the Red Sea on dry land, the ceiling being modelled to resemble high over-arching waves suddenly arrested in their progress and walled up on each side; while the other half is an imitation of a stalactitic cave, the stalactites (composed of long conical bundles of straw bound with string, and covered with cal-

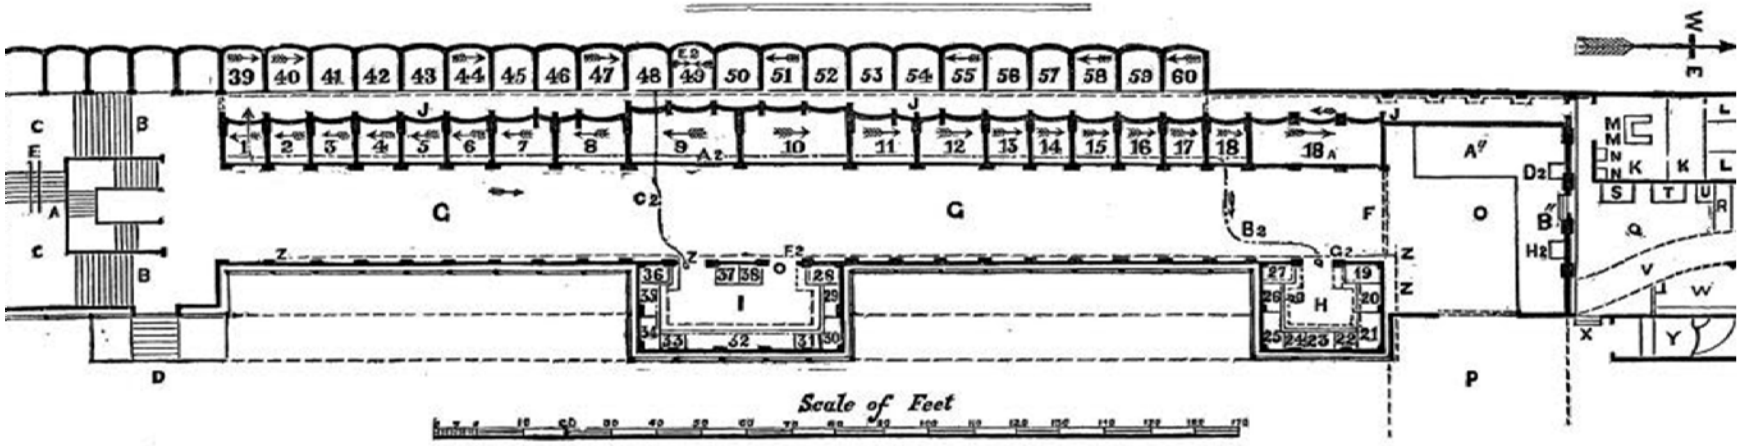
careous cement) hanging in masses from the ceiling. Between them rises what seems to be, but is not, a mass of coal left to support the ceiling of an imaginary mine, and externally the building is made to look like a great stratified rock. So also in the Berlin aquarium there are everywhere huge masses of rock imported from great distances at a great cost, but answering no real constructive purpose whatever, or supporting merely that which could be supported by iron columns of one-tenth the diameter of the piles of stone. The frames of the glasses of the tanks are made of irregular angles, with about as much reason as if the frame of a picture of a rough and broken landscape should likewise be made of irregular outline to correspond.

There are also there a “geological grotto,” can teach no geology, a blue grotto of Capri, illuminated at a wrong place and with spectators at the wrong end, stalactites lighted with coloured flames, ruined Gothic arches, and many other conceits. The object sought in all this and in much more of the same kind, is to make all look “natural “and in a sort of fancied “keeping “with the interior of the tanks. In fact, the error consists in the quite futile endeavour, as far as artistic result is concerned, to model instead of to draw a picture. When an artist makes a drawing of a rocky scene, he does not imply that his work is really the rocky scene, hat merely that he reproduces the idea left on his mind by the scene. He does not *imitate* what he saw, he only represents it; and in making that representation he employs only just as much material as is necessary, and is very careful not to use any of the materials of the things represented. Consequently, whenever, as in making an aquarium, an idea is sought to be suggested by the use of imitative means, a sense of incongruity is at once produced by the incompatibility of the ideal to be suggested with the reality which everywhere makes itself manifest, and contradicts the attempted ideal.

For example, if it be intended by making an aquarium in the semblance of a submarine grotto, to give visitors the impression that they are in a veritable cave beneath the surface of the sea, they at tuna' meet with things which could not there exist, as dry and smooth floors to walk on and plate glass through which the animals are seen, and thus the intended deception never deceives. Then comes the sense of waste at so much material having been used to do so little. In nature there is no waste. Natural rocks, mountains, and eaves may he, and are picturesque and beautiful; but they were not made only to be so. They are so merely because they are the result of some cause which had a use in the first place, and admiration of such things proceeds (often insensibly) from a recognition of that usefulness, and of a general fitness for a definite purpose. With regard to stalactites, too, they derive their peculiar shape and pendent position from the mode of their general formation; and to reproduce them in a manner which in any way permits the supposition that they have been made by nature, while they have not been so constructed, is wrong, because untruthful, and for this reason cultivated persons dislike such things, especially when they are associated with real objects having the gravity of a natura1 collection. They are accepted as illustrations in theatrical scenery, because there, usage and necessity allow an incongruous mixture of painting and modelling allied to what is of but a temporary character. Waste is also committed in the constant employment of disguise which the practice of imitation instead of representation gives rise to; for example, if in these objectionably-built aquaria, a flat or smooth surface presents itself as a pilaster or jamb, instead of being honestly displayed as being constructurally necessary, it is carefully concealed by having some rock-work cemented to it.

Waste, in the same way, is shown in the making of mock ruins, which in effect proclaim falsely that time has ruined them; and as the interest of an actual ruin is due only to a knowledge of such effects of time it is wasteful to make that which can have no other interest than the single one which has been thus carefully eliminated. Other contrary elements are set up by the primary error

PLAN OF CRYSTAL PALACE AQUARIUM.



KEY TO PLAN.

A Staircase from Palace.
BB Staircase to Palace.
CC Storerooms below Staircases.
D Communication with Palace Grounds (public).
E Turnstiles.
F Screen at north end of Saloon.
GG Saloon, containing Marine Tanks 1 to 18A.
H North Room, containing Marine Tanks 19 to 27.
I South Room, containing Marine Tanks 28 to 38.
JJJ Attendants' Gallery, containing reserved Marine Tanks 39 to 60. (Private.)

KK Room, containing as follows :—
LL Two Steam Boilers, and
MM Two Steam Engines, and
NN Two Steam Pumps.
O Junction, with Conservatory, to contain Fresh-water Tanks. A" B".
P Part of Conservatory (upper end).
Q Workroom.
R Slab for preparing Food for Animals.
S Store Cupboard.
T Slab.
U Sink.
V Flue.

W Office.
X Communication with Palace Grounds (private).
Y Heating Apparatus room.
ZZ Heating Pipes.
A2 Sea-water Pipes supplying Tanks 1 to 18.
B2 Sea-water Pipe supplying Tanks 19 to 27.
C2 Sea-water Pipe supplying Tanks 28 to 38.
D2 Point of issue of Sea-water from Reservoir to circulating system.
E2 F2 G2 Three points of entrance of Sea-water from circulating system to Reservoir.
H2 Float showing height of Sea-water in Reservoir.

The direction of flow of Sea-water in the Tanks is shown by arrows, which for want of space are omitted in Tanks 19 *to* 38, 41 *to* 43, 45, 46, 48, 50, 52 *to* 54, 56, 57, *and* 59.

referred to—such as the introduction of empty shells and corals into aquaria for decorative purposes, especially when placed in water (even when they are marine shells in sea-water tanks), inasmuch as an aquarium is a place for the exhibition of living animals, not for the houses of dead ones. Shells and corals are made to render certain services to animals inhabiting them, and they should not be placed in situations, especially in water, where it is implied even, without being directly stated, that they fulfil their legitimate and useful purpose. They are allowable only in museums, in illustration of natural history, or as articles of manufacture, as they are then employed usefully. It may be urged, on the contrary, that shells and corals are found dead and empty in the sea; but they are not placed there decoratively, and they are even then of probable service in restoring to the water some of its solid matters, which in aquaria can be more conveniently supplied by other means.

It may be and has been said in reply to all this, that mere decoration is a matter of fancy, and that even if ornamentation is incorrect in principle, it need not interfere injuriously with the practical working of an aquarium. But in every known case it has so interfered, and in a direct manner, for if such objectionable work is planned by a naturalist, it is impossible that he can have in him the true spirit which observes that nature never decorates merely for the sake of decorating, but, on the contrary, first makes a useful work, and then enriches its surfaces. Nature never introduces any member of a construction unless it has some real working necessity; and never, except in cases of deformity, which are accidental, gives anything the character of an excrescence or a deprivation. A naturalist knowing this, and being always impressed by it, will in his own work endeavour to imitate the same general principles. If he does not, the probability, or rather the certainty, is, that all will be wrong, not only in the decorative, but also in the mechanical arrangements and in the appliances generally for the maintenance of the animals—as the want of this spirit of following nature affects every part of his work.

One error leads to another, and many of these Continental aquaria have violated all the three fundamental rules laid down at the commencement of this pamphlet for the arrangement of aquaria, particularly the one against the introduction of animals which breathe air by lungs. When this rule is once overstepped, it immediately opens the door, not to the overcoming, but to the evasion, of the difficulties attending the management of aquaria, and at once converts an aquarium (then one only in name) into a heterogeneous assemblage, comprising every animal that can be maintained in captivity at all. Tint an aquarium, properly so called, has the one great advantage that all the animals can be maintained, at all seasons, within a covered building, without any ill smell arising from them or inconvenience to themselves; this cannot be the case with any animals, with but two or three small exceptions, which rank higher than tidies, and, moreover, when that is the case, the peculiar charm derived from seeing animals living immersed in an element so essentially differing from air, as water is, is at once done- away-with.

Professor Ruskin has well said that “buildings for scientific purposes should be plain and useful in all things, in appearance as is in fact," but in a building where the science is essentially popular, a little decoration is allowable, so long as it is in good taste and is unobtrusive, such as, for example, on the fronts of Tanks 19 to 38, where the ornaments are incised in the material decorated, and not applied or stuck on to it.

When any designs derived from the forms of plants or animals are used *decoratively* in any building used to contain such objects, they should be always conventionalized, or deprived of their naturalness, so that they may not come into imitative competition with the actual objects shown, they being not required as pictorial representations of them.

The difficulties generally of an aquarium, however, whether inland or by the sea, are so great, and

so much need all the money capital that can be spared for the surmounting of them, that but very little remains that can be honestly spared for mere ornamentation.

Since the opening of the Crystal Palace aquarium, two other public ones have been opened, one at Copenhagen, and one at Brighton. Five more are now in course of construction, namely, at. Vienna, Manchester, Southport, San Francisco, and Naples. Of these, the first should do much for the Adriatic fauna, and the last-named one, under the management of Dr. Anton Dohrn, will, it may be anticipated, be one of the most important, both as to the results to be obtained on the spot, and as to the obtaining of desirable Mediterranean animals from thence for British aquaria. Already, through the kindness of Messrs. Pickernell Brothers, and Messrs. A. Laming & Co. in painstaking transmission, some valuable specimens have been safely received. Messrs. Pearson and Langnese, of Hamburg, and Messrs. Drolenvanx and Bremner, of London, have also for several years greatly aided in this good work. Four other public aquaria are in contemplation, at Jersey, at Yarmouth, at Ramsgate, and at Torquay.

The building undertaken by the Crystal Palace Aquarium Company was commenced in July 1870, much too late, therefore, to be opened when at first contemplated (April 1871) though at Faster of that year half a dozen of the marine tanks were temporarily converted into freshwater ones, and some pike, tench, carp, eels, and other fishes were shown therein for three days, after which the place was closed, and the progress of the works continued; until the establishment was finally opened on August 22nd, 1871. It would have been well if the sea-water had been in good condition in the early part of the summer, so that advantage might have been taken of the then exceptionally cool weather to transport some of the great abundance of animals at that time on the coasts of England; but that was not possible; and when the water *was* fit, the weather became very hot, and the sending of many animals was thereby prevented. At first, and for many weeks after its introduction, the sea-water was much discoloured, unclean, and not fit to support life, in consequence partly of its being disassociated from growing vegetation in the sea, but chiefly because it took up such free lime as was used in the cement employed in making the reservoir and tanks, and in building the rock-work in the latter. Consequently, it became alkaline and poisonous, and continued so till the carbon of the atmosphere united with the lime and formed a harmless deposit of hydrate of lime; as this process went on, the water became clear, and vegetation formed, and animals were gradually introduced.

The accompanying plan on a folding plate, drawn to a scale of about fifty feet to one inch, shows the ground occupied by the Crystal Palace aquarium and its adjuncts to be nearly 400 feet long and 70 feet broad, and it is situated at the northern end of the Palace on part of the site of the portion which was burnt in 1806. It is of but one story high, and therefore this ground-plan shows everything, except the sea-water reservoir beneath the saloon G G, extending under its whole width, and running below Tanks 9 and 10, and going lengthwise from E to H 2. This reservoir contains 100,000 gallons of sea-water, while the tanks above contain 20,000 gallons, in all 120,000 gallons, weighing over a million pounds, supplied by Mr. Hudson, and brought from the coast by the Brighton Railway Company, at favourable rates of carriage, through the kindness of its manager, Mr. Knight. Contrary to what used to be supposed, shore-water, when purified, is perfectly fit for the maintenance of deep-sea and open-sea animals in health. The fact of the aggregate contents of the tanks being only one-fifth of the contents of the reservoir is extremely serviceable in keeping the water clear, as supposing the water in Tank 18a, holding 6,000 gallons, became turbid from any cause, it could be emptied by syphons in less than an hour into the reservoir, where so comparatively small a quantity of fluid would not appreciably disturb the purity of so great a mass, from which, in less than half an hour, No. 18a can

again be filled. Thus all the tanks where animals exist are always kept in good order by being constantly pumped into, day and night, from the large clear and cool reservoir below, where there are 110 animals.

The main aeration which is thus depended on for their health is thus produced by mechanical agitation, and the small quantity of sea-weed necessary to decompose the poisonous carbonic acid gas evolved from the animals, which could not be effected by mechanical agitation, is grown upon the rocks of the aquarium by the action of light on the spores of the algae existing invisibly in the water. As the motion of the water needs to be incessant, in the same manner that the motion of the sea is unceasing, all the machinery by Messrs. Leete, Edwards, Norman and Co. is in duplicate; there being each of four-horse power, two steam engines, each of three-horse power, and two of Forbes's patent pumps one of which is kept always in action, the other being in reserve in case of accident. Even in winter, when the lower temperature of the water enables it to absorb and retain more oxygen than in summer, the occasional stoppage of the streams for a few hours, to ascertain the rate of the evaporation of the water, occasions evident discomfort to some of the animals. Indeed, the creatures in especially in the taller tanks must be considered to some extent in the light of persons in a diving-bell, whose existence depends on the continuous pumping and injection of air. In this respect they are strikingly different from terrestrial animals living in captivity in cages or dens, in an atmosphere the same as that which is around them, in free and easy contact with it, and therefore not necessarily requiring as in an aquarium the mechanical injection into it of another third of a widely-different density. The sea-water issues from the pumps at the rate indicated by a counter while a tell-tale clock furnishes evidence of the attention of three engine-men, each working consecutively for eight hours; of from 5,000 to 7,000,gallons an hour, and passes in the first place into the two highest tanks, 9 and 10, half into each, from whence it runs, diverging north and south, through channels cut in the upper part of the walls dividing tank from tank, as far as Tanks l8a and 1. It is not possible for any poisoning or other deterioration to happen to the water in its passage, as the continuous aeration it receives in so many places causes it to be as pure at the end as at the beginning of its circuit. From 18a the water flows into 90, and from 1 into 39), in each case passing below the floor of the gallery JJJ, and then the two currents converge centrally through the series of reserve tanks, and fall together into the reservoir at Tank 49.

A portion of the water, however, is arrested above Tanks 9 and 18, and is by separate pipes conveyed into the rooms H and I, where after circulating in the Tanks 19 to 38, it finds its way into the reservoir below at F 2 and G 2. Independently, however, of the simple fall of water from one tank to another, in steps of from three to six inches in height in the series 1 to 18a (Tanks 9 and 10 being six feet high, while 1 and 18 are three feet high, internal measurement), other streams of water mixed with great quantities of air in minute babbles are driven from the main pipe into all the tanks with force through jets, so that myriads of such bubbles, controlled by stop-cocks, are forced in a state of fine division (resembling steam, or falling sand) nearly or quite down to the bottom of each tank; and thus the fluid is charged with as much atmospheric air as it will take up in open vessels. (See page 19.) This forcing in of air as nearly as possible resembles that which takes place in the ocean by rushing waves, especially when by their fall they drive much air into the depths below. It is possible that if an aquarium were arranged so as to resemble the ebb and flow of tides every six hours, some important results would be gained with some animals, and probably with such plants as grow in the sea between tide marks; but the complication and cost of such an arrangement would be great, and it would cause much inconvenience to some of the animals, as fishes, which in the sea escape beyond the tide at its ebb, but in a tank have no such means of escape, and would die if the water were

removed, or even much diminished in bulk. Then there would be also the unsightliness to visitors of having the tanks, or some of them, occasionally empty of water, and with the anemones and some other specimens closed, flaccid, and uninteresting.

Therefore, conventionally, tides can be considered as useful only as contributing by their means additional air, and as laying bare decaying substances and so more quickly hastening their destruction, by intimate contact with the atmosphere and its oxygen, and by afterwards washing them away. And these effects, for aquarium purposes at any rate, are otherwise attained with nearly the same end, though in a more limited degree. The amount of aeration (which depends much on the amount of water entering, as well as on the manner of its entrance) varies greatly according to the dimensions of the tanks—thus Tank 10 holds 4,000 gallons, and Tank 1 holds 400 gallons; and as Tank 10 has a stream equal to its own bulk running through it once an hour, it necessarily follows that as the same current flows through Tank No. 1 (of only one-tenth the capacity of Tank 10), then Tank 1 has a stream equal to its bulk ten times as often as Tank 10, that is to say once every six minutes; and as these grades of aeration vary in all the tanks, they can be chosen according to the varying requirements of different kinds of animals.

There is no intention to change the sea-water, but only to make up for accidental waste, as the breakage of pipes, &c., or to introduce from time to time a requisite quantity of distilled water to compensate for evaporation, and also to add whatever constituents the animals may eliminate from the seawater. For example, lobsters, craw-fish, crabs, oysters, worms with calcareous tubes, and many other animals, arc constantly making new shells, or adding to their old ones, and the solid matter necessary for their formation is derived from the seawater, and must he replaced. This is a direct representation on a small scale of what takes place in the actual sea, where the evaporation of fresh water ascends and forms clouds, and thence descends as rain and in rivers. In like manner, solid matters in solution are being constantly washed down rivers into the sea, to be there used, and they are also furnished from some unknown sources.

.

The material used for the pumps, strainers, cocks, and jets, and for nearly all the pipes (the exceptions being the stoneware pipes connecting Tanks 39 to 60), is vulcanite, or hard india-rubber. This was recommended by the late Professor Faraday for the purpose in 1857, as being practically unaffected by sea-water. But it is likely to be now superseded by a preparation of collodion patented by Mr. D. Spill of Homerton.

In Tanks 1 to 18a, the animals can be viewed only through the plate-glasses forming the fronts of the tanks, but in the twenty tanks of the rooms 11 and I (Nos. 19 to 38), which are made to contain small specimens, the view is through the surface of the water, as well as through the glasses of the fronts, as in the table-cases of a museum. The shallowness of these twenty tanks, varying in water capacity from 40 to 270 gallons each, much increases the accessibility of the objects they contain, as well as their aeration, inasmuch as, independently of the streams, the absorption of atmospheric air by water depends on its being exposed to the air in masses having large surfaces, and small thicknesses, as has been before slated. Thus in tanks 9 and 10, every column of water measuring six feet in vertical height and one foot square, has only one superficial foot of surface at the top exposed to the atmosphere; while in Tanks 28 to 38, every column of water measuring one foot high vertically, and one foot square, has also one foot superficial at the top in contact with the external air; and in Tanks 19 to 27, every column of water measuring half a foot of vertical height, and one foot square, has still as much as a superficial foot in contact with the surrounding atmosphere. It follows, then, that the passive surface absorption of air in the south room of this aquarium, is six times as much, and in the north room twelve times as much, as in the two great Tanks, Nos. 9 and 10. In the small tanks the much shaded position of some of them, as Nos. 19, 21, 25, 27, 28,

30, 34, and 30, also affords means of maintaining some organisms, both animal and vegetable, needing an unusual amount of darkness.

For example, it is unlikely that any green algae (*Chlorosperma*) will grow in the gloom of these tanks, while they are admirably suited for the *Rhodosperma* (or red algae), which always flourish best in much obscurity,*—not only because, contrary to the rule which obtains among most terrestrial plants, the deeper-coloured marine plants or sea-weeds grow best in the least light, and fade when exposed to much illumination,—but also when so exposed they become densely covered with, and have their form and character concealed by, various green or purple filamentous weeds, which, under the stimulus of light, tend to grow upon everything. Even when by chance some of the higher green algae, as *Ulva* and *Bryopsis*, have sprung up in aquaria, the lower insidious silky green kinds (as *Conferva*, *Spirulina*, and *Oscillatoria*) have appeared oftener than not, unbidden and unwelcome, and have concealed and spoilt those whose cultivation is desired. It is true that there are some vegetable-eating mollusks, and some fishes, which may be advantageously introduced to consume these growths, but they exercise no discretion, and eat that which should be saved, as well as that which needs removal. Therefore in the culture of all such sea-weeds as can be grown in aquaria, the management of light is the principal thing to be attended to. In the Regent's Park aquarium, from time to time, some growths of the higher and more beautiful sea-weeds have occurred, probably through some accidentally presented circumstances of light; but succeeding seasons of great illumination and warmth have destroyed them. At present, however, in March 1873, in one of the central tanks is a copious growth of a red weed (*Chondrus crispus*), the "Carrageen," or "Irish moss," of the shops, which, by reason of the much more darkened con-

TOP: Front view of Tank No. 10 (18 feet long). BOTTOM: Front view of Tank No. 9 (18 feet long).

dition of the building of late years, has continued for a long time.

* Since this passage was written, however, several of the red algae have grown luxuriantly in this aquarium, chiefly in the dark corners of the north and south rooms. The species are *Phyllophora rubens, Gymnocongrus Griffithsea, Polyides rotundus, Iridaea edulis, Chrondrus crispus, Gelidlium corneum, Rytiphlaea pinastroides, Corallaea officialis*, and others. (April 1873.)

The colours of some animals are also affected by light, and therefore no direct sunlight can enter Tank No. 1; and as it contains only sea- anemones, it may be expected that this intentional arrangement will somewhat retard the usual fading of the hues of these animals when in aquaria. Some of them are diurnal in their habits, however—notably *Anthea*, which likes much exposure to light, and does not fade, and has a tendency to close at night. It will be noticed throughout the whole of this aquarium, indeed, that the principle followed is to give the animals the very smallest amount of light consistently with their being seen at all by visitors. In the sea many of them are always in more or less darkness, and this shade they often seek in aquaria by hiding in crevices of rock-work, or by burrowing in the sand and shingle, many of them coming out of their retreats only at night.

The difference between the amount of light in the sea and in aquaria is shown strikingly by such creatures as lobsters *Homaras* and craw-fish (*Palinurus*), as these, when freshly caught, have their shells usually clean and bright, or at any rate free from the green weeds which come spontaneously from the influence of light. But after they have been in even an obscurely lighted aquarium fur a few weeks especially in summer, when heat and warmth are at their maximum, and stimulate vegetable growth, they gradually become more or less covered by such growths. Other animals, as the slow moving crabs, *Maja, Pisa, Stenorhychus* and others, sometimes arrive in the aquarium much covered with the higher red sea-weeds which grow upon them because in the sea they hide much among the concealing fronts of these algae; but after a sojourn in the tanks for a period, these red forms of vegetation often decay and disappear, mainly because they are exposed to too much light, and then the green minds take their place and grow, especially in warm weather, with much rapidity—the speed being assisted by the rough surface of the shells of animals—and it is owing to the necessity of keeping in check this green vegetation, which, if uncontrolled, will grow so fact as to cover and obliterate everything, choking up pipes and gratings, and doing much other mischief, that a properly constructed aquarium, with its shade and coolness, presents such a marked contrast with the light and heat of a conservatory for terrestrial plants.

Tanks 1 to 18a are lighted from a source not seen by spectators in front of the glasses, and persons standing there cannot by looking upward obliquely, or in any other way, see through the surface of the water, the surfaces of which have the appearance of mirrors horizontally laid on the top of the water, and reflecting all objects below them, when the fluid is not too much agitated by the currents. This is because the vision is at what is termed “the angle of total reflection”; and it is incidentally of value because it tends to confine the attention of spectators to what is contained in the tanks, and prevents distraction by the sight of whatever is above them.

In Tanks 39 to 60 the view is only through the surface of the water. These twenty-two receptacles, each holding about 300 gallons of seawater, contain animals which are at intervals drafted into the show tanks (1 to 38). Acting as reserves and not for public inspection, they enable large numbers of animals to be purchased when they are to be cheaply and easily got; and thus these store-places in part remove the uncertainty of supply which hitherto has attended inland marine aquaria. They are also used as stores for living food, as mussels and shrimps, for the other animals.

For the general supply of the aquarium the Company possesses a large marine pond in communication with the sea at every tide, and serving as a store for animals, with a resident agent at Plymouth. This pond is capacious enough to furnish many animals otherwise difficult to procure, to all the public aquaria in Europe. The Company has another agent and a store-place at Southend, Essex, and supplies are obtained also from Weymouth; from Menai and elsewhere in North Wales; from Tenby, in South Wales; from Ilfracombe; together with other contributions from North and South Devon and the Channel Islands.

The difficulty of procuring animals in good health, of sufficient variety, and of suitable size, is very great; so great, indeed, on account of periods of excessive heat or cold, or of rough weather, that there are probably not more than a dozen or fifteen weeks of any average year (with seldom a couple of weeks consecutively) in which animals can be most advantageously got; and this applies especially to fishes. The specimens are conveyed from the sea by fast trains, and by the facilities kindly given by railway companies, some of the cost ordinarily attending the transmission of goods by such a mode is much lessened. There are two modes of packing, namely:—firstly in a moist atmosphere; and, secondly, in actual bulks of water. The first method is adopted for such animals as sea-anemones and corals, with a few exceptions; some of the tube worms and other annelids; many of the echinoderms; a large number of crustaceans; nearly all the mollusks having a hard shell, and an operculum, or lid, to close it; and a few of which have no such provision. Those which form exceptions to this rule, together with all the fishes, must be conveyed immersed in a sufficient quantity of water, save about two species of the fish (eels and blennies), and these only when the time of the travelling does not exceed about six to ten hours, and the weather is favourable. In the moist system the animals are usually placed in layers of wet seaweed, contained in large cans or baskets, with ready access to air through their interstices; and, so long as the moisture from the weed is sufficient to keep wet the bodies of the anemones and corals, and the skin (and particularly the breathing organs) of the other creatures, this plan is a good one, inasmuch as not only is a considerable expense saved by avoiding the carrying of a heavy weight of water, but, as the moisture produced by the sea-weed in contact with the creatures (on their external and in their internal parts) is necessarily in very thin films, these, by reason of their thinness, art more rapidly oxygenated by the atmospheric air in contact with them, on the same principle as the shallowness of water in Tanks Nos. 19t to 38 has been described as being so advantageous.

But when animals are obliged to be transmitted in actual masses of water, the process of due aeration on a journey, notwithstanding the agitation the water then receives, is more difficult (as well as more costly, owing to its greater weight) because of its greater bulk, or, more exactly, of its greater thickness. The difficulty is in both methods much increased at periods of great heat, when the films of water are liable to be dried up, or the mass of fluid to be unduly warmed. The effects of such drying is that the gills of the creatures become desiccated, and the blood then not flowing through them to be aerated, death quickly follows. The result of the warming is, that the water then not retaining sufficient oxygen for the animals, death likewise ensues. So, too, is the difficulty increased, when, in a season of much cold, the films of fluid become dried up by frost, when the animals also die; or when, if conveyed in a bulk of water, it becomes cooled below that which the creatures live in in the sea, even if they are coldblooded organisms. It is this liability of comparatively small masses of fluid to become too much warmed or cooled on a journey which makes the transit of aquarium animals so trying to them; for it must be remembered that if attention to light, to vegetation, to temperature, and to other points, is so necessary for them when deposited in an aquarium, so it is necessary to be observed in travelling, where, however, such attention can be but very imperfectly given, and the hin-

drances to success increase in proportion to the length of duration of the journey.

These considerations account for the very few non-lung-breathing aquatic animals imported from abroad, in comparison to the lung-breathing creatures so imported. Of the crustaceans (to name only one class) obtained in Europe alive from non-European countries, there are only *Sesarma* from the Navigator Islands, (*Gecarcinus* and *Coenobita* from the West India Islands, and ***Lineatus*** **from** America; and these four, though provided gills for respiration, are so modified in structure that they can pass much of their time out of water, and thus survive a long voyage. *Proteus*, a creature sometimes kept in aquaria, and of great interest because of its anatomical peculiarities, and its position in the scale of beings, has been repeatedly brought to England from the south of Europe; but though in captivity it lives wholly under water, yet its reptilian character, and its possession of gills as well as lungs during its whole life, undoubtedly aid largely its transit, though how is not quite clear. The same may be said of two other members of the same family, *Siredon* and *Siren* of South America, both of which have been brought alive to England and to the continent of Europe. Another nearly-allied form, *Lepidosiren annectans* (the Mud-fish), has often been imported into England, France, and Germany from Africa; and. notably, in the warm waters of the tropical end of the Crystal Palace has thriven well. But its successful transport is owing to its organization, which permits it to be brought over in the state in which it is found in tropical dry seasons—contained in a case of hardened mud or clay, within which, and protected from evaporation by the dry envelope, is the small quantity of well-oxygenated moisture necessary to preserve its existence when no food is taken, and the heart pulsates very slowly, and therefore very little oxygen is needed. It was also owing to the ease with which their films of fluid can be aerated, that eggs of salmon and trout, in a cold and moist atmosphere, were conveyed to Australia and there hatched-out. They could not have been conveyed immersed in water.

All the animals in this aquarium have to be fed constantly; and as for the sea-anemones, of which there are in the aquarium over 5,000 individuals, every one of them has a morsel of food proportioned to its size, and according to the condition of the water, given it at frequent intervals with a pair of wooden forceps by an attendant who makes this his sole occupation; as these flower-like creatures being so non-locomotive as to be almost absolutely fixed, cannot pursue their food, or in an aquarium obtain it in any other manner. They are here deprived of the action of the waves which in the actual ocean brings them nutriment, which is arrested by their outspread and waving tentacles.

The food consumed by a few of the animals now present in the aquarium is vegetable, consisting of green weeds (*Ulva, Porphyra, Enteromorpha,* &c.), but by far the greater number have animal food given them. This consists of shrimps, alive or dead, crabs, mussels, oysters, and fish, but they are never fed on “butcher’s meat.” The large amount of organic substance thus continually placed in the water, and the correspondingly great quantity of excrementitious matter resulting from it is nearly all rendered harmless by being decomposed chemically by the oxygenation of the streams of water, and by the growing vegetation, without the use of any filter, and without the water being made turbid. In fact, the circulating system of the water in this aquarium is similar to, and avowedly made on the general model of, the circulating system of the blood of the animals which the aquarium itself maintains in life and health. Thus, the steam-engine represents a heart; the coals consumed by the boilers are the food; the pipes are the veins and arteries; the sea-water is the blood; and the wide-spreading air-charged streams discharged at the jets are the lungs.

Filtering arrangements, contrary to the usage obtained in most other large aquaria, are here omitted, as it is evident that if filters are necessary at all, some part of the tanks or reservoir must be in a turbid state; and to clear it mechanically

(otherwise than by the mechanical displacement of floating substances by the ever-entering current of water), so as to be absolutely trails parent when seen horizontally in masses of nine feet thick, and as rapidly as the circulation demands, would need a filter of enormous and impracticable size, and the constant renewal of its contents oi surfaces. Besides, it is necessary that the water should contain some organic matters or minute organisms (of which a filter would deprive it), and which serve as food for some animals which cannot be artificially fed, as the *Serpulae*, *Sabellae*, and others. Consequently, with the exception of the use of perforated strainers to arrest the grosser impurities, the purification is a chemical one—that is to say, the large quantities of oxygen constantly thrown in with the atmospheric air decompose the injurious dead organic matters present, present, both animal and vegetable, and consume them, resolving them into their harmless constituents, by a process exactly analogous to a consumption by fire, which is merely a decomposition at a high temperature and with the aid of oxygen, while the decomposition alluded to in an aquarium is one conducted at a low temperature and without the assistance of fire, but with the aid of oxygen. This latter form of decomposition or consuming is termed by the late Baron Liebig *oremacaus*, and the rate at which it is made to proceed in an aquarium depends on circumstances. Thus, when in summer the increased temperature of the water causes it to retain in solution a diminished quantity of ab. more air has to be injected by the machinery in compensation, especially as at such periods any annual or vegetable substances accidentally present have a tendency to rapid decomposition and quick dissemination of their particles through the fluid.

Consequently, the circulating apparatus is driven faster in warm than in cold seasons, and also at all times when the water is made turbid through accidentally giving the animals too much food, which is either left uneaten, or rejected as decaying matter; the feeding is then fur a time suspended, and the circulation of water made more vigorous, so as to bring the tanks into rapid contact with the large and clear mass of water in the reservoir, and thus to take all the advantage possible of this excellent system of counteraction; while at the same time any solid or semi-solid unconsumed substances are carefully removed by nets, forceps, or dipping tubes.

A blacksmith's forge fire in operation well illustrates what is here said respecting the similarity between the two modes of consuming by the aid of oxygen; thus, when the forge fire is being blown into, the coals become a clear white incandescent mass, because the fuel is having a large quantity of oxygen (contained in the atmospheric air, and urged by the bellows) driven into it; or, in other words, because the fuel is being rapidly consumed by being made to combine with the oxygen more quickly than if there were no stream of air; when more coals are added, the flame is for a time less bright and clear, but the blowing of air being continued, it soon regains its former incandescence; and again, when the blowing has ceased, the fire becomes red, dull, and smoky, because the union of coals with oxygen is then less rapid.

So it is with this aquarium: as it is constructed to maintain a certain number and kind of animals by the aid of a stream of oxygenized water constantly driven into every tank, the water is in a bright and sparkling condition so long as the stream is kept going, but when more organic matter is added in the form of food or fresh animals (both being carbonaceous matter answering to the supposed addition of coal or carbon to the forge fire), or when from excessive light there is a superabundance of floating plant spores, the water becomes slightly dull, till the continually entering and aerating current (increased to meet such a contingency) clears it in a short time. And when on rare occasions the current is stopped entirely for a few hours, the water in the tanks loses its transparent clearness for precisely the same reason that the forge fire becomes dull when its supply of oxygen ceases. The entering currents are not made to fall through a considerable height of

air in order to absorb more of it, as was formerly deemed necessary, and the points of the delivery tubes are therefore only between a quarter of an inch and an inch above the water surfaces of the tanks; and the force of the entering stream of water carries with it a current of air, so that both air and water are forced in together at the moment they impinge on the surface of that which is already in the tank: and it is to the force with which the mingled stream is dashed in, that the greatly comminuted state of the air is due.

Very few deaths occur, and the condition of the animals is being further improved as the vegetation grows. There are, however, reasons for supposing that in no aquarium yet devised can any pelagic animals be permanently kept, and that therefore the bulk of specimens must be littoral. But there are many marine animals, not only of the deep sea, but of the shore, which at present cannot be kept in captivity at all. The reason of this is in some cases known; but in others there is not the slightest clue us to the means to be adopted for their successful maintenance.

In front of Tanks 1 to 18 are placed obliquely, and over Tanks 19 to 38 are suspended vertically, glazed frames to contain drawings of animals; which when finished will be numbered to correspond with numbered descriptive paragraphs of future editions of this guide-book, so that any animals can be readily found. Although Tank No. 1 contains exclusively sea-anemones, and thus properly commences with the lower animals, yet the classification of the specimens throughout the building is not made with reference to any acknowledged system founded on organization; but they are, so far as the limits of tin place permit, arranged with reference to *habits* rather than *structure*, and in such manner that as much as possible one animal shall not interfere injuriously with another.

The building is very cool in summer, and during the hottest part of 1871, when the true temperature of the general atmosphere in the shade was 88°, that of the air in the aquarium was only 68°, and the sea-water never rose higher than 63° Fahrenheit. In winter, hot-water pipes are arranged to maintain the temperature of the air at from 60° to 65°, and the water at about 63° Fahrenheit. The ventilation everywhere is remarkably good, and there is no tank in any of the entire series of sixty which cannot be brought, when required, into free contact with the open air. The amount of daylight can be aim very exactly regulated. On winter evenings the tanks are illuminated with gas, and many nocturnal animals not visible by day are then seen. Indeed, in an aquarium, the difficulty always is to show animals which endeavour to avoid being seen.

The architect, Mr. C. H. Driver, of Victoria Street (the builders being Messrs. Jackson and Shaw), has shown much ingenuity in turning to good account every part of the space placed at his disposal; and in his simplicity of design he has not in any ease disobeyed any law of service in construction. Everything is done with a meaning, and with a definite and obvious purpose; thus, as animals cannot exist with comfort without rock-work in the tanks, it has been plentifully introduced; but whatever picturesqueness of form such rock-work possesses is merely a consequence of its being in the first place useful. And so strictly and severely is this principle carried out, that the rock-work does not project anywhere even an inch above the water level, instead of being employed (as already stated of most Continental aquaria, that of Berlin in particular) in the spectator's part of the building, where it is not wanted, and where, being perfectly useless, it is therefore ugly, and merely an expensive excrescence. Everything is made to look like what it is, and not like something else; not even to emulate some other and more expensive material.

Thus, if it is necessary to paint deal wood for its preservation, it is not also grained to look like oak or walnut-wood; nor is cement squared with imitation masonry joints, or otherwise treated to look like stone. Nor is there any use of sham marble. It

was certainly deemed advisable to make the building correspond externally with the arched iron framings which compose the Crystal Palace adjoining, and in which the gloss of that edifice is set; but even this frame on the outside of the aquarium walls is employed usefully to strengthen those walls, which are purposely made insufficiently strong if such framing were absent. And whenever, either inside or out-side the walls, a little enrichment has been indulged in, it properly consists only in the decoration of construction, and not in the construction of decoration.

Indeed, in this aquarium the strictest economy is throughout observed so that the largest number and variety of animals may be preserved in the best condition in the smallest space.

Site workers from the Crystal Palace Foundation have been involved with the excavation of the Aquarium since the early 1980s. Much about the history of the site and its significance in the world of aquaria has been gleaned in this time, and the learning process continues. The palace may have been gone for many years but there are still many reminders of the halcyon days.

THE LLOYD-KENT CONTROVERSY

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, July 9, 2016)

Based on the success and attraction generated by the fish tanks in the Zoological Gardens in London in 1853, other public aquariums were established in Great Britain, including The Crystal Palace Aquarium in Sydenham (1871), The Brighton Aquarium (1873), The Manchester Aquarium (1874), The Southport Aquarium (1874), Dr. Cocker's Menagerie in Blackpool (1875), The Rothesay Aquarium (1875), The Royal Aquarium in Westminster (1876), The Scarborough Aquarium (1877), The Yarmouth Aquarium (1877), The Rhyl Aquarium (1878), The Tynemouth Aquarium and Winter Garden (1878), The Edinburgh Aquarium (1878), The Aston Aquarium in Birmingham (1879) and the Plymouth Aquarium (1888).

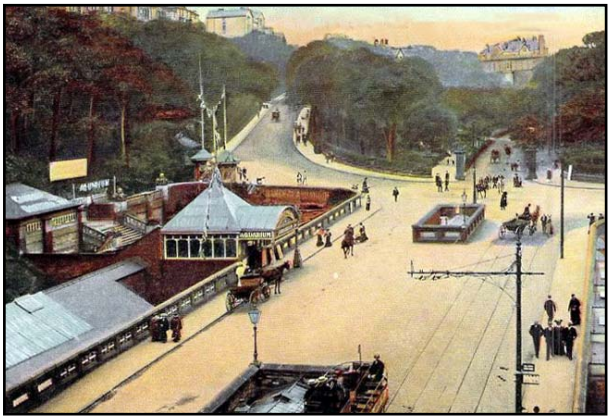
These aquariums used the system devised either by William Alford Lloyd or by William Saville-Kent. Lloyd's plan was to keep a large underground, dark reservoir for storage, removal of confervae and other small plants (they die without light), and temperature control purposes. The aggregate contents of the tanks at the Crystal Palace, for example, were only one-fifth of the contents of the reservoir. After circulating throughout the show tanks, the water ran into the reservoir, from which it started again on its circulatory rounds. Should something go wrong, any tank could immediately be emptied into it, and the slight admixture of any turbid water would be unable to significantly affect the condition of the reservoir. The main aeration was produced by the mechanical agitation caused by the circulation of the water and the constant injection of sprays of salt water that entangled air into them, into each tank.

Kent's plan was to aerate the tanks by jets of air, injected into the water in its simple form; thus the mechanical arrangements were less complicated than those in the Lloyd system. Also, a much smaller storage reservoir was required. The circulation of the sea water in the tanks was carried out individually by means of compressed air, which was supplied to their lower parts. By directly injecting air into the bottom of each tank, it ascended through the entire volume of water, first coming into contact with any organic substances lying at the bottom which was then oxidized. Although Kent referred to Lloyd's system as the "circulating system," and to his as the "aerating system," both are circulating, and both are aerating plans.

WILLIAM SAVILLE-KENT

William Saville Kent (1845-1908) was born in Devon, England, the youngest of ten children of Samuel Saville Kent, sub-inspector of factories. William was educated in boarding schools at Bath, Worcester and Gloucester. After study at King's College (University of London) and at the Royal School of Mines under Thomas H. Huxley, William became a naturalist and from 1868 worked at the British Museum. Later he became an accomplished marine biologist.

He married in 1872, but his wife died three years later. After marrying his second wife in 1876, he added a hyphen to his name, i.e., William Saville-Kent. A fellow (1869) of the Royal Zoological



The Scarborough Aquarium (1877).

Society, London, in 1873 he was also elected a fellow of the Linnean Society of London. At various times he used the nom-de-plume William Saville-Kent, and in early correspondence with the British Museum in London, as well as in his scientific correspondence, he signed himself William S. Kent, and occasionally W. S. Kent. In November 1870, in a personal letter concerning his engagement, he used his second name (i.e. W. Saville Kent) for the first time, perhaps in an effort to distance himself from the 'horrific events of the past' (see Addendum II). Note: I use "Kent," rather than "Saville-Kent" in the remainder of this essay since he did not use the hyphen until after the controversy between himself and Lloyd surfaced.

In 1870 he received a grant from the Royal Society to conduct a dredging survey off Portugal. Recognizing the potential for experimental marine biology of the public aquaria then being constructed in a number of British cities, in 1872-73 he was the resident naturalist at the Brighton Aquarium where his ambition was to establish a national marine research laboratory. Later, at the Manchester Aquarium (1873-76), he developed an interest in aquaculture. in March 1877, he took up a temporary position at the Zoological Society in Regent's Park (London) in order to restore their Aquarium and Fish House.

1877 he acquired a site on Jersey – partly because of its proximity to France (and hence with the potential to attract French visitors) but also be cause of the abundant local stocks of lobster (and the possibility of developing lobster culture), which were fetching high prices. He founded a registered company with shareholders, and the construction of a temporary building commenced in 1878. But the Government declined him a £ 250 grant and the fledgling project of establishing a national marine aquarium and laboratory, collapsed.

He hoped to make a further attempt a few years later - perhaps with the cheaper option of using an existing facility rather than building a new one, and he published the idea in a letter to Nature in 1883. It appears that the 'existing facility' he had in mind was none other than the Brighton Aquarium he knew so well. But Saville-Kent's personal interest in running a national marine laboratory was also shared by others, including some of the leading lights of the Victorian scientific establishment (e.g. Huxley's protégé, Lankester) and Saville-Kent was effectively excluded from the group who eventually drove the project through to fruition. The Marine Biological Asso-ciation was founded in 1884 and the Plymouth laboratory building was completed in 1888.

Following his work at the Great International Fisheries Exhibition in London in 1883, Huxley recommended him to the Tasmanian government to restore badly depleted oyster beds. Appointed superintendent and inspector of fisheries, in the following decade he produced the first comprehensive and scientific surveys of Australian fisheries and

William Saville-Kent (1845-1908).

their potential for development, covering not only the biological aspects of the stocks but also fisheries laws, the economics of the industry and the marketing of the catch. He fell out with members of a commission charged with acclimatizing salmon and trout in Tasmania's rivers and when his Tasmanian appointment was not renewed, he applied the same techniques in Victoria (1887-88), Queensland (commissioner of fisheries, 1889 -92) and Western Australia (commissioner of fisheries, 1893-95) for both edible and pearl oyster fisheries. He also examined and reported on fish, sea cucumbers, corals, sponges, dugong and turtles during this period.

In 1904 he worked for Lever Bros in a pearl culture experiment based in the Cook Islands. Forming a company back in England in 1905, the next year he began to culture pearls in tropical Australia, at Somerset, Torres Strait. He was probably the first to succeed in producing both blister and spherical pearls of commercial quality - a necklace believed to have been made with his pearls has recently attracted specialist attention. In poor health in 1908, he returned to England and, following surgery, he died. In his private research, Kent devoted much attention to corals, sponges and lizards, and these objects of his interest shared his residences. His grave in All Saints' churchyard, Milford-on-Sea, Hampshire, is decorated with corals.

He was the author of many scientific papers and reports and wrote three major books: "A Manual of the Infusoria" (three volumes, London, 1880-82), "The Great Barrier Reef" (London, 1893) and "The Naturalist in Australia" (London, 1897).

Clearly Kent was a scientist of the first order but he was not an engineer; but then Lloyd was not a scientist of the first order. Although Lloyd was not as educated as Saville-Kent (he left school at the age of 14), he was self-taught in both engineering and mathematics. He was also self-taught in natural history and in 1856, at the age of 31, he had two articles published in *The Zoologist*: "Occurrence in Britain of *Edwardsia vestita*," and "Note on a Sea-cucumber in Confinement." In his latter life Lloyd was often acknowledged as "the pioneer of aquarium science." The following is from Ray Ingle's 2013 article on Lloyd:

THE FIRST AQUARIST

Lloyd was the first aquarist to develop the 'closed systems methods' for successfully maintaining multiple aquariums and the first to recognize the importance of large settlement reservoirs, aeration, temperature control and filters for achieving water quality. He would not have been aware of detailed biological aspects of the water chemistry of his systems (most of this information became available only during the following century). However, he recognized the importance of vegetation in the aquarium and tried to culture seaweeds. He was an avid experimenter and intelligent observer, quickly learning from mistakes and, above all, highly capable of visualizing, calculating the requirements of, and successfully designing, large-scale aquatic closed systems.

THE CRYSTAL PALACE AQUARIUM

Since Lloyd was most closely associated with the Crystal Palace Aquarium and Kent with the Brighton Aquarium, I'll briefly summarize them, starting with Crystal Palace.

An oil painting of the interior of the Scarborough Aquarium.

In 1854 the Crystal Palace, a cast-iron and plate-glass structure originally built in Hyde Park, London, to house the Great Exhibition of 1851, moved from its temporary site in Hyde Park to its more permanent location at Sydenham, an affluent south London suburb of large villas. It had only been on the site for twelve years when in 1866 it experienced the first of a number of fires, which destroyed the North Transept. The fire left a large desolate area which had become a charred eyesore. There were insufficient funds to reconstruct the north end and it was not until 1870 that a plan was put before the directors to construct a marine aquarium.

What made the Crystal Palace Aquarium special was the fact that it was a marine and not a freshwater exhibit. No one before had created a working marine aquarium of this scale and diversity. The Crystal Palace secured the services of Lloyd, the leading aquarist of his day, who developed a system of continuous circulation of the water, which was kept in the dark as much as possible and at strictly governed temperatures. The Aquarium consisted of a building of one story high, measuring altogether about 400 ft. long and 70 ft. broad. There were 100,000 gallons of sea-water, of which 80,000 gallons were below the floor of the saloon, and 20,000 gallons in the tanks where the animals were shown. The water for the tanks was brought by train from the sea at Brighton, and briefly the aquarium was the largest of its type in the world.

The Crystal Palace Aquarium.

These tanks were sixty in number, and varied in capacity from forty to 4000 gallons each. Thirty-eight of the tanks were for the public exhibition of marine animals and plants, and were contained in a large room and two smaller rooms, but the remaining twenty-two tanks, for the storage of surplus animals, were in a gallery behind the large show tanks, and were not shown to the public (see the layout on page 8). All of the public tanks were fitted with plate glass, varying in thickness from three eighths of an inch to one inch. The sea-water was constantly pumped by steam power from the great reservoir below to the tanks above, day and night, at the rate of from 5000 to 10,000 gallons an hour; and, after it had traveled from tank to tank through the entire series, it disappeared below to be again pumped up Thus the same seawater was used continuously, without change, except for the occasional addition of fresh water to make up for the loss by evaporation.

To guard against the chance of a stoppage of the streams, all parts of the machinery in motion or liable to get out of order were duplicated. Thus there were two steam-engines, two pumps, and two boilers. Furthermore, all the pipes, strainers, stopcock and jets were made of vulcanite and stoneware to minimize corrosion by the sea water, and consequent injury to the marine plants and animals.

THE BRIGHTON AQUARIUM

It is a bit of irony to note that William Kent was not the first manager of the Brighton Aquarium. In the early summer of 1869 the newly formed Brighton Aquarium Company issued its Share Prospectus in which William Alford was listed as the Aquarium Manager. However, due to problems in obtaining the necessary permits for the construction - a new road and sea wall had to be built and securing the Royal approvals took time -

Lloyd, who needed an immediate salary, took the position of Manager of the Crystal Palace aquarium when it was offered. After Kent resigned his position at the British Museum, The Brighton Aquarium gave him the job. Kent was Curator and Resident Naturalist of the Brighton Aquarium from 1872 to 1873 but was forced to resign his post owing to some disagreements between himself and the management. In 1873 he accepted the positon of manager at the Manchester Aquarium. He left the Manchester Aquarium in 1876, working for other aquariums before entering his new career as a marine biologist.

The Brighton Aquarium was the brainchild of Eugenius Birch, the famous pier engineer and designer of Brighton's West Pier, who conceived the idea following a visit to the Boulogne Aquarium. Erected on the approach roadway to the Chain Pier, the Aquarium necessitated the construction of a new sea-wall and promenade, which was began in 1869. The whole project was completed in 1872 at a cost of £130,000, and the Aquarium was inaugurated by Prince Arthur at Easter although there were no exhibits at the time. It was formally opened to the public on August 10, 1872 by the mayor, Cordy Burrows.

The Italianate building extended for about 700 feet along the base of the cliff. The entrance was at the western end where a wide flight of steps descended into a large courtyard formed by five red-brick arches and terracotta columns. Here was located a restaurant and dining hall. From the entrance hall the visitor proceeded to what ☺ be termed the Aquarium proper, a corridor two hundred and twenty feet long and twenty-three wide, divided in the center by handsome columns, constructed alternately of Bath stone, serpentine, and polished granite. On the caps of the columns were carved designs of shells, fish, sea-birds, and other marine subjects, while the corresponding corbels from the piers were enriched in a similar manner.

The large tanks in this corridor were lit from behind to add to the air of mystery. On each side of the corridor the tanks were arranged for the exhibition of the specimens, varying in size from eleven feet six inches by twenty feet, to one hundred and three feet by forty. The center of this corridor housed a hundred-foot tank to Birch's unique design. Holding 110,000 gallons, it was the largest display tank in the world at that time.

The central square had a groined vaulted roof on each side, forming a sort of cloister, while the middle was covered with an elaborately ornamented iron roof, part of the covering being antique colored glass.

Passing through the principal corridor, which ran nearly from west to east, the visitor had access to another corridor at right angles to the one just described, running directly north and south. There were no tanks in this part of the building, its chief use being a communication between the two main corridors.

There was a conservatory opposite the second corridor at the end of the building. Its extreme length was one hundred and sixty feet, and its width forty feet, the eastern end being designed to form a rockwork waterfall, with ledges, dropping well, small aquaria and ferns. The conservatory proper was seventy feet long and twenty-three feet wide, the entrance facing the main corridor from the entrance hall. On each side were lofty arches forming arcades, having a tier of windows overlooking the terraces. The roof was in cast iron, resembling the iron roof already mentioned.

The Brighton Aquarium, 1873

The Grand Restaurant at the Brighton Aquarium.

The other main corridor, which was approached from the one running from north to south, corresponded in length to the conservatory, its width being the same as that of the principal one. It had twenty tanks, part for the exhibition of freshwater specimens, and part for tropical specimens requiring a higher temperature. The conservatory communicated on the south side to a part of this corridor, which was arranged for small table aquaria requiring minute inspection. The vaulting, lighting, glazing, and roofing of this corridor were similar to those of the first, and at the end were the engine rooms for pumps, machinery and boilers, and also naturalists' rooms.

THE ROYAL AQUARIUM IN WESTMINSTER

Since the Royal Aquarium was mentioned a number of times in the dispute between Kent and Lloyd that ultimately wound up in print, a few words will be said about that institution here. The Royal Aquarium and Winter Garden was a place of amusement in Westminster, London, opened in January of 1876. The board of directors included Henry Labouchère, the financier and journalist; William Whiteley the retailer; and Arthur Sullivan, the composer. It was intended to offer art exhibitions, concerts and plays, among other intellectual entertainments, like The Crystal Palace.

The main hall was 340 feet long by 160 feet wide. It was covered with a roof of glass and iron and decorated with palm trees, fountains, pieces of original sculpture, thirteen large tanks meant to be filled with curious sea creatures and an orchestra capable of accommodating 400 performers. Around the main hall were rooms for eating, smoking, reading and playing chess, as well as an art gallery, a skating rink and a theatre. The following is description of the aquarium proper:

The main avenue is 80ft. wide, being 8ft wider than that of the Crystal Palace. For the supply of salt water nine long tanks are constructed under the promenade floor, and occupy a rectangular area of about 260ft. long by 53ft. They are placed lengthwise, 3 in length and 3 in width. In section they are semi-cylindrical vaults, shown in our small section, with segmental inverts resting on a bed of concrete, and are faced with concrete. The arches are in three rings. These reservoirs or tanks are capable of holding over 800,000 gals. of water, one-fourth of which will be fresh and the remainder salt. The asphalting of the arches was a difficult operation.

The iron pipes and valves through which the water circulates are also coated with vulcanite, to prevent the action of the iron on the salt water. Wells, 15ft. deep and 8ft. square, at the west end communicate with the reservoirs, one with the fresh and the other with the salt water. The water will be pumped up from the reservoirs through these wells by two engines of 20-horse power (nominal) into the various tanks. The same water will serve for many years, as it undergoes a process of oxygenising, the "continuous circulating" system of Mr. W. A. Lloyd being adopted. The water will have to circulate 3-1/2 miles, and will thus be maintained in a state of clearness and healthfulness. The larger show tanks on each side of avenue have sills of polished granite, and are lighted by large semicircular lights from the outside and also from the top. The fronts are

of plate glass, having cast-iron mullions with slate fillets behind the rebates as security against leakage. There will be 9 fresh-water and 22 sea-water slate show tanks, and some reserved as a hospital for sick animals.

The all-day variety entertainments at the Aquarium turned less respectable, including billiards matches, novelty acts and side-shows of all kinds, and commercial stalls offering perfumery and gloves. The comedian Arthur Roberts (1853-1933) sang the following song about the Aquarium:

I strolled one day to Westminster,
The Royal Aquarium to see;
But I had to stand a bottle
just to lubricate the throttle
Of a lady who was forty-three.

The Royal Aquarium had its own tame royal in the shape of the Duke of Edinburgh to cut the ribbon and in addition, the organizers had roped in some other big names, with Sir Arthur Sullivan in charge of the music. What could possibly go wrong? Well, the Aquarium opened with magniloquent addresses from and to the Duke, but was found to be a hollow sham. It was then discovered that the building was still in a very unfinished state, that the tanks for the much-boasted aquarium contained neither water nor fishes, and that the general emptiness of the place was weakly disguised with colored calico and shrubs. The following is from the February1, 1876 issue of *The Musical Times*:

An Aquarium without fish can scarcely be said to offer a legitimate attraction to the public, and it is not surprising, therefore, that on Saturday, the 22nd ult., when the "Royal Aquarium, Summer and Winter Garden" opened its doors for the first time, the programme of entertainment provided for the visitors should include such items as Arrival of Lord Mayor and Lady Mayoress," "Arrival of H.R.H. The Duke of Edinburgh and Suite," and that military bands should relieve the monotony of staring at the gorgeously fitted up royal box, which was, however, placed in such a position that the occupants of the reserved seats in the gallery could only guess what was going on during the reading of the address and the reply thereto. But our business is only with the music; and here it must be said that, whatever deficiency may have been observed in other departments, no fault could be found with the band which Mr. Arthur Sullivan has formed, nor with the programme exclusively selected from the works of English composers, which had been drawn up for the opening concert.

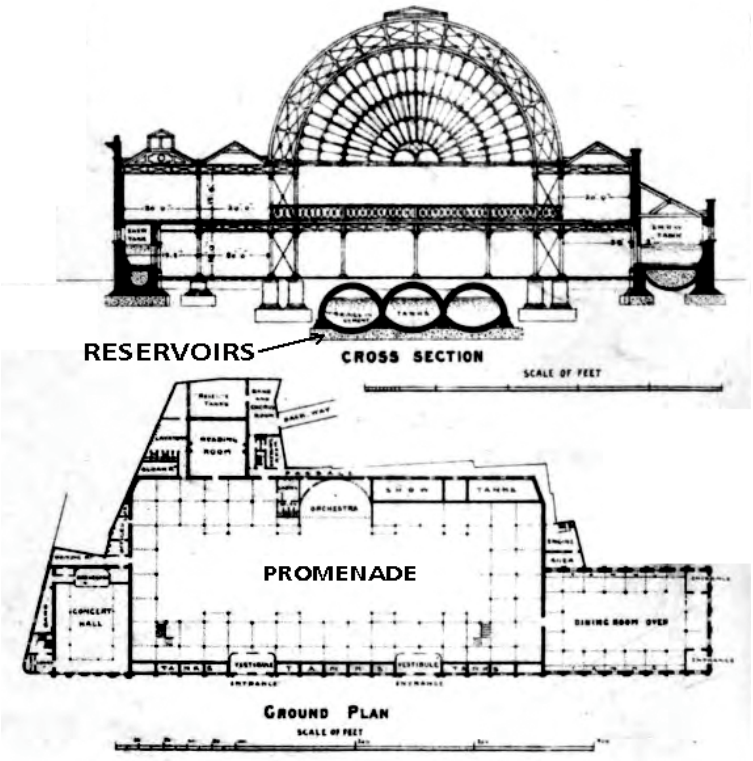
As it turns out, The Royal Aquarium had nothing to do with fish and not much to do with royalty, either. On the basis of his managing the Aquarium at Brighton, Kent was hired as the Aquarium's manager and, on the basis of his managing the Crystal Aquarium, Lloyd was a paid advisor

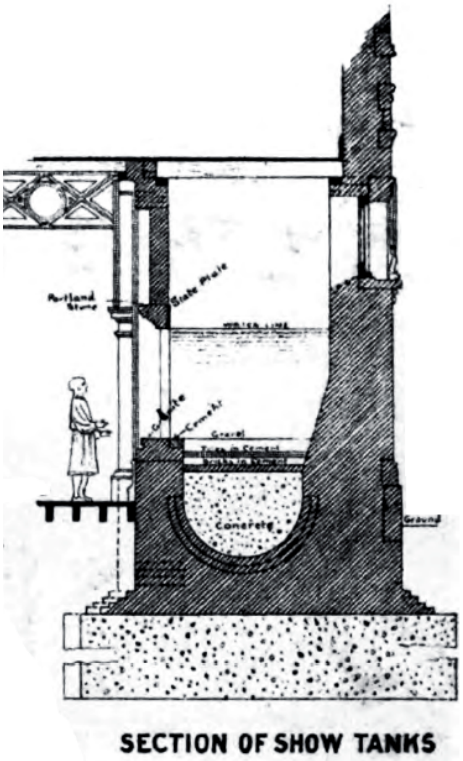
Entertainments at the Royal Aquarium.

with the aim of designing the Aquarium. It was his circulating system that was chosen but the huge hall at Westminster unfortunately allowed direct sunlight to fall upon the aquariums. If the aquariums were to maintain a constant temperature between the summer heat and the winter cold, Lloyd calculated that large reservoirs were essential and so he supervised the installation of three of them under the visitor's promenade.

However, because of the time it took to fill the reservoirs and then start the three and a half mile trip the water would take to fill the show tanks, plus the difficulty in making the large reservoirs waterproof, the stocking of fishes was delayed. Kent suggested that a temporary small cistern be built for the reception of the water flowing over the show tanks and the feeding of the pumps. This idea was rejected because of its impracticality and the unscientific character of the idea. The disagreement between them soon became public when Lloyd voluntarily resigned soon after the aquarium opened on January 22, 1876, leaving Kent to do the job he was hired for, i.e., running the Aquarium. As Charles Dickens junior put it in his *Dickens' Dictionary of London* in 1879:

Unfortunately the desire of the directors to obtain an immediate return for the large sums invested in the undertaking unduly precipitated the beginning of the campaign. Not only were the plans of the managers in an inchoate state, but the tanks without fish became a standing joke, and the dissension which arose among the discontented proprietors further tended to create distrust of the enterprise in the public mind. After some time, the tanks were filled and energetic management provided attractive entertainments of a superior music hall type.





The design of the Royal Aquarium. The three large reservoirs under the promenade are indicated by the arrow. The room on the left, bottom is concert hall; the one on the right is a dining room. The rooms at the top left include lavatories and a reading room. The rounded area seats an orchestra and to the right are two large marine tanks. There are thirteen small freshwater tanks at the bottom.

***Mrs. Jones*. "And pray, Mr. Jones, What is the matter now!"**
***Jones*. "I was only wondering, my dear, where you might have bought this fish."**
***Mrs*. Jones. "At the fishmonger's. Where do you suppose I bought it?"**
***Jones*. "Well, I thought that, perhaps, there might have been a remnant sale at the Royal Aquarium!"**

In March of 1877, the following notice appeared in a number of newspapers and journals:

Mr. John T. Carrington has been appointed "Resident Naturalist" to the Royal Aquarium Society, Westminster, in place of Mr. W. Saville Kent. Mr. Carrington has for the last year been studying aquarium management with Mr. W. Alford Lloyd, at the Crystal Palace Aquarium. Mr. C. P. Ogilvie, formerly a pupil of Dr. J. E. Taylor, F.L.S., and who studied aquarium management under Mr. W. S. Kent, at Westminster, has been appointed Curator to the Great Yarmouth Aquarium.

THE KENT ATTACK

The main portion of Kent's attack on Lloyd's system was on the grounds of its great expense and also that so extensive a store of salt water was not required. At the time of the dispute (1876), both Lloyd and Saville-Kent were in the employ of Yarmouth aquarium, Lloyd as paid advisor and Saville-Kent as manager; as I have mentioned, both briefly had worked together in the same capacities in 1875 at the Royal Aquarium. The following are excerpts from a paper by Kent that was that was read before *The Society of Arts* on March 3, 1876:

In addition to being the then largest undertaking of its kind in this country, though since greatly eclipsed in size, the Crystal Palace Aquarium prominent for the large space devoted to the stowage of reserve water, kept apart in the dark and uninhabited by the animals, and so corresponding with the spare cisterns, already mentioned in association with the aquarium at the Regent's-park. These spare cisterns, or reservoirs as they are now more generally termed, were constructed to contain no less than five times more water than did the show-tanks inhabited by the fish, the whole mass being circulated over and over again by powerful steam pumps. The entire series of tanks, both for exhibition purposes and for the storage of duplicate specimens in reserve, at the Crystal Palace Aquarium, contains 20,000 gallons of sea water; the longest single tank of these, about 18 feet in length, holding 6,000. Compared with these the reservoirs are constructed to contain no less than 100,000 gallons, making a total, with the tanks, of 120,000.

Large as those proportions seemed in comparison with its predecessors in this country, they were and are of a very puny size contrasted with the magnificent aquarium at Brighton, completed in the succeeding year, that of 1872. In this fine building the tanks alone were constructed to hold over 300,000 gallons of water, while the largest single one, more than 100 feet in length, could accommodate the whole contents of both tanks and reservoirs at Sydenham, allowing space, indeed, for the evolutions of porpoises, full-grown sturgeons, and other monsters of the deep never previously displayed to the public under similar advantages.

As already remarked, the Brighton Aquarium is conspicuous as representing that system of maintenance characterised by the injection into the tanks of air in its simple form, and which system was distinguished as the aerating one. With the exception of the fine aquarium now building at Scarborough, which will be associated with the same system, being indeed planned by the same architect, all the other aquaria here enumerated are already, or will be, maintained on the circulating system first typified at the Regent's-park, and recently in its more perfected stage at the Crystal Palace. In certain important details, however, several of these aquaria depart widely from the Crystal Palace type. Foremost in this respect must be mentioned the vast bulk of water stored in reservoirs in comparison with that held by the tanks containing animals which obtains at that institution, and which is asserted by the superintendent, Mr. Lloyd, to be absolutely essential to maintain the fish in health and the water clear.

Until experiments were instituted and contrary results arrived at, this dictum was implicitly accepted by the recent advocates of the circulating system, and in all aquaria undertaken with the assistance of Mr. Lloyd, reservoirs of these greatly preponderating proportions were insisted on as the *sine qua non* of success. The greatest length to which this fancy for reservoirs of such excessive size has been, and probably is likely to be, carried, is exemplified at Westminster—where, with water in the show tanks to the amount of under 150,000 gallons, or less than the contents of the two largest tanks in the Brighton Aquarium, accommodation has been made for storing no less than 600,000 in enormous reservoirs, which, to use the designer's own words, resemble "three railway tunnels placed side by side" occupying the whole space underneath the grand promenade. How many thousands of pounds have been spent, and must yet he spent, upon these reservoirs before they fulfil the purpose for which they were devised—that of holding water —it is impossible at present to estimate, though the filling of them with seawater alone, at the same rate paid at Sydenham, i.e., one penny per gallon, would amount to no less than £2,500.

To illustrate that this provision for reserve water, at both the Westminster and Crystal Palace aquaria, is altogether excessive and unreasonable, it may be stated that the Manchester Aquarium, adjacent to a densely-populated manufacturing centre, and with tank accommodation closely approximating that provided for at Westminster, has been, and is still, most successfully maintained with reservoirs constructed to hold a supply of water only equal to that contained in the show-tanks. Practically, however, it has been kept in the highest state of efficiency, that is, with the water clear, and an abundant supply of fish of the largest size, with less than one-half of this full complement in the reservoir.

The superintendent of the Crystal Palace Aquarium has thought fit to question the truth of this assertion in print, but if more substantial proof is needed, it may be remarked that the promoters of both the Yarmouth and Westminster Aquaria, who visited the Manchester undertaking while under my charge, were so satisfied with the results there obtained, that in the latter case it was recognised that a most needless expenditure

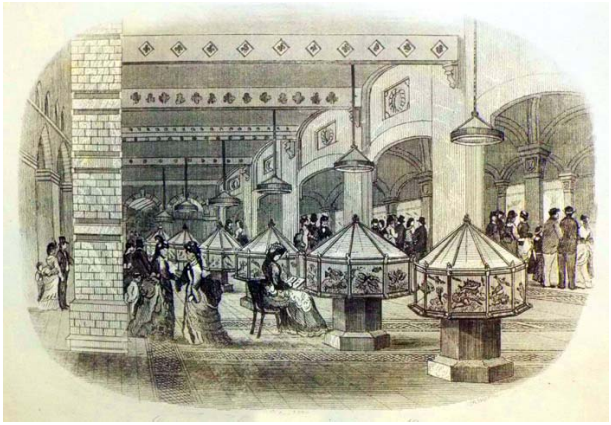


Table-top aquariums at the Brighton Aquarium.

upon the reservoirs had been made; while in the case of Yarmouth, then uncommenced, and with the construction of which I am now associated, it was at once decided to alter the previous plans, embodying huge reservoirs of enormous coat, and to substitute in their place others corresponding only in capacity with the tanks above, as at Manchester. In fact, the show-tanks of the Yarmouth Aquarium being designed to hold an aggregate of 200,000 gallons of water, it would be necessary, in order to maintain the same ratio in the reservoirs as obtains at Westminster and the Crystal Palace, to construct reservoirs large enough to hold no less a quantity than 1,000,000 gallons.

It is, in fact, this great primary expense of reservoir construction, usually incited, on as on altogether indispensable necessity, that has in many instances proved an insuperable bar to the carrying out of large public aquaria that have been proposed, and has certainly seriously hindered the more general establishment of these institutions throughout the country. As an argument in defense of reservoirs corresponding in proportional size with those of Sydenham and Westminster, it has been urged that the greater proportional amount of water in the reservoirs must necessarily carry with it greater clearness of water in the show-tanks. Surely, however, there is a limit to even the transparency of water, and when that is gained, such an argument becomes surely a *reductio ad absurdum*, involving a lamentable waste of time and money, when reservoirs and bulk of water in reserve ore insisted on over and above what is proved to be all-sufficient for the purposes they are required to fulfil.

It has been already intimated that at Manchester the reservoirs correspond with the tanks in their cubical contents, and that the same proportions will be maintained at Yarmouth. It is not inferred by this, however, that the limit in the reduction of their size has been marked by the equalising of their respective bulks. Experience at Manchester has, on the contrary, illustrated that successful results may be obtained with a considerably less amount of water in the reservoirs; and, although it might be a bold experiment to attempt for the first time in some new aquarium, it is an open question whether, by a trifling increase of the pumping power, and acceleration of the circulating stream, reservoirs might not be done away with altogether, substituting in their place a mere well or cistern, for the reception of the water flowing over from the tanks and feeding of the pumps. This suggestion has been already made by me to the authorities temporary arrangement for the working of their aquarium, pending the removal of the chief obstacle which has delayed the stocking of the various tanks with fish—that obstacle being the unmanageable size of the reservoirs, involving a "three miles" circuit before the water returns to its starting point, and the difficulties associated with rendering such enormous reservoirs watertight. If here or anywhere else it could be shown that large aquaria can be efficiently maintained without the aid of reservoirs, the saving of one-half of their present cost as aquaria *per se* will he accomplished.

Lloyd claimed the following in favor of his system: (1) Because they need light to survive, Confervae and other minute plants that make the water cloudy in an aquarium are killed off in his large, dark reservoirs; (2) The reservoirs afforded a means of controlling the temperature, both dur-

The interior of the Brighton Aquarium.

ing the summer heat and the winter cold. The following were Kent's views on these subjects:

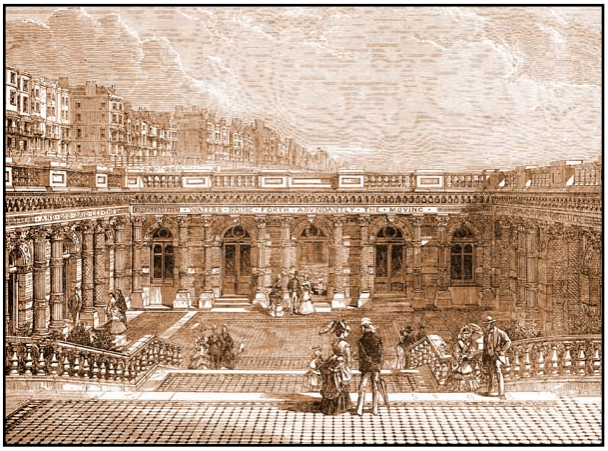
It has been further represented by Mr. Lloyd that large dark reservoirs are indispensable to prevent the appearance of the multitude of vegetable-spores, which occasionally multiply in aquaria to such an extent as to render the water turbid. This, however, may always be prevented by judiciously screening the tanks from undue access of the sun, and the Brighton Aquarium affords a practical illustration of water constantly exposed to the light, but where, through such judicious screening, these spores are not harmfully developed. It has also been asserted by the same writer that reservoirs of preponderating size are necessary to equalise the temperature of the water, which, he argues, would otherwise become too hot in summer and too cold in winter for the well-being of the animals; but the Brighton and Manchester Aquaria are again cases in point, to prove the fallacy of this argument, which, however, might be of some value if associated with an aquarium at Calcutta, or other tropical station. Under any other circumstances, the construction of these comparatively enormous reservoirs is an undoubted misapplication of capital.

Light being a problem in any aquarium, Kent suggested the following solution:

A circumstance frequently drawn attention to in relation to the growth of seaweeds in aquaria is the tendency of the finer silkweeds, or confervoid *algae*, to spread themselves over the larger kinds, until, like the insidious mycelium of some parasitic fungus, they completely choke off and destroy the higher form. Such mishaps do not occur under the ordinary conditions of their growth, and, on inquiry into the matter, an explanation is readily afforded. These low conferva, in fact, do not naturally grow in association with the more highly organised varieties we want to cultivate, but rather in those localities where the tide is sluggish, and more especially in pools, where they are undisturbed by the waves, except at only the highest tides. It would seem, indeed, that where a strong current prevails, such as the higher seaweeds luxuriate in, the conferva are unable to obtain a foothold. This explanation still further recommends the adoption of a more rapid rate of circulation in our tanks. At the Yarmouth aquarium, as soon as it is opened this coming summer, this question of seaweed culture will be especially attended to.

Lloyd's answer appeared in *The Society of Arts* on March 3, 1876 and the following are extracts from that article:

Mr. Kent's chief point seems to be his objection to the plan of aquarium construction which I have successfully pursued for many years, and which consists in using unchanged sea and fresh water, kept in constant circulation, between a series of show tanks containing animals and plants exposed to light, and an underground dark cool reservoir, containing several times as much water as the collective capacity of the show tanks, Mr. Kent maintaining that large dimensions in the reservoir are unnecessary, for reasons which he does not set forth. I therefore have now to describe why I believe and know they are requisite.



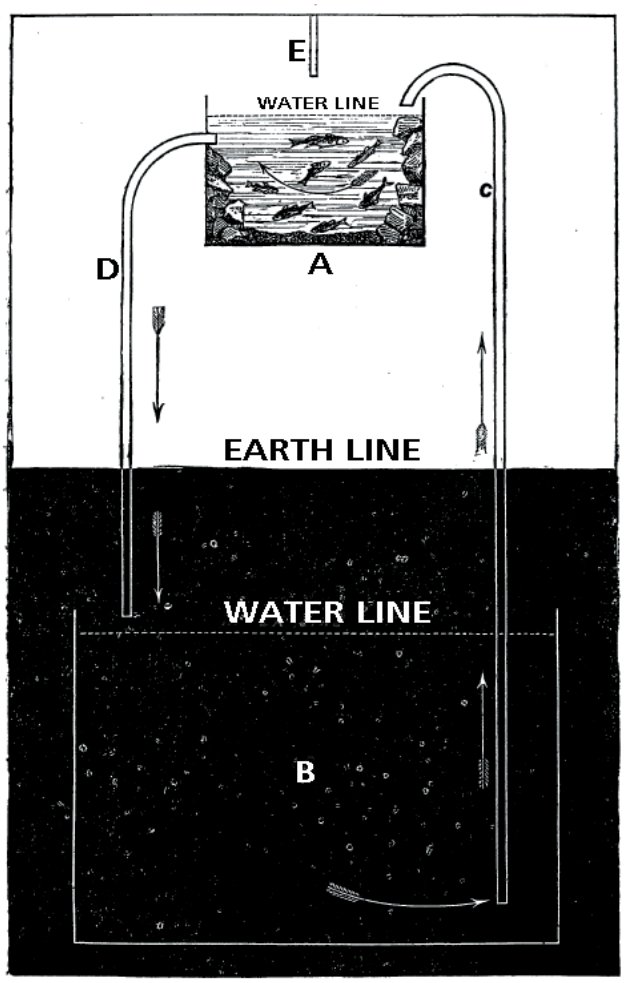
The entrance court of the Brighton Aquarium.

At or near the surface of the seas of our islands, where aquarium animals came from, the range, however, is very much less, the water being neither so hot nor so cold as the air, especially of the air in inland places, the temperature of our sea water being from 45° F. to 65° F., and having an average of about 60° F. This tolerably uniform temperature of the sea water tends to give a similar uniformity to the air immediately in contact with it, which accounts for the mildness of the climate at seaside places in winter.

The main principles involved in the water circulating system in all public aquaria constructed under my supervision, turn on the law governing the following facts: If a quart of water at 100° F. be added to a quart at 60° F., the mixture of the two will be 75° F. If one at l00°F. be added to two at 50°F., the result will be 66.6°F. If one at 100° F. be added to three at 50° F., the mean will be 62.5°F. If one at 100°F. be added to five at 50°F., the result will be 58.3°F.; and if the proportions be one to twenty, the mixture will be 52.3°F., and so on; the larger the proportion of the colder mass being to the warmer, the nearer the mean of the two masses will approach to the temperature of the larger mass. The entire thing is shown in the accompanying diagram, where B is a large underground, cool, dark, reservoir, C is a pipe conveying water from B to the show tank A, containing fishes, or other animals, and D is a pipe conveying water from A to B. The six arrows indicate the direction in which the water flows. E is a pipe to re-supply the water which evaporates. As this is an ideal representation, showing only results, all the machinery (as engines and pumps) giving these results, by moving the water, are omitted.

Now let it be supposed that—which really would be the case in an English summer, without any circulation going on between A and B—the tank B would have its water at about 60° F., and A would have its water at about 75° F. On the circulation being established, and continued for some time, the water in A would become cooler, and that in B warmer, than before, and the mean temperatures of the two, varying according to the proportionate quantity of water in B., would be according to the seven following formulas:

No. 1. A2, B1; result, 70°F.
No. 2. A1, B1; result, 67.5° F.
No. 3. A1; B2; result, 65° F.
No. 4. A1; B3; result, 63.7° F.
No. 5. A1; B4; result, 63° F.
No. 6. A1; B5; result, 62.5° F.
No. 7. A1; B20; result, 60.7° F.



Lloyd's geothermal system for maintaining show tank temperatures in both winter and summer.

So that by increasing the quantity of water in B, that in a is made to approach very near to the temperature of B, whether the surrounding atmosphere tends to increase or decrease the temperature of A. The water rises through C at an even temperature, exactly as it would if rising from a natural well, or spring, whether the spring be cold or hot, as in nature, and we can so increase the speed of the flow through C that the fluid is not allowed time to become unduly warm or cold in A We know, by many years of observation in the Observatory at Greenwich, that at a depth of six feet below the ground there, the mean daily range of the thermometer is less than one degree, while at the surface it is often twenty degrees. These facts, and the results to be deduced from them, are alike incontrovertible.

We also know, from Bunsen's tables, how much atmospheric air in solution water will retain when not under pressure at varying temperatures, and it is also known that it is upon the presence of such air in solution that the value of the water for aquarium animals proper mainly depends. It is true that, as Mr. Kent states, the quantity of air injected into a under the conditions No. 1, may be increased by accelerating the flow, but that does not diminish or increase the temperature, and *that* is the primary thing. It is also true that some local circumstances may affect these results, such as a very equable and mild climate, or an aquarium building of extreme temperatures either way, or the use of tanks which are very shallow or very high, which increase or diminish the surface absorption of air, but, as giving general and broad results, the figures just quoted may be depended upon, and they were true in their results at the Manchester Aquarium, Mr. Kent cites as a contradiction to my theory.

In all aquaria, the work to be done is the oxygenation of certain organic matters, so that the animals may be healthy and the water clear, and if sufficient means he not used to do this work, the water must he more or less turbid, or the amount of organic matter must he proportionately lessened. Now, at Manchester this was the case, for the water, when I saw it, was not sparklingly bright, nor was the amount of organic matter to be oxygenated, i.e., the animals and their food, adequately large in comparison to the size of the place. Once I remember, on a very hot day in July, I telegraphed to Manchester that our Crystal Palace temperature was as follows:—

Maximum external air at Sydenham and Greenwich	92° F
Maximum air in shade in Crystal Palace	84° F
Maximum air in shade in Crystal Palace Aquarium	77° F
Maximum in water in Crystal Palace Aquarium, everywhere	61° F

and I asked for similar information about the Manchester, but it refused me.

L'aquarium du Jardin d'Acclimatation de Paris, designed by Lloyd. The building was 130 feet long and 33 feet wide, containing 14 show tanks. He was its Director from 1860 to 1861.

This brings me to explain why I chose the formula No 6—five to one—for the great London aquarium now preparing to be opened at Westminster, where the circumstances are quite different to those at Manchester, and where the aquarium is not, as at Westminster, placed in the very midst of a great city, with a soot-laden atmosphere. Moreover, in this latter aquarium, some of the tanks measure twenty feet wide from back to front being more than in any other aquarium where the water is maintained in so clear a condition as to satisfy my fastidiousness. When this width is so great, the size of reservoirs must be relatively increased, because a very small addition of foreign matter in suspension or solution then increases the apparent turbidity. Moreover, the Westminster building itself is not exactly such a one as should prefer for an aquarium, if I could have controlled it, with reference to all things, but as it has to be used for many other purposes I must make the best use of it that I can for my purpose. It is, in effect, a huge conservatory of glass and iron, supported on brick walls and, in spite of much good ventilation, it will be very hot in summer. Yesterday, for example, was a cold and blowing March day—the 9th—with strong sunshine and at noon the temperatures were thus:—

External air,	
Maximum	55° F.
Minimum	35° F.
Internal air in Westminster	
Aquarium building	61° F.
Water in reservoir of Aquarium	
at bottom	49° F
at top	50.5° F.
Water in Crystal Palace Aquarium	
Everywhere	54° F.

(It will be seen that the Crystal Palace Water is higher than that in the Westminster reservoir, because the show tanks above are exposed to warmth, while at Westminster there are at present no show tanks to raise the temperature of the reservoir.)

This water at Westminster was fresh water, used to test the soundness of the reservoir, and as it had been in for ten. days, it had had time to assume its normal temperature, and it was ton feet deep vertically. No water was in the show tanks, and no circulation was going on. This indicates, clearly, that a valuable equalising effect will be gained by the reservoir, which these figures show, is not at all too large; in fact, I tried to get it made to hold a million gallons instead of only about 600,000 gallons. Really, such a reservoir cannot be too great for the general purposes of an aquarium, the goodness of which a naturalist, if he be true to his cause, will only regard, and for such excellence, and for the animals it contains, he will alone care. He will, if he be genuine and zealous, regard the creatures he has to keep, not as unfortunate prisoners for whom it is policy to do as little as possible for their comfort, but as friends and guests, for whom he cannot do too much.

Therefore, the only limits to the dimensions of aquarium reservoirs are considerations of cost and space. But long experience points out that for all general purposes the proportion of formula No. 6 is an excellent one as a minimum, and to gain this, or better, a much larger proportion, as even ten or twenty to one, as being, in the end, an excellent invest-

The Crystal Palace at Sydenham.

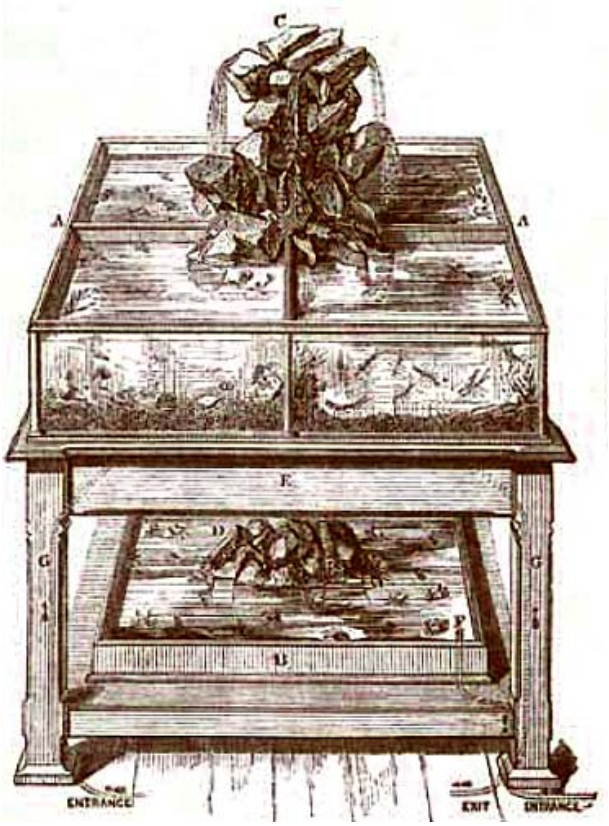
Is this the wildest or is it the best design for an aquarium in history? It was built for the Paris L'exposition universelle de 1867.

ment of capital, a right-minded naturalist will do much, even to the extent of recommending the sacrificing of the features of building which are not constructurally necessary, but merely decorative. The slight enrichment of surfaces of necessarily constructive parts is all which a well-educated man will aim at. He cares only for the decoration of construction, and is content to leave the construction of decoration to the ignorant and vulgar.

Lloyd then passed on to other matters brought up by Kent:

With reference to the curious circumstance of sea and fresh water becoming greenly opaque from an excess of light, Mr. Kent is in error in saying that at the Brighton Aquarium the water is constantly exposed to light, and does not, therefore, become green. The water in that establishment is periodically changed, wholly or in part, and allowed to run into the sea, and therefore the ocean itself is the dark and great reservoir of the Brighton Aquarium. This arrangement would he an excellent one if the water could be drawn from so great a distance from the polluting land that the incoming current of sea water would be pure and constant. But as it is impure and inconstant, the result is biologically most unsatisfactory compared with the large money expenditure on this Aquarium, as Mr. Kent well knows, and as he has stated in print, in *Nature* for October 23, 1873.

All that Mr. Kent has said on the maintenance of the higher marine algae in aquaria has been better said by Mr. Warington a quarter of a century ago. But it is a positive error to state that the silk weeds (confervae), marine and fresh water, do not grow in fast running currents. What affects them is light more than motion, for I have known these plants to be developed and to grow freely, attached to the polished interior surfaces of glass tubes through which water was flowing rapidly, with exposure to light. And it is a most astounding mistake to compare these chlorosperms to the infinitely lower fungoid forms of vegetation, when both grow on other and higher plants.



Lloyd's 'Compound Aquarium'. This shows all the concepts of his marine circulating closed systems sold for private residences, which later formed the basis of the public aquariums he designed.

A fungus does, or may, destroy another plant, or an animal, upon or in which it grows, as e.g., the "smut" in wheat, or the "ergot" of rye, or the "potato disease," or the fungus which appears on some fishes or insects, but a conferva which attaches itself to a red seaweed, or to the shell of a crab or lobster, or to oysters, or to the hard parts of other plants and animals, does not destroy the plant or animal upon which it is parasitic. Thus, Warington has shown that when a conferva has grown upon and obscured some rhodosperm, as *Ghondrus* or *Iridcea*, because of excess of light, yet that when that light is artificially coloured by the interposition of glass of a particular hue, the chlorosperm dies, and leaves the rhodosperm as fresh and beautiful and uninjured as before it was grown over.

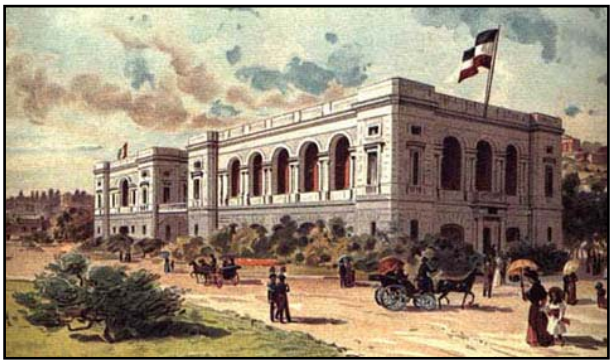
Mr. Henry Law (an engineer whom, from his great knowledge, I should choose by preference to all others to be associated with in aquarium construction), in stating that large underground reservoirs are valuable in preventing a large growth of conferva, stated that which is just possible, but which is not proved. What they do prove is that they prevent the multiplication of what are called "zoospores," which cause turbidity, but Professor Ferdinand Cohn, as an authority on these excessively minute bodies (they being but 1/2000 of an inch in diameter) is not certain if they are ultimate forms of plants or not.

He [Kent] mentions Mr. C. L. Jackson, of the Southport Aquarium. When that establishment was commenced I was consulted, and I gave the best advice I could; but the architect, being no physicist, determined to make one-half of the place on the Crystal Palace system, and one-half on the erroneous Brighton plan. The whole is, however, now being changed into the former system (as I advised at first), under the direction of Mr. Jackson. If I had had him to deal with at the beginning, he being an engineer, some thousands of pounds would have been saved, and I have his fullest written permission to say that he believes in the large reservoir system, and not at all in Mr. Kent's unreasoning crotchet of small reservoirs.

Mr. W. B. Woodward, the proprietor of a large aquarium at San Francisco, has just been to Europe to examine all public aquaria, and he is convinced that the turbidness he is troubled with is due to his having a too small reservoir, and he intends enlarging it. As to saying that a large reservoir is necessary at Calcutta, but not in England, I possess the sea and air temperatures of Calcutta, and find they have the same relations, nearly, as in Britain. The isothermal charts of Professor Dove and others may be consulted in proof of these points. So [it is] with three places in Australia, respecting which I am being consulted for great public aquaria.

Lloyd goes on to correct Kent's many errors in aquarium history as, for example, Kent's statement that Dr. Ball's air-blowing in the first Dublin aquarium was effected by their feet in walking to and fro when in reality it was effected by having visitors working bellows with their hands. If Kent had known anything about engineering he would have realized that constructing such a floor would have been expensive, not to mention almost impossible with the technology of the day.

Finally, Lloyd's following comment addresses Kent's ungentlemanly behavior. It would not be



The Stazione Zoologica at Napoli, 1873, designed and built under Lloyd's supervision.

too far afield to suggest that much of it was due to jealousy:

Mr. Kent, in referring to the Yarmouth Aquarium Society, where he is now engaged, does not state that I, too, am officially employed there, and that I seriously disagree with much which he is there doing, as being contrary to the interests of our mutual employers, and as to having the Yarmouth Aquarium open in this coming summer of 1876, it is quite impossible. He is not only ungenerous in thus omitting my name in reference to the Yarmouth, Paris, Crystal Palace, Naples, Frankfort, Rhyl, Teignmouth, Rothesay, and other Aquaria, but he does not even mention the one at Hamburg, I being more or less intimately connected with all of these.

Lloyd was not hard-nosed in favor of his system when it was not the optimal solution. One of the problems in the water supply system used in Brighton was that the tanks were not connected to each other, thus minimizing any circulation of water. A well-functioning system of permanent water exchange, resulting from an interconnecting pipe system for all the tanks (i.e., an "open circulation system," where the water was directly circulated to refresh the aquariums and then discharged back into the sea, thus negating the need for the large reservoirs required by an inland marine closed circulating system) was the invention of Lloyd; he used it first in Hamburg (1868), and then in London (Crystal Palace, 1871) and Naples (1872). Kent did not comment on any of this. Ironically, while the London aquarium in the end had cost £12,000, building costs for Brighton amounted to £100,000.

Naples, at that time, was still recently the capital of the Kingdom of the Two Sicily's and was a sufficiently important center of tourism and commerce to ensure keen interest and support for such a novelty. Taking advantage of the site of the new Naples aquarium, Lloyd designed a system for pumping water into the cisterns directly from the sea. Although supplied with them, the Aquarium experienced good results without any need of filtering. Such a method of circulation was an immediate success and was imitated in many other aquariums, including the one in Monte Carlo.

The Naples aquarium still uses this open circulation system, in which the water is pumped from two large underground cisterns into the tanks and then flows back down, during which time about one third of the volume of water is renewed. The water is drawn from the Bay of Naples at a point 300 yards offshore and 12 yards deep, and is left to decant in a large tank before going into the ciscterns. The twenty three tanks on display, ranging in capacity from 66 gallons to 18,000 gallons, use volcanic rocks to create a natural setting and are chiefly illuminated by daylight from the skylights in the roof. All the specimens come from the Bay of Naples, which in spite of pollution, is still one of the richest breeding grounds of marine life.

A much larger problem that neither Lloyd nor Kent addressed, was the rapidly diminishing interest of the paying public, confirmed by the falling revenues of most town and city aquariums, something that would be soon affect both of them. A good example is the Margate Aquarium that Kent mentioned as one of those being contemplated. On July 25, 1874 The Margate Aquarium, Limited, announced the following:

The Southport Aquarium, 1874.

Capital, £50,000, in £10 shares. The undertaking is formed to establish an aquarium at Margate, for which purpose a lease has been acquired of the foreshore from the Pier Hotel and Fort Point to the Second Point.

Due to the declining attendance at public aquaria throughout Britain, investors were not interested. Only half the amount was raised, the company went bankrupt in December of 1877 and the Margate Aquarium was not built.

With regard to the technical issues involved in this dispute - and not the personal ones - as technology has moved on they have become moot. Advanced filtration, better aeration, more efficient equipment and improved materials of construction have resulted in public aquaria today that resemble neither the Lloyd or the Kent systems. *Fugit inreparabile tempus*.

THE BIRMINGHAM (ASTON) AQUARIUM

In 1874 the Birmingham Natural History and Microscopical Society appointed a committee to obtain information with the view towards promoting a marine aquarium in Birmingham, the subject having been introduced by its President, Mr. William Richard Hughes - a friend of both Gosse and Lloyd - in an address at the annual soiree of the Society. This Committee, after procuring information from various aquariums in England and on the continent, sent a deputation to visit and examine the Crystal Palace Aquarium and the Brighton Aquarium for the purpose of obtaining practical information about the requirements needed to be provided for, and especially to enquire into the two different systems of circulation and aeration of the water that were used and the results of their implementation. As has been examined here in detail, the Crystal Palace Aquarium used the system advocated by William Alford Lloyd and the Brighton Aquarium used the one advocated by William Kent.

The result of the examination and enquiry of the Committee was a recommendation for the Crystal Palace system, in consequence of their finding the Brighton Aquarium not so successful with regard to the health and condition of the animals and the clearness of the water in the tanks. The Crystal Palace Aquarium was found by the Committee to be eminently successful in these respects, the most delicate animals being maintained in perfect health and almost free from those parasitic growths to which they were so subject in confinement, whilst the water in the tanks was beautifully transparent and brilliant.

The action of the Committee resulted in a proposal to construct an Aquarium in the basement story of the Midland Institute Building, facing the Town Hall, and plans were prepared by W.P. Marshall for this purpose under the advice of Mr. Lloyd, who was called in to examine and report upon the proposal. That proposal, however, had ultimately to be given up, in consequence of it being found impracticable to adapt the existing building satisfactorily for the desired object. The idea had been to establish a public aquarium pure and simple, with appliances for scientific study and instruction, in close connection with the Public Library and Art Gallery, and supported only by a small admission charge. The original cost of construction was intended to be materially reduced by the circumstance of adapting a portion of an existing building and thus avoiding the cost of erecting a new building.

The idea of the Birmingham Aquarium was ultimately revived in a definite form by Mr. Arthur

The Yarmouth Aquarium, 1877.

Ryland (1807-1877), founder of the Birmingham and Midland Institute), and he succeeded in enlisting the support and cooperation of a number of influential gentlemen to a proposal that led to the formation in 1877 of a Limited Company for the construction of the Birmingham Aquarium. It was felt that an aquarium alone could not be made to succeed financially, and it would require to be combined with some other attraction, such as first -class music, and must consequently involve the erection of a large building in some central situation. The great difficulty experienced was the obtaining a suitable site in a sufficiently central situation, but this was overcome in a highly satisfactory manner by obtaining the site of the old Hen and Chickens Hotel, in New Street, a classic ground of the old coaching days. This site was a remarkably favorable situation for the ready access of the public in the principal thoroughfare of the town, and in close proximity to the two railway stations. The hotel would be converted into a first-class restaurant, the largest in the town, and in the rear would be built the Aquarium, with a spacious and convenient Concert Room above it, affording facilities for concerts that had been long felt to be much needed in the town.

The Aquarium would consist of a large, handsome Hall, upwards of 100 feet in length, with a series of tanks extending along each side and forming the sides of the Hall, amounting in total extent to about as much as those of the Crystal Palace Aquarium. There would also be an extensive series of table tanks and in the rear there would be a large and commodious space for the food and store tanks, the machinery, and the general working purposes of the Aquarium. The public approach would be through a large Entrance Hall from New Street, from which a handsome flight of steps would lead down to the Aquarium, which would be constructed of red terra-cotta, with the ceiling supported by arches resting on ornamental pillars.

The large Assembly Room, on a level with the New Street entrance and over the Aquarium, would be 165 feet long and would consist of three divisions, the first portion being appropriated to the table tanks, the central transept for a similar purpose, and at the end would be the large Concert or Lecture Room. This would be surrounded by galleries, and capable of holding 1,000 persons. The block of the present building facing New Street would be retained, and converted into a large Restaurant on the first floor, 70 feet long; and the kitchens would be at the top of the building. Large shops and sets of retiring rooms would be arranged on each side of the New Street entrance, and means of exit in the rear into Worcester Street would be provided for the Aquarium and Concert Room.

One might wonder why these public aquariums were such a small part of something called "The Aquarium." The following extract is taken from a paper, "Notes on the Construction of Aquaria," read before the London Architectural Association in 1879 by John Norton (1823-1904), a famous architect of the time:

As no aquarium in its present highly developed form is supposed to contain sufficient interest to secure permanent success, it is now considered necessary to supplement its attractions by subsidiary features; and hence

The Laboratory of the Marine Biological Association at Plymouth, 1888. Kent had been trying to establish an aquarium for scientific purposes for years but was unsuccessful. The Plymouth Aquarium was built shortly after he left for Australia.

the necessity to provide music and concert halls, winter gardens, skating-rink, club-rooms, restaurants, baths, and pleasure-grounds.

CONCLUSION

I'll finish with the following extract from Lloyd's reply to Kent:

Rightly considered, an aquarium is a beautiful philosophical contrivance for illustrating the manner in which the various forces of nature harmoniously balance each other. Thus, cold balances heat, and produces a certain mean temperature, while darkness balances light, and represses an excess of vegetation which is so constantly being urged into existence by that light, in order to decompose the poisonous carbonic acid gas which animals evolve. Then, motion, gained from whatever source, balances the quiescence which water is ever desirous of attaining, and without such motion vegetation would be useless, just the same that motion would be useless without the vegetation. And, if these things are rightly understood, and applied skillfully by thoughtful mechanical adjustments, there can be attained a tolerably accurate control over the growth and decay of organic matters, both vegetable and animal, to suit named and definite circumstances.

It is impossible for mere human beings to refine too much on the means by which these ends are endeavoured to be secured, seeing that nature herself is most infinitely painstaking in the construction of the objects which are wished to be maintained in life and health in aquaria. The only limits to such refinements are such great money costs as may be plainly and evidently prohibitory. Thus, by endeavouring to follow Nature in a humble and inquiring spirit, we succeed in our trials to a certain extent, and we are thankful, but are always trying to do more and more; and, to attain the highest excellence, we do not adopt the motto of "rest, and be thankful." To a real and earnest seeker after knowledge there can be no rest, and no contentment to do anything but his very best.

The Tynemouth Aquarium, 1878.

ADDENDUM I:
THE FIRST USE OF ARTIFICIAL SEAWATER IN A PUBLIC AQUARIUM IN ENGLAND

Since the Aston Aquarium site was far from the coast where seawater is easily obtained and transportation of the water from the coast would be expensive, Lloyd decided that the use of artificial seawater was justified. Thus was the first use of artificial seawater in a public aquarium in England. The following is an extract from an article by Lloyd titled, "The Birmingham Aquarium" (Lloyd, 1878):

A large aquarium is being built in a flourishing pleasure garden—Aston Lower Grounds, Birmingham. The range of larger tanks measure in their aggregate over three hundred feet long, seven feet broad, and from four to five feet high internally, and there are ranges of smaller tanks for lesser marine species of animals, and for salmon and trout breeding, &c. In addition there is a series of reserve tanks to contain living food till wanted, and to accommodate sickly creatures, &c.

Being in the centre of England, it is the place where sea water, brought from any coast, will be dearest, and consequently it is intended to compound the water artificially, and thus save many hundreds of pounds—remembering that in every 1030 lb weight of sea water only the odd 30 lb weight consist of sea salts and other solid constituents, all of which are soluble in water, and can be

The Ashton Aquarium, Birmingham, 1879.

added to it in such manner that alter a while it cannot be told from real sea water; and, moreover, it improves by keeping and using, and such of the subtle elements which are found in the actual ocean are conveyed to the compounded water by the small but inevitable quantities of real sea water brought with each consignment of animals.

All sea water has been compounded gradually, and artificially, so to speak, since the beginning of time, by the rains falling on to the land, and washing down into rivers, and thence into seas, the salts of the land, and especially of the salts of its rocks, which are gradually disintegrated. But it is quite easy and practicable to mix together, in a short time, and in inland receptacles, that which has taken an enormous lapse of. time (uncountable ages) to mix together and gather from all parts of the universe, yet without paying large sums for the conveyance from a long distance of the mere fresh water which forms so large a part of the bulk of the whole, and which can be found sufficiently pure, or made nearly so, everywhere.

Consequently, reservoirs of large dimensions relatively to the exhibition tanks in this Aston aquarium are being prepared for the getting ready of this water, and from these receptacles it will be afterwards continuously pumped into the tanks, overflowing which, it will return to the reservoirs, and so maintain an incessant circulation, without any change being ever needed, and without any manual cleaning or filtering of any kind, all decaying organic matters being decomposed by the action of the oxygen in the atmospheric air, which, with water, and as a consequence of the circulation which is ever presenting new air-absorbing surfaces, will be thrown in or injected ceaselessly, day and night.

I have to add that the large public aquaria at Berlin and Hanover have been successfully conducted for the last eleven or twelve years with "factitious sea water," made at my suggestion—if "factitious" is a right term for a compound which, as far as ultimates are concerned, is a precise representation or what is done by Nature. I used successfully such artificial sea water so long ago as the summer of 1865.

The details of the artificial seawater itself were supplied in an article titled, "The Artificial Sea-Water at the Aston Aquarium" (Southall, 1879):

To Philip Henry Gosse, the eminently well-known Naturalist, who, with his pen and pencil, has made so many of us familiar with the wondrous beauty of the inhabitants of the sea, belongs the credit of the introduction of the Marine Aquarium. In the second edition of his excellent book, "The Aquarium," published in 1856, he gave the world the benefit of his thoughts and experiments, by publishing a formula for producing easily and cheaply a supply of artificial sea-water such as had been found sufficient for the purposes of small aquaria.

Many other formulas have since been suggested, and nearly all, like that of Gosse, have been based on the analysis of Brighton sea-water, published by Dr. Schweitzer in the "Philosophical Magazine" for July, 1839. However much such made-up water has answered the purposes required, theoretically it has been at fault, inasmuch as in chemical composition it has not been identical with real sea-water, and on this account, perhaps,

The Margate Aquarium, 1877.

many Naturalists have been unable to keep certain animals alive in such water, and have affirmed that made-up sea-water is so lacking in certain elements or properties as to be unfit for the maintenance of marine animals in a state of health.

Opinions being thus divided, the boldness of the directors of the Aston Lower Grounds Company, in deciding to use none other than artificial sea-water in their magnificent Aquarium, is to be admired; and Naturalists all over the country are looking with interest upon the scheme new carried out for the first time in England on a really great scale. The following tabular statement of the composition of the concocted sea-water may, therefore, be deemed interesting. In the first place, it may be stated that the fine series of tanks and the underground reservoirs are capable of holding, in the aggregate, 300,000 gallons, and sufficient water has been made to fill the whole of the show and reserved tanks, and to nearly fill the reservoirs, enough space only being left to accommodate the contents of a few tanks in case leakages should occur.

My firm (Southall Bros. and Barclay) was appointed to manufacture the water, and about fifty tons of chemical substances have been used. Each ingredient was subjected to analysis, and allowance made in every case for water of crystallization, hygroscopic moisture and impurities, and the various constituents of the well-water used were also allowed for in calculating the working formula. The analysis of Dr. Schweitzer was taken as a basis, supplemented by our own analysis of water recently taken near Brighton, a mile from the shore; and from the latter the data necessary for the required amounts of iodine, &c., were obtained. As a result, the water in use in the Aquarium contains the following compounds in solution, and in the proportions given, from which it will be seen to completely represent chemically real sea-water (amounts are in grains per gallon):

Sodium chloride 1894.1
Potassium chloride 53.6
Magnesium chloride 256.6
Magnesium bromide2.0
Magnesium sulphate 160.7
Calcium sulphate 98.4
Calcium carbonate 5.8
Magnesium carbonate 1.5
Magnesium citrate 0.3
Sodium nitrate 0.2
Oxide of Iron 0.1
Silica 1.0
Iodide of Sodium - traces
Ammoniacal salts
and organics matter - slight traces

For the thorough admixture of the water in the various tanks, and the preparation and filtration of solutions, a considerable length of time was required; and it is only at the present date that the water is assuming what may be termed its permanent and representative character. Time will prove how far the sanguine anticipations of its promoters will be realised; so far it is certain that all animals hitherto placed in the tanks, under fair conditions, have done exceedingly well.

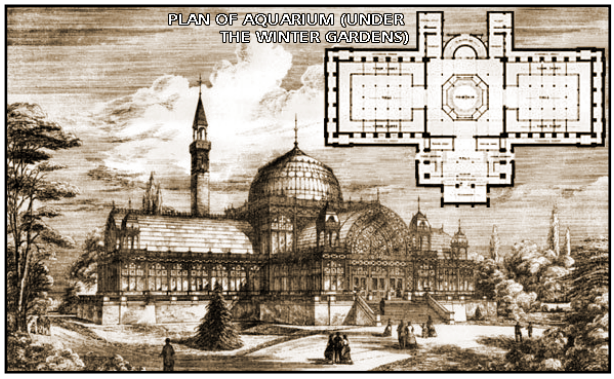
When Gosse published his formula for artificial seawater in 1854 (Gosse, 1854), it only had four constituents (not counting water) and some took exception to his removing three from Schweitzer's formula . Lloyd, however, was very sup-

Dr. Cocker's Menagerie in Blackpool (1875).

portive. The following is from a letter Lloyd sent to Gosse in 1854:

P.S. Some letters which have been lately published by Mr. W. A. Lloyd in the 'Athenaeum' confirm my experience. Perhaps I may be excused for citing a few words contained in a private letter from the same gentleman to myself:— "In reference to what has recently been published on an improvement (or a supposed improvement) on your receipt for the manufacture of sea water, a friend of mine took me by the button and said, 'My dear Sir, Mr. Gosse is altogether wrong; he has not salt enough; he has no—.' To which I replied, pointing to two fine *Actinia dianthus* in full blow in one of my vessels,— 'But if Mr. Gosse is altogether wrong, why do these *Actiniae* flourish.' This was unanswerable."

Neither Gosse nor Lloyd, however, attempted to keep vertebrates - fish in particular - using Gosse's formula. Over time, Lloyd experimented and modified the formula, ultimately using the one devised by Southall that used fifteen constituents. Lloyd, by the way, found a way to deal with those constituents that were very difficult to dissolve, such as silica and calcium sulphate.



The Proposed Llandudno Aquarium
Quite a few public aquaria in Britain were proposed but never built. This is one of them, in Llandudno, a seaside resort in Wales. the building contained a Winter Garden constructed of iron and glass on its upper floor, with a large Aquarium constructed of brick and slate in the basement below. At the center of the building was a 60ft high Dome.

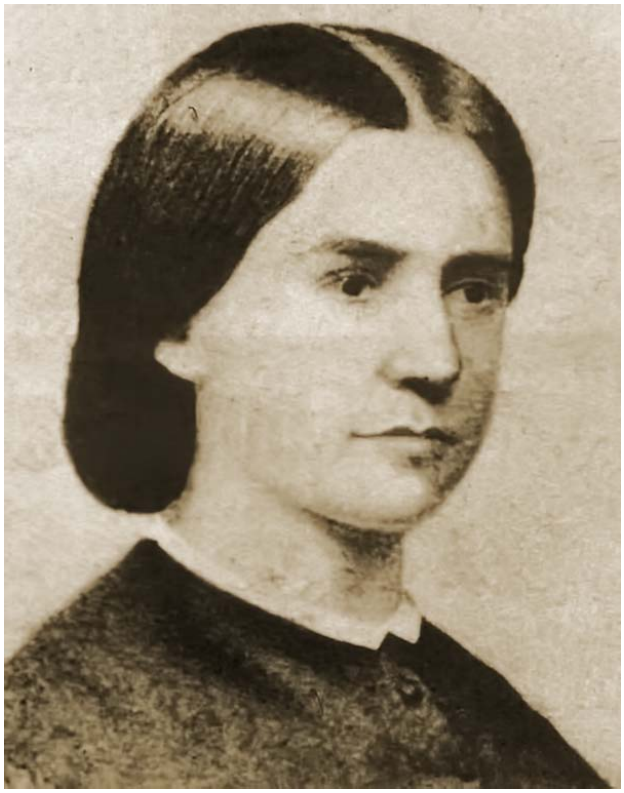
In an article titled "Artificial Sea-Water After Six Month's Use" by Henry William Jones (Jones, 1880), Jones found that the artificial seawater maintained its sea-like condition after six months. Jones examined the growth and reproduction of small invertebrates over a six-month time and found that,

"It may be taken for granted, however, that not only has the water been favourable to the two forms of the same animal [referring here to the zooplankton, *Coryne eximia*]**, but that it has gone through the entire "alternation of generations."**

ADDENDUM II:
A CHILDHOOD TRAGEDY

Sometime during the night of June 29th and the morning of June 30, 1860, Francis Kent, William's half-bother, disappeared from his home. Almost four years old, the child's body was found in the vault of an outhouse on the property. The child, still dressed in his nightshirt and wrapped in a blanket, had knife wounds on his chest and hands, and his throat was slashed so deeply that the body was almost decapitated. The boy's nursemaid, Elizabeth Gough, was initially arrested.

Elizabeth was released when the suspicions of Detective Inspector Jack Whicher of Scotland Yard moved to the boy's 16-year-old half-sister, Constance, William's sister. William was 17 years old at the time. She was arrested on July 16th but released without trial owing to public opinion against the accusations of a working class detective against a young lady of breeding. This difference in class was used as subplot by Wilkie Collins in his detective novel "The Moonstone" (1868). After the investigation collapsed, the Kent family moved to Wrexham in the north of Wales and sent Constance to a finishing school in Dinan, France.



Constance Emily Kent (1844-1944).

Constance Kent was prosecuted for the murder five years later. In 1865 she made a statement confessing her guilt to an Anglo-Catholic clergyman, the Rev. Arthur Wagner, and expressed to him her resolution to give herself up to justice. He assisted her in carrying out this resolution, and he gave evidence of this statement before the magistrates. The substance of the confession was that she had waited until the family and servants were asleep, had gone down to the drawing room and opened the shutters and window, had then taken the child from his room wrapped in a blanket that she had taken from between sheet and counterpane in his cot (leaving both these undisturbed or readjusted), left the house, and killed him in the privy with a razor stolen from her father. Her movements before the killing had been conducted with the child in her arms. It had been necessary to hide matches in the privy beforehand for a light to see by during the act of murder. The murder was not a spontaneous act, it seems, but one of revenge – and it was even suggested that Constance had, at certain times, been mentally unbalanced.

There was much speculation at the time that Constance Kent's confession was false. Many supposed that her father, Samuel Kent, a known adulterer, was having an affair with the toddler's nursemaid and, in a fit of rage, murdered the child after coitus interruptus. It fitted a pattern with the senior Kent, who had romanced the family nanny Mary Drewe Pratt while his first wife Mary Ann Kent, née Windus, (Constance's mother) was dying, and subsequently married Pratt (who was Francis' mother). Many were suspicious of Samuel Kent from the start, including the novelist Charles Dickens.

The substance of the Constance's confession was that she had waited until the family and servants were asleep, had gone down to the drawing-room and opened the shutters and window, had then taken the child from his room wrapped in a blanket that she had taken from between sheet and counterpane in his cot (leaving both these undisturbed or readjusted), left the house and killed him in the privy with a razor stolen from her father.

However, in her book, “The Suspicions of Mr. Whicher or The Murder at Road Hill House” (2008), author Kate Summerscale comes to the conclusion that Constance Kent's confession omitted facts to shield another person, not for the benefit of her father but for her brother, William Saville-Kent, with whom she shared a very close sibling relationship that was even deepened by her father turning his paternal attentions away from the children from his first marriage to the children he had with his second wife. William was indeed suspected during the investigations but was never charged. Summerscale suggests that if William was not the actual murderer, he was at least an accomplice to Constance and, after reviewing all the evidence, I tend to agree with her.

Constance Kent never recanted her confession, neither after her father’s nor her brother's deaths. She also kept her silence about the motive for the murder. In all of her statements, she emphasized and insisted that she bore no hatred nor jealousy toward her half-brother.

Constance Kent was sentenced to death, but this was commuted to life in prison owing to her youth at the time and her confession. She served twenty years in a number of jails and was released in 1885, at the age of 41. Kent emigrated to Australia early in 1886 and joined her brother William in Tasmania, where he worked as a government adviser on fisheries. She changed her name to Ruth Emilie Kaye and trained as a nurse at The Alfred Hospital in Prahran, Melbourne, before being appointed sister-in-charge of the Female Lazaret at the Coast Hospital, Little Bay, in Sydney. From 1898 to 1909, she worked at the Parramatta Industrial School for Girls. She was then made matron of the Pierce Memorial Nurses' Home at East Maitland, New South Wales, serving there from 1911 until she retired in 1932. Kent died on April 10, 1944, aged 100, in a private hospital in the Sydney suburb of Strathfield.

The Brighton Aquarium at night.

THE ROTHESAY ROYAL AQUARIUM

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, July 23, 2016)

The following excerpts are from an article that appeared (the author is unknown) in the January 9, 1875 issue of *The Spectator*, a weekly British conservative magazine first published on July 6, 1828, making it the oldest continuously published magazine in the English language; its principal subject areas were and are politics and culture. In addition to some interesting information as to those pubic aquaria that were successful and that were not, Lloyd's discouraging economic analysis shows why public aquaria were not profitable or long-lasting.

FISH SHOWS AS PECUNIARY SPECULATIONS.

The great public aquaria of to-day are giants when compared with the toy aquariums of the drawing-room which were a fashion some twenty years ago. One of the tanks at Brighton is quite as large as some, and much larger than many of the drawing-rooms of which little glass fish-prisons used to be an ornament. As a matter of course, the great aquaria of to-day are simply commercial speculations, money-making shows originated by joint- stock companies with a view to profit only. Scientific instruction or popular information are with their projectors only incidental considerations, and hold no part, or only a very small part, in their inception. But we should not look down upon them in consequence. Although they are only the product of breeches-pocket enthusiasm, they will in spite of that defect afford us much information that we are much in want of, and aid in developing that accurate knowledge of fish-life of which at present we are singularly ignorant.

Before, however, entering upon speculations as to what may be incidentally achieved in the way of gaining knowledge of the life and habits of our food fishes, it may be interesting to state that Mr. W. A. Lloyd, of the Crystal Palace Aquarium, who is an excellent authority, asserts that no Aquarium pure and simple will pay its way, even in a very large town or city, unless its cost be limited to £3,000, and its annual expenses be restricted to £500! Allowing a sum of £150 as interest on the capital sum, the total receipts would require to be £650 per Annum, or about two guineas a day, which would represent forty - two persons at a shilling each, or double that number if the charge for admission should be fixed at sixpence for each person. Sunday admissions are not counted upon. This presents

Figure 1: The locations of the Island of Bute and of Rothesay.

a rather dark aspect of the question to enthusiasts in Natural History, for at the present prices of building materials and the high rate of wages now paid, only a very indifferent aquarium could be erected for the sum named. At Rothesay, a small pleasure town on the river Clyde, it was found that the five thousand pounds subscribed for the erection of an aquarium was an insufficient sum, and the capital has in consequence been more than doubled.

A really great Aquarium, to "pay," must be something more than an aquarium; or, if not that in itself, it would require to form a portion of some greater exhibition, as in the case of the Crystal Palace, where the Aquarium is a parasite of the larger building. The Brighton Aquarium is both a fish-show, concert-room, and general lounge; and the suite of buildings recently erected at Southport, in Lancashire, is extensive. Several acres of ground are occupied altogether, the place being a winter garden as well as an aquarium. The Aquarium at Hamburg has been very successful, so much so, that the whole of the sum expended in its construction, £3,000, was recouped in six years. The current expenditure involved in keeping up the fish-show is £600 per annum. The success of the Aquarium at Hamburg has been in part owing to the popularity of the gardens in which it is situated; as many as 250,000 persons (a number equal to the population of the city) have been known to enter these gardens in the period of a week. Mr. Lloyd, who presided at the furnishing of the Hamburg Aquarium, and who has revised his estimates with special relation to the facts of the Hamburg case, nevertheless holds and appears to prove that no fish-show will pay of itself unless the expenditure be restricted to the sum named. The Aquarium attached to the Crystal Palace cost about £12,000, exclusive of the ground on which it is erected, and Mr. Lloyd feels sure that it never would have been remunerative, but for its being an accessory of the greater building. The cost of erecting the Aquarium in the Jar-

**Figure 2: Rothesay Bay during the time of the Aquarium.
The Aquarium was situated so that it overlooked the Bay.**

din d'Acclimatisation in Paris was 100,000 francs, or £4,166. It contains only fourteen tanks of small size, and is entirely thrown into the shade by our Brighton Aquarium. The average number of visitors to the Parisian institution is about 450,000 annually, but it has never yet paid any dividend!

These figures are exceedingly interesting, although they do not, if we are to accept the opinion of Mr. Lloyd, say much for the national love of scientific inquiry. The capital invested in the Brighton Aquarium is about £100,000, and at present an excellent dividend is paid to the shareholders. The Southport Aquarium, which was opened in the autumn, is yet too much of an experiment to enable us to say how far it will prove remunerative. The capital invested amounts to £60,000. An Aquarium Company is at present being started in Liverpool, under the auspices of Mr. Willert Beale, also with a capital of £60,000. Great Yarmouth, Ramsgate, and Margate are each to have an aquarium, and for these a sum of £140,000 will be required, whilst the Rothesay Fish Show already alluded to requires for its completion £12,000, instead of the £5,000 originally contemplated.

Counting the Winter Garden and Aquarium lately projected in London, and that meditated for Dublin, we are safe in assuming that as much as £700,000 is either invested or about to be invested in Fish Shows in England, Ireland, and Scotland. There can be no question that the creation of numerous other buildings of the kind will speedily be designed. Such towns and cities as Birmingham, Bradford, Glasgow, and Edinburgh are sure, sooner or later, to have their grand Aquarium. In large towns where there is a paucity of picture-galleries, museums, and kindred exhibitions, an aquarium forms a welcome place of resort, especially for ladies and children. There is no practical difficulty in constructing and maintaining an aquarium, even in cases where its site may be a hundred miles from the sea. It is important to state this fact, as many persons suppose that an aquarium cannot be properly organised in an inland town. The sea-water at the Crystal Palace is brought by railway from the Coast, and the animals are always in excellent health.

Even, however, when a large sum of money is subscribed for the erection of an aquarium, it may not all at once become a success. The Berlin Aquarium, for instance, has proved almost a failure, whilst the Brighton Aquarium is not a great success, considered zoologically, though, as a show, it is entirely successful. The organisation and working of such an institution is attended by much worry and anxiety. It was a long time before the Aquarium at Hamburg could be got into working order. To ensure good health for the fish and crustaceans, and provide suitable food as well as keep up the supply of both, is a work that requires considerable organisation and not a

The Rothesay Aquarium Company, Limited.

FIFTH DIVIDEND, YEAR ENDING 31ST DECEMBER, 1876.

No. 35

ROTHESAY, 31st January 1877.

Mr. John Wallace.

The Directors having, with the sanction of the Shareholders at the Annual Meeting held on the 24th Inst., declared a Dividend of One per cent. per annum, free of income-tax, for the year ended 31st December, 1876, the amount payable on 10 shares held by you is £1-10-0

I annex a draft for this amount, payable at the Royal Bank of Scotland here, on and after 1st March next.

I am,

Your obdt. servant,

JOHN T. WILSON, Secretary.

Figure 4: A ten-share note issued by the Rothesay Aquarium Company.

little scientific knowledge. The mortality of some aquariums is very great indeed, although, we daresay, it will not be observable to the ordinary run of visitors.

Lloyd remarks that the £5,000 subscribed at Rothesay for the erection of an aquarium was an insufficient sum, and the capital in consequence had been more than doubled. Actually, the final cost for the Rothesay Aquarium was £15,000.

ROTHESAY

Rothesay (from the Gaelic *Reogh-siudh*, "King's seat") is the capital of the Island of Bute, on the Firth of Clyde just off Scotland's Ayrshire coast and less than two hours from Glasgow some 40 miles to the north-east (Figure 1). From reliable evidence it would appear that the town has Viking origins. From the late 8th century onwards, Vikings raided and settled much of Scotland's western seaboard. This culminated in an all-out invasion of the Scottish islands by Magnus Barfod in 1098. He claimed Bute as his own and is credited with building the first castle at Rothesay.

The old town centered around the Castle and, long-ruinous, it is nevertheless picturesque, and formed a focal point for tourists from the beginning of its evolution into a seaside resort. During the Victorian era, Rothesay developed as a popular tourist destination. It became hugely popular with Glaswegians going "doon the watter" (literally down the water, where the 'water' in question is the Firth of Clyde), and its wooden

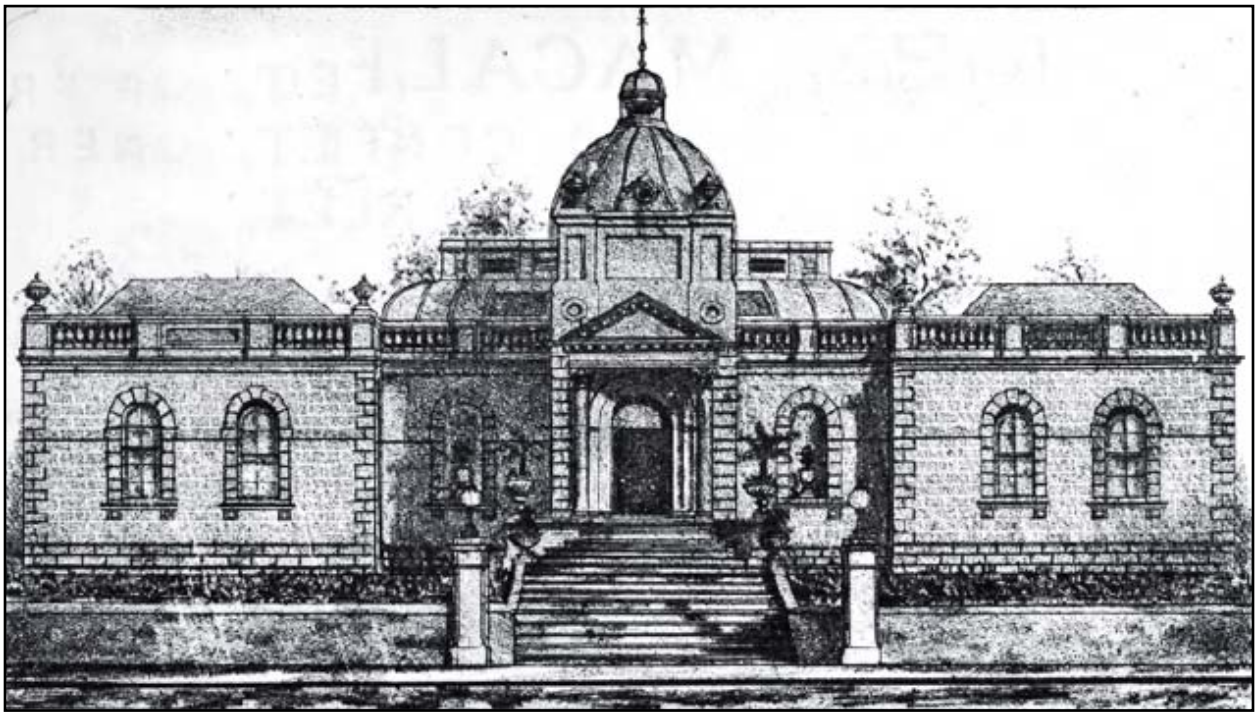

Figure 5: The architect's rendition of the Rothesay Aquarium.

pier was once much busier with steamer traffic than it is today. The situation of the town is both beautiful and sheltered, being finely situated. It enjoys a mild climate, and was and still is a favorite watering-place and a center for visiting places on the River Clyde at the head of Rothesay Bay (Figure 2).

THE ROTHESAY AQUARIUM GETS STARTED

The idea of The Rothesay Aquarium - known later after the visit to it of Prince Leopold as the Rothesay Royal Aquarium - had been in the air for some time, and the Archaeological and Physical Society of Bute took it up and formed a company to float the scheme. The Reverend William Ross, a prominent member of the Rothesay clergy (Minister of the Chapelhill Gaelic Church) and one of the founders of the Society, was first a member of the committee of investigation and then a Director for several years of the company. It was he, for example, who traveled to London to consult the Engineer of the Crystal Palace Aquarium with regard to the details of designing and running a system for the proposed Aquarium. The Aquarium was opened in June 1870 and, at the opening ceremonies, the Rev. Ross gave an address on the uses and purposes of such an institution. The following is an extract of an announcement that appeared in *The Freemason* in June 1875:

Laying Memorial Stone of
The Rothesay Aquarium

To Rothesay belongs the honour of giving to Scotian its first public Aquarium, the memorial stone of which was on Saturday, the 5th inst., laid with full Masonic honours by Bro. Charles Dalrymple, M.P. for Buteshire and Provincial Grand Master of Argyle and the Isles. The Aquarium occupies an excellent site on the Ascog shore, at the spot occupied by the old battery. When completed the building will have an imposing appearance. Externally it has a frontage of 102 feet, is graced below with a rusticated basement and cornice, is surmounted by a chaste open balustrade, and rising from the centre there will be an ornamental tower 47 feet in height. A short flight of circular steps leads from the outside to a

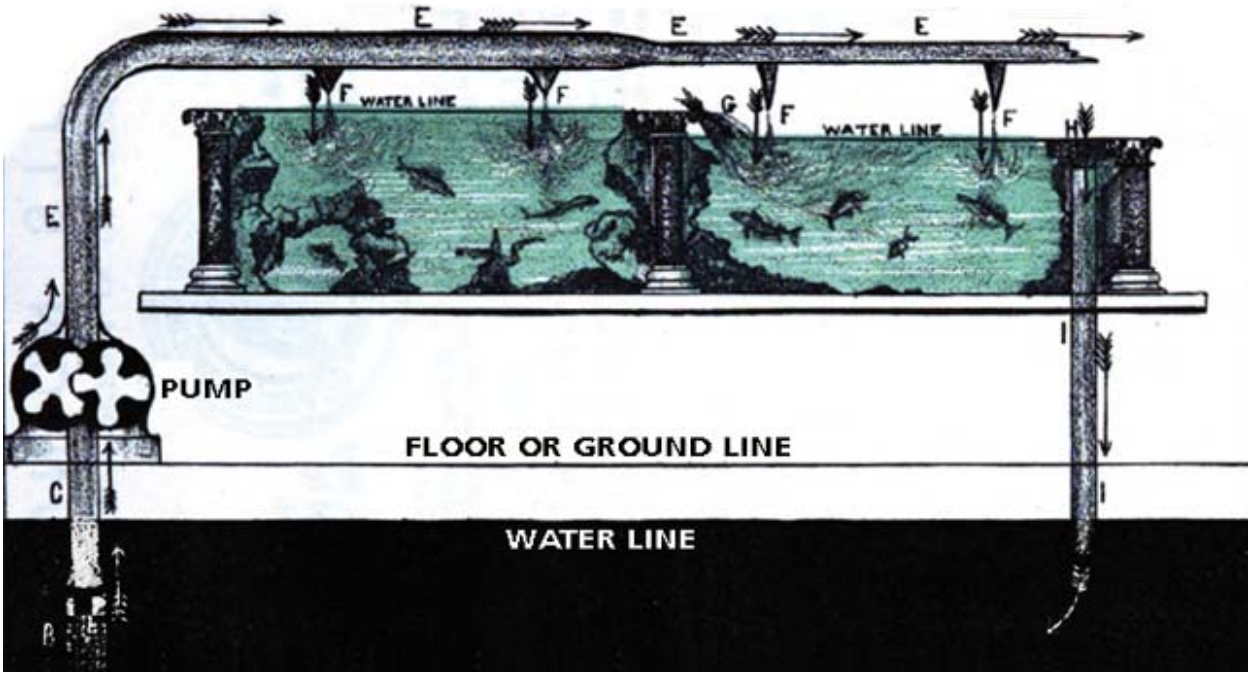

Figure 6: The system used by the Rothesay Aquarium was modeled after Lloyd's design that he used in the Crystal Palace Aquarium.

commodious vestibule which communicates with a promenade hall, lighted by a dome, and intended for concerts social gatherings, and the like. [Note: The architect's drawing of the front of the Aquarium is shown in Figure 5.] **Adjoining the hall are smaller rooms as suitable accessories, and also rooms it which will be fitted table tanks. Entering from the promenade hall is a magnificent corridor, forming the main portion of the building, and measuring 90 feet by 15 feet Ranged on each side of it will be sixteen tanks, while in two adjacent rooms are to be placed twenty others, for the reception of the smaller species of salt and fresh water animals. Besides those mentioned there will be nine tanks to be used chiefly for experiments.**

For the tanks 20,000 gallons of sea water and 12,000 gallons of fresh water will be required; but it has been considered necessary to have to supply reservoirs beneath the building capable of containing 100,000 and 40,000 gallons respectively, the extra quantity being indispensable in having the water thoroughly aerated. [Note: The Rothesay Aquarium was modeled on William Alford Lloyd's design, rather than on William Saville-Kent's. See Figure 6.] **A water engine pumps the water into pipes from which it is sent in a spray from jets in the roof, and in the event of an accident to this engine, a supplementary one, worked by steam, is to be provided. The tanks in which the animals are to be placed will be similar to those in the English Aquaria, three sides being of slate, and the front of one-inch plate glass. Artificial rock work is to be placed inside, and the bottom will be covered with shingle. It is not yet known from what source the sea water will be drawn, fears being entertained that the water in the vicinity of the Aquarium may prove unsuitable.**

the reservoirs are filled there will be little need of replenishing, the sweetness of the fluid being maintained by machinery, and as each tank is placed in a lower level than the one

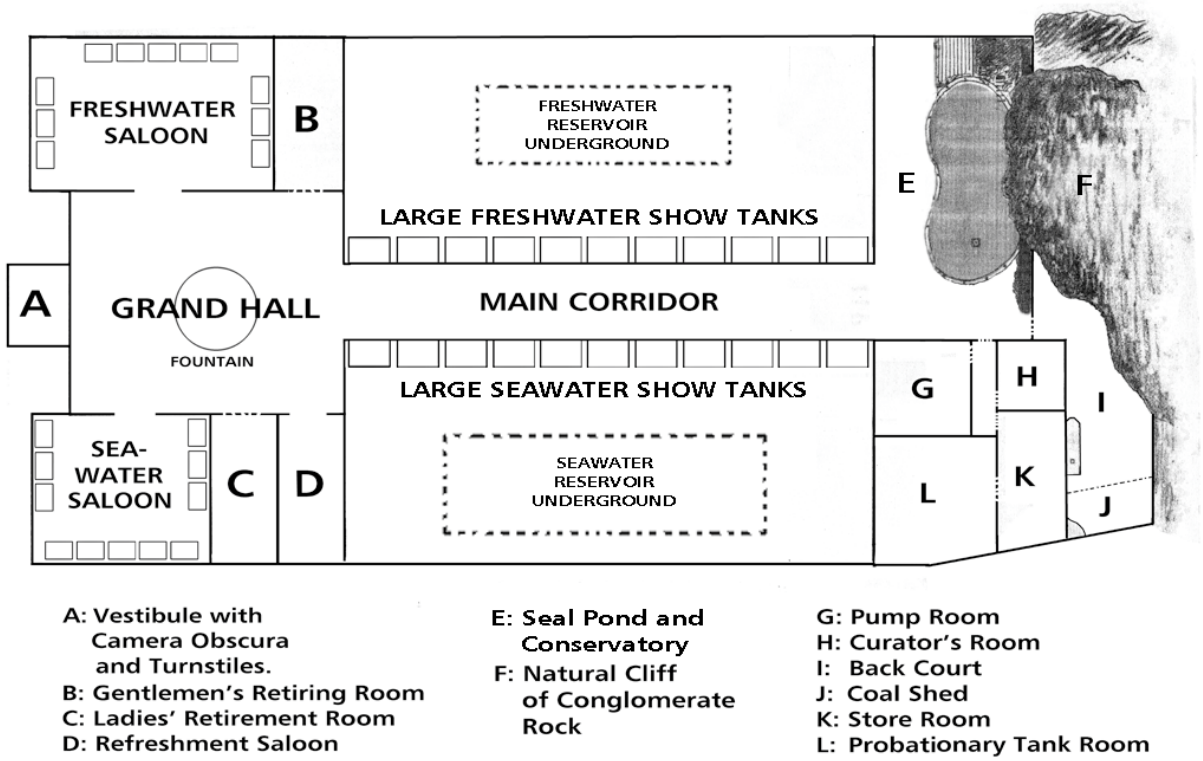

Figure 7: The layout of the Rothesay Aquarium.

next it, the water, by an overflow pipe, finds its way back to the reservoirs. To maintain an equal temperature of water, and in the building, hot water pipes are to be brought into requisition. It is proposed to use several tanks in promoting scientific research, more particularly in the department of embryology, and after the Aquarium has been fairly started the directors hope to be able to add a seal ground, and also a home for porpoises. The total cost is estimated at £10,000, and of this £1,000 has been contributed by the Marquis of Bute, who, in addition, gave a free site for the building, and £1,000 by the Corporation of Rothesay, the remainder being made up by shares of £5 each.

A DESCRIPTION OF THE AQUARIUM

It is helpful to refer to Figure 7 as one proceeds through this description. The building, which faces Rothesay Bay, is approached by a broad circular flight of stone steps, leading from an Esplanade or long, open level area (see Figure 8). About the close of the 1700's, when the stirring events in France led Great Britain to fear an invasion, a battery of several 18-pounders was placed on the east side of the Bay of Rothesay, some of the guns being set beside the aquarium on each side of the stairs.

Ascending the stairs one reached the Vestibule, the left of which led to the Camera Obscura (Figure 9). At the top of the dome there was a lens and a mirror in a revolving turret, the latter being protected by a hood and a pane of glass. The mirror was angled so that natural light reflected downwards into the camera obscura room. The light passed through the lens, which enabled it to focus onto the table, projecting a moving picture of the surrounding area. The lens also switched the image so that it appeared the right way up on the viewing table. When the room was darkened, the visitors' eyes adjusted to the light and they could then see the

Figure 8: The Rothesay Aquarium as it looked after its construction.

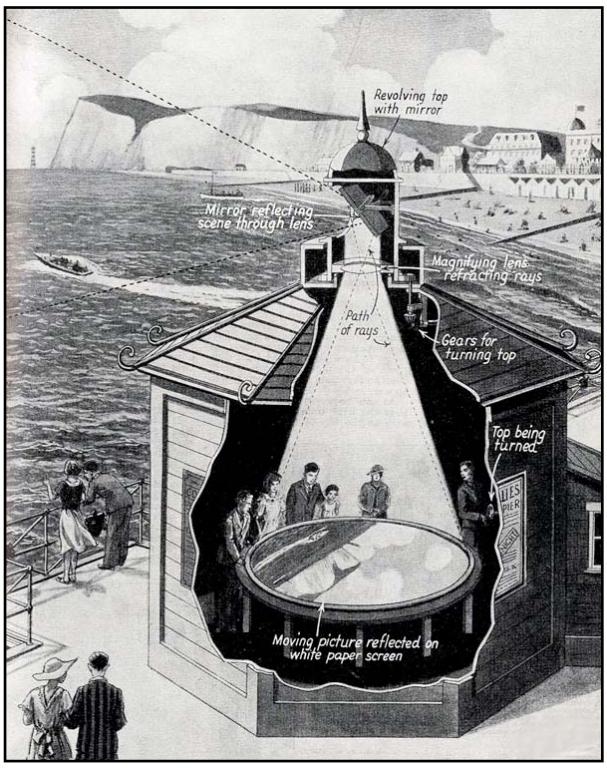

Figure 9: An example of a Victorian seaside camera obscura.

reflected, moving image. In Victorian times, camera obscuras became popular seaside attractions, offering a unique way to see the surrounding area and an opportunity to spy on courting couples.

After passing through the turnstiles in the Vestibule one then entered the 45 feet x 48 feet Grand Hall (Figure 10). Visitors were struck with admiration at the artistic elegance of this spacious room. Its beautiful tessellated pavement of mosaic tilework and the elaborate Corinthian enrichments of its walls and ceiling were toned by the tinted light transmitted through the enameled windows of the roof. In the center of the Grand Hall a bronze fountain threw its refreshing spray into a large marble basin. Round the walls were a handsome set of meteorological instruments and a valuable clock, the timepiece being a marvel of ingenuity and delicate mechanism. It represented birds of the most brilliant plumage, and of the smallest size, flitting from twig to twig, warbling their sweetest songs and fluttering their resplendent wings with all the appearance of animation.

To the right of the Grand Hall was the Freshwater Saloon and forming the left wing of the building was the Seawater Saloon. In each of these side saloons there were eleven table tanks, which, with the four in the Grand Hall, totaled twenty-six. Their average size was five feet long, three feet six inches wide, and two feet high, with an average capacity of two hundred and twenty gallons each. The contents of these tanks could be viewed either through the glass fronts or from the top by the open surface of the water, and from this latter circumstance they were called Table Tanks. The bottoms, backs, and ends of these tanks were of white polished marble slabs two inches thick, the first tanks constructed of this material in any public aquarium. Not only were the polished surfaces kindly to the touch and pleasing to the eye, but they were capable of being tightly joined so there was not even the least sign of leakage. Each of the Saloons had Retirement Rooms - what we would nowadays call fancy toilets with tables and chairs - and on the Seawater side was a “Refreshment Room.”

The Grand Room opened up to the 90 by 15 feet Main Corridor. Here the large show tanks were arranged along both sides, forming a double wall of water between which the visitor passed. There were sixteen seawater tanks and 7 freshwater tanks. The main internal framework of these tanks was of slate slabs, nine feet long, five feet high, and two inches thick; these were dovetailed together and further secured with bolts and clamps. The sides that faced the Corridor were of polished plate glass one and an eighth inch in thickness. In front of each tank, and supporting the arc stretched above it, were two pillars of polished St. Ann’s marble, and these were based upon a broad slab of the same material, which stretched across the front of the tank, as would the sill of a window (Figure 11). In front of this sill was placed the case containing the names of the various creatures in the tanks, and before this was a handsome mahogany rail, which formed a rest for the visitor and a protection for the tank.

Passing through the central door of the Main Corridor the visitor entered the Seal House and Conservatory. The rustic style of the Conservatory contrasted pleasingly with the Corinthian style of the main building. The pond was surrounded on three sides by a rustic walk, and on the other was a perpendicular cliff of conglomerate rock. This cliff had been utilized to form one of the retaining walls of the Conservatory, and it, consequently, supported one side of the arched glass roof. At the east end of the Conservatory was a rustic grotto and stairway. This was formed of the famous columnar sandstone obtained from the south end of Bute. This formation of rock was most remarkable, for its shape was the columnar of the igneous rocks of Staffa and the Giant's Causeway, while its consistency was sedimentary sandstone, the columns being transversely stratified. This rare geological formation is only known to exist in three or four places on the globe, of which Bute is one. The walls were treated with rustic cork and trellis work, in which flourished British and exotic ferns, and various creeping plants. Two large New Zealand Tree-ferns (*Dicksortia medullaris* and *D. squarrosa*) also spread their luxuriant fronds overhead.

From the Seal House private access was obtained to the Engine House, the Probationary Tank-Room (used to quarantine new arrivals or as a piscatorial hospital; there were six seawater reserve tanks and three freshwater reserve tanks), a store room, the Curator's Room and other private offices. Unlike the Crystal Palace Aquarium and the Royal Westminster Aquarium with their music and concert halls, winter gardens, skating rinks, clubrooms, restaurants, baths, and pleasure grounds, the Rothesay Aquarium was an aquarium in the full sense of the word (save for the camera obscura) in that it was dedicated to an aquatic biota.

THE PROBLEM OF LEAKAGE

In July of 1876, thirteen months after the opening of the Rothesay Aquarium, John T. Carrington, who was working under William Alford Lloyd at the Crystal Palace Aquarium (Carrington was to replace William Saville-Kent at the Royal Westminster Aquarium eight months later), wrote the following:

Scotland, so far from being behindhand, has, within the last few days already opened its first, at that charming little place, Rothesay, so much frequented by the people of Glasgow. There, through the influence of its patron, the Marquis of Bute, has been established an aquarium, which, when quite complete and in working order, will not only be an ornament and attraction to the town, but I have every reason to believe will be of great scientific value, for on this rock-bound rock-bound northwest coast of Scotland is a grand marine fauna. This, without some aid and central base for

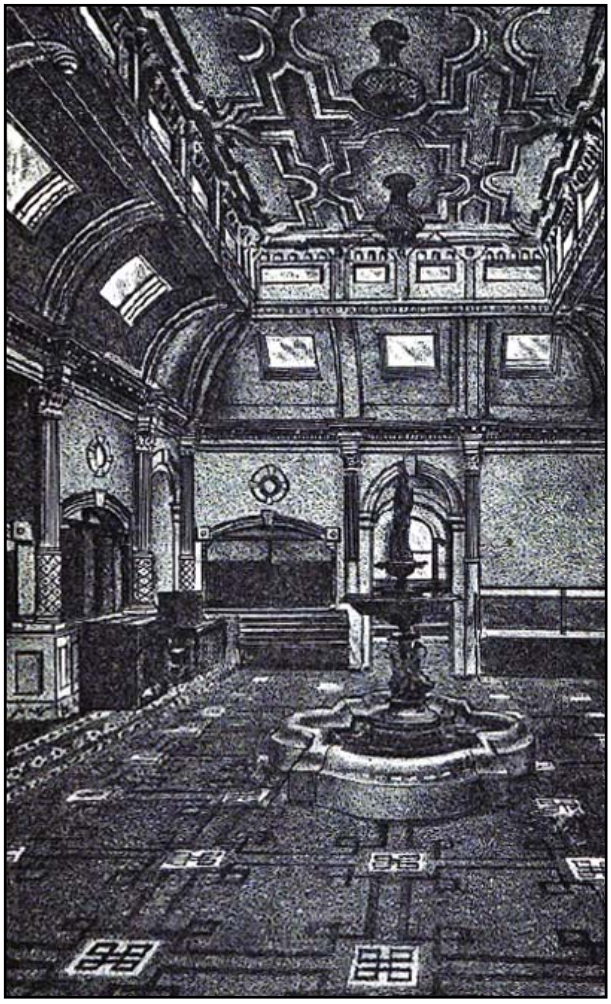

Figure 10: The Great Hall.

operations, such as this aquarium will afford, could hardly ever be worked out satisfactorily.

Rothesay will I hope prove to be a famous place in future aquarium reports, especially in its record of rarities and new species discovered in Britain. It is fortunate in having a curator, Mr. Barker, who has his "heart and soul in the cause," and from whom we hope much. Already he reports to me that the northern stone crab (*Lithodes arctica*), which, up to the present lime, has only been reported as British from one or two isolated captures by the trawlers of Yorkshire and Lincolnshire, has been discovered in some numbers by the collectors sent out on behalf of this aquarium. Large *Nephrops Norvegicus* also have been found abundantly by them: this species, although known by the name of the " Norway lobster," has hitherto been found in Britain most commonly on the eastern Irish coast, from whence the English, and even some of the continental, aquaria have been supplied. In Dublin I have often seen this species sold in the streets, after being boiled, as "prawns," at a few pence per dozen ; they are a very great delicacy, and quite equal to the common lobster (*Homarus vulgaris*) as an article of food. As an aquarian animal they are very attractive; their bright colour, their dignity of bearing, their habit of throwing up great earthworks for the protection of their hiding-places—make them great objects of attraction to visitors.

At the Rothesay Aquarium marble has been greatly used, for the first time, in the construction of the tanks. This I believe is a very important application, one which will be largely adopted in place of slate, as at present used for smaller tanks. Slate, from its laminated structure, is liable to split when any lateral pressure is put upon it, while marble remains intact. Again, though slate is somewhat unsightly unless enameled, it unfortunately happens that this so-called "enamel" chips or peels off under the action of any sea-water with which it may come in contact; and the tanks then become unsightly and untidy in appearance. My readers will naturally say that

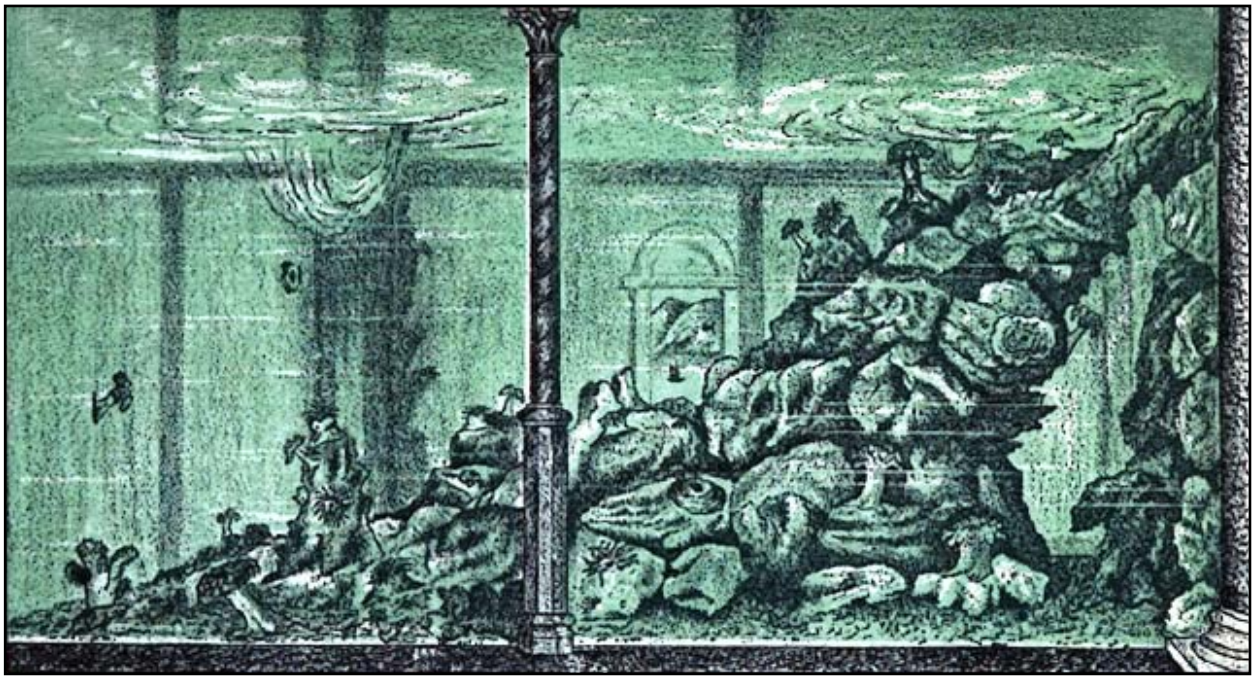

Figure 11: Sea anemone tank no.3 as seen through from the corridor.

the enamel being outside the tanks, it should not come in contact with the sea-water; but all who know the great difficulty of making large show-tanks absolutely water-tight will see the inadvisability of using a material which, in the present immature stage of aquarium construction, adds greatly to the first cost, and then afterwards only adds to the many complications of management.

Carrington continues, talking now about leaks and laying the blame upon the architects:

Unfortunately the aquarium at Rothesay suffers from the same failing as every other aquarium yet constructed—namely, the miserable leakage of water from reservoirs and tanks. It seems such a pity that, for the sake of a comparatively small fee, Aquarium Companies have hitherto persistently refused to engage a really competent engineer to superintend the earlier stages of construction. Had this been done there is little doubt that much anxiety in the management would have been saved, besides the disastrous consequences of the wear from leakage, which, from its very insidiousness, is a dreadful enemy to cope with. Aquarium construction has so far been treated entirely from an architectural standpoint, whereas it is eminently engineering, and large sums of money have been spent upon external decorations, which earn nothing, while tanks, pipes, and especially reservoirs, being out of sight, are neglected, to the infinite damage of future dividends. In fact, it amounts to this, that a well-constructed aquarium is a most valuable property, which, with little outlay after first cost, will earn large results, both biologically and financially; while a badly constructed one is a veritable "white elephant."

The leaks however, were in the large reservoir, not in the small one or in the show tanks. The following is from *The American Architect and Building News* of February 1878:

Rendering Portland Cement Concrete Water-Tight

With reference to the discussion in recent issues of the Journal on the question of Portland cement concrete, our Glasgow correspondent quotes the experience gained by the practice at the Rothesay Aquarium. He says : "Concrete tanks can be made practically water-tight by first using a good stiffish body of concrete, composed of just such proportions as should be used in order to make a good job, judging by the quality of the cement. Use clean sand, thoroughly free from soil, and then give a coat, one inch in thickness, of pure cement, finished and polished as hard as possible. By adopting such a course of procedure the tank is practically water-tight. This is what was done in the large reservoir-tank at the Rothesay Aquarium, and it succeeded famously, whereas under the ordinary method it leaked like a basket." —*Journal of Gas-Lighting*.

The slate tanks at the Rothesay Aquarium were the first that differed from those in any public aquarium. The adoption of slate slabs was highly preferable to the previously used bricks and mortar, not only on account of their thinness, providing a great economy of space, but they required no calcareous

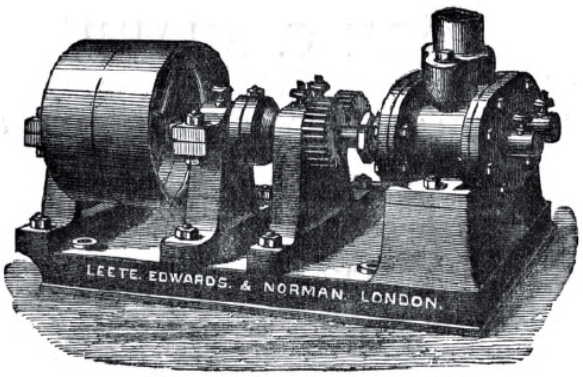

Figure 12:
The Forbes & Edwards rotary pump, adapted by the Leete, Edwards & Norman Aquarium Engineers for the Rothesay Aquarium. These pumps were made with vulcanite, a hard black insulating material made by the vulcanization of rubber with a high proportion of sulfur (up to 30%). The pump was driven by an 8 HP motor.

cementing as was the case with a construction of masonry, which rarely, if ever, proved watertight. Each side of the tank being of one piece - the only fissures in it were at the four corners and round the edges of the bottom - it was a simple matter to make a perfectly watertight tank which in reality was a huge box composed of seven pieces, including the two plates of glass forming the front, when compared to the difficulty attending the multiplicity of jointing necessary in the construction of a tank of bricks. The tanks being therefore made perfectly secure and tight before the rockwork was put in, it was not necessary to construct a rockery of such artificial materials. The Curator, Ernest E. Barker, has this to say about leakages:

Leakages are the Aquarium manager's bugbear, his nightmare in fact. When these occur in accessible places they sometimes may with great difficulty be overcome; but when they are known to exist out of sight and out of reach, they prey upon his mind continually. In some inland aquaria the loss of seawater by leakage through the intricacies of the rockwork, is so great, that large sums of money are annually expended to keep up the supply. In others the leakage has been so great, in spite of every effort, that the whole of the rock-work had to be completely taken out of every tank, and replaced by enormous quantities of cement which was fashioned to imitate rocks, at exceeding great cost. Hence we find it officially set forth in the records of one Aquarium, that "the loss of seawater through inaccessible leaks is continually going on at the money rate of over £200 per annum!' Another records, "Unfortunately the cementing at the back (of the tanks) had been so imperfectly performed, that water was running to waste through the walls of every tank, to an extent that involved the loss of many hundred pounds." I am happy to announce that the introduction of the slate slabs has relieved us of the loss and annoyance which otherwise might have attended the construction of the tanks: and as each one is independent of the fixing of the rock-work, "as sound as a bottle," it has left us free to use the natural rocks, and to represent them in their natural formations.

THE AQUARIUM COMES TO AN END

To begin with, the Aquarium was a prodigious success. It was the first in Scotland and therefore a novelty. It had an almost unlimited constituency in the summer visitors from Glasgow and all parts of the world. And Royalty set the example of paying it a visit. In the first four weeks of its history 25,000 people visited it, and in the first year nearly 100,000. The Aquarium also worked closely with the Fishery Board of Scotland, hatching herring eggs and lobster roe, spawning codfish and providing the Board with tank space for their experiments. Thus it partially fulfilled the hopes of Wil-

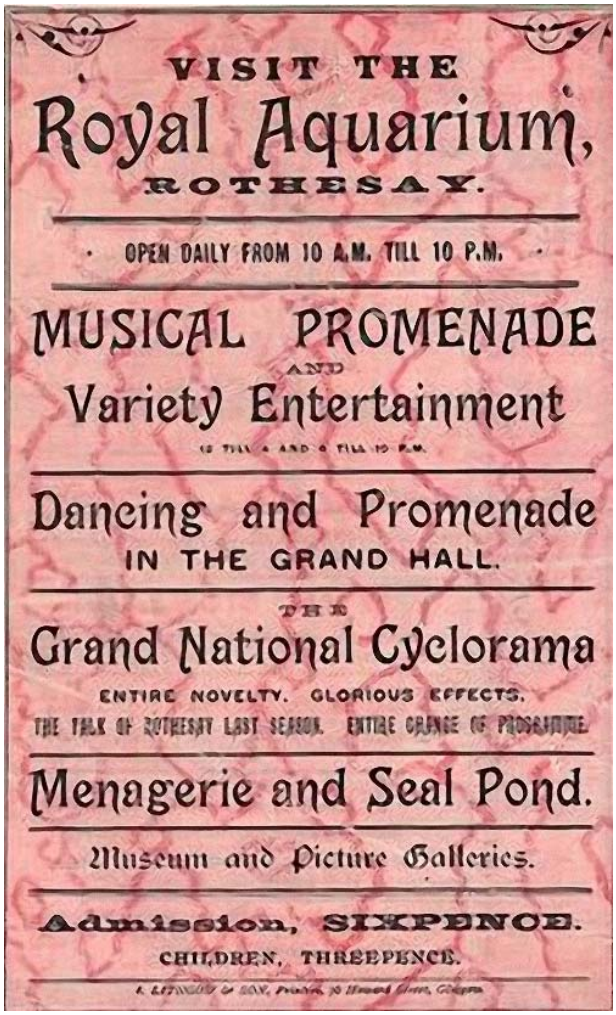

Figure 13: A flier for the Rothesay Aquarium.

liam Saville-Kent to establish a national marine aquarium and laboratory using the Brighton Aquarium, an idea that never came into being, and it predated the establishment of the laboratory of the Marine Biological Association at Plymouth by four years.

But after a time the Aquarium fell on evil days. It was no longer a novelty and there was much competition. The interest of the public gradually fell off, and the Company had to be wound up. The following appeared in the Edinburgh Gazette on November 27, 1908:

The New Rothesay Aquarium Company Limited, in Liquidation.

A General Meeting of the New Rothesay Aquarium Company Limited (in Liquidation) will be held within No. 14 Hart Street, Edinburgh, on Wednesday, 13th January 1909, at five o'clock afternoon, in order that the final accounts, showing the manner in which the winding up of the Company has been conducted and the property of the Company disposed of, may be submitted.

J. Dan Easson, Solicitor, Liquidator.
10 George Street, Edinburgh,
27th November 1908.

The building was later used as a home for the Buteshire Natural History Society's museum, and then as a music hall, before reopening in 1938 as the town's first indoor swimming pool, with hot seawater baths to attract those keen on the town's seaside health-giving properties (Figure 14). But while its time of popularity lasted it did good service, both on the scientific and on the recreation side. And the fact that it was the first in Scotland gave a reflected glory to the town.

PHILIP HENRY GOSSE'S $5,600 AQUARIUM!

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, July 29, 2016)

In the spring of 1876, Philip Gosse decided to build a marine aquarium using Lloyd's design used at the Crystal Palace Aquarium where the ratio of the water in the show tanks to the water in the reservoir was 1 to 5. As Gosse put it,

My old kind friend, Mr. W. Alford Lloyd, contemporary and fellow laborer from the first in aquarian development, gave me the invaluable aid of his counsel in every step of the work; ever suggesting and improving, as it went on, with a zeal which could not have been exceeded if the scheme had been his own. The mechanical contrivances and fittings were supplied by the eminent engineers, Messrs. Leete, Edwards, and Norman, to whose courtesy, skill, and thoroughness of work, I bear willing witness. The Tanks were made and put together, and the whole erected and set a-going, by mechanics of the place.

THE GENERAL PLAN

In Gosse's house in his servant's quarters was an apartment used as a lumber room, whose floor was about 12 feet from the ground. Gosse took out the window in the room and enlarged the opening for the reception of the tank. (Gosse referred to this aquarium as the "Tank" and the room it was in as the "Aquarium"; I will keep both these designations in this essay.) Gosse's house was a stone

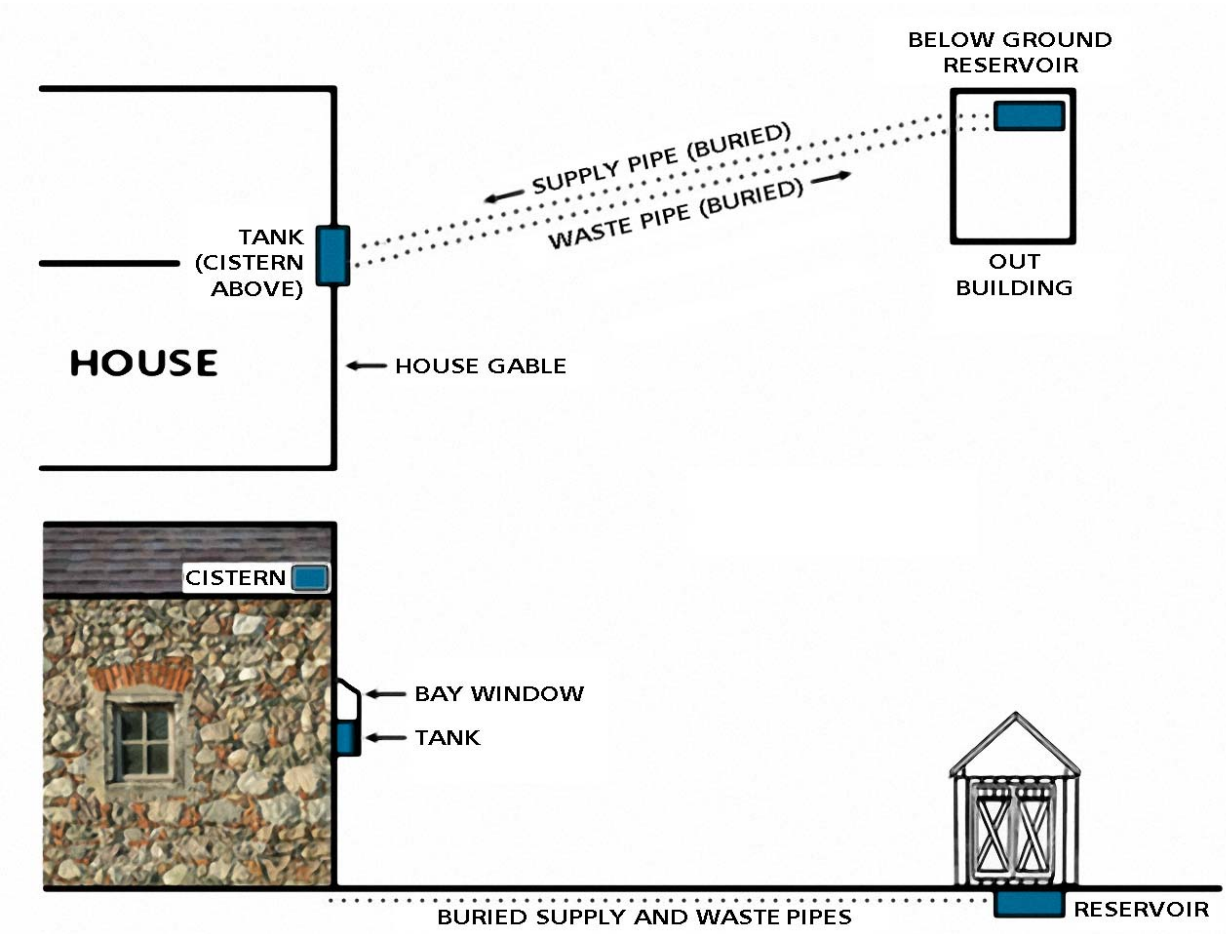

FIGURE 1: The overall siting plan for Gosse's aquarium.

structure so the Tank was to be placed half-way out of the room so that its center rested on the stone foundation of the house in a newly-constructed bay window. The window looked out upon a yard, across which was an out-building currently used as a coal cellar. Gosse excavated the farther corner of this building for the reception of the "Reservoir," which was sunk so that its top was level with the ground. This was protected from dirt and debris by a strong and tight cover of wood, divided and hinged in the middle so that the contents could easily be examined (Figure 1).

A large opening was made in the gable above the window and two cross-joists, 4 inches square, were inserted in the ceiling from the gable-wall to the center beam. Another tank - the "Cistern" - was placed within the roof, immediately over the Tank. This tank rested partly on the summit of the stone wall of the house and partly on the rafters, which were reinforced with the 4 inch square cross-joists.

THE CONSTRUCTION OF THE VESSELS

Three vessels were made of squared slabs of the best slate, varying in thickness from 1-1/2 in. (base) to 1 in. (sides), which were bolted together with iron rods, tightened by screws and nuts at the ends, a common construction method at the time (Figure 2). All the internal angles were filled with Portland cement. The side of the Tank that faced the interior of the room was made of 1/2 in. plate-glass.

The dimensions and capacities of these vessels were as follows. The Tank was 42 in. long, 18 in. wide, 18 in. deep, each inch of depth equal to 2.73 gallons for a total of 49 gallons. The Reservoir was 62.75 in. long, 35.25 in. wide and 26.25 in. deep, each inch of depth equal to 8 gallons for a total of 210 gallons. The Cistern was somewhat squarish, 34 in. long, 31 in. wide and 27 in. deep for a total of 112 gallons. Note that the dimensions of all three of these vessels represented their capacities and not their overall height or width since the end pieces had to be wider and higher to accommodate the iron rods.

THE ASSEMBLY GETS STARTED

Early in June, a water cart was filled three times with the crystal-clear water of Oddicombe Beach, near to St Marychurch (a suburb of Torquay) where Gosse lived at the time, and emptied by a hose into the Reservoir, providing Gosse with 210 gallons of pure seawater. Early in September the pump, pipes (1 inch ID) , valves, etc., arrived from the engineers. Vulcanite is a hard rubber produced by vulcanizing natural rubber with large amounts of sulfur (up to 30% or more) and at longer temperatures. The vulcanite pipes were all made in lengths, with the requisite angles and connections; and were sent from London, carefully numbered, according to copious working-drawings. No bend could in the least degree be changed, vulcanite being inflexible and brittle. Every piece was fitted and screwed to its fellow, using a red-lead sealant; some of the joints were also wrapped with muslin for this purpose.

Immediately the masonry of the house was opened to receive the Cistern and the Tank. The base of the Cistern was introduced and laid in situ, square and level, save a 1/2 in. inclination so that it might be emptied to the last drop. A hole was made in this part of the base for the insertion of a pipe - the "jet pipe" - over the Tank. This pipe extended down to near the surface of the Tank ending in a pin-point nozzle that forced a spray of water from the Cistern downward into the Tank to a depth of about a foot, entrapping air in the process (Figure 3).

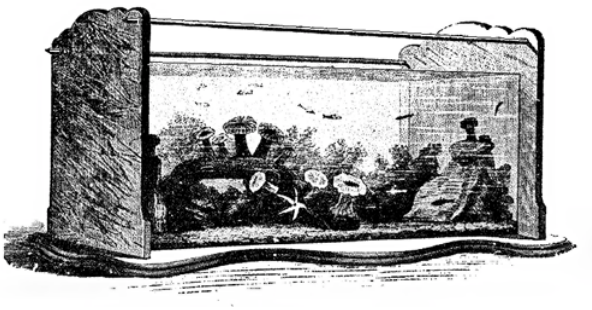

FIGURE 2: A typical marine tank of the time. The bottom had grooves to accommodate the bottom of the slate sides and the glass. The top was supported by the steel rods.

Gosse used four jets of which the orifices, perfectly true and round, graduated from the thickness of a lady's medium pin (No. 1, about 1.5 millimeters) to that of a cambric needle, (No. 4, about 30 micrometers). With No. 1, 18 pump strokes delivered an hour's supply of water into the Tank; with No. 2, about 10 strokes; with No. 3, 5 strokes; and with No. 4, about strokes. The orifice of each jet was just an inch from the surface of the Tank. A white cloud of dust-like air-bubbles was driven perpendicularly downward (about a foot with No. 1), after which they could still be followed, with a lens, moving swiftly to every part of the Tank.

The Cistern when being filled was out of sight in the roof above. In order to know when it was full and not allowed to overflow, a small pipe - called a "warning pipe" - was inserted into the side of the Cistern opposite to where the jet pipe was placed, an inch below the brim (Figure 3). This led down through the ceiling and ended at a few inches over the surface of the Tank. This was in sight of the person who was pumping water up into the Cistern and could not help hearing the noise of the stream as it came suddenly pouring down the warning-pipe. At such time, pumping was stopped immediately. The sides of the Cistern were then set up in Portland cement, bolted together and smoothed within and without.

A vulcanite pipe - the "Waste pipe" - coming from the right side of the Tank near the front carried away the excess water to the Reservoir. The position of its exit, about 2 in. from the margin, determined the level at which the water always stood in the Tank. It was at first proposed that this should be a simple pipe, screwed into a hole in the side, but this would have carried off only the surface water. To make the circulation complete, Gosse chose to take it from a point very near the bottom. To avoid the inelegant appearance of a pipe, however, Lloyd devised the following contrivance. A slab of slate, 2-1/2 in. wide, 1 in. thick and as high as the Tank, had a semi-cylindrical 1 in. groove gouged out it, but not reaching quite so far as either end. Its upper end met the hole in the side of the Tank at the surface (Figure 4A shows the slab's front and side). This was duplicated and then turned 180 degrees so the hole was at the bottom (Figure

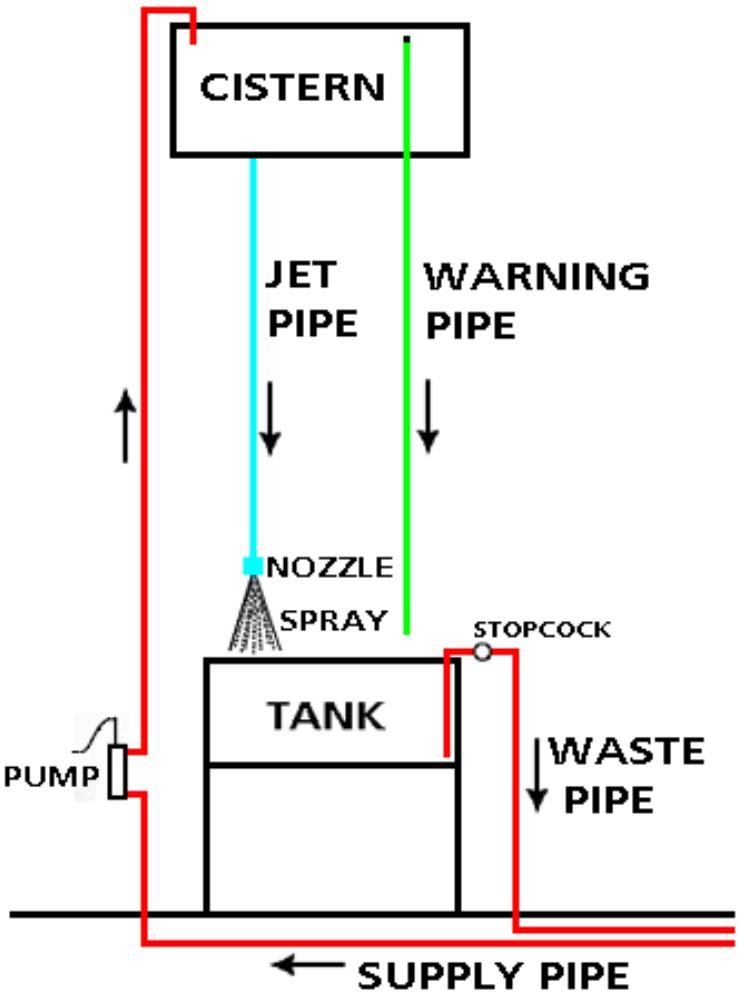

FIGURE 3: The arrangement of the four pipes.

4B). The two pieces were then cemented together, resulting in a single piece with a circular hole, 1 in. diameter, within (Figure 4C). This was firmly cemented in place. The water in the Tank entered through the bottom hole and rose in the hidden groove until it reached the exit hole in the Tank where it continued to trickle out through the waste pipe. The Tank could never overflow unless the inflow was more than the bore of the waste pipe could carry off or this pipe became choked.

To solve the latter problem, a shallow box of vulcanite, to which there was no cover, had its bottom drilled with a number of holes, 1/8 in. wide. This was set up on one of its sides on the Tank-bottom with its lidless top in contact with the lower part of the slab, the perforated bottom (now becoming the side) facing the interior of the Tank. Because Gosse needed at times to remove it in order to clean the holes, it was not cemented but merely kept in position by a heavy piece of rock work. By this contrivance, while the water can freely percolate and escape, nothing larger than the small holes can pass into the 1 in. bore waste-pipe and therefore it could never become choked.

In order to be able to lower the water surface in the Tank without dipping it out, the waste-pipe was cleverly turned into a Siphon. The waste pipe, after leaving the Tank, ran horizontally for a foot before it turned to the perpendicular. In the midst of this space a stopcock of vulcanite was inserted (Figure 3). This ordinarily was left open and served as an air vent. When Gosse wanted to draw off the water from the Tank, he took the tip of the stopcock into his mouth, and sucked strongly until the salt water came rushing up. In practice he found it necessary to suck such a mouthful at least three times before the up-current of water was strong enough to pour continuously down the perpendicular waste-pipe. He had to carefully to close the stopcock with is fingers at each suck, before he withdrew his mouth or the vacuum in part formed would again be destroyed. The water sucked into his mouth he instantly discharged into the Tank at each effort. After the water in the Tank was lowered to the desired level, the stopcock was opened, destroying the vacuum and the outflow instantly ceased. The jet-pipe in due course refilled the tank.

THE PUMP

The Pump supply pipe, a stout tube of vulcanite commencing 6 in. from the bottom of the Reservoir, passed over its edge, under the surface of the soil, across the yard, through the foundation of the house, up the interior of the wall, through the ceiling of the ground-floor and joined the bottom of the pump barrel, a cylinder of polished glass, 3 in. in diameter internally and 8 in. high. After allowing for the thickness of the piston it had a capacity of 1-1/ 2 pints when making its available stroke of 6 in. The engineers made two metal caps, one above and one below, grooved to hold the top and bottom of the glass cylinder (Figure 5). The caps were then joined by two metal rods

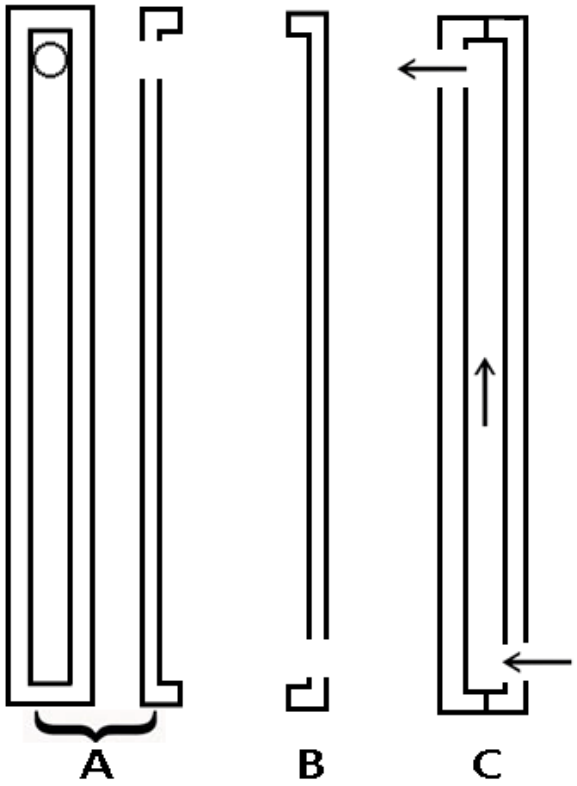

FIGURE 4: A 1/2 inch circular groove and a 1 inch hole were drilled in slabs A and B. When joined (C) and cemented to one side of the tank with the top opening at the end of the waste pipe, the waste water now entered at the bottom.

parallel to the glass barrel, screwed and nutted to the caps much in the manner of using rods to fasten the sides of the Reservoir, Cistern and Tank.

To avoid any oscillation during pumping, the fulcrum (handle) was fixed, independent of the barrel, to a stout wooden plank to which the pump was fastened. The end of a fulcrum travels in a slight arc that exposes the barrel to side strains that might break it. A "fork and cradle" motion, however, insured that the piston rod traveled strictly up and down . A guide to keep the fulcrum from moving side to side was also provided and fixed independently to the plank (Figure 6). These measures relieved the barrel from all side strains. The piston rod was of polished steel; the fulcrum of iron.

The basic operation of the pump is shown in Figure 7. The valve ball - a turned and polished ball of glass - descending by the up-stroke of the fulcrum, opened a chamber in which there was a second ball. This was forced in from the barrel by the incoming water and opened the Cistern supply pipe which, proceeding up through the ceiling, delivered the water into the Cistern above. At every downstroke of the handle, the pump delivered one and a-half pints of water from the Reservoir into the glass barrel, which water was the very next moment poured into the Cistern above by the following upstroke.

THE SYSTEM FINALLY GETS STARTED

The pump, pipes and the slate of the Tank were all painted black. An ornamental rim of polished Spanish mahogany was made to sit on the edge of the Tank and a curtain was hung to conceal the pump. By the end of September the whole was in place, and water was admitted into the Tank. Not till the last of October, however, were organisms admitted in the forms of growing Algae and Fishes, for not all went quite smoothly. The pump would not draw at first; the pipes leaked, and would not deliver until much

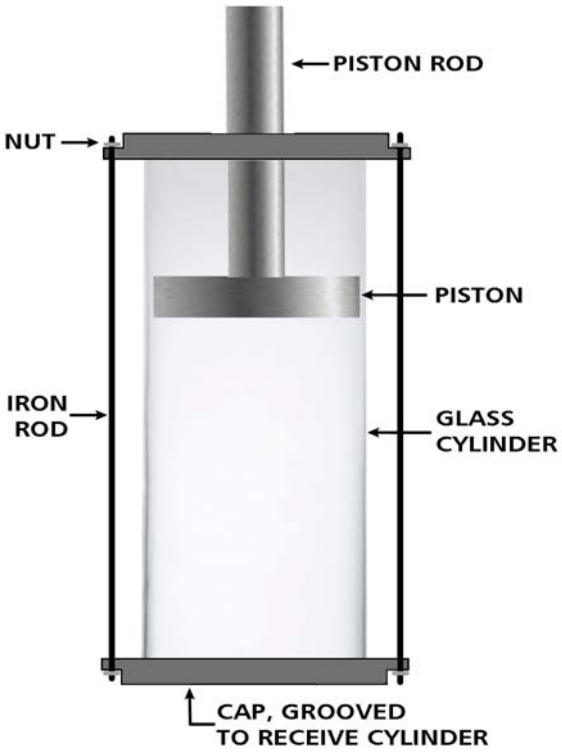

FIGURE 5:
Construction principle of the pump barrel (input and output not shown).

labor was expended in getting them water-tight. The water in the pump would drop back to ground level sooner or later after the pumping had ceased, so that sometimes it required more

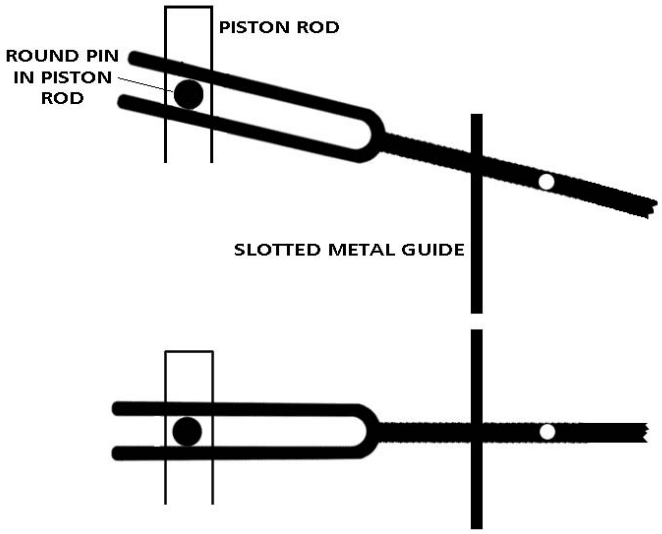

FIGURE 6: The "fork and cradle" movement .

than a hundred strokes of the handle before the water would rise to the barrel of the pump. This difficulty still continued in a mitigated form; it was the only one which Gosse never quite overcame. (Clearly the check valves were not tight. Gosse should have placed a ball-valve on the incoming supply line just before the pump, open during pumping and closed when pumping ceased.)

Then the siphon would not act at all for some time but, after several months, one day quite suddenly and unexpectedly it acted perfectly and operated without difficulty ever afterwards.

As soon as the system was operating regularly, Gosse found that his supply of water was inadequate. Some had been wasted and some had leaked in the imperfect fitting of the pipe joints. Accordingly, a further quantity was brought from Oddicombe beach, which made his stock as follows: Reservoir, 180 gallons; Cistern, 60; Tank, 40; equal to 280 gallons in all. This quantity was never afterwards needed to be replenished and its quality steadily improved.

Unfortunately, not enough time was spent in conditioning the vessels before adding specimens to the

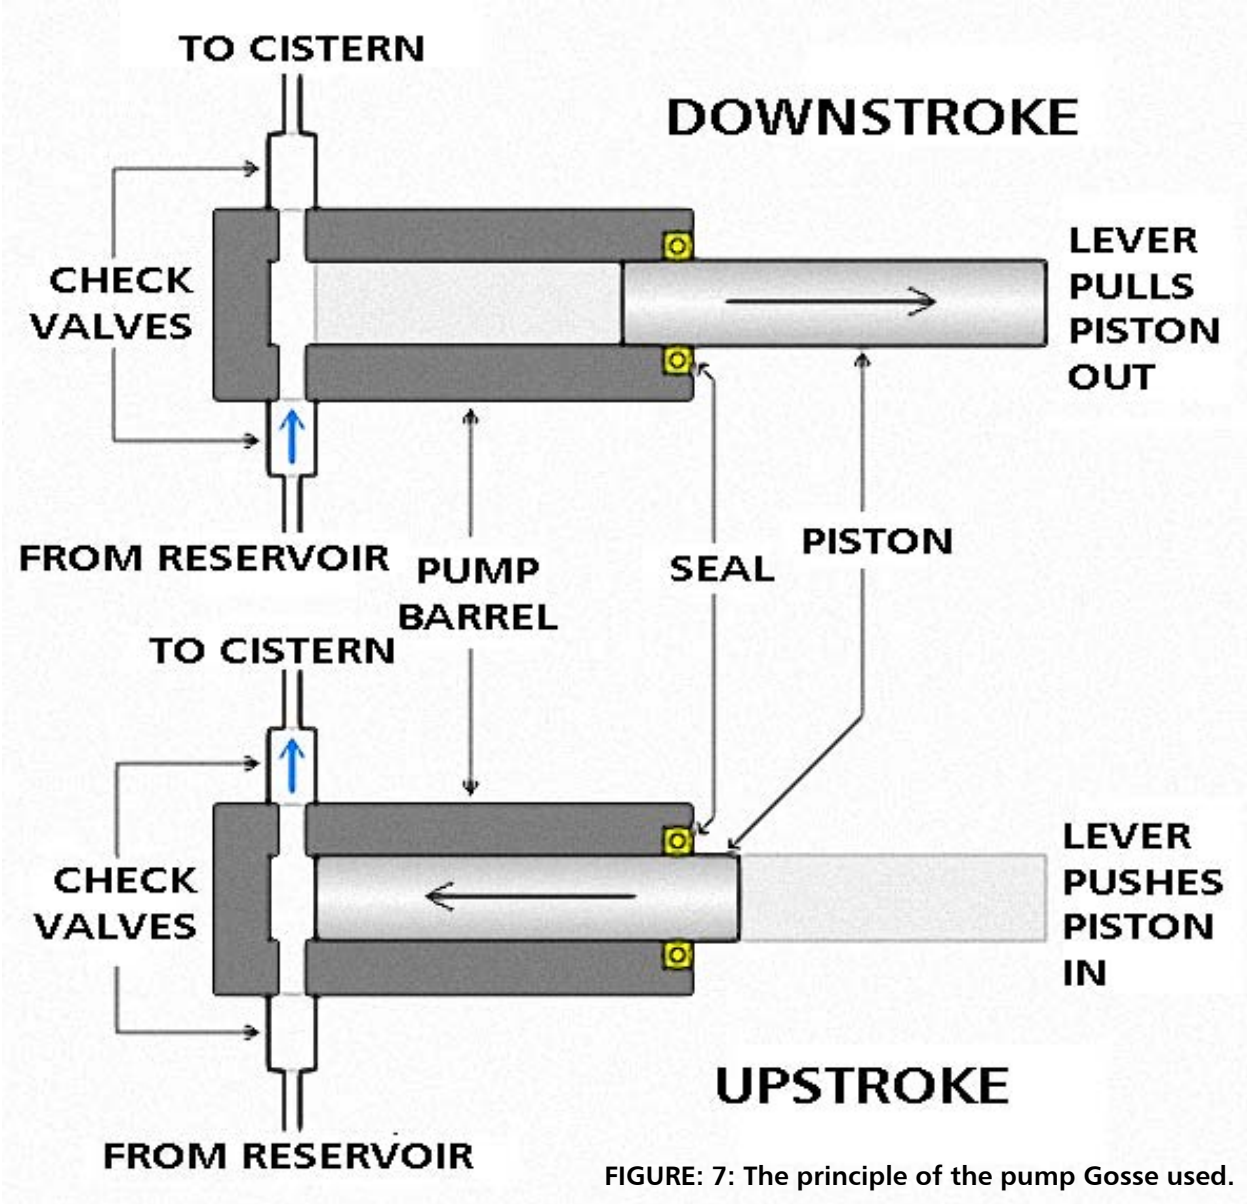

FIGURE: 7: The principle of the pump Gosse used.

Tank. Portland cement must be totally cured, as fresh cement leaches out materials that are poisonous to many aquatic animals. Vulcanite - a plastic - also requires conditioning time, as well as do the sealants Although many creatures died after a few weeks or even days a year before, a year later new arrivals lived in full health .

The system operation was as regular as clockwork. On Tuesday, Thursday and Saturday evenings, Gosse's servant pumped until the warning-pipe streamed, averaging some 675 strokes. The total of 675 strokes was performed in about half an hour. If the larger-bored jets were on, there had to be supplementary pumping in the off days to a varying amount. For fishes and the higher crustacea, etc., the fuller supply of jet No. 1 was required, and this took at least 250 strokes on each of the off days.

Not counting the cost of the pump, which was a gift from his friend Lloyd, the total cost was £60. Converting this amount to 2016 dollars, the result is $5,613, a pretty fair amount of change for a 40-gallon tank!

REFERENCE

Gosse, Philip Henry, "A Marine Aquarium," *The Midland Naturalist*, Vol. II, pp. 1-6, 1879.

Note: There are many methods available on the Internet for the historical conversion of Pounds Sterling to Dollars. This has given me a range of $4,540 to $9,300. However, I prefer Dr. Eric W. Nye's method. In order to convert British currency of former generations (I used 1876) to present-day (2016) American dollars, Nye uses the three following three sources in concert:

1. Davis, L. E. and Hughes, **J. R. T. "**A Dollar-Sterling Exchange, 1803-1895, *Economic History Review*, 2nd ser. 13:1, pp. 52-78, August 1960.
2. Douglas Jay, "Sterling: Its Use and Misuse, a Plea for Moderation" esp. "Appendix: The Purchasing Power of the Pound Sterling 1264-1983," London, Sidgwick & Jackson, 1985.
3. McCusker, John J., "How Much is that in Real Money?: A Historical Price Index for Use as a Deflator of Money Values in the Economy of the United States," reprinted from *Proceedings of the American Antiquarian Society*, 101:2 , American Antiquarian Society Worcester, MA., 1992.

Nye's calculation returns the value of $5,612.91.

DAVID WILLIAM MITCHELL

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, September 5, 2016)

The beginnings of what we think of as the aquarium hobby had its origins in the mid 1850's in England. Four individuals were at the fore in this development, three of the most prominent being Robert Warington, Philip Henry Gosse and William Alford Lloyd. The fourth, David William Mitchell, is lesser known but important in the development of the public aquarium. Like Shirley Hibberd and Hugo Mulertt, both of whom were known for their activities other than the aquarium - horticulture in their case - David Mitchell was known for his contributions to ornithology.

David William Mitchell was born in Chalfont St. Peter, a town about 23 miles northeast of London, on August 4, 1813. His parents were financially well-off, his father's occupation variously described from the 1841, 1851 and 1861 censuses as "Independent means" or "Fund Holder." The family moved to Gerard's Cross, Bucks County and then, when David Mitchell was at Oxford, to Cavendish Crescent in Bath. Mitchell graduated from Christ Church, Oxford in 1836 with a Bachelor of Arts and an interest in ornithology. The following year he married Prudence Philips Willes, the daughter of a Bath cleric.

PENZANCE

By 1838 Mitchell and his wife were settled in Penzance, Cornwall, a town about 255 air miles from London. Towards the end of 1838, the *Penzance Natural History and Antiquarian Society* was founded by the Mayor of Penzance, Richard Moyle, in response to a petition drawn up at a meeting held on the 4th of that month by 69 people. The Society, whose aim was "the cultivation of the science of Natural History, and for the investigation of the Antiquities referring to the early inhabitants," was established at a public meeting on November 20, 1839, with an annual subscription of 10 shillings or life membership of £5. The society held meetings where lectures were delivered and discussed, had an annual excursion to visit the antiquities of the area and maintained a museum.

The Officers of the Society included a President, three Vice-Presidents, a Treasurer, four Secretaries who were also Curators of the Museum, and ten other members that constituted a Council, all elected yearly at the annual meeting. David Mitchell was one of the Council members. Despite the initial enthusiasm, very little happened; the Secretaries and Curators' Report at the 1845 Annual General Meeting concluded: **The society having somewhat revived from the torpor which has for some time hung over it, the council hopes that its increased energy will**

Figure 1: David William Mitchell (1813-1859), 1850 portrait.

be continued without further interruption. The first volume of *Reports and Transactions* was finally published in 1851, covering the years 1845–51.

The problem is that the first printed *Reports and Transactions of the Society* was for the year 1845 and Mitchell's last year in Penzance was 1842. However, the following appeared in the *Report of the Society for 1847*:

In the ornithological department of our society, several interesting discoveries of rare species of British birds have been made… At the same time that it is gratifying to record the above interesting captures, it is to be regretted that we have been deprived of many valuable services which we formerly were able to avail ourselves of in this department of our society, by the absence of one of our late secretaries, Mr. Mitchell…

Thus, either in 1841 or 1842 or both, Mitchell served as Ornithological Secretary and Curator. Among his other activities, Mitchell was also a collector and dealer in bird skins and eggs.

Mitchell was well-known among the ornithologists of the day during his stay in Penzance. He is mentioned, for example, in William Jardine's "Birds of Britain and Ireland," William Yarrell's **"**A History of British Birds," Isaac William North's, "A Week in the Isles of Scilly," Henry E. Dresser's, "A History of the birds of Europe" and Jonathan Couch's "Jonathan Couch's Cornish Birds."

Figure 2. Species and subspecies of birds named after Mitchell. Upper Left: Diademed Plover (*Phegornus mitchellii*); Upper Right: Mitchell's Lorikeet (*Trichoglossus forsteni mitchellii*); Lower Left: Purple-throated Woodstar (*Calliphox mitchellii*); Lower Right: Grey-Capped Pigmy Woodpecker (*Dendrocopos canicapillus mitchellii*).

Jonathan Couch (1789-1870), a surgeon apothecary of Polperro, was one of the pioneering natural historians of his day, and his reputation is secured by his great works, notably his four-volume "Fishes of the British Islands," published in 1864 in four volumes and illustrated with 259 color plates based on his drawings. It is a classic still used by zoologists today. Couch was a good friend of William Yarrell (1784-1856) and stayed with him, for example, in Yarrell's London home in 1835 and 1849. In 1835-1836 Yarrell published "A History of British Birds," in two volumes and nearly 400 woodcuts, followed by a supplement in 1839; he also had an avid interest in fishes. Mitchell on the other hand, showed no interest in fishes during his stay in Penzance.

Mitchell also contributed to natural history magazines; the following istaken from *The Magazine of Natural History* in 1839:

Capture of rare Birds.—To the instances of the rose-coloured pastor mentioned by Mr. Yarrell, I have to add another (in mature plumage), which occurred in the beginning of last month at Gwithian, about twelve miles from this place, on the north coast.

On the 29th April I obtained a fine specimen of the greyheaded wagtail—a male—having the slight mixture of olive green in the grey feathers of the head, which Mr. Yarrell states to be characteristic of the bird of the preceding year. It was first noticed on the margin of a pool near the sea, between this place and Marazion.

Two instances of the little gull in this neighbourhood have come to my knowledge. The first, in St Ives' Bay, on the 26th of December last, was a young male in moult, and I suppose in transition to the mature plumage, as several grey feathers appear among the brown of the back. It seems to be a rather large specimen, the total length being 12 inches; wings from tip to carpal joint, 10-1/2 inches ; total extent, 33 inches: tarsus l-1/4 inch ; middle toe and claw l-1/4 inch; gape l-1/2 inch. The central feathers of the tail are 1 inch shorter than the outermost.

The other was also a male, but in the adult winter plumage, and of great beauty. It was shot here, in the harbour, March 4th, and is said to have been accompanied by another, which escaped. The only respect in which it differs from Temminck's description is the colour of the legs and feet, which were a delicate flesh colour.—D. W. Mitchell.—Penzance. July, 1839.

Towards the end of 1842 Mitchell was offered a job by George Robert Gray illustrating birds. Gray (1808-1872) was an English zoologist and author, and head of the ornithological section of the British Museum (now the Natural History Museum) in London for forty-one years. Gray had first published "A list of the Genera of Birds" in 1840, publishing a revised list in 1841 and an

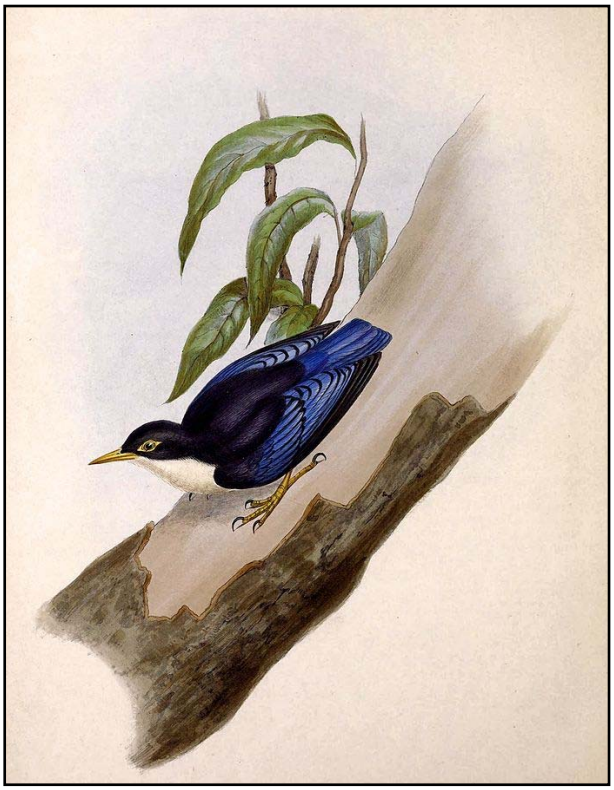

Figure 3. *Sitta azurea nigraventer*, one of Mitchell's illustrations in Gray's "The Genera of Birds."

updated list in 1842 before expanding it into three volumes called, "The Genera of Birds" (1844-1849), which was illustrated by Mitchell. In order to work closely with Gray and for easy access to the resources of the British Museum, by 1843 Mitchell and his wife had moved to London.

THE LINNEAN SOCIETY OF LONDON

The *Linnean Society of London* is the world's oldest active biological society. Founded in 1788, the Society took its name from the Swedish naturalist, Carl Linnaeus (1707–1778), whose botanical, zoological and library collections have been in its keeping since 1829. In the early 1800's, a cultural antipathy towards post-Napoleonic France generated a desire among British naturalists to wrest from French hands the intellectual leadership in zoology. In 1825, Yarrell was elected as a Fellow of the *Linnean Society*, and in 1849 was appointed treasurer, an office that he filled together with that of vice-president until his death.

However, The Linnean Society's botanical bias was seen as an obstruction in their path. Consequently, a group of zoologists banded together to form their own institution. On November 29, 1822 - the birthday of John Ray, "the father of modern zoology" - a meeting consisting of politically conservative natural theologians was held in the Linnean Society where it was resolved to form a *Zoological Club of the Linnean Society of London*. The group favored a method of zoological classification called the "Quinarian system," largely developed by the entomologist William Sharp MacLeay in 1819, in which it was proposed that all taxa were divisible into five subgroups, and if fewer than five subgroups were known, then they believed that a missing subgroup remained to be found.

Under the aegis of the *Linnaean Society*, the *Zoological Club* struggled from its inception for greater autonomy from the parent organization, in great part due to the Linnaean Society's overwhelming emphasis on botanical studies but also as reaction against Linnaean systematics and what they considered the Society's autocratic and outmoded restrictions on methodology.

THE ZOOLOGICAL SOCIETY OF LONDON

Our modern zoological gardens and zoological parks owe their origins to the enthusiasm and foresight of one man, Sir Stamford Raffles and a group of collaborators. Raffles had for a long time cherished the idea of establishing in London a collection of animals from all parts of the world. Most of his life, however, was spent in the Far East as a distinguished servant of the East India Company, and it was not until he returned home for good in 1824 that he was able to go ahead with the project. He had already been in contact with a number of people in London, and even while he was on the way home a meeting of "friends of a proposed Zoological Society" met in London and drew up a prospectus. The earliest record we have from Raffles himself is in a letter he wrote to a cousin, Dr. Thomas Raffles, in 1825:

Figure 4. Sir Thomas Stamford Raffles (1781-1826).

I am much interested in present in establishing a Grand Zoological Collection in the Metropolis, with a Society for the introduction of living animals bearing the same relations to Zoology as a science that the Horticultural Society does to Botany ... Sir Humphrey Davy and myself are the projectors, and, while he looks to the more practical and immediate utility to the country gentleman, my attention is more directed to the scientific.

Next to Raffles, Sir Humphrey Davy, President of the *Royal Society* from 1820 until 1829 and the acknowledged leader of British Science at that time, played the most important part in the development of the new Society. His backing probably had a considerable effect in enlisting the support of other eminent and influential men. When asked for support by Raffles, Davy helped to recruit but took a different approach. He was interested in recruiting members from those landed gentlemen who preferred to collect exotic animals rather than to discuss scholarly nomenclature. Unlike the first prospectus, the second comprised several short paragraphs, which proclaimed that the object of the society was the display and domestication of wild animals and the provision of successfully bred specimens for the subscribers. It omitted references to "a philosophy of Zoology," with its associations with the Quinarian system of taxonomy.

In this prospectus there was no mention of the existence of the *Zoological Club of the Linnean Society* but there was an overlapping of interest, and Aylward Vigors, an Irish zoologist who popularized the classification of birds on the basis of the Quinarian system and who was the first secretary and last chairman of the *Zoological Club*, was the first secretary of the *Zoological Society*. By 1829 the club was dissolved, by which time most of its members had joined the new Society.

Between 1824 and 1826 discussions between Stamford Raffles, Humphry Davy, Joseph Banks and others led to the idea that London should have an establishment similar to the *Jardin des Plantes* in Paris.

Frequent meetings of the committee over a period of nearly two years led finally to the first General Meeting of the Friends of the proposed Zoological Society. This took place on the April 29, 1826 at the offices of the *Horticultural Society*. It was at this meeting that the *Zoological Society* was definitely constituted, and a series of resolutions adopted fixing its principle features. The affairs of the Society were to be conducted by a President, Secretary, Treasurer and Council, and not unnaturally Raffles was elected first President.

At this meeting it was also announced that the Commissioners of Woods and Forests had agreed to allocate to the Society a plot of Crown land in Regent's Park extending to about five acres. There were 77 original subscribers, among whom included Sir Stamford Raffles, Sir Humphrey Davy, president of the Royal Society at the time, the duke of Bedford, the Marquis of Lansdowne,

Figure 5. Sir Humphry Davy (1778-1829).

Robert Peel and Alexander Baring, M.P. William Yarrell was one of the original members or founders of the Society and took an active part in its proceedings, both as a naturalist and as a man of business.

Raffles, however, died in July 1826 after only a few months in office. He was succeeded by the Marquis of Lansdowne who supervised the building of the first animal houses, the parcel of land in Regent's Park having already been obtained from the Crown at the inaugural meeting. (It received a Royal Charter from George IV on March 27, 1829.)

The purpose of the Society was to create a collection of animals for study at leisure, an associated museum and library. A house was obtained in Bruton Street in Mayfair for the new Society where meetings were held, a museum established, and a certain number of living birds and mammals kept. In the course of 1826 negotiations with the Crown were successfully conducted for the use of part of Regent's Park, and the latter part of 1826 and 1927 were occupied with the laying-out of the new Zoological gardens.

Early in 1828 there were a few pinioned wild duck on a lake, an emu, an otter, some silver-haired rabbits and several birds of prey. It is reported that on February 25, 1828, there were four visitors to the gardens, but under what conditions they were admitted is not known. On April 27, 1828, a superintendent was appointed, and the Zoological Gardens were opened to members. It was decided that visitors should be admitted on the presentation of a voucher from a Fellow and the payment of 1 shilling. Considerable progress was made during the remainder of 1828 in stocking and laying out the gardens.

In 1831 William IV presented the royal menagerie

Figure 6. The Gardens of the Zoological Society of London, Regent's Park, 1829.

to the *Zoological Society*, and in 1847 the public were admitted to aid funding, and Londoners soon christened the Zoological Gardens the "Zoo." The London Zoo soon had the most extensive collection of animals in the world. In its early days, when as property of the *Zoological Society*, the Zoo was open only to members and such of the public as obtained the consent of its members. At that period it was said, "The vulgar are too fond of irritating the fiercer animals and of teasing and hurting those that are gentle."

MITCHELL IN LONDON

On November 21, 1843, Mitchell was elected into the Fellowship of the Linnean Society of London. His many proposers included William Yarrell; Edward Doubleday (1811-1849), an outstanding ornithologist who doubled at the British Museum as an entomologist; and John Gould (1804-1881), a distinguished ornithologist, bird artist and publisher. In 1827, at age 23, Gould was appointed a taxidermist on the staff of the *Zoological Society of London*, of which society he was to become a leading figure in later years. With backers like these (especially Yarrell), it is not surprising that on December 6, 1843 Mitchell was elected into the Fellowship of the Zoological Society London. On November 6, 1844, he was elected Secretary of the Zoological Gardens and Arrangement Committee of the Zoological Society.

In 1827 it was resolved by the Society that "the Gardens be opened to the Public every Wednesday and Saturday, on the payment of 1s./each person." Members were however admitted at all times and they had the opportunity to introduce a non-member. But less than a year later it was decided that strangers could only be admitted to the Gardens by written orders from a member. There also existed a system of different tickets, with different privileges attaching to them. This meant that since the Council issued the tickets, the Society had total control of who visited the Gardens,. The purpose of this system was explained as follows:

It is evidently proper, that in the admission of

Figure 7. Three-Island Park. The Aquarium was located next to this pond.

Strangers, some degree of system should be observed, especially at the Garden, for the sake, both of preventing mischief and injury to the Animals, and to the Garden itself, and of contributing, in some degree, to save the visitors themselves from the accidents that sometimes attend exhibitions of wild beasts of prey. The vulgar are too fond of irritating the fiercer animals, and of teasing and hurting those which are gentle; and both vulgar and others are often exceedingly rash, in introducing their hands into the dens and enclosures, or careless in placing themselves so near the bars, as to defeat the effect of every precaution for their safety. The necessity for order almost prevents young people from coming without some superintendence.

This system was continued throughout the 1820s and 1830s but eventually changed at the end of the 1840s as will be described shortly.

The number of visitors to the Zoological Gardens had gone down steadily since 1836, a record-breaking year when more than a quarter of a million people passed through the gates. The 1830s and '40s were hard times in Britain generally and this most probably affected the entertainment industry as a whole with decreasing attendance at museums, panoramas and the like. At a special meeting in 1845 the Council tried to find out whether the wages paid to the officers and staff in the various establishments of the Society, i.e. general, museum, menagerie and carpentry and engineering, could be reduced.

The Committee of Receipts and Expenditure, however, could not find where these reductions were to be made. The only area that could perhaps be slimmed was the menagerie, but there had already been layoffs during the previous four years. Five people had had to go, including the medical superintendent (a measure not altogether beneficial for the collection in general) and three keepers. Therefore, the Committee could not see that any further reductions would be realistic. Unfortunately, the situation did not improve over the next few years, but instead grew worse.

Figure 8. Strolling next to the Parrot and Elephant Houses.

Another problem was that the Secretaries, important positions in an institution that had to be run like a paying business, traditionally were honorary and unpaid. The consequence of this was that they were prone to look to their own business rather than the Society's if they felt the need. In the beginning of 1847 the current Council Secretary, William Ogilby, sent a letter to the Council where he asked to be relieved of his duties. As an Irish magistrate and landlord his duties lay elsewhere. The Great Famine or the Great Hunger being a period of mass starvation, disease, and emigration in Ireland between 1845 and 1852, he informed the Council:

I am myself giving daily employment to from 30 to 40 heads of families to keep them from actual starvation: the distress is daily increasing, and though this part of the Country has been hitherto free from outrage no man can tell how long it will continue so...

The Council now decided that the position must carry a salary. The secretaries had hitherto been appointed from within the closest circle of the Society but now the net was cast a bit wider. At a special meeting on February 10, 1847, David William Mitchell was appointed a member of the Council and Secretary with a salary of £250 per annum. On April 27 of this same year, Mitchell's daughter, Lillian, was born.

JOSEPH WOLF

When Mitchell was appointed as Secretary to the Zoological Society he decided that he could no longer cope alone with illustrating Gray's "The Genera of Birds," and so looked to someone who could help in completing the project. That someone was Joseph Wolf (1820-1899), a young German artist who specialized in natural history illustration. Wolf depicted animals accurately in lifelike postures and is considered one of the great pioneers of wildlife art. Sir Edwin Landseer thought him "...without exception, the best all-round animal artist who ever lived." In 1847 Mitchell sent him a letter, inviting him to London to help with the book. Wolf declined at first but nine months later changed his mind and met Mitchell at the British Museum 1848.

At The Museum he was cordially welcomed by Mitchell (who was able to converse with him in French), and was straightway carried off to take possession of some temporary quarters in Howland Street, Fitzroy Square. Finding these quarters to be to his satisfaction, Wolf afterwards settled down permanently nearby. Mitchell was determined to counteract the depressing effect of the weather, and on the very first evening, he made up a little party for the theatre, including Mr. Trübner the publisher who acted as interpreter. The next day Wolf was installed in the Insect Room of the Museum, and began his work for Gray's Genera of Birds. Mitchell, in his "Postscript by the Illustrator," wrote:

It is perhaps scarcely necessary to state that the illustrations of this Book have no claim to be considered as works of art. My constant object has been to represent as closely as possible those characteristic variations of form

Figure 9. Joseph Wolf (1820-1899).

which are relied upon by ornithologists as the distinctive marks of generic separation. When I accepted the office of Secretary to the Zoological Society and found myself no longer able to devote to the completion of the series of plates the time which the work demanded, I was fortunate enough to obtain the assistance of Mr. Wolf of Coblenz [Mitchell did not know Wolf's native place]; and I have the pleasure of believing that, as I thus secured the best available talent in Europe as a substitute for my own pencil, my friends will have no cause for regret that the latter part of the work has been entrusted to another hand.— Montague Street, August 29, 1849."

If the illustrations by the veteran naturalist (Mitchell), are compared with those by the young, self-taught artist of twenty-seven (Wolf), one can at once see a difference and agree that the friends of the former had little cause to regret his relinquishing the work, even though only eleven or so of the hundred and eighty-five colored plates and fifty-nine out of the hundred and forty-eight plates of detail in the book are of Wolfs doing . It is especially noteworthy that while Mitchell often conscientiously copied the "distortions of the bird-stuffer," Wolf's work in no single instance ever suggests a stuffed specimen. It is in this power of revivifying a dried skin - and not merely revivifying, but showing the most characteristic and beautiful attitude and expression of the living bird or animal - that Wolf stood alone then and stands alone even now.

MITCHELL'S RISE TO PROMINANCE

Since the economy had not improved and it had not helped to cut expenses, only one thing remained for the Society to do: let the general public into the Gardens. The system with signed tickets had persisted until now, but it had to go. In 1847 in their annual report at a special meeting, the Committee of Auditors suggested that the public should be admitted to the Gardens:

Figure 10. The Monkey House at the Zoo.

…if active and energetic measures are taken for affording greater facilities to the Public of participating in that enjoyment, and for keeping constantly before the eyes of the Public, not only in London but throughout the kingdom, the collection of Quadrupeds, Birds and Reptiles [...] the Society will rapidly recover its ground and be again restored to its former gratifying and prosperous position...

Though unwilling in the past, the Council relented and resolved that the public should be admitted into the Gardens on Mondays and Tuesdays for payment of a shilling. This admission was furthermore extended to Easter and Whitsuntide (the 7th Sunday after Easter), both of which were legal holidays in England, Wales and Ireland. The following item appeared in *The Illustrated London News* May 22, 1847:

GARDENS, REGENT'S PARK. The Public are informed that Visitors will be admitted to the Gardens on the Zoological Society on WHIT MONDAY, and the Four Following Days, on the payment of 1sh. for each Person. An Exhibition of Domestic Poultry will take place on July 29th, 30th and 31st; the particulars of which and a list of the Prizes, may be had at the Office, No. 11, Hanover Square.

Judging by contemporary sources, Mitchell was the single most important person during this period in the Society's and the Gardens' history. Albert Gunther, later foreign member of the Society and curator of the Natural History Museum in London, wrote in his diary after a visit in 1854:

Wednesday to the zoological gardens; grandiose, excellently arranged and the animals happy. The Secretary, D.W Mitchell, must be something of a genius.

The Athenaeum, although not as enthusiastic as Günther, was still impressed:

The Zoological Society—started under the most favourable auspices—had fallen a few years ago into the condition of its older brethren. The gardens drooped,—the museum was closed, the meetings were dull, prosy and thinly attended. When things were at the worst, a new officer was appointed,—and 'hey, presto!' all was changed. The gardens grew into the most fashionable, as well as the most popular, of resorts.—the museum again courted the light of day,—the meetings of the Society were well attended...

Mitchell also invented the so-called starring system, which proved to be a long-lasting success at the Gardens. The condition of the system was that there should always be a "star" at the Zoological Gardens, an animal or an attraction that would be the primary reason for the public to visit the Gardens. Once there, they would be encouraged to feast their eyes upon the rest of the collection as

Figure 11. The Western Aviary.

well. This star was furthermore generously promoted in the press by articles and advertisements. The 1850s started with the four-ton hippo Obaysh, obtained in 1851. Other animals would soon follow; a female elephant and her calf, an anteater, a female companion to Obaysh and so on. The *Quarterly Review* thought that Mitchell:

…has shown by his system of 'starring' how alive he is to the fact that it is to the sixpenny and shilling visitors who flock to the gardens by tens of thousands on holidays that he must look to support the wise and liberal expenditure he has lately adopted.

In 1852, William White Cooper, who was a prominent ophthalmic surgeon and friend of Richard Owen, Frank Buckland, George Lewes and Thomas Huxley, wrote the following inscription in his "Adventures with Animals: Zoological Notes and Anecdotes":

To David William Mitchell, Esq., B.A., secretary to the Royal Zoological Society of London, etc. this volume is inscribed by an admirer of the zeal, energy, and talent, displayed by him in advancing the science of natural history.

Mitchell was on the crest of a wave of popularity.

MITCHELL'S INTEREST IN FISH IS BORN

Robert Warington married the daughter of surgeon George Jackson F.R.S. (1792-1860), a keen microscopist of repute. It was around this time that Warington joined the Mathematical Society of Spitalfields, which he attempted to regenerate by organizing a number of lectures at their meeting place in Crispin Street, but with little success. It was here that he was introduced to his father-in-law's close associate, James Bowerbank. James Scott Bowerbank, (1797 - 1877) was a British naturalist and paleontologist best known for his studies of British sponges. He devoted much time to the study of natural history while running a family business, Bowerbank and Company, distillers, in which he was an active partner until 1847.

In 1841 Nathaniel Ward set up an aquarium for fish and plants in a large earthenware vessel. In this vessel, which contained twenty gallons of water and in which he surrounded with rock-work raised several feet above its margin, he placed goldfish and several aquatic plants, viz. *Valisneria spiralis, Pontederia crassipes, Pistia stratiotes,* and *Papyrus elegans*. In this miniature lake, the water of which was never changed but kept in a constantly pure state by the action of the associated plants, the animals lived in a healthy condition for many years. However, he never published this in-

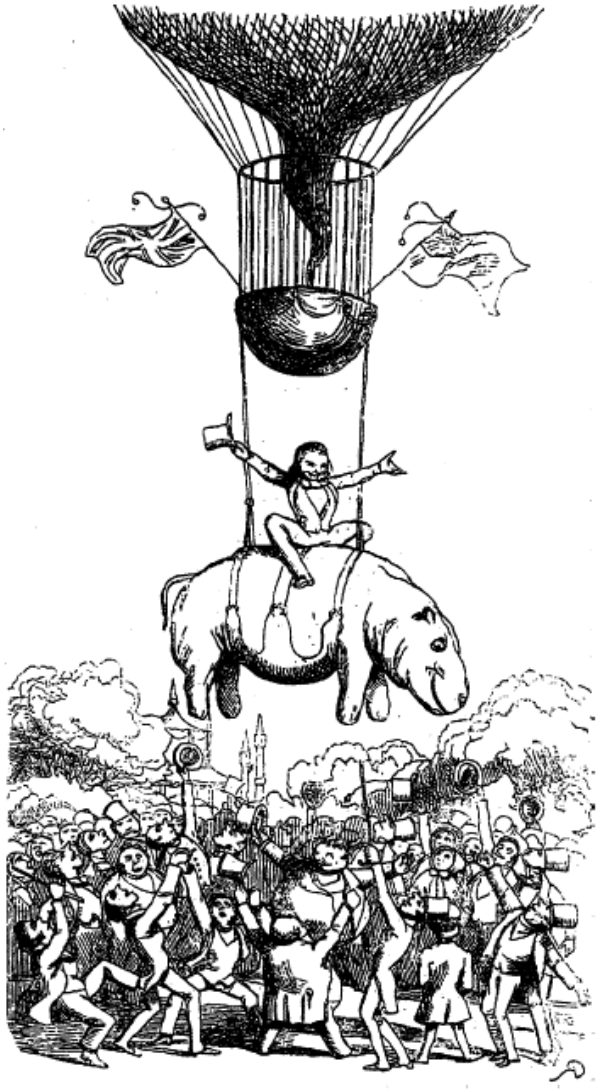

Figure 12. Punch pokes fun at the starring system. The hippopotamus with another popular attraction, the hot-air balloon (*Punch*, 1850).

formation. This aquarium gave Bowerbank (both he and Ward were members of the Microscopical Society of London and knew each other) the idea of taking a large glass jar, in which he placed sticklebacks, minnows, and snails along with plants of *Valisneria*, and covering it with a piece of glass. It was this jar of Bowerbank's that attracted the attention of Mitchell and gave him the idea for the public aquarium that was opened in 1853 in the Zoological Gardens in Regent's Park. The following is from Newman's aquarium history (*The Zoologist*, October 1873):

At our delightful reunions at Mr. Bowerbank's, first at Critchell-place and afterwards at Highbury, the lamented David William Mitchell, then the energetic Secretary of the Zoological Society, who was ever on the alert for something to "draw," was a frequent visitor; the sticklebacks arrested and riveted his attention, and he was not long in taking a lesson from Mr. Bowerbank's book: every one urged it; and Mr. Mitchell listened with marked attention, and conceived the project of an aquarium in the Regent's Park. With Mr. Mitchell there was seldom much time lost between the conception and the execution of a plan. In this instance these followed each other with unparalleled rapidity; he commenced building forthwith, ordered his tanks, and stocked them with their appropriate inhabitants, availing himself of every observation previously made either by Mr. Bowerbank or Mr. Warington.

Lloyd also credited Warington as being the inspiration for Mitchell's projects (Lloyd, 1879):

Mitchell's venture with the animals lower down in the scale of existence than birds [Lloyd is talking here about the first reptile house in any zoo, established at the Zoological gardens in 1849] **was so successful that he resolved at going down still further—namely, from and including fishes and to the very beginning, as it were of life, even down to zoophytes and sponges, thus comprising the mollusks, the animals, the worms, the starfish and their allies, and the sea anemones, so that visitors should be able to see in clear sea and fresh water, and through translucent plates crustaceous of thick glass, all manner of marine and fluviatile creatures, swimming, climbing, creeping, and almost or quite fixed, and of the most elegant forms and unusual coloring. This resolve was taken in 1850, and it was a direct consequence of the reading of a paper on the 4th of March in that year, by the late Mr. R. Warington, the chemist to Apothecaries' Hall, London, before the Chemical Society, on the manner in which he succeeded in maintaining some gold fish in unchanged water for a prolonged period.**

THE FISH HOUSE BECOMES A REALITY

On February 18, 1852 the Council of the Zoological Society agreed that work should start immediately on the building of an "Aquatic Vivarium," an early term for a fish tank or fish enclosure. The site chosen was between the Capybara's Pond and Eagle's Aviaries and the Three-Island Pond (Figure 7) consisting of chiefly British waterfowl. Mitchell conferred with both Gosse and Warington on the

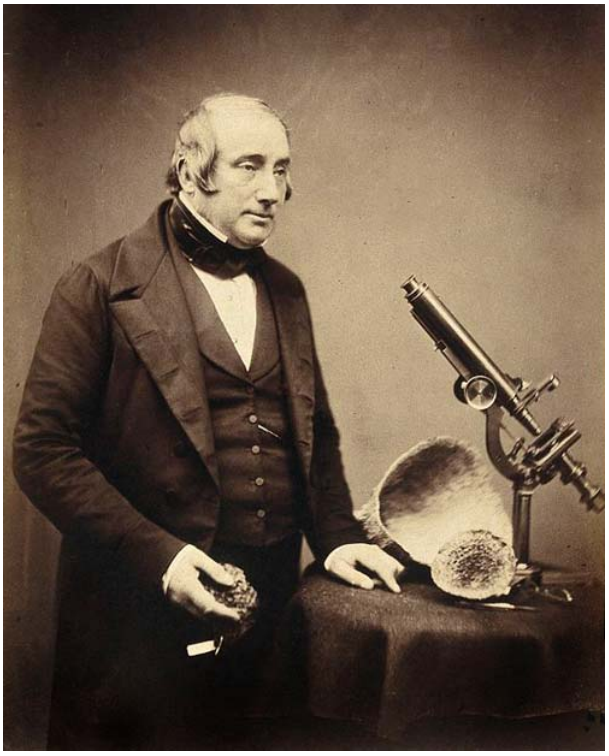

Figure 13.
James Scott Bowerbank (1797-1877).

Fish House. Gosse's idea for the larger display marine tanks was to place a small tank below each display tank. Using a hand pump, water was pumped from each of these tanks to a single large cistern and from there it flowed into the display tanks, being oxygenated as the water fell.

This was a scaled-up variation of the "drip-glass" method Gosse used for his own aquariums. (One should also note that the principle involved was put into practice by Anna Thynne in 1846 when she had her maid pour seawater back and forth in two glass bowls containing madrepores.) In fact, it was basically the system favored in the public aquariums designed some years later by William Saville-Kent. Neither Gosse's system in the Zoo's Fish House or Kent's system were adequate, however; the water became turbid, threatening the health of the marine animals and their visibility to the public, and had to be replaced often.

This, however, was not the case with the large freshwater display tanks. In 1823 a well was sunk and a steam-engine erected in the gardens, at a cost of about £2000. The steam-engine pumped water throughout the Gardens and was operated an average about eight hours daily, the average daily supply of water being about 1900 tons. The freshwater aquariums were connected to this system, allowing the water to run through them, the overflow then once again being available to the Gardens. The first tank that was installed contained freshwater, and this was set up according to Warington's instructions, with aquatic plants planted in the bottom and populated with a large pike.

Regarding tank construction, Warington actually invented the form of the aquarium as we know it today. The following is from the January 1852 issue of *The Garden Companion*:

Since the reading of my paper before the Chemical Society, on March 4, 1850, respecting the Miniature Aquarium (*Quarterly Journal of the Chemical Society,* iii 52), I have continued the investigations, introducing other water plants, and also three other varieties of water snail. But the principal alteration has been the construction of a better form of vessel for holding the water, as I found that the globular form of the glass receiver, produced a distortion in the vision of the fish, besides being very inconvenient for observation. I have therefore adopted the form of vessel, of which a sketch is appended, having flat surfaces of plate-glass at the back and front, the bottom and ends being formed of slate, and supplied with a loose plate of glass at the top to keep out dust and soot.

To render the whole more ornamental, as it was to stand in a sitting room, some pieces of tufa, or sandstone, were attached to the ends by means of Roman cement, so as to form ledges and slopes rising from the water line,

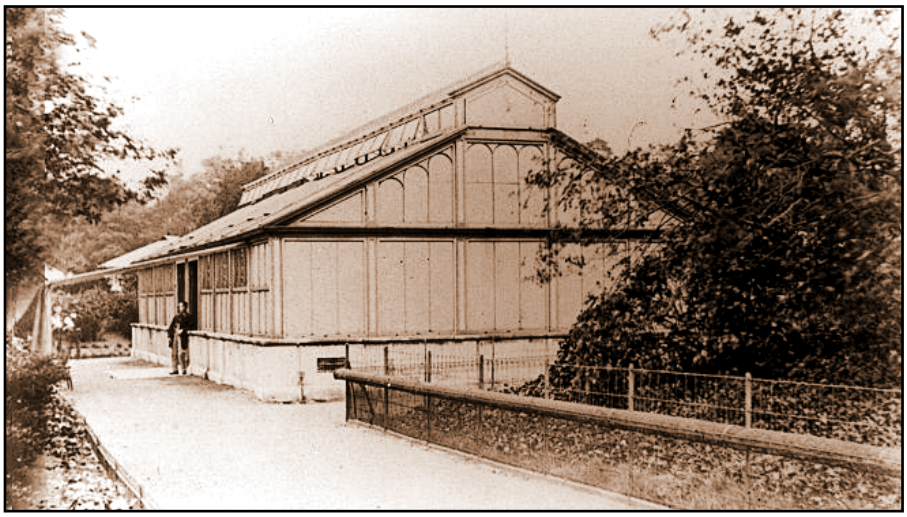

Figure 14.
The Fish House.

on which mosses and ferns, such as luxuriate in an atmosphere loaded with moisture, could be grown. These materials are set in a stout angular zinc framework, and connected with a mixture of white-lead ground in oil, to which about an equal quantity of red-lead is added. This arrangement I have found to answer all my expectations, as it has been going on most flourishingly since January 1851. The plants consist chiefly of *Hymenophylum tunbridgense*, and *H. Wilsoni*, *Trichomanes speciosum*, *Blechnum boreale*, *Adiantum Capillus-Veneris*, and several mosses. The whole of the interior can be viewed with the greatest ease, so that the natural habits of its living inhabitants can be watched and accurately noted in every particular.

The tanks destined for the Fish House that Mitchell obtained from Sanders &Woolcott (they had installed the piping in the Zoo's Hippopotamus House in 1850) followed Warington's design, save Mitchell opting not to place ornamental tufa or sandstone in them (See Figure 15).

Some more details were provided some years later by William Lloyd in the August 1879 issue of the *Scientific American Supplement*:

The erection of the Regent's Park Aquarium, or as it was and is called, the "Fish House," was proceeded with slowly in 1851, and I first saw it from its outside, through its glass walls, on Thursday, November 18,1852, at noon. It was not open, or even wholly complete, and it was indeed not opened to the public until 11 A.M. on Saturday, May 21, 1853, it being pictorially illustrated and described on one whole page of the Illustrated News of the following Saturday, May 28. It was and is a conservatory-like building, running north and south, measuring 54 ft. long, 80 ft. broad, and 12 ft. high to the upper part of the vertical portion, and 20 ft. high to the apex of the doubly-sloping roof. Surmounting the breast-high brick walls, which originally formed the only opaque part of the building, are seven tanks on one side and six tanks on the other, each measuring about 72 in. long, 24 in. broad, and 24 in. high. Placed on the floor in groups, with walking spaces between them, are about eight other and smaller tanks, standing on wooden-inclosed cupboard-like frames, and one of these cupboards contains an arrangement something like an inverted iron balance, by means of which the two tanks placed over it can be alternately depressed and elevated in such a manner that the water may run in and out and so give a kind of semblance to a tidal action. This apparatus, however, has never been used. All these tanks, which still remain in the same position of more than a quarter of

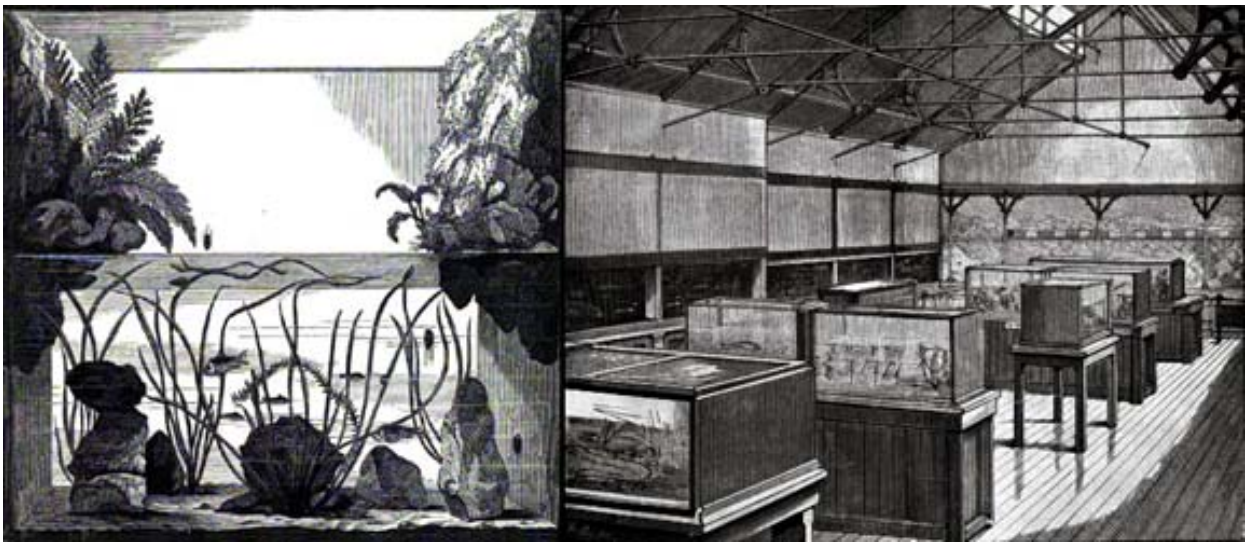

Figure 15. Left: Warington's aquarium design. Right: The aquariums in the Fish House.

a century ago, have, save one, slate bases and ends, and glass sides. The two ends of this "Fish House" are arranged for small aquatic reptiles, as tortoises and alligators, and for the lesser aquatic birds.

Fresh water from the ordinary sources supplying the gardens generally, ran into one end of the larger series of tanks (those on the side walls), and, running right and left of the entrance door, emptied their uncontaminated streams into two sunken and not glazed tanks at the ends of the house, and from them it flowed to waste (so called), into the garden sewers. The smaller fresh water tanks standing on the floor, and unconnected with each other or with any other tank, had no current in them, and their water was but occasionally renewed, as it seemed necessary.

The larger marine tanks had their water drawn from them, in part, every morning and every evening, by a gutta percha siphon, into slate cisterns placed below them, and from these cisterns it was pumped into a large slate cistern several feet higher up, and placed in the midst of a fresh-water cistern through which cold fresh water ran; the same cistern, in fact, which supplied, and supplies, the fresh water tanks. Thus the sea water received some degree of coolness in summer from the fresh water as it rose from the earth, it being raised by the steam engine generally supplying the gardens, and from this cistern it dribbled back into the show tanks through stoneware taps, being thus much aerated and refreshed by falling from a height twice daily. The other tanks, standing in the center of the "Fish House," and unconnected with any other tanks, were not thus cooled and aerated, and were changed or renewed occasionally as seemed needful.

It should be noted that save the aquatic creatures and plants, neither Warington, Gosse nor Mitchell actually installed anything themselves in the new aquarium. This was left up to Richard Sanders of Sanders & Woolcott, as he was the one installed the tanks his firm had made, and also the pipes, plumbing fixtures and pumps. An unfortunate aside: On November 10, 1857, Edward Woolcott, Sanders' partner, committed suicide (an irony as will be seen at the end of this essay) and, on November 21st of that year, Sanders filed for bankruptcy. William Lloyd had established his Aquarium Warehouse in 1856 and after Sanders' bankruptcy, obtained the rights and production facilities and was in a position to offer Sanders & Woolcott aquariums to the public once more.

The London Zoo's "Fish House" opened in May 1853; it was revolutionary for its time, the possibility of making tanks from large sheets of plate glass enabled visitors to have an underwater view of the life in tanks. Actually, the idea of keeping marine animals at the Gardens was not completely new; the *Athenaeum* had suggested it in 1850, saying that if the Society could procure a hippopotamus, then why not a whale?

The following is an excerpt from *The Illustrated London News* of May 28, 1853:

The arrangement is simple enough, and the effect of it is altogether charming. The whole length of the ponds is about eighty feet; they occupy two sides of a building of glass and iron, constructed expressly for this purpose at the beginning of 1852. [Note: At this point, no one was sure what to call the tanks. The *News* elected to call them "ponds."**] Each pond is six feet in length, and the water is enclosed by walls of plate-glass, each in a single piece. At the bottom of**

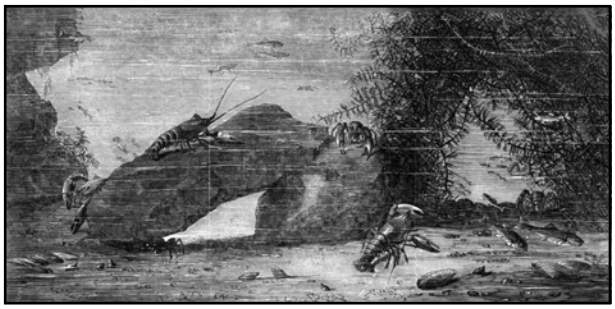

Figure 16. Engraving of a freshwater tank made in 1853 when the Aquarium was just opened to the public.

these translucent ponds, rocks, shingle, and sand, with seaweed growing in it, present a model of some nook at the bottom of the sea; and there we have a group of shell-fish, of living shells, of star-fish, of sea-anemones, or of nudibranchs, as the case may be, disporting themselves in precisely the same manner as if they were still uncaptured and free in the depths whence they were borne.

The singular mechanism by which these creatures move - by which they seize and devour their prey-the extraordinary changes of colour and form which some of them undergo, render each of these ponds the occupation of a day for a close observer; for, however long he may stand, contemplating the wonders which they inclose - some new action, some movement which he has not seen before, is constantly presented to him. The abundance of specimens which each pond contains, the numerous retreats which the rocks and plants afford to them, and of which a portion of the Inhabitants appear to avail themselves successively, will always prevent the exhaustion of the subject by the visitor; and we foresee in this fact, as well as in the extreme beauty of the objects themselves, a power of attraction which no previous work of the Society has ever yet attained; and we heartily congratulate them upon the success which cannot fail to attend so spirited, so interesting, and so instructive an attempt to carry out the most elevated principles of the science which they are associated to render popular.

That the people of this country are not only willing to appreciate such attempts, but anxious to benefit by them, is satisfactorily shown by the crowds who throng the Gardens on all public holidays; and that this feeling has not yet by any means reached its full development is evident from the result of Whit-Monday, when even the best days of 1851 were far exceeded, and the number of visitors amounted, as we are officially informed, to upwards of 22,000.

Gosse, by the way, anxious to let everybody know that he, not Warington was responsible for the marine part of the exhibit in the Fish House, wrote the following in his book, "A Naturalist's Rambles on the Devonshire Coast," published in 1853 shortly before the Aquarium was opened to the public:

What then is necessary but the presentation of the water, so charged with organic matter, to the atmosphere in a minutely divided state? This I did, and found the objectionable qualities of the water at once removed, and my difficulties vanished. I even took sea-water, containing animal matter in suspension, so putrescent as to be highly offensive, and after passing it through the air in a slender stream a few times successively, the water was restored to purity.

Another advantage is secured by the same process, viz. the aeration of the water. For though the requisite oxygen may be supplied by the agency of the plants alone, the mechanical admixture of the atmospheric air with the water by artificial aeration is highly conducive to the health and comfort of the animals, as is evident from their vigour and increased action under its stimulus.

Should any of my readers wish to see these experiments in operation, or to cultivate a personal acquaintance with many of the individual specimens whose history has been recorded in the preceding pages, they may do both by

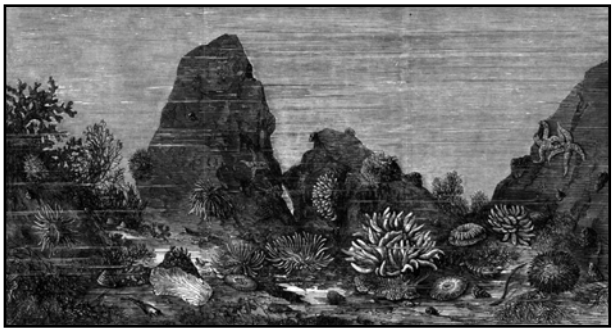

Figure 17. Engraving of a marine tank made in 1853 when the Aquarium was just opened to the public.

visiting the Zoological Gardens in the Regent's Park. The able and zealous Secretary, D. W. Mitchell, Esq., has already set up one large glass tank, filled with sea-water, (the purity of which is maintained in the manner I have just described,) and stocked with marine plants and animals so as to resemble one of those charming tide-pools, so often mentioned in these pages, with the advantage of having its sides formed of plate-glass, and its whole contents therefore clearly visible. There the visitor may see the *Sabellae*, the *Actinia* of brilliant hues and many kinds, *Mollusca* both shelled and naked, *Crustacea*, and *Annellida*, all pursuing their various avocations and enjoying themselves without restraint, under circumstances scarcely distinguishable from those of nature. All who have seen this aquarium concur in considering it a most attractive exhibition; and it is fairly anticipated that when seven other tanks of equal dimensions are added to the one already stocked, each containing some of the numerous tribes of marine creatures (a result which we hope to accomplish in the course of a few months), the whole will form one of the most unique and interesting features of these beautiful Gardens.

It has often been written that Warington's and Gosse's papers on the establishment of the marine aquarium were published very closely apart, suggesting that both deserved the credit equally. These authors, however, overlook the fact that like Hyperion to a satyr, Warington's paper was far superior; indeed, Gosse's paper really added nothing new of any consequence.

Early on there was much controversy over what to call these vessels that contained aquatic organisms and plants. Edwin Lankester, a stickler for Latin, called a tank an "aqua-vivarium," which technically was correct but rather unwieldy. During the planning stage of the Zoo's aquarium Mitchell used the term "Fish House," but changed this to "Aquatic Vivaria" by the time the aquarium opened. A year later Gosse's book, "The Aquarium," was published and in 1854 "aquarium" was taken up and popularized by the Zoo. However, in 1860 Holdsworth was still referring to the building as the "Fish-House" in his guidebook, although he did use "aquarium" to refer to the tanks themselves. It should be noted that Warington had used the word "aquarium" two years before Gosse did and therefore gets the credit for introducing the term to the aquarium hobby.

The first photograph of a living fish (a pike, *Esox lucius*) was taken in 1853 at the Fish House by the Count of Montizon (Don Juan de Borbón y Braganza, 1822-1887), a grandson of King Carlos IV of Spain. Although his childhood was spent at the court of his uncle Fernando VII, the king of Spain, Prince Juan de Borbón spent the major part of his life in England, in exile following his father's violent challenge to the succession of Fernando's daughter Isabel II in 1833. Apparently harboring no royal ambitions, Juan assumed the somewhat obscure title of Count de Montizon in public and, when the dubious title of pretender to the Spanish throne passed to him from his elder brother, he

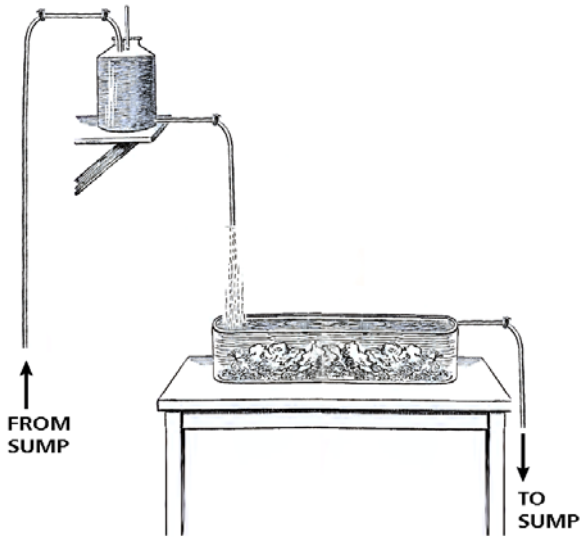

Figure 18. The drip method recommended by Gosse for the marine tanks. The water in the upper header tank was pumped up from a cistern below each display tank and the overflow from the display tank was directed to the cistern. It was a failure because the sizes of the header and sump tanks were too small.

renounced all claims in favor of Queen Isabel. His passions instead ran to physics, chemistry and natural history; photography, it seems, was an appropriate amateur pursuit that combined all three interests. His photograph of a pike (Figure 19) was the forerunner of an immense global interest in underwater photography and previously hidden aquatic habitats.

In 1852, Mitchell published the first guide to the Gardens (Mitchell, 1852) and this was followed by a number of editions written by him. In 1856 he edited and supplied notes to Wolf's book, Zoological Sketches. The following is an extract from the 1856 *Quarterly Review*:

Out of this large number many curious animals have doubtless left no trace; but through the care of Mr. Mitchell, no rare specimen has died within these five years at least, without previously sitting for his portrait. The first part of the valuable collection of coloured drawings, from the inimitable pencil of Mr. Wolf, accompanied by a description from the pen of Mr. Mitchell, the editor of the work, is just published, under the title of 'Zoological Sketches, &c.,' and the others will speedily follow. The work, when completed, will be unique in the annals of zoology, both for the extreme beauty of the drawings, which may be said to daguerreotype the subjects in their most characteristic attitudes, and for the nature of the letter press, which proves that the editor has written from the life.

PROBLEMS IN PICATORIAL PARADISE

All, however, was not well as William Alford Lloyd pointed out twenty-four years later (Lloyd, 1876):

In the earlier books on aquaria - notably in Mr. Gosse's two volumes, his Devonshire Coast and his Aquarium (the latter having gone through two editions, 1853 and 1856, besides a recent reprint without the plates, which have been accidentally destroyed) — aquaria are associated in idea with conservatories, especially as to the growth of plants in each. This notion was very natural. Accordingly the Regent's Park Aquarium was made virtually as a conservatory. But it was a diametrically wrong notion, as the first summer proved; and the second summer (1854) showed this still more conclusively; and the third (1855) yet more so, the evil being an accumulating one. It was then remembered, when too late, that marine and fresh-water plants and animals live in seas and rivers, where the temperature is much more restricted in range than that which obtains in the atmosphere.

It was seen that success was to be obtained by representing these conditions of nature just named, and that to place such organisms in a glass house, where the rays of a summer's sun heated a mass of imprisoned air, was to kill the animals and to stimulate the plants to unnatural growth, or rather to cause them and some of the animals to be covered with a parasitic growth of the lower green algae, which obscured them. The errors of this earliest aquarium were strikingly shown by its solitary merit, the latter being its fresh-water division, occupying one side of the building, where the water coursed through the tanks in a constant

Figure 19. The first photograph of a living fish (a pike*, Esox lucius*) was taken in 1853 at the Fish House by the Count of Montizon.

stream, it being clear and cool, and peopled with an adequate number of healthy animals; while on the other side of the building, and in its centre, were the marine tanks, in which the water was, and still is, turbid and warm, and sparsely inhabited by not healthy creatures.

These good results were, however, obtained by accident and not design. [Note: I disagree with Lloyd here. One does not by "accident" do a major plumbing job like this. I suspect that Richard Sanders observed that Gosse's more complex system was not necessary for the freshwater tanks and suggested this alternative arrangement to Mitchell.**] The society possessed already a steam-engine, which pumped up water for the general use of its gardens, and it was a mere matter of course to connect the aquarium with this engine, and allow the water (which chanced to be drawn from a pure source) to run through the fish tanks, and then be applied to ordinary purposes, drinking or other, for which its passage through the tanks in no way unfitted it; I reasoned with the society that if the sea-water tanks were similarly treated on some such system as the fresh-water series, a correspondingly good result would be attained; and I pointed out that the same law governed both, because in the centre of the building were some isolated fresh-water tanks having no stream in them, and these were in a similarly ill condition as the marine tanks by their side.**

In reply, the society answered that a circulatory system did exist in a part of the sea-water series, but that it was almost useless; and I then pointed out that that was because the reservoir into which the sea-water entered after it had run through the show-tanks was too small in relation to the dimensions of the latter, and that the reservoir should be several times greater than the show-tanks. My reasoning was all in vain, however, for the society went on throwing away the sea-water when it was only temporarily unfitted for use, and getting at a cost of several hundreds of pounds yearly a weekly supply from the sea, especially when soon afterwards another evil made its appearance, consisting of a greenish-brown dense opacity, permeating the water and quite hiding from view all it contained. This was caused by excess of light, for I found that darkness removed it and made the water clear again…

Because of the light and heat problem, the glass of the building, sides, ends and roof were painted opaque and white, and to further exclude the sun, heat and light, it was screened with canvas in hot weather. This, however, only partially solved the problems. In the first edition of Gosse's "Aquarium," published in April, 1854, he mentions the survival of several marine animals placed in the gardens "nearly a year" before, and that some of the sea water had not been changed for "seven months." This passage of praise was, however, omitted in the second edition of the book, published in August, 1856, twenty- eight months later. Furthermore, these problems still existed as of 1871, as illustrated by the following extract from

Figure 20. The Zoological Society's Headquarters, Hanover Square.

an article in *The Illustrated London News* of that year:

Consequently, in the first summer of its existence, the mortality of the animals in the Regent's Park aquarium was very great, and the vegetation was stimulated into far too rapid a growth, which rendered the water turbid. The modifications which have since been made in the building, and which still exist there, have but partially remedied its original defects, among which have also to be enumerated the very serious ones of the small dimensions and tall and narrow proportions of the tanks (thus giving insufficient air-absorbing surfaces of water); and, chiefest of all, the very serious fault (in any but very diminutive tanks) of the absence of adequate means of purification by keeping the water ever in motion; as in the sea, and in rivers, and even in ponds; this motion being needed in addition to the aeration effected by plants growing in the water.

Mitchell, however, glossed over these problems when making his reports to the Council, An example is his report to the Council of February 28, 1854:

Aquatic Vivaria.
The principal new work of the year has been the arrangement of living fish, Mollusca, zoophytes, and other aquatic animals, first projected in 1851, which has probably excited more attention from its novelty and the intrinsic beauty of the objects themselves, than any other of the recent additions to the collection.

Although the series of tanks is limited to a length of 84 feet by the present extent of the building in which they are placed, an immense number of species have been exhibited in them, and it is a satisfactory proof of the control under which the method of management has been reduced, that there are at this moment several of the fish and zoophytes in the tanks which were placed there in May last; and, in the case of the fish more particularly, several others which formed part of the number experimented on in 1852.

The fish have spawned, and the zoophytes have produced their young in considerable abundance.

Algae are growing luxuriantly in those tanks which are not agitated by the vivacious evolutions of the sea-fish, and this secondary feature is well worth the attention of botanists, to whom the opportunities thus afforded of studying the development of these plants are of the most complete character; while the extremely beautiful effect of colour, dependent partly on the Algae themselves, and partly on the peculiar action of transmitted light, are not less instructive to the artist.

The present arrangement of the house consists of six tanks of freshwater animals, chiefly fish, on the western side; and seven of marine animals on the eastern side; exclusive of several movable tanks of smaller size, which are placed as occasion requires in various parts of the central area.

The zoophytes which are most attractive in appearance are the Actinias or Sea-Anemones. The finest examples of them are to be found in tanks 9, 10, and 11, in which every age of these curious animals is well illustrated.

Figure_21.
Meeting Room of the Zoological Society.

A good illustration of that most singular fact in the physiology of zoophytes, the alternation of generations, is at present afforded here by the appearance of the detached young of Campanularia which appeared for the first time on the 9th of February.

The Crustaceans have been represented throughout the year by several of the smaller British species, among which the young of the hermit crab have also recently appeared in considerable numbers.

None of the Mollusca which have been obtained are more interesting or have lived more successfully than the species which belong to the Nudibranchiate genera, Aeolis and Doris. Ribands of spawn have been deposited by the last-named, and as the water in which they live is never disturbed, there is very little doubt that the whole existence of these animals will be here subjected to observation. The elaborate monograph of Messrs. Alder and Hancock, published by the Ray Society, facilitates the study of this group in the most delightful manner, and places a complete knowledge of it within the reach of every one who chooses to consult their work.

The curious group of Ascidian Polypes (which take an intermediate station between zoophytes and Mollusca) have been copiously illustrated, frequent specimens of Botryllidae, or compound Ascidians, of Ascidiadae, or simple Ascidians, having been received, although from their sluggish leathery appearance they may not have attracted so much attention as their peculiar organization deserves.

As can be seen, no mention was made of the turbidity of the water in the marine tanks, their generally unhealthy condition and the necessity of having to replenish the seawater frequently with new seawater, an expensive proposition.

GOSSE GETS INTO TROUBLE WITH THE COUNCIL

Although I have discussed this in my essay, "The Warington-Gosse Controversy Revisited" (Klee, 2016), I'll expand upon it in some detail.

Figure 22. The London Zoo Lion House.

The Surrey Literacy, Scientific and Zoological Society was formed by Edward Cross in 1831 with the intention of setting up a public zoo. Cross had previously owned a menagerie on the Strand and he sold his animals to the Society who had leased a 13-acre site from Lord Holland. The Surrey Zoological Gardens were laid out in 1831-2 on the south side of the river Thames, about a mile and a half from Blackfriars Bridge and an hour's walk from Regent's Park. Cross built a large circular domed glass conservatory in the gardens, 300 feet in circumference with more than 6,000 square feet of glass, to contain separate cages for lions, tigers, a rhinoceros and giraffes.

In its time this was the largest conservatory in England. It was also used for flower shows and exhibitions. The gardens were heavily planted with native and exotic trees and plants, and dotted with picturesque pavilions. The site also contained a lake of about three acres. From about 1840 on there were lavish fireworks displays, which seemed gradually to have taken priority over everything else. On Cross's retirement in 1844 his secretary and assistant, William Tyler, took over the place, whereupon it declined rapidly and in November 1856, the collection came under the auctioneer's hammer.

In 1854, Nathaniel Hawthorne (1804-1864), who was the American Consul in Liverpool at the time, visited both aquariums and had this to say in his diary of September 9, 1855 about the Regent's Park aquarium:

The Aquarium, containing, in some of its compartments, specimens of the animal and vegetable life of the sea, and, in others, those of the fresh water, was richly worth inspecting; but not nearly so perfect as it might be. Now I think we have a right to claim, in a metropolitan establishment of this kind, in all its departments, a degree of perfection that shall quite outdo the unpractised thought of any man on that particular subject.

Whether Hawthorne was disappointed in the quality of the water, the difficulty in seeing the marine fish or some other reason, he unfortunately did not, say. The menagerie at the Surrey Zoological

Figure 23. The Surrey Zoological Gardens circa 1830.

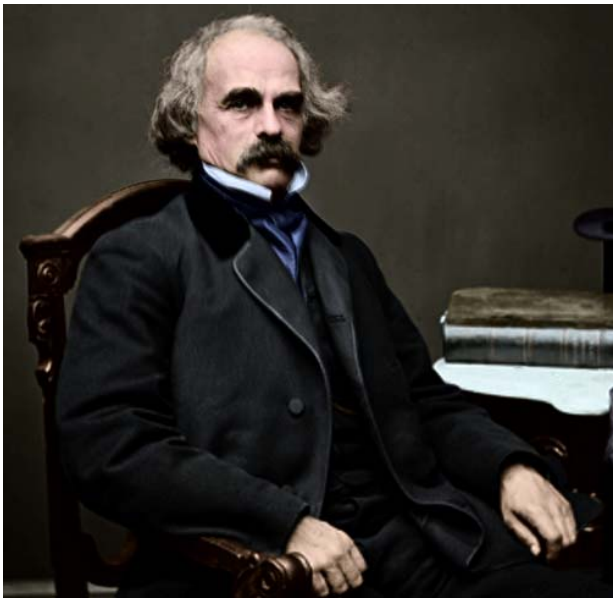

Figure 24. Nathaniel Hawthorne (1804-1864).

Gardens did not escape his disapprobation, either. The following was his diary comment of October 3, 1855 regarding his visit there:

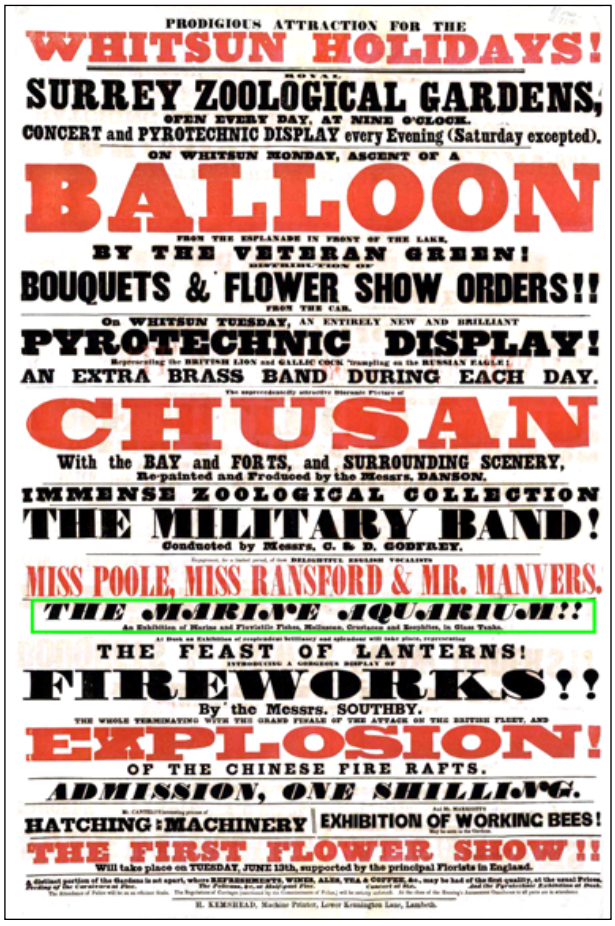
The menagerie, though the ostensible staple of the gardens, is rather poor and scanty; pretty well provided with lions and lionesses, also one or two giraffes, some camels, a polar bear, --who plunged into a pool of water for bits of cake,--and two black bears, who sat on their haunches or climbed poles; besides a wilderness of monkeys, some parrots and macaws, an ostrich, various ducks, and other animal and ornithological trumpery; some skins of snakes so well stuffed that I took them for living serpents till J----- discovered the deception, and an aquarium, with a good many common fishes swimming among the sea-weed.

The fish Hawthorne saw obviously were freshwater fish, so the marine specimens Gosse collected for the Surrey Zoological Gardens did not last long. A poster in the British Library dated 1854 that advertised the various attractions included:

The Marine Aquarium!! An Exhibition of Marine and Fluviatile Fishes, Mollusceae, Crustaceae and Zoophites, in Glass Tanks.

Whitsun in 1854 would have occurred on July 4, and this is probably the date on which the Surrey aquarium opened. It is often said that the Surrey aquarium lasted only a "few weeks" or "a short time," but this is true only of the marine part of the exhibit, albeit, the most important part. As seen by Hawthorne's visit, parts of the freshwater exhibit lasted at least for another fourteen months.

Gosse ceased his association with the Zoological Gardens somewhat under a cloud. Gosse's main contribution to the aquarium at the zoo was to provide marine plants and animals, including fish, for which he was to be paid. However, at the time Gosse was collecting marine life for the Regent's Park zoo, the Surrey Zoological Gardens built their aquarium and contracted with Gosse to supply the same sort of specimens. When he submitted his bill



PRODIGIOUS ATTRACTION FOR THE
WHITSUN HOLIDAYS!
ROYAL
SURREY ZOOLOGICAL GARDENS,
OPEN EVERY DAY, AT NINE O'CLOCK.
CONCERT and PYROTECHNIC DISPLAY every Evening (Saturday excepted).
ON WHITSUN MONDAY, ASCENT OF A
BALLOON
FROM THE ESPLANADE IN FRONT OF THE LAKE,
BY THE VETERAN GREEN!
DESCRIPTION OF
BOUQUETS & FLOWER SHOW ORDERS!!
FROM THE CAR.
On WHITSUN TUESDAY, AN ENTIRELY NEW AND BRILLIANT
PYROTECHNIC DISPLAY!
AN EXTRA BRASS BAND DURING EACH DAY.
The unprecedentedly attractive Dioramic Picture of
CHUSAN
With the BAY and FORTS, and SURROUNDING SCENERY,
Re-painted and Produced by the Messrs. DANSON.
IMMENSE ZOOLOGICAL COLLECTION
THE MILITARY BAND!
Conducted by Messrs. C. & D. GODFREY.
Engagement, for a limited period, of four DELIGHTFUL ENGLISH VOCALISTS
MISS POOLE, MISS RANSFORD & MR. MANVERS.
THE MARINE AQUARIUM!!
An Exhibition of Marine and Fluviatile Fishes, Molluscæ, Crustacea and Zoophites, in Glass Tanks.
THE FEAST OF LANTERNS!
INTRODUCING A GORGEOUS DISPLAY OF
FIREWORKS!!
By the Messrs. SOUTHBY.
THE WHOLE TERMINATING WITH THE GRAND FINALE OF THE ATTACK ON THE BRITISH FLEET, AND
EXPLOSION!
OF THE CHINESE FIRE RAFTS.
ADMISSION, ONE SHILLING.
HATCHING MACHINERY | EXHIBITION OF WORKING BEES!
THE FIRST FLOWER SHOW!!
Will take place on TUESDAY, JUNE 13th, supported by the principal Florists in England.
A Refined portion of the Gardens is set apart, where REFRESHMENTS, WINES, ALES, TEA & COFFEE, &c., may be had of the first quality, at the usual Prices, according to the Carriages or Place.
The Policemen, &c. at their usual Post.
Concert of Mus...
and the Pyrotechnic Exhibition at Dusk.
The Regulation of Carriages (purchased by the Commissioners of Police) will be strictly enforced. At the close of the Evening's Amusement Omnibuses of all sorts are in attendance.
H. KEMSHEAD, Machine Printer, Lower Kennington Lane, Lambeth.

Figure 25. The text in the green box indicates the Marine Aquarium attraction. The poster is dated 1854.

to the Zoological Society of London, Mitchell presented it to the Society's Council and they directed him to try and persuade Gosse to reduce it, the reason being that they had discovered that Gosse had also collected and sent specimens to the Surrey Zoological Gardens during his time collecting in Weymouth but charged the Zoological Society of London for this time. The Council was incensed and angrily denounced his want of consideration for the Society. Gosse, replied, however, that if he wasn't paid then all collections would stop.

Gosse requested that the matter go to independent arbitration, with Thomas Bell, an older cousin and Fellow of the Zoological Society representing his interests. The Council agreed and appointed James Scott Bowerbank to represent the Society. Gosse argued that when he submitted his plan to the Zoological Society and offered to supply living specimens at a fixed rate, there was no stipulation that he should limit his supplies to that Society. Gosse maintained that he was not the salaried servant of the Zoological Society of London, and the council had no more right to forbid him to sell specimens elsewhere than to prohibit the tradesman who glazed their tanks from selling glass to anyone else. This was certainly true but it had nothing to do with the Council's actions, which involved Gosse's fee and nothing else. Therefore, after the arbiters had discovered that Gosse had also collected and sent specimens to the Surrey Zoological Gardens during his time in Weymouth but charged the Zoological Society for this time, the arbitrators found in favor of the Society, awarding Gosse only £150, which he quietly accepted. Thus ended Gosse's relationship with the Society.

Gosse was not a dishonest man, but he did make poor decisions, certainly this one. He should have realized that the Regent's Park aquarium and that of the Surrey Gardens were in competition. Another bad decision occurred when he concealed his knowledge about Schweitzer's seawater formulation when he met Warington in January of 1854 (see Klee, 2016).

MITCHELL RESIGNS FROM THE SOCIETY OF LONDON

Mitchell was interested in one of the original aims of the Society, acclimatization, and was a member of the French Société Zoologique d'Acclimatation. A letter is preserved in the Society's archives where Mitchell communicates with an unknown person residing in Paris. He addresses the recipient as "Your highness" so this person could either be Napoléon III, who expressed an interest in French acclimatization or, more likely, Prince Jérôme Napoléon, the emperor's cousin, who was appointed honorary president for the Société Jardin d'Acclimatation. In the letter, Mitchell specifies 28 species of deer and 38 species of antelope that would be suitable for acclimatization in England and France and states in the end:

I am confident that the acclimatisation of exotic animals in Europe may be carried out to a much greater extent than has yet been supposed possible—and I am happy to be able to acquaint you with the interesting fact, that the Council of the Zoological Society have at my earnest request within the last year applied themselves seriously to this object.

These attempts however do not seem to have been as successful as his measures to popularize the Gardens, and in April 1859 he resigned in order to oversee the building of the Jardin d'Acclimatation in Bois de Boulogne. This Jardin was the brainchild of Isidore Geoffroy Saint-Hilaire who based it on the descriptions in Bacons *New Atlantis* and it was to be devoted to "applied natural history"

Figure 26.
The Aquarium du Jardin d'Aclimatation.

rather than theoretical science." The aim was to "acclimatize, domesticate, breed, and sell new exotic animals that would meet the needs of industry, agriculture, and animal amateurs."

When Mitchell resigned, the Council praised him highly and in appreciation and gave him a gratuity of £500:

The Council cannot conclude this Report without placing on record their sense of the great obligations which the Zoological Society owe to Mr. Mitchell, who for the period of twelve years has filled the important situation of Secretary. They feel that the present prosperous and satisfactory position of the Society is chiefly, if not entirely, owing to the great ability and zeal of Mr. Mitchell.

With the view of bringing in a succinct form before the Fellows the improved position of the Society at the present time, as compared with what it was at the time of his appointment in 1847, they beg to call the attention of the Society to the subjoined statement.

The average Income of the Society, for the seven years previous to 1847, was £9,199. The average of the seven years, to Dec. 31, 1858, amounts to £15,062. For some years previous to 1847, the Income of the Society had been gradually falling off, and in that year was only £7,765, whereas in 1858 it amounted to no less a sum than £14,034—almost double of what it was at the time of Mr. Mitchell's appointment.

This great increase is mainly owing to the important improvements which have been made in the Gardens under the advice and superintendence of Mr. Mitchell. During that period, large additions have been made to the Collection of Animals, and most important improvements and additions have been made to the Buildings for their reception.

Great expense has been incurred on both those objects; but the Council have the satisfaction of being able, at the same time, to state, that, owing to the judicious manner in which the money has been laid out under Mr. Mitchell's direction, the attraction of the Gardens, and the interest felt in them by the Public, attested by the number of Visitors, has so greatly increased, as to give an excellent return for the money expended. The average number of Visitors for the seven years previous to 1847 was 111,500, and for the seven years ending Dec. 31, 1858, was no less than 350,620.

The Buildings which have been erected of late years are of a substantial construction, will require little or no repair for many years to come, and as an investment of capital, might be fairly considered as forming part of the Assets of the Society; but leaving them, and the additional value of the Collection of Animals, out of the account, the Net Assets of the Society, after deducting all Liabilities, and notwithstanding the very heavy expenses incurred in the erection of new Buildings and the repairs of the old, have increased since 1847 by the sum of £912, the Assets in 1847 being £5254, and in 1858, £6166. For these great improvements in their circumstances the Society is indebted to Mr. Mitchell.

Greatly as the Council must regret the loss of the services of so valuable an officer, they have the satisfaction of feeling that the whole of the concerns of the Society are now placed on so sure and solid a basis, that the task of maintaining them in their present satisfactory condition will be comparatively easy.

Figure 27. The Tortoise House of the Zoo.

The Council, in order to mark their sense of the value of Mr. Mitchell's services, of his zeal and assiduity, and of his unremitting attention to promote the prosperity of the Society, at their Meeting on the 20th inst., came to the unanimous resolution to present to him, on his retirement from the office of Secretary, a Gratuity of £500, in consideration of his long and valuable services to the Society.

Resigning his post as secretary of the Zoological Society of London on April 6, 1859, Mitchell became the Aquarium Director of the Jardin d'Acclimatation in Paris, but died suddenly on November 1, 1859, only months after taking up the position. The Jardin contracted with William Alford Lloyd to finish the work on the Aquarium.

THE MYSTERIOUS DEATH OF DAVID MITCHELL

At the Anniversary Meeting of April 30, 1859 Mitchell, having undertaken the direction of the new Jardin d'Acclimatation at Paris, retired from the office of Secretary, and Mr. Philip Lutley Sclater, M.A., Fellow of Corpus Christi College, Oxford, and Barrister-at-law who had been a Member of the Council during the previous two years, was nominated by Richard Owen and William Yarrell and elected in his place at a salary of £250 a year. In zoology, Sclater was an expert ornithologist, and identified the main zoogeographic regions of the world. Although ornithology was his chief study, he also did a large amount of work in mammology.

Sclater found that the Society's affairs were in a sad state of neglect and for the next three years, nearly his whole time was occupied in bringing its records and publications up to date, reorganizing the Gardens into separate departments under the Superintendent and having many of the animal houses rebuilt. Shortly after he became Secretary, however, Sclater discovered what appeared to be a discrepancy in Mitchell's last financial accounts that amounted to embezzlement.

Just before the Council meeting in November 1859, Daniel Elliot informed him of Mitchell's death. (Elliot, 1835-1915, was one of the founders of the American Museum of Natural History in New York, of the American Ornithologists' Union and of the Société Zoologique de France. He was also curator of zoology at the Field Museum in Chicago. From 1869 to 1879 he was in London and established strong links to British ornithologists and naturalists.) It was at this meeting that Sclater announced Mitchell's death to the Council and also advised them of the discrepancy in Mitchell's accounts. The result was that Sclater and two other members of the Council instructed that the Society's solicitors lay a claim to the executors of Mitchell's estate while the matter was investigated further. In the Report of the Council, April 29, 1861, the following was announced by Sclater:

The Council deeply regret to have to communicate to the Members that the sum of about £480, which has been ascertained to be due from the Estate of the late Secretary, Mr. Mitchell, to the Society, not been yet recovered; but the Council have taken, and will con-

Figure 28. Philip Lutley Sclater (1829-1913).

tinue to take, all steps in their power for this purpose Society.

However, the two council members, having completed their investigations, found that the allegations were unfounded and the matter was dropped. Most likely if the Secretary had been anyone else than Sclater, the charges would never have been brought to the Council. Sclater was never an object of admiration nor did he attract loyalty from the Zoo staff. He became involved in several arguments with the public, and appeared to them, and even to some of the Society's Fellows, to be stubborn and at times even arrogant. "Reformer" wrote to the *Marylebone Mercury* in 1875:

… to appeal from Mr. Sclater as Secretary to Mr. Sclater as Council is to appeal from Lord Eldon, sitting as Chancellor, to Lord Eldon, sitting as Judicial Committee of the House of Lords. Lord Eldon used to boast that he never had a judgement reversed. Mr. Sclater can similarly claim that the Council has never overruled his decision.

Sclater eventually resigned in 1902, and his son, William Lutley Sclater, whom he had hoped would succeed him and who was then Director of Cape Town Museum, was temporarily appointed until ratification by the Fellows at the next Annual General Meeting. However, at that meeting in April 1903, a second candidate was nominated by a group of Fellows. This other candidate was voted Secretary with a majority of 200 votes. The Society had enough of Sclaters. Ironically, when the news leaked out that Sclater was retiring at the age of seventy-two, a rumor had spread that bad management was the cause. The Council President arranged for a Special Committee to examine all the affairs of the Society and the administration of the Gardens. After a stringent investigation, Sclater was completely exonerated.

Journal articles discussing the history of the Jardin d'Acclimatation provide no details about Mitchell's death, only vague comments such that it was "sudden" or "premature." This led me at first to believe that it was a stroke or fatal heart attack, but the paucity of detail did have me wondering.

Most of the notices in England were no better, usually citing his death as sudden, also. Further research has indicated that there was some discussion as to whether Mitchell committed suicide and/or became insane, and if this might be connected to the alleged embezzlement of the Zoological Society's funds. Whether the allegations had anything to do with Mitchell's death is unlikely, however. They were presented to the Council after Mitchell's death and only then became public knowledge and so couldn't have affected him then. However, it is possible that someone was indiscrete and that Mitchell learned of it while he was still alive.

In any event, with regard to the possibility of suicide or insanity, there was a lot of controversy about the nature of Mitchell's death. The following appeared in the *The Morning Chronicle*, December 5, 1859:

THE LATE MR. D. W. MITCHELL.
The London correspondent of the *Manchester Guardian* writes as follows in reference to the death at Paris of Mr. Mitchell, the late Secretary to the Zoological Society: —

In the absence of political news I think it my duty, not without much consideration, to give

Figure 29. Library of the Zoological Society.

the publicity of your pages to some most mysterious circumstances attending the death of the late widely-known Secretary of the Zoological Society, Mr. D. Mitchell, which recently took place in Neuilly, and which has been ascribed in the brief newspaper paragraphs, which furnish all the information as yet published on the subject, to his own hand. Whether the wound of which Mr. Mitchell died was self-in-flicted or not, I think you will admit, in the face of the facts I am about to mention, to be very doubtful. At any rate, it seems to me that those facts are such as to make out a strong *prima facie* case for such judicial inquiry as the French laws admit.

Mr. Mitchell had married a second time, about six months ago. The marriage was not entered upon under circumstances that indicated, on Mr. Mitchell's part, any great hope of happiness, or the eagerness that is usually looked for in a bridegroom. I am afraid the wound of which he died was a pistol-shot in the groin. His death was not immediate. He lingered for days in a lunatic asylum, near his residence, to which he was received, at the request of his wife, who stated that he was insane, and had attempted self-destruction in a paroxysm of his disorder. On his death, she made application to have him buried as a pauper lunatic.

These circumstances, vaguely stated, had meanwhile come to the knowledge of two of Mr. Mitchell's English friends in Paris, These two gentlemen interfered, on learning the humiliating conditions under which their friend's body was about to be committed to the ground—uncoffined, and without the rites of the church—and, thanks to them, the interment was conducted with all befitting decency, and with the usual offices for the dead of the Romish Church, to which Mr. Mitchell had recently attached himself. His body was followed to the grave by these two friends, and by a large body of workmen employed in the New Zoological Gardens, in the Bois de Boulogne, which Mr. Mitchell, at the time of his death, was engaged in organising.

Figure 30. The Camel House at the Zoological Gardens.

Mr. Mitchell leaves an orphan daughter in England, who is entitled in her own right to a very considerable property. This poor girl is at present in a convent not far from London, where she was placed for her education. By a will of her father's, executors were appointed, who have not yet, I believe, made formal proof of the will, owing to a very natural desire not to saddle themselves with any responsibilities of executorship in the case of a testator so involved as Mr. Mitchell is known to have been. But I am informed that application for Miss Mitchell has been made to the convent by three gentlemen—her father's eldest and most trusted friends—and that the applica-tion has been met with a refusal to give up the young lady, based on directions received from her step-mother.

Those who best know Mr. Mitchell find the greatest difficulty in the supposition either of suicide or insanity. They refer to the position of the wound (in the groin) as the strongest *prima facie* ground for concluding against suicide. As to the idea of self-destruction prompted by embarrass-ment, they declare that Mr. Mitchell had been so long embarrassed, and had borne embarrassment so lightly, that they consider that explanation intrinsically improbable. Nor were there in this case any special circumstances of embarrassment—accumulating and driving their subject into a corner, or complicated with disreputable and illegal acts, as in the instance of Sadleir [This is a reference to John Sadleir who was a Junior Lord of the Treasury in 1853, and was found in 1856 to have by a long course of fraud swindled the Tipperary Bank of over £400,000, and escaped punishment by suicide.]**—to account for unwonted desperation taking refuge in self-destruction. There is extant, I am informed, a letter from Mr. Mitchell to an intimate friend in this country, written shortly before the catastrophe, and speaking of some impending calamity, suffering or danger, which is considered by the gentleman to whom it is ad-dressed to be consistent with the contemplation of a duel. But I do not wish to go into conjecture as to the mode of death. What I wish to insist on is, that the circumstances do not point to suicide, in the ordinary sense of the term; and that they are of so dark and mysterious a cha-racter as to render it a duty to have them investigated, in justice to the memory of Mr. Mitchell, as well as for the sa-tisfaction of his surviving child, and the many friends who have been shocked by the tidings of his sudden and un-looked-for end. I should not have stated these facts, which I only put on paper after considerable hesitation, on any insufficient or doubtful authority. My informants arc very old and intimate friends of Mr. Mitchell, and persons accus-tomed to weigh their words. I need hardly add, in conclu-sion, that my motive is one of respect for the dead, and pity for his poor orphan child, not any desire to spread a tale of horror, or to stimulate a prurient and aimless curiosity. I believe investigation to be called for, and I think publicity the best road to investigation.**

This report, were it true, would be the most fantastic account I have ever read that dealt with a figure prominent in the aquarium hobby. However, as it turns out, there is little in the report that is true, the only exception perhaps being Mitchell's letter where he speaks of some impending calamity, suffering or danger. The letter pokes a hole in the *Manchester* Guar*dian* correspondent's argument, as it clearly indicates Mitchell was not sound of mind when he wrote it. The following is from *Lloyd's Weekly London Newspaper*, January 8, 1860:

Figure 31.
The Ape House at the Zoological Gardens.

THE LATE MR. MITCHELL,

We extract the following from the *Critic* :—A short time ago we were misled in reproducing certain state-ments which were made by some of the French corre-spondents of the daily press respecting the death of the late Mr. Mitchell, ex-secretary of the Zoological society, and more lately of the Société d'Acclimation at Paris. As nothing was farther from our purpose than to hurt the feelings of any member of Mr. Mitchell's family, we are rejoiced to be in a po-sition to make some atonement for the fault which we unwittingly committed, and to prove beyond doubt that the lady whose char-acter was most maligned and tra-duced in the statements we have referred to is not only guiltless of what was most shamefully insinu-ated against her, but that her conduct in the matter was that of a brave, an upright, and most tender wife. First come the certificates of the medical men who attended Mr. Mitchell to the last, including one from the celebrated Pi-nel, whose reputation for the treat-ment of the insane is world wide. [Philippe Pinel (1745-1826) was a French physician who was instrumental in the development of a more humane psychological approach to the custody and care of psychiatric patients, referred to today as moral therapy. He also made notable contributions to the classification of mental disorders and has been described by some as "the father of modern psychiatry".]

I certify that Mr. Mitchell is attacked by an in-stinctive monomania for suicide and homicide (*aiteinte de monomonie instinctire homicide et suicide*) marked by his threats, and by a blind violence, of which he was not master, towards his wife, and by an attempt at self-murder which took place yesterday, October 29th, by means of a pistol shot which caused an acute wound in the chest. The situation of Mr. Mitchell inspires uneasiness; it is indispensable he should be treated in a special lunatic asy-lum (*maison de santé spéciale*). Signed, Dr. PINEL, Neuilly, 30th October, 1859.

Next comes a letter from the curé of Neuilly to the Hon. Mrs. Grantley Berkeley. who is the godmother of Mrs. Mitchell, describing the circumstances which attended Mr. Mitchell's death, and bearing full and honourable testi-mony to the conduct of the wife on such a try-ing occasion:—

Neuilly-sur-Seine, Nov., 1851. Diocese de Paris, Eglise Paroissille de Saint Jeon Biptiste.

To the Bon Mrs. Berkeley, Hampshire:

Madam, — I cannot let your excellent godchild leave without giving her a line for her dear godmother. I will not undertake describing to you the scene of horror which has passed, nor the outrage from which your much loved child escaped miraculously, and of which, to a great measure, I was an eye-witness. I leave to her to enter into all the details; but what I must re-veal to you, and what she will doubtless not tell you from a sense of modesty which I can-not cease admiring, and above all praise, is that calm, that of mind (d'âme), in the midst of the raging of the tempest, that superhuman perseverance in the faithful accomplishment of her duty; it is those minute and credulous cares, lavished on the suicide and assassin,

Figure 32.
The first cage in the Zoological Gardens, originally built for macaws.

whose wound she herself bathed and dressed, whom she nursed alone while her unhappy servants sought some repose, and from whom she only consented to be separated when I at last succeeded in making her comprehend that conscientiously, and for her responsibility to God and man, she must permit the dying man to be removed to the lunatic asylum, whither she actually followed him to wait on him with her own hand, and to soften as much as lay in her power the last moments of a madman who acknow-ledged no other regret than that of having failed in his attempt to have buried his wife in the same grave with himself. Thus, by this heroic conduct, of which we have no example, Mrs. Mitchell has acquired the universal esteem of all those who witnessed it, and especially that of her unworthy curé who feels in this moment the most lively and sincere regret to lose in your godchild one of his best and most devout parishioners,—I have the honor to be, madame, yours, &c., (Signed) P. Roy, Curé Doyen de Neuilly.

As it is to be feared that the abominable calumnies insinuated against Mrs. Mitchell were the result not of idle gossip, but of a shameful conspiracy organised by interested persons, the following letter from Dr. Pinel conclusively proves that those friends of Mr. Mitchell who took the trouble to inquire into the facts of the case were fully informed upon them: —

Chateau de St. James, Avenue de Madrid à Neuilly, prés Paris, le 24 December, 1859.
Maison de Santé de Dr. P. Pinel, Chevalier de la Légion d'Honneur, &c.—
Madame, I learn with indignation that persons have permitted themselves to insinuate odious calumnies about you with regard to the death of your husband, Mr. Mitchell. I should be sorry if they could be attributed to those who came here to obtain information from me, for having related to them the facts precisely as they took place, I cannot understand how they can incriminate your conduct.

I informed the three persons who presented themselves what took place at your house, which was attested by the evidence of Drs. Semelaigne, Becquet, and Follin, by that of M. le Curé de Neuilly and of your servants, and

Figure 33. The Terrace of the Zoological Gardens, from the main entrance.

also by the inquiry made by the Commissaire de Police and by him transmitted to the Procureur Imperial [an officer of the imperial court who either personally or by his deputy prosecutes every one who is accused of a crime according to the forms of French law**]. I told them that about three o'clock on the following day. Mitchell had been brought to my house, in accordance with the opinion of the three medical men above named, on account of his renewed attempt at suicide and of the difficulty of attending and watching him at his own house. I added that shortly after his arrival he was visited by Dr. Ferrus, the inspector general of Asiles d'Aliénes [**Asylums for the Insane**], who entirely agreed in the opinion of his brethren as to the nature of the malady and the necessity for his removal to a special establishment. I related how that, a few moments after his arrival, you came to see him; that he received you affectionately; that you paid him a second visit, in the evening; that the following day you remained with him to the moment of his death.**

In a word, Madame, your responsibility in the matter has been entirely shielded by the certificates of the three physicians named, and by the entire approval of the opinion given by Dr. Ferrus and by myself.

Is there any need to refute the absurd assertion which would lead to a belief that my house is a hospital?

Trample, them under your feet, Madame, these stupid calumnies, and derive from your own conscience, and from the truth of these facts the religious calm of a candid soul and the feeling of an accomplished duty. Receive, Madame, the assurance of my most distinguished considerations.

PINEL.

This ended the controversy and a typical report one year later is the following that appeared in the *Obituary Notices of the Proceedings of the Linnean Society* in 1861:

Figure 34. The Seal Pond.

D. W. Mitchell, Esq., B.A. Oxford, was elected Fellow, Nov. 21, 1843. He died in Paris, under very painful and melancholy circumstances, in November 1859. Mr. Mitchell was well known as a zoologist, and as Secretary for twelve years to the Zoological Society, which owes much of its prosperity to his tact and zealous exertions.

The bottom line is that Mitchell was insane and committed suicide. His demise was indeed a sorry end to a distinguished career and, at age forty seven, one that would have been even more distinguished had the Fates not decreed otherwise.

THE EARLY HISTORY OF ARTIFICIAL SEAWATER FOR AQUARISTS

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, October 15, 2016)

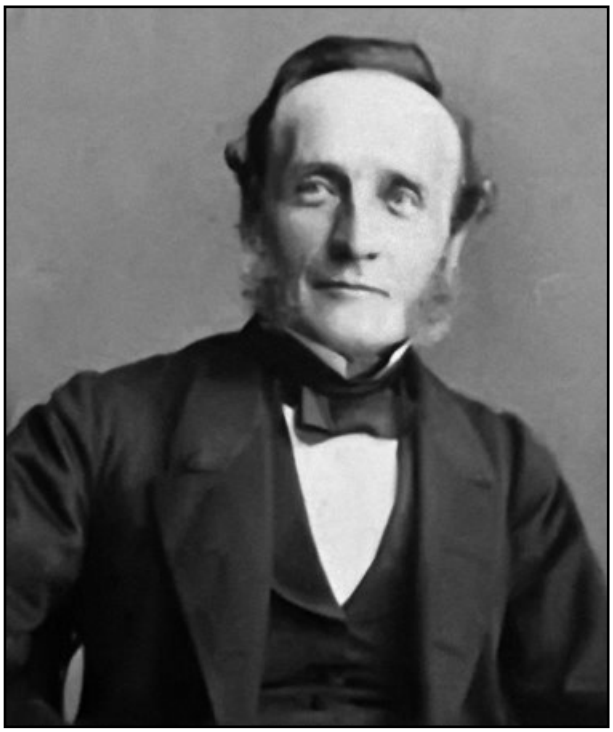
It was shortly before Christmas in 1853, a time when people were counting their blessings and eagerly anticipating the New Year. Philip Henry Gosse, however, was not one of them. The past few years had not been particularly joyous for him. In 1850, Warington was the first one to demonstrate the proof of principle of the balanced freshwater aquarium, and in 1852, he even preceded Gosse by nine months in publication priority for the marine aquarium.

In 1851, Gosse had recommended the system for the marine tanks at the new Fish House in the London Zoo, designed so as to not require replenishing, except for adding freshwater to replace that had evaporated; but by 1853, it was proving to be a failure and the Zoological Society of London had to keep buying expensive additional seawater in order to keep the exhibits alive. Then in July of 1853 when Gosse presented his bill for the marine specimens he had collected for the Fish House, the Society's Council found that Gosse had also collected and sent specimens to the Surrey Zoological Gardens (a competitor to the London Zoo) during his time collecting in Weymouth but charged the Zoological Society for this time. The Council was incensed and angrily denounced his want of consideration for the Society. Gosse was henceforth *persona non grata* with the Zoological Society of London.

However, there was an opportunity for him to increase his reputation within the scientific community. He had come across a paper written by Edward G. Schweitzer who presented his results in analyzing the waters in the English Channel off the coast of Brighton (Schweitzer, 1839). Schweitzer was a German physician and chemist, and Director of the Royal German Spa in Brighton. Schweitzer and Warington, by the way, knew each other. A list of the officers and members of the *Chemical Society of London* dated June 1843 shows Warington as one of its two Secretaries and Schweitzer as one of its members. I'll explain Schweitzer's interest by quoting the final paragraph of his paper:

I cannot conclude this paper without drawing the attention of medical men to the importance which the brine springs on the Continent have lately acquired, as, for instance, the springs near Kissingen, the Adelheids quelle, near Heilbroun, and above all, the springs of Kreugnach, which have been found highly beneficial in scrophulous diseases

Philip Henry Gosse (1810-1888).



Robert Warington (1807-1867).

when internally administered, their action being dependent entirely on the chlorides, iodides, and bromides they contain. Sea-water would afford similar advantages for bathing, and when evaporated to dryness, the residue might be kept in earthen vessels, and thus be conveyed to any distance; and as its constituents are very soluble, sea-water in perfection might be procured at any place. The evaporation of sea-water should be performed with care, and the ingredients kept by chemists. One great advantage would accrue from this method, viz. that sea-water could be had of any degree of concentration which the practitioner might deem necessary. At the baths of Kreugnach, for example, extraordinary effects have been produced when from 40 to 70 quarts of the mother liquor were added to the natural salt-water of that spring, and this mixture used for bathing.

It is amusing to note that the start of the development of artificial seawater for marine aquaria began with desire of the Victorians to immerse themselves in a tub full of water containing bath salts, and the more genuine or natural the salts the better!

Now there are a number of reasons why aquarists might be interested in artificial seawater rather than using the real thing. The density of the final solution is controllable, it is more stable, the formula can be varied for specific uses (e.g., for marine plants versus for marine animals) and it is sterile and thus diseases cannot spread. In Gosse's time, however, the main reason was economics. It was a lot less expensive to reconstitute the seawater with local freshwater than to bring seawater to the aquarium. Water is heavy, its salts are not.

GOSSE'S PLAN

Gosse could have made up the Schweitzer formula, added marine animals and plants and, if everything worked out satisfactorily, he could have written the very first paper on artificial seawater for aquarists. However, based upon his past experiences he wondered if Warington was preparing a paper on this subject; there had been some rumors to the effect that he had experimented with artificial seawater. His concern that Warington might be preparing such a paper is understandable. Warington's interest was but a pastime. In 1704, the House of Lords gave apothecaries the right to practice medicine, and so they may be viewed as forerunners of present-day family physicians. Furthermore, in 1815 the Apothecaries Act granted the society the power to license and regulate medical practitioners throughout England and Wales. Warington had an important job in Apothecaries' Hall and thus was limited in the time he could spend on aquarium research. For Gosse, on the other hand, a significant source of his income involved writing popular books on nature, and it was important for him to maintain a favorable reputation, not only among the masses, but with the scientific community as well. If he could write and publish a paper on artificial seawater before Warington did, it would be a very great advantage in this regard.

Apothecaries' Hall where Gosse met with Warington on January 16 and 21, 1854, and discussed artificial seawater.

Therefore, Gosse devised the following plan. He would visit Warington and steer the conversation in such a way that it would not be a consultation but Warington would talk about his experiences. Executing his plan, Gosse visited Warington in 1854 on two occasions at Apothecaries' Hall: on January 16th and again on January 21st. As it turns out, however, Warington did consider Gosse's visits to be consultations. During these "chats," Warington had no idea that Gosse already knew about Schweitzer's paper. However, Gosse did discover that Warington had no plans to publish a paper dealing with artificial seawater.

Gosse then went ahead with his plan to write his article and by April 21, 1854 he had devised an artificial seawater formula, made up a tank with the solution and added some marine invertebrates. Everything went well and on June 9th he submitted his paper to *The Annals and Magazine of Natural History*. On July 1854 it was published (Gosse, 1854) and Gosse had achieved his goal. For once, he had beaten Warington to the printed page and went down in history as the first to write about - and to provide a formula for - artificial seawater for aquarists!

For comparison purposes, Schweitzer had included the seawater formula based upon a sample from the Mediterranean Sea devised by G. Laurens. I wanted to find out something about him and why he did his analysis but unfortunately, Gosse had labeled him three times in his paper as "M. Laurent" (the M standing for Monsieur). Gosse wasn't the only one who made this error, however. In a report made on the action of air and water on cast iron, wrought iron and steel, Robert Mallett (1841) also misspelled the name as "Laurent." I finally went to Schweitzer's paper - something I should have done in the first place - and found the correct spelling. I also consulted Laurens' paper and found out that Gosse had made errors in Laurens' calcium sulphate and calcium carbonate numbers, and had also omitted entirely Laurens' entry for magnesium carbonate. Clearly Gosse had been in too much of a hurry to get his paper published.

In any event, in the original source (Laurens, 1834) I found that Laurens was a pharmacy student in Marseille and had sent a note to the *Société de Pharmacie* containing an analysis that he had made of the water of the Mediterranean Sea. The commentary on the article included the following (translated): "**In summary, the note from Mr. Laurens, describing the composition of the water of the Mediterranean Sea in a new, well-done analysis, should interest those doctors who prescribe the use of sea bathing.**" Thus, Laurens' purpose was also the same as that of Schweitzer's.

Unfortunately, Gosse had included the following paragraph in his paper:

Several scientific friends to whom I mentioned my thoughts, expressed their doubts of the possibility of the manufacture; and one or two went so far as to say that it had been tried, but that it had been found not to answer; that though it looked like sea-water, tasted, smelt, like the right thing, yet it would not support animal life. Still, I could not help saying, with the lawyers, "If not, why not?" - *Experientia docet* [i.e., Experience

teaches]. **I determined to try the matter for myself.**

From this, there were unexpected, disastrous consequences. One wonders what Warington really thought when he read Gosse's paper. He must, at the very least, have been dumfounded but as will be seen, he actually only used the word "surprised."

In any event, Gosse had miscalculated converting from grains to avoirdupois pounds and ounces, and had mistakenly assumed that the magnesium sulphate in Schweitzer's paper represented the ordinary crystallized salt, and not the anhydrous sulphate that is always the case in giving analytical results. Furthermore, Gosse had eliminated the following from Schweitzer's formula:

1. Magnesium bromide because of its small concentration and because Laurens did not find any in the water of the Mediterranean;
2. Calcium carbonate because calcium could be found in abundance in the fragments of shell, coral and calcareous material that made up the bottom of the aquarium;
3. Calcium sulphate because it was difficult to dissolve and because it was found by Laurens in a minute concentration.

Gosse's decision to eliminate magnesium bromide and calcium sulphate simply because Laurens found them absent or in a minute concentration made no sense. The composition of Mediterranean waters differs from that of the water in the English Channel. The English Channel sits on top of a layer of chalk and it was to be expected that its calcium content would be higher. Since Schweitzer's analysis was appropriate for marine animals found off the southern cost of England where most specimens would be collected for British aquaria, it was the relevant analysis and logically the one that should have been followed.

Warington responded to Gosse's paper thusly (Warington, 1854):

In the 'Annals and Magazine of Natural History' for July last, you published a short communication from Mr. Gosse, on the artificial formation of sea water, and having lately had my attention especially directed to this paper by a friend who wished to put the formula given into practice, I was surprised at the difference in the proportions of the ingredients as compared with what I had myself employed in the course of 1853, more particularly from the circumstance, that when Mr. Gosse called upon me in January last, and consulted me on the feasibility of the plan, I told him that there could be no difficulty in the matter, as I had made and had then in use several small quantities artificially produced, and that all that was required was that a good analysis should be taken as the basis for deducing the proportions, and at the same time referred him to the source from which I myself had worked, namely Dr. E. Schweitzer's analysis of the water of the English Channel taken off Brighton. Now, as numerous parties have been inquiring respecting this subject, and the erroneous formula has been copied into other journals, it may prevent much annoyance as well as disappointment if this matter is set right.

Upon reading Warington's corrections to his paper, Gosse had two reactions, the first being a rather acrimonious one (Gosse, 1855):

If Mr. Warington supposes that I obtained from him one atom of information previously unknown to me, on the subject of making sea -water from its constituent salts, he is most thoroughly mistaken. He is no less wrong in saying that I "consulted" him; since I merely mentioned what was on my mind in familiar conversation. With this, however, the public are of course not concerned, and I shall say no more on that head.

In this regard I fault Gosse. Up to this point Gosse and Warington had been good friends and Gosse should not have kept Warington in the dark

about what he knew, In any event, the two never corresponded or met again.

GOSSE DEFENDS HIS FORMULA

The second reaction was a defense of his formula. At one point Gosse states:

That Mr. Warington's calculations are correct I do not at all deny; but that they convict mine of "error" I by no means admit; as my facts will presently show. The "error" (which is of that kind technically called "nidus equæ") [a humorous comment meaning a "mare's nest, implying that the criticism was a "humbug"] lies altogether on the other side.

Essentially Gosse claimed in his rebuttal that (1) his formula was "…for practical people, to whom minute accuracy is impossible and to whom a chemical formula expressed in quantities of four or five decimals would certainly act as a prohibition," and (2) by actual experimentation, examples of Crustacea (crabs, etc.), Mollusca (sea snails, etc.), Annelida (worms, etc.) and Zoophyta (sponges, etc.), as well as *Ulva* and *Conferva* plants, thrived for over eight months. As can be seen from Table I, the differences between his formula and that of Schweitzer's were large enough to raise some eyebrows. Ironically, with regard to simplicity it was Warington who suggested the simplest solution of all (Warington, 1854):

There cannot be a question that by far the simplest plan would consist in the evaporation of the sea water itself in large quantities at the source, preserving the resulting salt in closely stopped vessels to prevent the absorption of moisture, and vending it in this form to the consumer; the proportion of this dry saline matter being 56-1/2 oz. to the 10 gallons of water, less the 3 pints. This plan was suggested by Dr. E. Schweitzer himself for the extemporaneous formation of sea water for medicinal baths, and, on inquiry since writing the above, I find that such a preparation is manufactured by Messrs. Brew and Schweitzer of No. 71 East Street, Brighton, under the title of "Marine Salts for the instantaneous production of sea water." Mr. H. Schweitzer writes me, that he has for many years made this compound in accordance with his cousin's analysis. The proportion ordered to be used is 6 oz. to the gallon of water and stirred well until dissolved.

TABLE I
THE SCHWEITZER, GOSSE AND LAURENS FORMULAS COMPARED
The numbers are lbs./ 100 lbs. of water (= 10 Imperial gallons).

COMPONENT	(1) SCHWEITZER	(2) GOSSE	% INCREASE (1) OVER (2)	(3) LAURENS
Sodium chloride	2.7060	2.1875	24%	2.722
Potassium chloride	0.0766	0.0563	36%	0.001
Magnesium chloride	0.3666	0.2813	30%	0.614
Magnesium bromide	0.0029	-	-	-
Calcium sulphate	0.1407	-	-	0.015
Magnesium sulphate	0.2296	0.1563	47%	0.702
Calcium carbonate	0.0030	-	-	0.009
Magnesium carbonate	-	-	-	0.011

TABLE II
THE SIX MAJOR IONIC COMPONENTS OF SEAWATER

COMPONENT	Mg/L
Chloride	19,000
Sodium	10,500
Sulphate	2,600
Magnesium	1,350
Calcium	400
Potassium	380

Now the major ionic components of seawater are the same as those ions responsible for maintaining the electrical and osmotic balance within the cells of living animals and for the transmission of nerve impulses. What is an ion? Well sometimes atoms gain or lose electrons. The atom then loses or gains a "negative" charge. These atoms are then called ions. For example, when common salt is dissolved the Na (sodium) loses an electron and the Cl (chlorine) gains an electron; the Na becomes Na+ (the sodium ion) and the chlorine becomes Cl- (the chlorine ion). The major ionic components are shown in Table II. The complete absence of any one of these major ions is fatal. A fish placed into artificial seawater that contained no calcium, for example, would soon die as a result of the chemical imbalance. Therefore, one of the theoretical problems with Gosse's formula was that he had omitted the calcium.

Fortunately for Gosse, laboratory grade chemicals are not 100% pure and technical grade chemicals are far less so, especially in Gosse's day. Thus Gosse's formulation not only contained the necessary calcium but it also contained trace elements, such as silica and iron, that known to be biologically active.

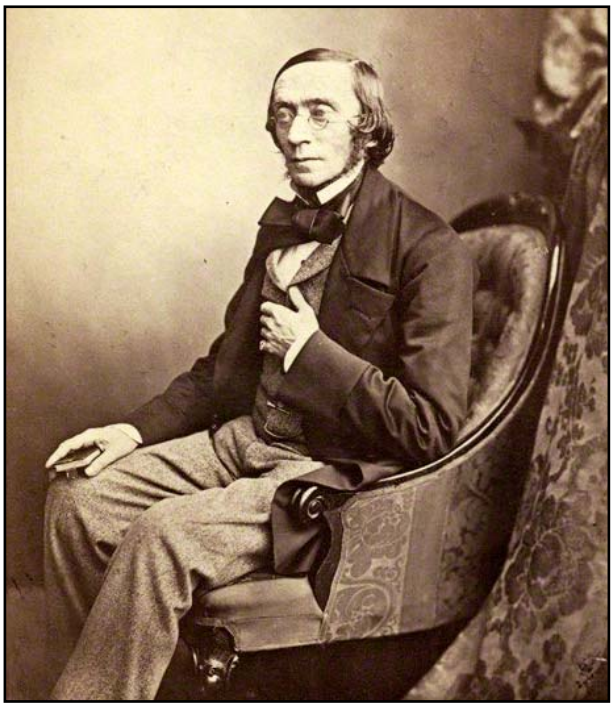
In support of his assertion that his formula worked, Gosse provided the following postscript to his article:

P.S. Some letters which have been lately published by Mr. W. A. Lloyd in the 'Athenaeum' confirm my experience. Perhaps I may be excused for citing a few words contained in a private letter from the same gentleman to myself: — "In reference to what has recently been published on an improvement (or a supposed improvement) on your receipt for the manufacture of sea water, a friend of mine took me by the button and said, 'My dear Sir, Mr. Gosse is altogether wrong; he has not salt enough; he has no—." To which I replied, pointing to two fine *Actinia dianthus* [an anemone] in full blow in one of my vessels, — 'But if Mr. Gosse is altogether wrong, why do these *Actiniæ* flourish ?' This was unanswerable."

However, except for the Crustacea, all of the animals studied by Gosse and Lloyd were invertebrates; no fish were involved.

OTHER PEOPLE CHIME IN

At first Gosse was criticized in the scientific community for his decisions made when he modified Schweitzer's formula. George Wilson (1818-



George Wilson (1818-1859).

1859), a Scottish chemist and physician, lecturer in the School of Arts, director of the Industrial Museum of Scotland and regius professor of technology in the university of his native city was reported as saying (Wilson, 1854):

Dr. Wilson considers, however, that the less abundant, but still essential, constituents of sea-water—such as carbonate of lime, sulphate of lime, phosphate of lime, fluoride of calcium, silica, iodine, and bromine—should not be absent, as these latter substances are found in marine plants and animals; and it is therefore plainly evident that the medium in which they live ought to contain the same substances.

However, after Gosse had learned of Wilson's remarks, he sent Wilson two samples of his artificial seawater, both of which had sustained living plants and animals, one for six months and the other for ten months. By the next year, Wilson had completed his analyses of Gosse's samples. The following is an extract from *The Eclectic Magazine*, reporting on the meeting of *The British Association for the Advancement of Science* in Glasgow in 1855 (Anon., 1855):

Professor George Wilson, of Edinburgh, read a paper on "The Chemical Changes undergone by Artificial Sea Water after Ten Months' Use in the Marine Vivarium." The author stated that the communication which he now made to the section was in continuation of one read to it at the meeting in Liverpool last year. Mr. Gosse, the distinguished naturalist, who has done so much for the improvement of marine vivaria, had given him two specimens of artificial sea water, in which living plants and animals had been kept in full vigor for periods respectively of ten and six months. On analysis, it appeared that, whereas magnesia, sulphuric acid, potassium, sodium, and chlorine, were the only substances originally present in solution in the artificial sea water; lime, phosphoric acid, silica, iodine, and iron now occurred in it. The lime [i.e., calcium oxide] was probably dissolved by carbonic acid [i.e., the name given to solutions of carbon dioxide in water] evolved from the animals; the phosphoric acid was taken up as phosphate of lime by the same gas, along with water; the iodine was separated from the sea weeds; the silica from the *Infusoria* and fragments of rock within the vivarium; and the iron from many sources. It was further stated, that certain important substances which were likely to be present could not be detected, owing, as the author believed, solely to the small amount , of water which could be spared from the vivaria not permitting a minute amount of such bodies as bromine, fluorine, ammonia, or nitric acid to be discovered. The success of Mr. Gosse's artificial sea water was shown to be complete.

Wilson, therefore, found trace elements of calcium, phosphorus, silica, iodine and iron in the sample, and offered some ideas on how they arrived there. He neglected, however, to mention the impurities of the constituents and also that trace elements could find their way into the artificial seawater through the foods and the water used to reconstitute the seawater. He did note that most likely other substances, such as bromides, fluorides, ammonia and nitrates, were in the samples but the samples were small, defying detection using the analytical tools available at the time.

Aquarists were satisfied by this report coming from a scientific person of such high stature and began to experiment themselves with Gosse's formula. However, a year later, Hibberd wrote (1856):

"But artificial water is quite unsuited for animal life of any kind, until it has been brought into condition by means of growing weeds for eight or ten days, and for Crustaceans, Starfishes, and Fishes proper, it is not suitable till it has been in use for many months, and even then some species lose their health in it, and at last perish…"

ARTIFICIAL SEAWATER GETS A BIG BOOST

In his Hand-Book to the Marine Aquarium (June 23, 1873), Lloyd was still favorably disposed to Gosse's formula: **Such artificial sea-water answers very well: indeed the large aquaria at Hanover and Berlin have no other.** It was Lloyd, by the way, who suggested that these two public aquaria use artificial seawater.

However, by 1879 Lloyd had changed his mind. He had secured the post of Superintendent of the Aston Aquarium and since it was located far from the coast where seawater was easily obtained and transportation of the water from the coast would be expensive, Lloyd decided that the use of artificial seawater was justified and selected the Schweitzer formula. Thus was the first use of artificial seawater in a public aquarium in England. In an article titled, "The Artificial Sea-Water at the Aston Aquarium," William Southall (1879) wrote:

My firm (Southall Bros. and Barclay) was appointed to manufacture the water, and about fifty tons of chemical substances have been used. Each ingredient was subjected to analysis, and allowance made in every case for water of crystallization, hygroscopic moisture and impurities, and the various constituents of the well-water used were also allowed for in calculating the working formula. The analysis of Dr. Schweitzer was taken as a basis, supplemented by our own analysis of water recently taken near Brighton, a mile from the shore; and from the latter the data necessary for the required amounts of iodine, &c., were obtained.

Table III provides a comparison between the Schweitzer and Aston Aquarium formulas, the latter being supplied to Lloyd by H. W. Jones, analyst to Messrs. Southall Brothers and Barclay

TABLE III
THE ASTON FORMULA COMPARED TO THE SCHWEITZER FORMULA
The numbers are lbs./100 lbs. of water (= 10 Imperial gallons).

	SCHWEITZER	ASTON
Sodium chloride	2.70595	2.72143
Potassium chloride	0.07655	0.07857
Magnesium chloride	0.36666	0.37643
Magnesium bromide	0.00293	0.00400
Calcium sulphate	0.14062	0.14429
Magnesium sulphate	0.29578	0.23700
Calcium carbonate	0.00330	0.00841
Calcium carbonate		0.00329
Magnesium carbonate		0.00217
Silica		0.00148
Magnesium sulphate		0.00046
Oxide of Iron and alumina		0.00022
Sodium chloride		0.00201
Magnesium nitrate		0.00050
Sodium nitrate		0.00040
Potassium chloride		0.00006
Sodium iodide		traces
Ammoniacal salts & organic matter		slight traces

Those below the dashed line were those present in the well water.

Johan Georg Forchhammer (1794-1865).

of Birmingham. Above the dotted line are the concentrations of the salts added to the well-water (as can be seen, the components and concentrations are essentially identical to those of the Schweitzer formula) and below are the components and concentrations of what was found in an analysis of the well water. Added together they are the actual components and concentrations in the Aston tanks.

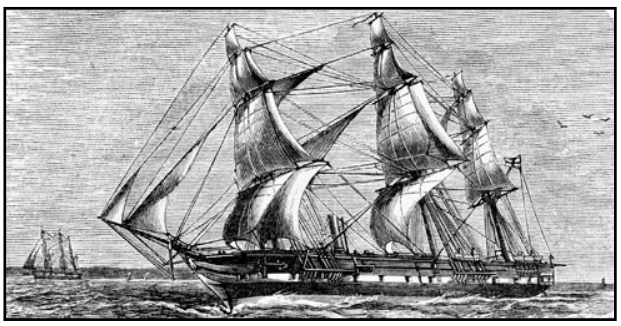
It is clear from these measurements that the water added to a basic group of components is a major consideration with regard to trace elements. All freshwater contains one or more of those used in the Aston Aquarium, more or less, but usually more. Lloyd pointed out that the Thames at London contains about 0.02 or 0.03 pounds of trace elements instead of the roughly 0.01 lbs. per 100 lbs. of water of the Aston well water (Lloyd,1879). Considering the accuracy required for the correct reproduction of certain of the minor constituents, the purity of the added salts and of the water used is critical, endangering the final formulation unless the quantity and quality of the impurities are known. For example, if the sodium chloride used is the commercial grade or household salt, the arsenic and barium levels (even though these are in minute quantities and can be measured in single figures in parts per million) can present problems unless accounted for. In addition to these two, sodium chloride of this grade contains as many as twelve other elements in substantial enough quantities to give rise to doubt as to what their final concentrations would be.

FORCHHAMMER'S PRINCIPLE

The concept of salinity was introduced in 1865 by the Danish chemist and mineralogist Johan Georg Forchhammer (1794-1865). Forchhammer worked under great disadvantages: his samples of water were brought home by seafaring men from different parts of the world in corked bottles, and they were necessarily all taken from the surface or immediately beneath it. Forchhammer did not attempt to determine quantitatively all the elements that occur in sea water, but confined himself to the very accurate estimation of the principal salt components, such as chlorine, sulphuric acid, magnesia, lime, potash and soda. Forchhammer found that the ratio of major salts in samples of seawater from various locations was constant. This constant ratio is known as Forchhammer's Principle, or the Principle of Constant Proportions. One of the most interesting of his scientific work, “On the Constitution of Sea Water at Different Depths and in Different Latitudes” (1863) started a new era in the history of ocean chemistry.

THE H.M.S. CHALLENGER EXPEDITION

The 1870s voyage of H.M.S. Challenger lasted 1,000 days and covered more than 68,000 nautical miles. Many consider it to be the first true oceanographic expedition because it yielded a wealth of



HMS Challenger, 1872.

Dr. Charles Wyville Thomson (1830-1882).

information about the marine environment. Those aboard identified many organisms then new to science, and they gathered data at 362 oceanographic stations on temperature, currents, water chemistry and ocean floor deposits. The scientific results of the voyage were published in a 50-volume, 29,500-page report that took 23 years to compile. Specialists in numerous scientific disciplines studied the collections and data, and helped produce the reports. Also, the reports written by members of the Challenger expedition provided rich descriptions of the flora, fauna and cultures of the lands visited. Photography - new at the time - was highlighted as well, along with scientific illustration.

The HMS Challenger originally was designed as a British warship - a steam corvette in the Royal Navy - outfitted with 17 guns and an engine capable of over 1,200 horsepower. The 200-foot ship was three-masted, square-rigged and built of wood.

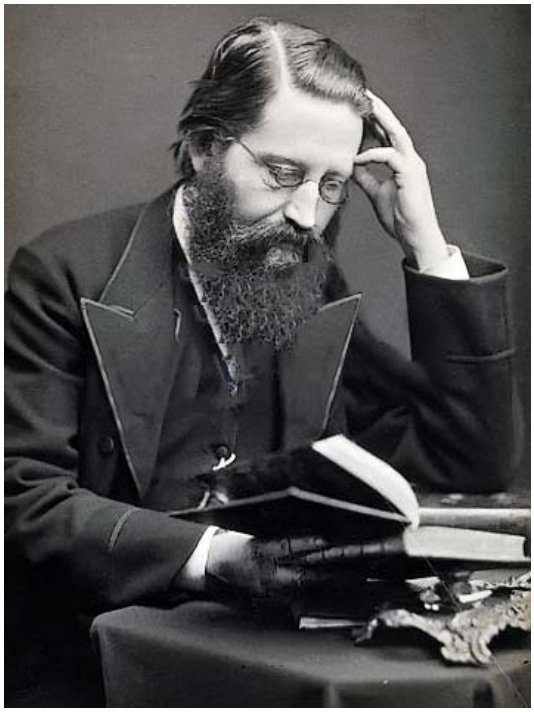
In 1870, Dr. Charles Wyville Thomson, a Scottish natural historian and marine zoologist, suggested that the *Royal Society of London* ask the British government for the use of one of its ships for an extended research cruise. The government agreed, and the HMS Challenger was modified to conduct oceanic research. Ammunition and 15 of the guns were removed from the ship and replaced with laboratories, workrooms and storage space. The HMS Challenger used sails rather than the steam engine most of the time to allow for frequent stops when collecting data. The steam engine was used only during dredging operations to collect samples from the depths of the ocean

At the start of the voyage in 1872, the science and ship crew consisted of six civilian/scientific staff, led by Dr. Thomson. It also included 21 naval officers, including Captain George Nares (replaced by Captain Frank Thomson in 1875), and approximately 216 crew. When the voyage ended in 1876, only 144 crew remained on the ship. Seven people had died, five left when Captain Nares did, 26 were left in hospitals or were unable to continue the journey, and several had deserted at the various ports of call.

The following are the "Editorial Notes" taken from the report on the scientific results of the voyage:

The physical and chemical investigations conducted by Mr. J. Y. Buchanan, during the three and a half years' cruise of H.M.S. Challenger, are among the most important and valuable of the Expedition.

The Challenger's Natural History Workroom.



Wilhelm Dittmar (1833-1892).

Mr. Buchanan collected daily, with much care, samples of the surface, water, and determined the specific gravity. At all Stations, a slip water bottle was attached to the sounding line, and the specific gravity of the specimen of bottom water thus collected was also ascertained. At every Station, where practicable, waters were collected from intermediate depths at 25, 50, 100,200, 300, 400, and 800 fathoms from the surface, with a stop-cock water bottle attached to a separate sounding line, under Mr. Buchanan's personal supervision. The specific gravity of these waters was also determined.

The routine chemical work of the Laboratory consisted in boiling out the gases from, and in determining the carbonic acid in, as many samples as possible. A very large number of samples of sea-water were collected from the surface, bottom, and intermediate depths, and preserved in glass stoppered bottles. These were either sent homo along with other collections from various ports touched at during the Expedition, or brought home by the ship.

It is difficult for any one, except those who actually witnessed the daily work at sea. to form an adequate idea of the labour, skill, and continuous effort required to carry on these observations in all sorts of weather, and to form, and bring home successfully, collections and observations like those which have resulted from Mr. Buchanan's exertions.

THE DITTMAR ANALYSES

The most comprehensive early study of the composition of seawater was that made in 1884 by Wilhelm Dittmar (1833-1892), a German-born chemist renowned as a chemical analyst, on the 77 samples collected by chemist J.Y. Buchanan during the Challenger Expedition.

It should be noted that the analysis of seawater is primarily concerned with its ions, notably chloride, sodium, sulphate, magnesium, calcium and potassium. To construct a formula useful for the manufacture of artificial seawater, however, this information must be translated into specific chemical compounds. This is an arbitrary procedure since it doesn't make any difference what chemical compounds and their concentrations are chosen as long as the mixture after being dissolved contains the ions in their correct amounts. An example is potassium. Schweitzer added it as potassium chloride and adjusted the amount of chloride elsewhere; Dittmar added it as the sulphate and adjusted the amount of sulphate elsewhere. Thus, combining the acids and bases in the arbitrary mode shown in Table IV, Dittmar held that the seven numbers in the table expressed as percentages of the total salts - Column (1) - may be taken as holding approximately for any sample of seawater, in other words, the ratios of these components is constant. I quote Dittmar here:

From my analysis (which I do not pretend exhaust the subject), it would appear that the composition of seawater is independent of the latitude and longitude whence the same is taken. Nor can we trace any influence of the depth from which the same comes, if we confine ourselves to the ratio to one another of chlorine, sulphuric acid, magnesia, potash and bromine. I emphasize the bromine because,

while present in very small proportion, it is taken up preferably by sea-plants, and consequently must be presumed to be more liable than any of the major components to at least temporary local diminution. And yet my analyses of the three mixtures of Challenger waters, and of the Arran water referred to, gave identical values for the bromine present per 100 of the chlorine. [As shallow shore waters did not occur in the series of Challenger samples, Dittmar also analyzed a water that had been collected for him near Port Arran, Scotland, at a shallow place where there was an abundance of marine vegetation.] But the determination of the lime in the same set of waters make it most highly probable that the proportion of this component increases with the depth.

In order to derive a formula for artificial seawater, one has to know the salinity, i.e., the total amount of the salts in the water. For Table IV, I chose the average ocean salinity of 3.5 grams of salts per 100 grams of seawater. By multiplying the percentage figures in Column (1) of Table IV by this number, I obtained the gram weights for each compound; these are listed in Column (2) as grams per 100 grams of seawater. As Warington showed in his critique of Gosse's paper, we can consider these numbers as lbs./100 lbs. of water and the Dittmar and Schweitzer formulas, therefore, can be compared directly in Table IV. There are some significant differences, mainly in the magnesium sulfate, calcium carbonate and magnesium bromide.

If Dittmar's formula may have been of some interest to public aquaria, it had no effect on the aquarium hobby. The interest in marine aquaria had waned because it was expensive and required careful attention on the part of the hobbyist. In this country Stage IV of the aquarium hobby (the Stage we are in now) started just before 1900, but the emphasis was on freshwater and, to a very limited extent, brackish water fishes. Some public aquaria, particularly those situated inland, did use artificial seawater but this had no real effect on the hobby until after World War II ended. This did not, however, stop oceanographers from devising new formulas, such as McClendon et al. in 1917 and Brujewicz (in Subow, 1931). Furthermore, every time the International Atomic Weights were revised, the formulas were revised also. In 1940, for example, Lyman and Fleming recalculated Dittmar's figures using the 1938 Atomic Weights.

TABLE IV
THE SCHWEITZER AND DITTMAR FORMULAS COMPARED

The numbers in Column (1)are the % of each salt in the total of the salts in the sample. The total used in this comparison was the average ocean salinity of 3.5 grams per 100 grams of water. The numbers in Column (2) are in grams/100 grams of Water and they are obtained by multiplying the percentages in Column (1) by 3.5; the numbers in Column (3) are in lbs./100 lbs. of water. Note that they are identical scales.

COMPONENT	(1) SALT %	(2) DITTMAR	(3) SCHWEITZER
Sodium chloride	77.758	2.7215	2.7060
Magnesium chloride	10.878	0.3807	0.3666
Magnesium sulphate	4.737	0.1658	0.2296
Calcium sulphate	3.600	0.1260	0.1407
Potassium chloride			0.0766
Potassium sulphate	2.465	0.0863	
Magnesium bromide	0.217	0.0076	0.0029
Calcium carbonate	0.345	0.0121	0.0030
TOTAL	100%		

THE ORIGIN OF MARINE MIX

The Lilly Ackerland Fleischmann Memorial Aquarium at the Cincinnati Zoo opened on Friday, May 26, 1950. I moved to Cincinnati in June of 1950 and by 1951 I was a consultant to the Aquarium, mostly engaged in identifying species of newly-obtained fishes. The Aquarium was interested in displaying marine life - it was all freshwater at the time - and wanted to set up some experimental ma-

rine aquaria. However, at that time there were no artificial seawater mixes on the market, so I was asked to provide a formula.

In early 1952 I turned over a copy of what I had come up with to the Chief Aquarist and we sat down for a lengthy discussion over the details. It was decided to go ahead with the experiments and so the Aquarium had a quantity of the mixture made up by a local commercial chemist, enough for about 100 gallons of water. In May of that year, however, I entered the United States Army (the Korean War still was in full tilt) so I was not around to see how things turned out. The following, however, is from the *Cincinnati Enquirer* of Sunday, November 16, 1952:

Something's Latest addition to the Fleischmann Aquarium at the Cincinnati Zoo is a collection of tropical fish, some of which are pictured on these pages. The first of their kind to be shown in Cincinnati, these specimens were flown here from the gulf of Mexico. Special water prepared from a formula, is required to keep the marine inhabitants who are used to a saltier atmosphere than Cincinnati.

The caption under one of the pictures read: **J.F. Heusser, Zoo Director, checks the temperature of the artificial sea water in one of the seven new exhibition tanks for tropical fish in the Fleischmann Aquarium.**

After my tour of duty ended (I had been Commanding Officer of the 501st Chemical Depot Company), I spent a year in graduate school and returned to Cincinnati at the end of August 1955. I renewed my acquaintances with the Cincinnati Zoo and Fleischmann Aquarium staff and was able to examine the seven tanks that utilized the formula that I had provided. Everything was fine; the vertebrates, were in good health, as well as were the anemones and other marine creatures.

Much to my surprise, I learned that during my absence the Aquarium had decided to sell the salt mixture to aquarists under the name of "Marine Mix." This was done mainly because it was cheaper to manufacture in large quantities than small. Thus, in 1956 the first artificial seawater mix appeared on the market in this country. It was only on the market briefly since the Fleischmann Aquarium was satisfied that artificial seawater was feasible and so they planned to build an East Wing on the building to house small marine tanks. This took some time to plan, secure the necessary funds and build, but the addition was finally opened in June 1972. By this time, of course, there were a number of improved mixes on the market and the Aquarium did not need to manufacture its own as it did in the 1950s.

ADDENDUM: THE COMPOSITION OF MARINE MIX

The element strontium, one of the major constituents of seawater, had not been isolated in Dittmar's time. The usual wet-chemical analysis methods for calcium register any strontium present as an equivalent amount of calcium As a result, the strontium went unreported in the early analysis of seawater. I had briefly looked over several older formulas, but settled on that of Lyman and Fleming (1940) since they had included strontium. Their formula yields a water containing all of the major ionic components in their correct proportions, lacking only in the minor elements.

First, some biographical information. Dr. John Lyman (1915-1977) directed studies of the ocean for three agencies in the course of 20 years with the federal government. Born in Berkeley, Calif., Lyman did undergraduate work there and received his master's and doctorate degrees from Scripps Institution of Oceanography, part of the University of California in Los Angeles. He began his career in Washington in 1946, when he became director of oceanography for the Navy Hydrographic Office. He later became director of oceanography at the National Science Foundation and then chief adviser for oceanographic research at the Bureau of Commercial Fisheries. Before going to Chapel Hill in 1968, he worked for the Office of Naval

Dr. John Lyman (1915-1977) in 1936.

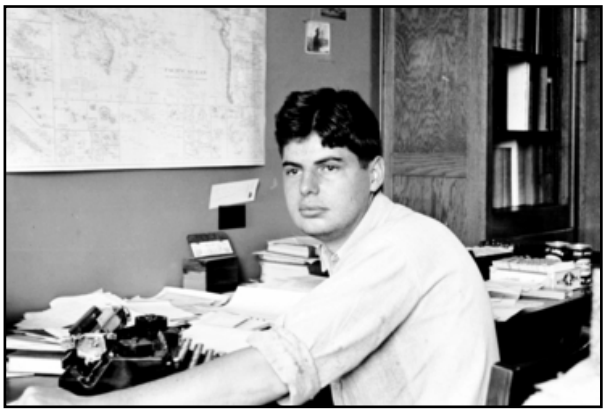
Research. At the time of his death, at age 62, Lyman was professor emeritus of environmental chemistry at the University of North Carolina, where he had moved in 1968 to head the school's office of marine sciences. He served in the Navy in World War II and was a member of the Washington Academy of Sciences and the American Association for the Advancement of Science.

Richard Howell Fleming (1909-1989), was a Canadian-born American oceanographer who conducted wide-ranging studies in the areas of chemical and biochemical oceanography, ocean currents (particularly those off the Pacific coast of Central America), and naval uses of oceanography. He joined the Scripps Institution in La Jolla, California, in 1931 and served as assistant director from 1946 to 1950, when he left to become professor of oceanography at the University of Washington. Fleming measured the amounts of chemical elements in sea water and in marine life. His work on ocean currents included measurement of tidal-current velocities, description of upwelling of seawater, and observations of seasonal variations in currents. He also explored sedimentation in moving and stagnant bodies of water. With H.U. Sverdrup and Martin W. Johnson, Fleming wrote *The Oceans* (1942).

Those aquarists not interested in an arithmetic exercise can safely skip this part of the Addendum and go directly to Column (2) of Table V.

Referring to Table V, lines 1-10 in Column (1) comprise the Lyman and Fleming formula; lines 11-17 are my additions. The sum of lines 1-10 in Column (1) is 34.481 grams. This, by the way, rounded is a salinity of 34.5 (in grams of salts per 1000 grams of seawater). Subtracting this from 1000 grams (1 kilogram) we obtain 965.519 grams of water. (Items 11-17 were not included since they are in quantities too small to have any effect on these calculations.) Since 1 gallon of water = 3.79 kilograms, 965.519/3790 = 0.2547543 gallons. (At this stage in the computations I like to keep as many decimal places as possible in order to minimize rounding errors.)
Now I wanted a formula for 10 gallons of water, not 0.2547543 gallons. Therefore, I multiplied the lines 1-17 in Column (1) by 10/0.2547543 = 39.253508 and obtained the final formula for Marine Mix shown in Column (2). The salinity of this formulation was not affected and remained at 34.5.

There has always been controversy over the relative merits of natural and synthetic seawater, especially with regard to trace or minor elements. Most synthetic seawaters have at some stage



Richard Howell Fleming (1909-1989) in 1935.

TABLE V
COMPONENTS AND CALCULATIONS FOR MARINE MIX

COMPONENT	(1) AMT./1 KILOGRAM	(2) AMT. ADDED TO 10 GAL.
1. Sodium chloride, NaCl	23.476 grams	921.515 grams
2. Magnesium chloride, $MgCl_2$	4.981	195.522
3. Sodium sulphate, Na_2SO_4	3.917	153.756
4. Calcium chloride, $CaCl_2$	1.102	43.257
5. Potassium chloride, KCl	0.664	26.064
6. Sodium bicarbonate, $NaHCO_3$	0.192	7.367
7. Potassium bromide, KBr	0.096	3.768
8. Boric acid, H_3BO_3	0.026	1.021
9. Strontium chloride, $SrCl_2$	0.024	0.942
10. Sodium fluoride, NaF	0.003	0.118
11. Disodium phosphate, Na_2HPO_4	0.250 milligrams	9.813 milligrams
12. Potassium iodide, KI	0.077	3.023
13. Alum, $AlK(SO_4)$	0.044	.727
14. Zinc sulphate, $ZnSO_4.7H_2O$	0.015	0.589
15. Manganese chloride, $MnCl_2.4H_2O$	0.005	0.196
16. Barium chloride, $BaCl_2.2H_2O$	0.005	0.196
17. Copper sulphate, $CuSO_4.5H_2O$	0.002	0.076
18. Water	65.519 grams (0.2547543 gal)	10 gallons

failed in certain respects, such as in maintaining a specific marine organism or plant, or in the breeding and rearing of the higher forms of marine life such as the fishes. A list of components in seawater of proven or suspected biological activity, in order of their concentrations in micrograms per liter (μ/l), is shown in Table VI. Copper, Barium and Nitrate (as NO_3) are found in Cincinnati water. If I had such a list when I was putting together my formula for Marine Mix, I might have replaced the Barium, Aluminum and Copper with Silicon, Iron and Molybdenum.

TABLE VI
A LIST OF COMPONENTS IN SEAWATER OF PROVEN OR SUSPECTED BIOLOGICAL ACTIVITY

COMPONENT	CONCENTRATION, MICROGRAMS PER LITER (μ/l)
SILICON	500-2900
NITROGEN AS NO_3	500-700
IODINE	45-65
PHOSPHORUS AS PO_4	1-90
BARIUM	6-90
IRON	1-40
MOLYBDENUM	9-16
ZINC	5-21
MANGANESE	0.4-10
VANADIUM	0.2-7
NICKLE	0.5-6.6
ARSENIC	2.1-2.7
COPPER	0.9-3
COBALT	0.1-0.7
NIOBIUM	0.015
YTTRIUM	0.01-0.3
VITAMIN B_{12}	0.001-0.05
GOLD	0.004-0.01

THE HISTORY OF FLAT GLASS AND THE AQUARIUM

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, October 29, 2016)

The history of the modern-day aquarium is essentially the history of flat glass, and the history of flat glass is essentially the history of window glass. This essay traces the history of window glass over the past five centuries in England, where it ultimately became the special "four-sided window" we call an aquarium.

Almost all window glass has been, and continues to be, produced from sand, which is composed almost entirely of silica, a chemical compound that is an oxide of silicon with the chemical formula SiO_2. In order to melt silica, however, it is necessary to add a flux, i.e., any material which will lower the melting temperature of the silica. The most common fluxes used in window glass manufacture are the alkalis sodium and potassium. The more alkali that is added, the lower the melting temperature; however, an excess of alkali will leave the glass prone to weathering. Therefore, in order to increase the chemical durability of glass, a stabilizer is usually added. A wide variety of elements can act as glass stabilizers but the most important have been calcium and magnesium. Early glassmakers were not necessarily aware of the range and concentration of the different elements in the raw materials they used, yet in spite of this they developed working practices that were successful.

FOREST GLASS (before c. 1567)

The first phase of historic window glass manufacture covers the medieval period up to the arrival in England of French glassmakers in 1567, although documentary sources hint that glass production may extend back into the thirteenth century. The glass of this period was made using sand and ashes from woodland plants and was characterized by high levels of potassium and magnesium. While written sources appear to recommend the use of a wide range of plants, the chemical composition of most English medieval glass was most consistent with the use of bracken as a source of the alkali. Unfortunately, the glass of this period was not particularly stable and it is rare for it to have survived in contemporary windows. This glass type was also used to manufacture a wide range of other goods, including drinking vessels.

It is probable that the flat glass was formed using the cylinder glass technique. A bubble of glass would be blown and elongated to form a cylinder; the ends were removed and the cylinder cut along its length and flattened (Figure 1). The flattening process was undertaken with blocks of wood

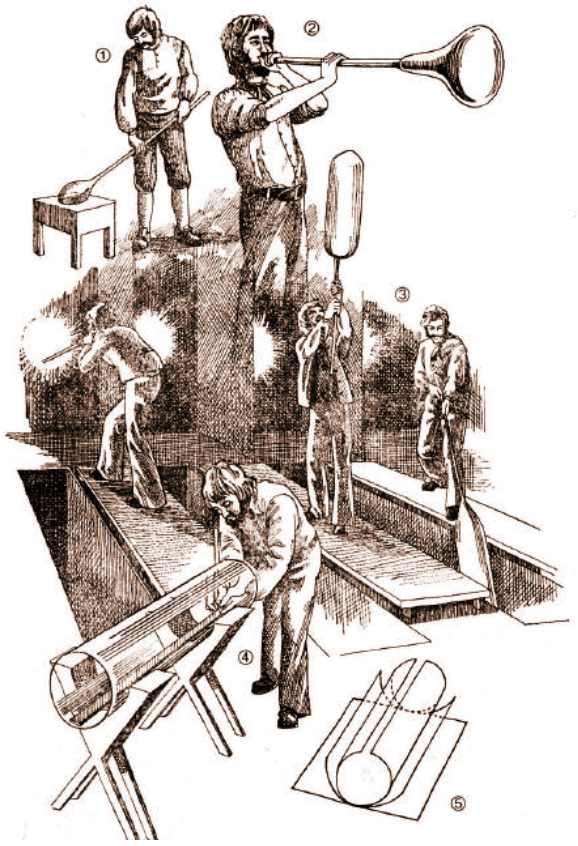

FIGURE 1: Cylinder window glass Manufacture. A bubble of glass was elongated to form a cylinder, which was then cut open and flattened to form a large sheet.
(Image © Pilkington Group Limited.)

while the glass was still sufficiently soft, but this left a more-or-less rough surface on the glass. At some stage, a second forming method was developed that came to be known as crown glass. The glass was blown as a bubble, which was then opened and spun round until it formed a disc of glass (Figure 2). Crown glass did not have to be flattened and so had a superior surface finish compared to cylinder glass. The drawback with crown glass, however, was the central swelling or bull's eye, which prevented the production of large panes of glass. Since almost all glass of this period (whether cylinder or crown) was made using plant ashes, it had a natural tint or color which came primarily from the traces of iron present in the raw materials used.

HIGH-LIME, LOW-ALKALI GLASS (c. 1567 to c. 1700)

The second phase started in 1567 with the arrival of the French glassmakers. The glass of this period was characterized by a high calcium content and relatively low levels of sodium and potassium. It has long been argued that these French glassmakers brought with them a number of technical developments and it is now clear that the glass made by the French glassmakers was indeed of a new type. This new high-lime, low-alkali (HLLA) glass appears to have been produced using different types of plant ashes as the source of the alkali. The high lime content of this glass strongly suggested the use of wood ash. Contemporary sources mention the use of a wide variety including trees (oak, birch, fir etc.) and a variety of other plants, such as thistle, hops, brambles and even tobacco. HLLA glass was also used to manufacture a wide range of goods including tableware and bottles.

The late-sixteenth-century influx of glassworkers (again, mostly from France) is well known from documentary sources; however, it has not been clear what effects this had on the nature of the window glass produced. The glassmakers from Lorraine were traditionally associated with the production of cylinder glass, while those from Normandy were usually thought of as crown glass manufacturers.

Window glass continued to be manufactured in the forests until the beginning of the seventeenth century. The early seventeenth century saw a major change in the glass industry as a whole when the use of wood as a fuel was banned. The glass makers in southern England (those established by French Huguenot refugees) were burning wood at such a rate that a law of 1615 made it illegal to use wood for glass furnaces. This caused the first shift of fuel for glassmaking in its long history, leading ultimately to the use of coal and the inevitable migration of glass industries to areas of Britain with surface coal and good communications, such as Stourbridge and Newcastle.

FIGURE 2:
Crown window glass manufacture. A bubble of glass was spun to form a circular sheet that was cut to form small panes.
(Image © Pilkington Group Limited.)

Written sources are equivocal about the types of window glass made during this period. This is not helped by the fact that the term "cylinder glass" (or its cognates, "broad" or "muff glass") was widely used to mean any sheet glass suitable for windows. Although crown glass was described as "first made" in England in 1691, there is abundant archaeological evidence for its manufacture in the early sixteenth century.

The identification of cylinder or crown glass in extant seventeenth-century windows is also made difficult by the fashion for small diamond panes of a rather small size. The panes were held together with lead strips, each window often containing 20 to 50 panes. The small size of the panes, the lead strips and the greenish quality of the glass all contributed to a window that would provide much less light than a modern window and that could give only a rather distorted view of the outside world (Figure 3). The late seventeenth century saw the introduction of the sash window that used cords and counterweights, and these quickly made use of larger panes of glass. The sash window became increasingly popular during the eighteenth century and was used to allow more light into a room and a more useful view of the outside world.

KELP GLASS (c. 1700 to c. 1835)

This phase saw wide-ranging changes in the manufacture and use of window glass. Glass of this phase was a mixed alkali glass and contained substantial proportions of both sodium and potassium. In addition, the glass contained a relatively high proportion of strontium, suggesting the use of a marine plant. The analysis of strontium isotopes in this glass has confirmed the use of seaweed, and historical sources corroborate the use of seaweed (usually referred to as kelp) from at least the middle of the eighteenth century. Also, the chemical analysis of this glass shows that it was used in windows from at least the beginning of the eighteenth century. During the eighteenth century the production of cylinder glass declined and crown glass came to dominate the market. While crown glass may have been an aesthetically superior glass, the system of taxation on window glass production at the time worked in its favor since window glass manufacturers were taxed on the weight of the materials they used to make the glass but derived their profit from the glass they sold. As crown glass was routinely thinner than cylinder glass, there was more profit to be made in it than in cylinder glass.

A new technique for producing sheet glass suitable for windows had developed in France in the late seventeenth century. The molten glass was cast onto a metal table and rolled flat. Once cooled, the glass was laboriously ground and polished to produce two perfectly flat and polished surfaces called "plate glass." The long polishing process made plate glass very expensive compared to crown or cylinder glass, It has been estimated that in the early eighteenth century plate glass was five to twenty times more expensive than ordinary sheet glass, and so its use was largely restricted to mirrors. Plate glass was also used for the windows of coaches but was only used for domestic windows in the houses of the fabulously wealthy. Plate glass production was introduced to England in the late seventeenth century but production seems to have been short lived. The technology was reintroduced in the late eighteenth century and continued into the twentieth century. Very little is known about the sorts

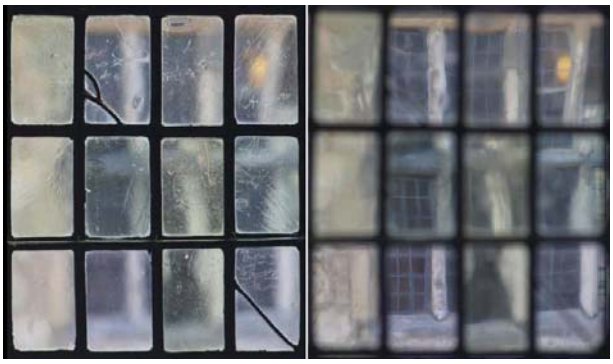

FIGURE 3: An example of the quality of glass and its transmitted image. The left image is focused on the glass, the right on the exterior).
(Photograph by David Dungworth.)

of ingredients used in plate glass manufacture but the apparent concern with transparency is likely to have encouraged the use of more select materials than those employed by crown or cylinder glass manufacturers.

LEBLANC SODA GLASS (c. 1835 to c. 1930)

The nineteenth century saw many significant developments in the English glass industry, including the nature of the raw materials and forming techniques. It also was the period that supplied aquarists with the flat glass needed for their aquariums. For centuries all window glass had been made using the ashes of selected plants, but by the eighteenth century it was increasingly appreciated that the active ingredients in plant ashes were the alkalis, sodium and potassium. Although common salt was rich in sodium, it would not react with sand to form glass. Towards the end of the eighteenth, Nicolas Leblanc developed a technique for converting sodium chloride into sodium carbonate and this worked for the glass. The technology was imported to England in the late 1820s, and by the late 1830s Leblanc soda had largely displaced plant-based alkalis. Window glass made using Leblanc soda is a soda-lime-silica glass which contains very low levels of impurities compared with any of the earlier plant-ash glasses. In particular, glass made after circa 1835 contains little or no phosphorus.

Most people experience window glass as a fully transparent material and, since the early nineteenth century, most window glass has been manufactured from materials that gave virtually no tint to the glass. Before the industrial production of synthetic (Leblanc) soda, however, almost all glass had at least a slight tint that gave a distinct character to both transmitted light and images viewed through the glass. The exact tint of the glass could vary considerably depending on the composition of the glass and the way in which the original glass had been melted. The most significant element in glass which affects its color is iron. It results in the green tint shown in Figure 4. Before the use of synthetic soda, the sands employed by window glassmakers all appear to have contained enough iron to give the glass at least some color. Due to the use of better quality sand, the glass of this period rarely has any significant color.

Documentary sources indicate that Leblanc soda was first manufactured in England in the late 1820s but it did not make any serious impact on the glass industry until the 1830s.This phase also introduced the practice of using refining agents. Refining agents are used to remove bubbles from glass; paradoxically, this is usually achieved by using a material which produces glass bubbles. The introduction of arsenic, saltpeter and even potatoes will evolve gas bubbles that, being large, will rise quickly and tend to gather in small bubbles.

Glass made for the first few decades after the introduction of Leblanc soda usually contained significant concentrations of arsenic and its use as a refining agent is mentioned in several contempo-

FIGURE 4: An example of the green tint in old glass produced by iron impurities.

rary documentary sources (written sources also mention the use of saltpeter, i.e., potassium nitrate, as a refining agent). Around the 1870s, the arsenic disappeared from window glass but there was a small increase in the potassium content.

The 1830s saw the Chance Brothers introduce what they called improved cylinder glass. Chance Brothers and Company was a glassworks originally based in the West Midlands in England. It was a leading glass manufacturer and a pioneer of British glassmaking technology. This glass was made using some variation on the traditional cylinder glass technique, although it is not immediately apparent what the improvements were. Chance made use of skilled labor brought from continental Europe and appears to have been able to supply sheets that were larger than those made by traditional cylinder producers. It is likely that, like so many industrial developments of this time, the improvement was actually embodied in the manual skill of the workers and so was not easily captured in a written text. Contemporary observers contrasted the quality of traditional, English cylinder glass, "coarse in texture, of a wavy wrinkled surface, and very cheap," with the new improved cylinder glass. The quality of improved cylinder glass also probably benefited from the recent availability of Leblanc soda. Its production expanded rapidly and by 1844 accounted for almost a quarter of the flat glass made in England. Crown glass production continued to decline and by the early twentieth century the technique was described as "nearly obsolete."

MECHANIZED SYSTEMS (from c. 1890)

There are two ways whereby flat glass can be produced: manually and mechanically. The latter, however, can be either batch or continuous. The processes described here so far have included the cylinder, crown and plate glass processes, all of which are manual. However, all produced their flat glass in batches and so were both batch as well as manual processes. The problem with all of them involved the use of labor, which is time-intensive and expensive. The early twentieth century saw the mechanization of window glass production with the introduction of the Lubbers Process that originated in the United States in the 1890s (Figure 5: additional information can be found in Klee, 2014). The process essentially mechanized the production of cylinder glass but it still was a batch process that required a fair amount of labor.

By the late 1920s continuous sheet drawing techniques had been introduced to England, especially the Fourcault process. First developed in Belgium by Émile Fourcault during the early 1900s, the process was used globally. Fourcault is an example of a "vertical draw" process, in that the glass is drawn against gravity in an upward direction. Gravity forces influence parts of the process.

The process used a ceramic die to shape molten glass into a ribbon of rectangular cross section. The die, known as a Debiteuse, floated in the molten glass inside of the pit to a prescribed depth that pushed a part of the molten glass slightly above the top surface of the die. A slot was cut through the center of the Debiteuse, which was shaped to produce the best quality of

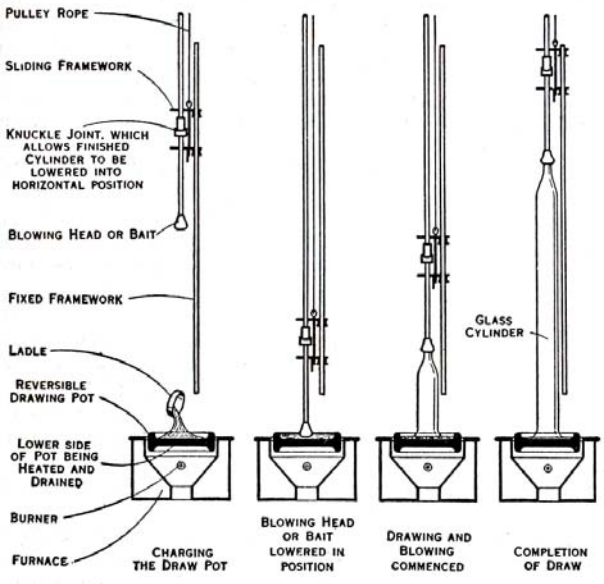

FIGURE 5: The Lubbers Process.

glass. The Debiteuse was the starting point of the vertical draw, where the glass began to change from a hot syrupy mass into a useful flat glass (Figure 6).

From the point of the Debiteuse until it was cut, the glass resembled a ribbon. The base of the ribbon was shielded from heat radiation from the fused glass so that it continued to hold the shape imparted to it by the Debiteuse. This preserved the rectangular cross section of the drawn glass by cooling the ribbon glass below the temperature where it would collapse into a column or break back into the melted glass. Immediately after being drawn, the ribbon was cooled using mechanical coolers so that it maintained its rectangular shape in two dimensions but assumed a ribbon like structure that extended down into the Debiteuse and upwards into a drawing assembly. This mechanical cooling allowed the ribbon to hold its integrity. The mechanical coolers used water contained in specially shaped radiators to remove the heat radiated by the ribbon.

The scale of this process was such that the glass produced had to be kept hot for longer periods compared to the earlier manual techniques and this resulted in a tendency for the glass to devitrify, the formation of small crystals in the glass obviously detracting from its transparency. Various attempts were made to alter the composition of the glass to avoid this problem but the lasting solution was found to be the replacement of a proportion of the calcium in the glass with magnesium. In any case, the resultant product is a form of flat glass which is suitable for lesser quality uses. Due to process instabilities, Fourcault process glass could have waves, seeds (small gas bubbles) or stones (undissolved materials).

The Colburn/Libbey-Owen process also drew its sheet vertically from an open bath, the glass ribbon being drawn vertically from the tank for about 30 inches by a metal bait before being bent over a roller into the horizontal plane ready for cutting and annealing (Klee, 2014). The process was twice as fast as the Fourcault process so the glass had less time to cool and so the annealing process eliminated or limited the stresses previously mentioned. However, the bending tended to spoil the surface of the glass.

The third process, the Pittsburg process, combined and enhanced the main features of the Fourcault and Libbey-Owens processes. The glass was drawn from the melt and conveyed vertically through an annealing shaft around 40 feet long prior to cutting. By 1928 these processes replaced the mechanical cylinder-drawing machines.

Continuous processes such as these were fast and economical, but not necessarily of high quality. In

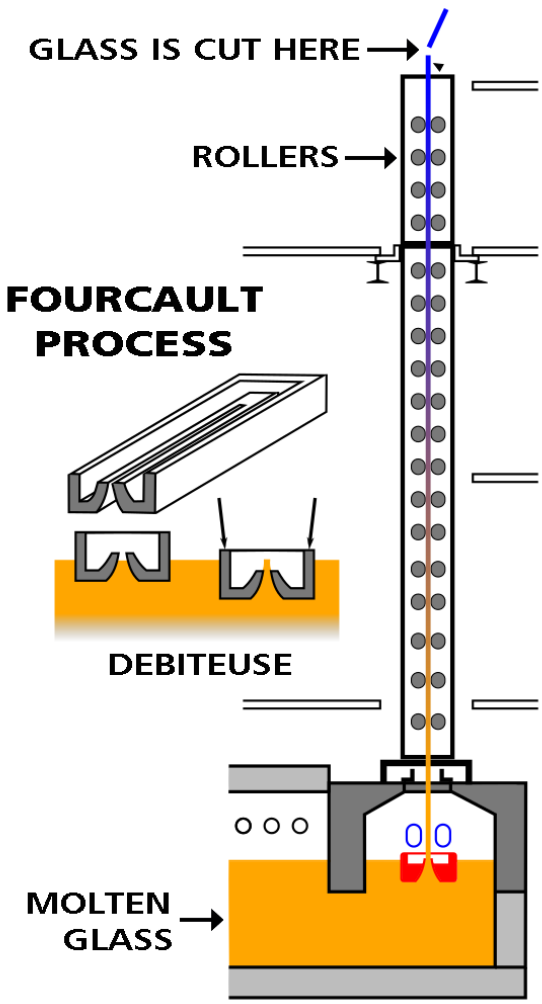

FIGURE 6: The Fourcault Process.

terms of economics and product quality, they were supplanted by the Float process developed by Pilkington. The company was founded in 1826 as a partnership between the members of the Pilkington and Greenall families, based in St Helens in the historic county of Lancashire in England. The venture used the trading name of *St Helens Crown Glass Company*. On the departure from the partnership of the last Greenall in 1845, the firm became known as *Pilkington Brothers.* In July 1894 the business was incorporated under the Companies Act 1862 as *Pilkington Brothers Limited*.

Between 1953 and 1957, (Sir) Alastair Pilkington and Kenneth Bickerstaff invented the Float Glass Process, a revolutionary method of high quality flat glass production that involved floating molten glass over a bath of molten tin, avoiding the costly need to grind and polish plate glass to make it clear. Pilkington announced the float glass process in 1959, but further development work was necessary before the process could be fully exploited commercially. Pilkington decided on a policy of licensing the process to existing major glass manufacturers. At the same time, the company encouraged its licensees to assist in the further development of the float process by granting them free use of any improvements they might make on condition these were also made available to Pilkington itself. The first float license was granted, to *Pittsburg Plate Glass*, in 1962. Others quickly followed. Pilkington stopped making polished plate glass in 1967 and others soon followed suit.

The process is fairly simple (Figure 7):

1) Sand, limestone, soda ash, dolomite, iron oxide and salt cake are mixed together with cullet in the batch plant.
2) The raw materials are then charged into a large furnace to be melted at 1600°C. They combine in a process of physical transformation to form molten glass.

3) A continuous ribbon of molten glass is fed out of the melting furnace onto the surface of an enclosed bath of molten tin at 1100°C. The molten glass literally floats on top of the tin, and as it flows along the surface of the tin bath away from the delivery canal, it forms a ribbon of uniform thickness. Its thickness is controlled by the speed at which the solidifying glass ribbon is drawn off from the bath. Tin, however, oxidizes in a natural atmosphere to form tin dioxide (SnO_2). Known in the production process as dross, the tin dioxide adheres to the glass. To prevent such oxidation, the tin bath is provided with a positive pressure, protective atmosphere of nitrogen and hydrogen.

4) The glass is then lifted from the tin bath onto rollers to the annealing lehr to be cooled down. Despite the tranquility with which float glass is formed, considerable stresses are developed in the ribbon as it cools. Too much stress and the glass will break beneath the cutter. To relieve these stresses, the ribbon undergoes heat-treatment in the lehr where the temperatures are closely controlled both along and across the ribbon.

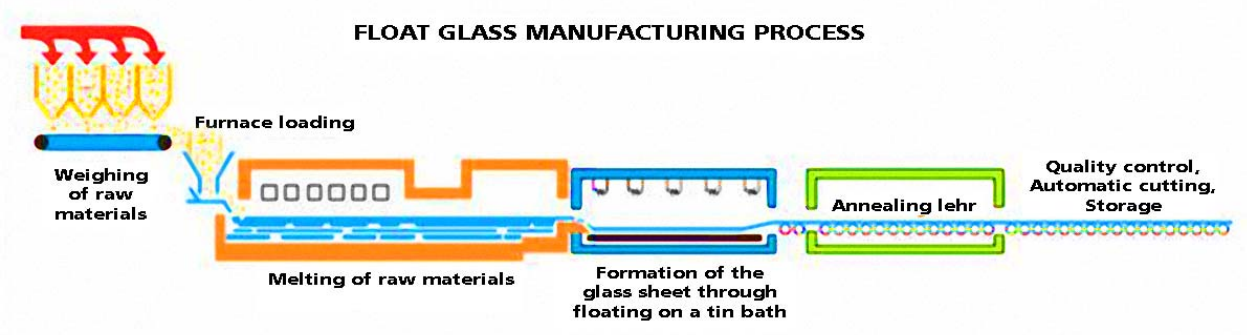

FIGURE 7: The Float Glass Process.

5) Once cooled down and solidified, the glass goes to the cutting area where it is cut into sheets specific to customer orders before being stacked for transportation. The float process produces glass sheets with a uniform thickness and perfectly smooth surfaces that need no further grinding or polishing.

The production techniques used for the manufacture of almost all historic window glass left the glass with a non-plane surface, variations in thickness, and bubbles and other defects within the glass itself. Float glass usually has a perfectly plane surface which distorts neither reflected nor transmitted images (Figure 8). In addition, this glass is effectively free from any bubbles and is of uniform thickness. Almost all flat glass today - including that for aquariums - is made from float glass.

Molten glass floating on tin in a nitrogen/ hydrogen atmosphere will spread out to a thickness of about 6 mm and stop due to surface tension. Thinner glass is made by stretching the glass while it floats on the tin and cools. Similarly, thicker glass is pushed back and not permitted to expand as it cools on the tin. The standard maximum thickness for float glass is 22 mm or 0.87 inches.

FIGURE 8:

(Photograph by David Dungworth.)

A final observation: One type of glass manufactured before the development of the float process that was capable of producing glass with aesthetic qualities that approached float glass was plate glass. The polishing process employed in the manufacture of plate glass left it with a perfectly flat surface, making it at times impossible to distinguish from float glass.

THE EARLY HISTORY OF AMERICAN FISHERIES

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, December 3, 2016)

Culturing fish is actually a centuries-old practice. Historically, the Egyptians raised Tilapia 4,000 years ago and ponds for fish culture were built in the Honan Province of China as early as 1100 B.C. when Wen Fang made the first written reference to fish culture. In 460 B.C., Fen Li described the culture of common carp for food and related the details of his experiments on fish farming in his book, "Fish Culture Classics." In Europe, the Romans had farmed fish and shellfish for at least 1000 years before fish culture began in America.

For more than a century before the Pilgrims arrived in 1620, hardy fishing crews had established temporary settlements on the northern coast. There they salted and dried their catches before returning home to Normandy, Brittany, Devonshire or Portugal. Catholic Europe needed Friday fish that would remain unspoiled for many months, and even Protestant England practiced the no-meat-on-Friday custom to reduce the demand on the national meat supply and to promote the fishing industry. Much of the economy of early America revolved around the exportation of salted fish.

The fishery resources of the New World were very important to England long before fish culture began in America. It has been estimated that England derived greater wealth from fisheries in the New World than Spain did from American gold. However, as early as 1762, overfishing had eliminated striped bass and sturgeons (*Acipenser* spp.) from the Exeter River in New Hampshire. Dams blocked the spawning runs of the alewife (*Alosa pseudoharengus*) and destroyed that fishery at Exeter before 1790. Throughout the New England area, other fisheries were similarly degraded or totally destroyed by habitat alterations or overexploitation.

Indirectly, the fisheries were destructive. As much as a bushel of salt is required to cure 100 pounds of fish, and a salt boiling industry thrived on Cape Cod as long as the firewood lasted. In the late 1790's, at the salt works near Syracuse, N.Y., it took a cord of wood to make 11 bushels of salt from a brine that was many times stronger than sea water.

pounds of fish, and a salt boiling industry thrived on Cape Cod as long as the firewood lasted. In the late 1790's, at the salt works near Syracuse, N.Y., it took a cord of wood to make 11 bushels of salt from a brine that was many times stronger than sea water.

Deposits of iron ore were discovered and little settlements in Pennsylvania like Mary Ann Furnace in Berks County and Union Forge in Lebanon County sprang up to smelt and work the iron. The iron industry was notably wood-hungry and a large furnace consumed an acre of forest a day. By 1775, colonial iron production exceeded that of England and Wales combined, and comprised 15 percent of the world promotion. However, the destructive influence by industry on the forests was second to that of the settlers.

To obtain land for plowing and planting, the settlers followed the practices of the local Indians. The large trees were girdled, the underbrush grubbed up, smaller trees cut and piled around the larger trees and burned. The fertile humus of the former forest floor produced good crops for the first few seasons, but eventually the land was abandoned and new areas were sought after farther west. This mining of the soil altered the character of the landscape, and the resulting erosion and silting of the lakes and streams, as well as flooding and fluctuating water levels, had far reaching consequences. The streams were also changed by the erection of dams to power the mills and to operate the bellows and trip hammers of the forges. Dams had destroyed an alewife run at Exeter, N.H. prior to 1790, and overfishing had eliminated the striped bass and sturgeon from the Exeter River by 1762.

The Striped Bass, Morone Saxatilis. By 1762 It was eliminated by overfishing from the Exeter River.

In the early development of this country these were but isolated incidents that were harmful to the fishery resources. While none of the marine fisheries was directly overexploited, the fluctuations in the size of the catch caused concern. While the causes of the decline of the inland fishery resources were not understood, an aroused public demanded corrective action. The most logical solution appeared to be direct action to increase fish stocks. Therefore, the climate was created for the development of fish culture in North America.

THE BEGINNINGS

Fishery science began in the U.S. in 1812 when the Philadelphia Academy of Science was formed and a curriculum in aquaculture was established for undergraduates at Cornell University. Ichthyologists began to travel throughout America to study and describe the nation's aquatic resources, while others sought to transplant and propagate native species. As the public demanded corrective action to restore and maintain traditional fisheries, the culturing and stocking of fish appeared to be the most positive direct action. The very first fish managers in the U.S. were also fish culturists.

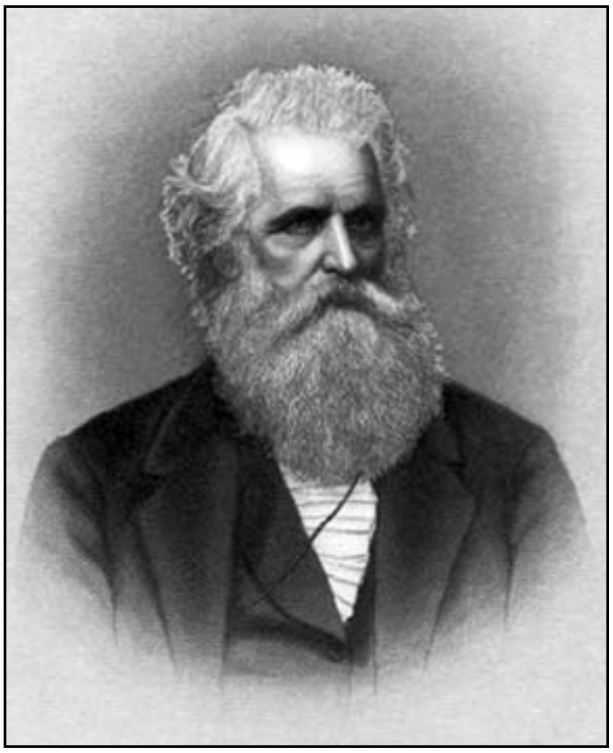
Both state officials and private citizens transplanted fish outside their natural ranges to augment the supply of native fish and to supply fish familiar to new immigrants, e.g., the common carp (*Cyprinus carpio*). As early as 1831, common carp were established by Captain Henry "bully" Robinson, the owner of one of the Havre packets, in a pond at Newburgh, New York, from which some escaped into the Hudson River. In 1832, carp were being reared and sold in Sonoma, California.

The first efforts to restore the fish stocks included the transfer of adult fish into depleted waters to renew the breeding stocks. Fertilized eggs and fry were also collected from spawning areas and transported to depleted waters. Often the eggs or fry were held in incubating devices and given care and attention during incubation and, for a short time, after hatching. In addition, many fish were introduced into waters where they were not native. The European custom of confining and feeding fish in impoundments was also practiced.

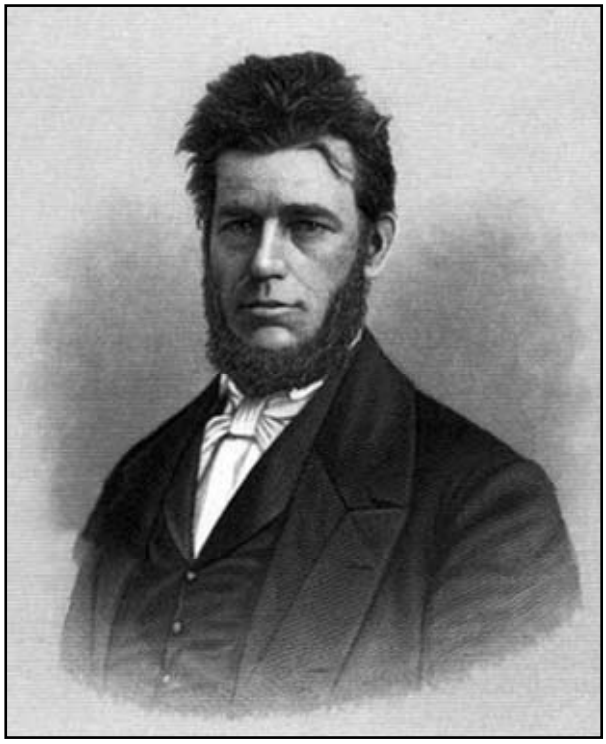
Brook Trout (*Savelinus fontinalis*).

By 1850, fish culture was an established practice in most of Western Europe, the Balkans and in Scandinavia. Various published works, particularly those from France, Germany and the British Isles, were readily available in the United States. After reading these reports in 1853, two Cleveland physicians, Theodatus Garlick (1805-1884), and Horace A. Ackley, accomplished the then amazing feat of fertilizing the eggs of brook trout (*Salvelinus fontinalis*). They displayed the resulting fish at the Ohio State Fair and "received much admiration and many awards" for their demonstration of "practical and economical fish culture."

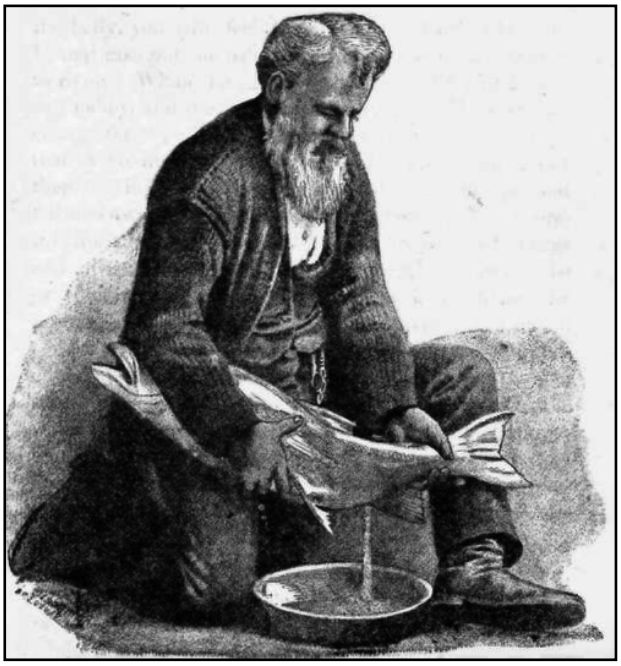
Their establishment on Ackley's farm near Cleveland, Ohio consisted of three ponds totaling less than two acres, a hatching house built over the spring water supply and a convoluted spawning channel between the two largest ponds. Adult brook trout were obtained from Sault St. Marie, Michigan and Port Stanley, Ontario. Spawning behavior among these fish was first observed on November 15, 1853. Five days later a spawning pair was captured, the eggs were stripped from



Dr. Theodatus Garlick (1805-1884).



Dr. Horace A. Ackley (1810-1859).

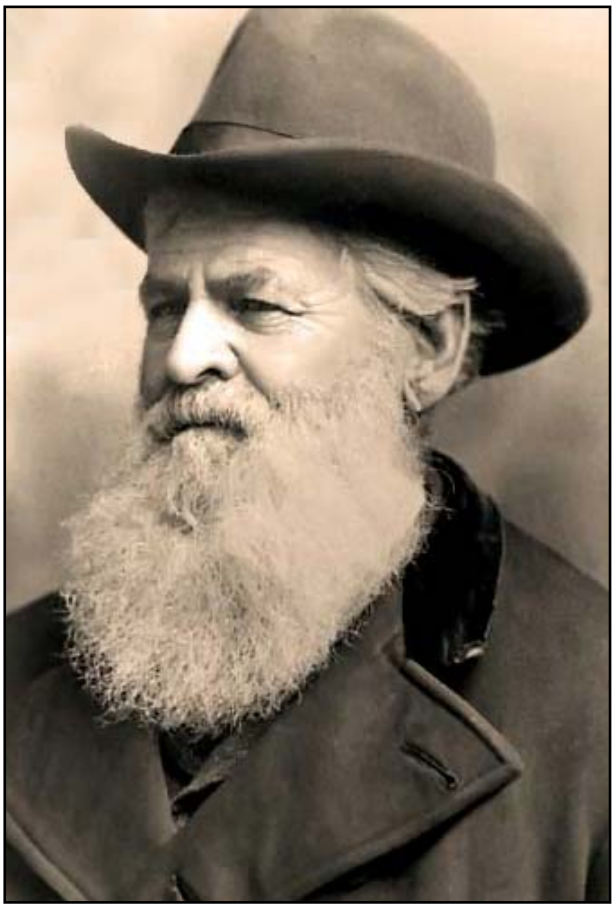


Seth Green stripping eggs from a salmon-trout (Salmo trutta).

the female and fertilized in an earthen vessel with sperm from the male. The eggs were incubated in running water until they began hatching on January 22, 1854. Sediment had smothered most of the eggs, so the remainder were moved to Ackley's office and incubation was completed in a glass jar, the water being changed daily. These results were sufficiently encouraging and, during the next three years, Garlick and Ackley built up a considerable enterprise.

E. C. Kellog and D. W. Chapman began in 1855 at Simsbury, Connecticut by hatching 75 of the 2,000 eggs they had obtained from one female brook trout. (In that same year, Garlick published his treatise on the artificial propagation and culture of salmon and trout.) The second year they hatched "very few" but in 1857 they succeeded in producing 4000 fry. The lucrativeness of hatcheries encouraged a rise in private efforts during the mid-nineteenth century, including a venture from Samuel Colt, whose Colt .45 took on legendary proportions in the West, but his mid-nineteenth-century construction of a Connecticut hatchery received comparatively little notice as one of many such establishments. In 1860, Kellog managed an extensive facility set up by Colt and produced 4,000 fry.

Incidentally, Colt was by no means the only gunmaker who set up a trout hatchery. Retired from a career of developing the famous rifles that bore his name, Christian Sharps' last days were spent sloshing through a secluded brook in the southern part of Vernon, Connecticut. There, thousands of plump trout that he had been breeding for three years were finally ready for shipping to hotels, restaurants and dinner tables nationwide. Historians say the bearded, gentlemanly entrepreneur was on the verge of becoming the nation's most profitable trout farmer when the coughs he had ignored caught up with him. He succumbed to tuberculosis in March 1874, leaving behind trout orders never met, expenses never paid and dreams never accomplished.



Seth Green (1817-188).)

Stephen H. Ainsworth of West Bloomfield, New York, began hatching brook trout in 1859 as a hobby. His water supply was only 5-10 gallons per minute, but he hatched 60,000 eggs and reared up to 2,500 pounds of fish. Sales as high as $500 per year paid his expenses, allowing him to stock nearby streams and ponds, and left ample supply of fish for his own use.

The most notable of the trout breeding enterprises was started just before end of the Civil War in 1864 by Seth Green, with advice and assistance from Ainsworth. For $2, Green purchased a mill site near Caledonia, New York with a water supply of 150,000 gallons per minute. He created ponds by erecting barriers in the forebay (i.e., an artificial pool of water in front of a larger body of water) and millrace (the current of water that turns the water wheel), and captured brood fish from the creek. After one year of operation, he sold a half interest in his hatchery to A. S. Collins. Green's enterprise was immediate success. Green recognized Ainsworth for having shown the practicality of fish culture, but Green proved that trout fanning could be profitable.

Stephen H. Ainsworth (1809-1893). Ainsworth conceived the very ingenious plan of making trout spawn naturally, and at the same time of saving the eggs. This idea he carried out in what is now everywhere known as the Ainsworth Spawning Races.

While Green was eager to learn from of fish culturists, he was secretive about the details of his own operations, he was, however, willing to give lessons in fish culture for $10 per day. His profits were $1000 in 1865 and had increased to $10,000 by 1868 when he sold 800,000 eggs.

The imbalance between supply and demand for eggs, fry and food fish caused instability in market prices in 1868, just as it does today. The price of fish at the Fulton Fish Market in New York, for example, varied from $3.60 to $6/lb. Innovative fish culturists began to look for new market

Dr. Livingston Stone was born in Massachusetts in 1836, graduated from Harvard in 1857, entered Meadville Theological School, and was ordained a Unitarian Minister. In 1866 he resigned his clerical duties and began a career in fish culture. In

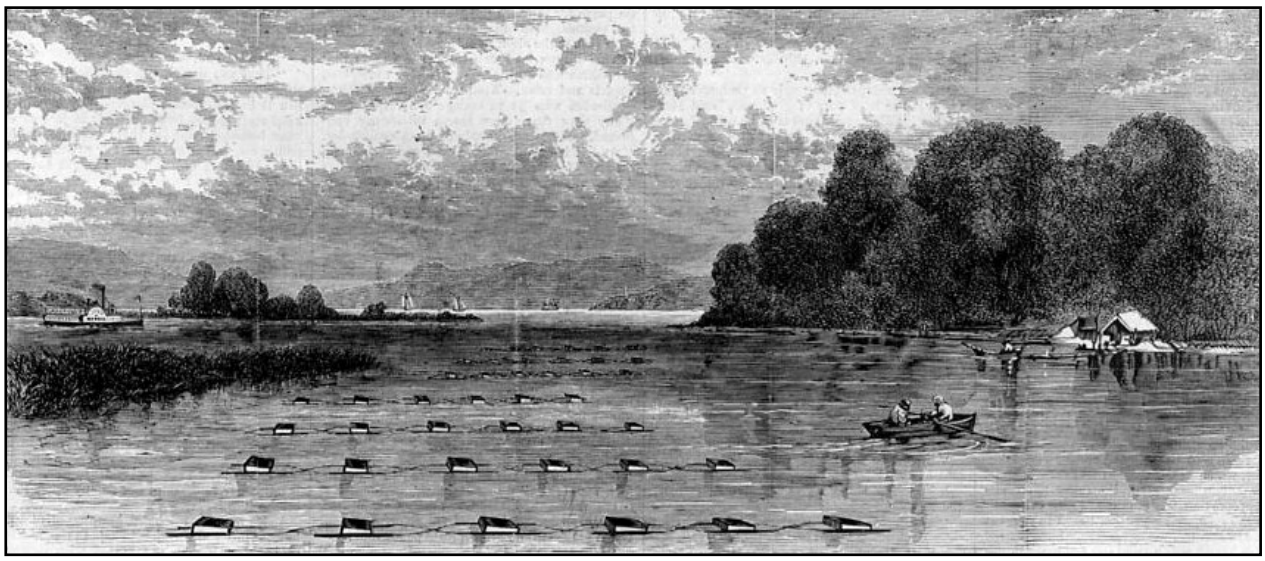
Livingston Stone (1836-1912).

1870, Dr. Stone was one of the founders of the American Fisheries Society, its first secretary and one of the drafters of its constitution. In 1872, he was named U.S. Deputy Fish Commissioner and assigned to establish the Baird Hatchery, the first Federal fresh water fish hatchery located in California. He published the classic fish culture book "Domesticated Trout" the same year and it soon became a standard manual for fish culture. In 1873, he was assigned the task of moving fish across the continent by railroad. In 1898, he was recognized as America's Senior Fish Culturist. Stone early on recognized the interaction between the biological science and fish culture and was the first to recommend and request a trained biologist for hatchery staff.

Stone created a new market when he began selling Atlantic salmon (*Salmo salar*) eggs and largemouth bass fry (*Micropterus salmoides*) for $50 per thousand. By 1870, the culture and sale of brook trout were well established, and six other species— Atlantic salmon, American shad (*Alosa sapidissima*), lake trout (*Salvelinus namaycush*), largemouth bass, lake whitefish (*Coregonus clupeaformis*), and yellow perch (*Perca flavescens*) were being cultured. Fish culture was primarily in the hands of about 200 private citizens until 1870 when it was practiced in 19 of the then 37 states, plus the territories of Colorado and Kansas.

During these early years, fish culturists were making observations and developing techniques that eventually evolved from an art to the science of aquaculture. It was soon recognized that the addition of ice to water extended the time during which live fish could be successfully transported. Seth Green was the first American to use the dry spawning technique (stripped eggs are emptied into a bowl which contains a quantity of water in the wet method; the bowl contains no water in the dry method, thus the eggs reside only in ovarian fluid after expulsion) with which he achieved a 75 to 98% fertilization compared with 25% when the eggs were manually stripped into running water. Although Green offered fish culture lessons, he attempted to keep the dry fertilization technique a trade secret from 1864 to 1879. This technique was the first significant contribution of Americans to the practice of fish culture (although today there is some controversy as to whether the eggs should be stripped dry or wet).

Other culturists soon began to add their refinements to the art of fish culture. Livingston Stone was apparently one of the first to combat fungal growth on eggs, doing so by charring the inside of wooden hatchery troughs. Seth Green painted his wooden egg troughs with asphalt to control fungus. Livingston Stone was also one of the first fish culturists to use salt as a therapeutic for fish. He found



Seth Green's Shad Hatchery on the Hudson.

that salt was useful in the control of fungus, the parasitic trematode *Gyrodactylus*, and the protozoan parasite *Trichodina.* Livingston Stone described a total of 23 diseases on the basis of their signs in fish and determined that the best way to control disease was to improve the environment. He was the first person in the U.S. to apply the scientific method to investigations in fish culture and used controlled experimentation to evaluate the effectiveness of treatments.

Even with Stone's contributions, fish culture in the early 20th century was not a glamorous business. The simple act of feeding fish was not simple; feeds had to be acquired, transported, prepared and delivered to the fish. Early feeds consisted of a wide variety of materials: raw or cooked fish; boiled lean meat; egg yolk; liver; clabbered milk (produced by allowing unpasteurized milk to turn sour at a specific humidity and temperature; over time, the milk thickens or curdles into a yogurt-like substance with a strong, sour flavor); a mixture of ground beef heart, liver, and lungs of beef and pork; and live minnows, worms, and insects (including maggots).

The end of the Civil War in 1865 and the return to a peacetime economy encouraged others to enter the fish breeding business, among them, the Rev. Livingston Stone, Thaddeus Norris and Samuel Wilmot. In 1866 Stone built a large hatchery at Charleston, New Hampshire where he intended to rear trout as a food item. Although the demand for trout eggs and young fish remained high, prices had became unstable by 1868 and he realized that the market would soon collapse. The market for table trout, on the other hand, remained strong and prices in the New York Fulton Fish Market varied from $0.75 to as high as $1.25 per pound. Stone also created a new market by selling Atlantic salmon eggs and bass fry for $50 per thousand.

In my book, *The Toy Fish* (Klee, 2014) I introduced in some detail Fred Mather, the Superintendent of Fish Culture for the New York Aquarium from 1876 to 1879. Henry Dennison Butler was its Superintendent at the time and a picture of the two of them together is shown on page 105. Fred Mather entered the field in 1868 when he purchased a farm near Honeoye Falls, N.Y. He attempted to obtain the advice of his neighbor, Seth Green, but with no success, and eventually learned fish culture by "many expensive experiments and mistakes." Although the most profitable part of trout farming at the time was the sale of eggs and fry, the competition of Green, the largest producer in the business, forced him to concentrate on the production of 8 to 10-inch table trout but the demand for eggs and small fish, created by others desiring to enter this high-profit business prevented him from raising many fish for the table. Mather's name will crop up again later in this essay. Prices per thousand for brook trout were: eggs $8-10, fingerlings $30-40 and 2-year-old fish $250(!). Table trout sold for $1 per pound, at a time when the going wage was $ 1 per day.

Frederick Mather (1833-1900), a founder of the American Fish Culturists' Association, Recording Secretary, 1883-1889, and Vice-President, 1882-1883.

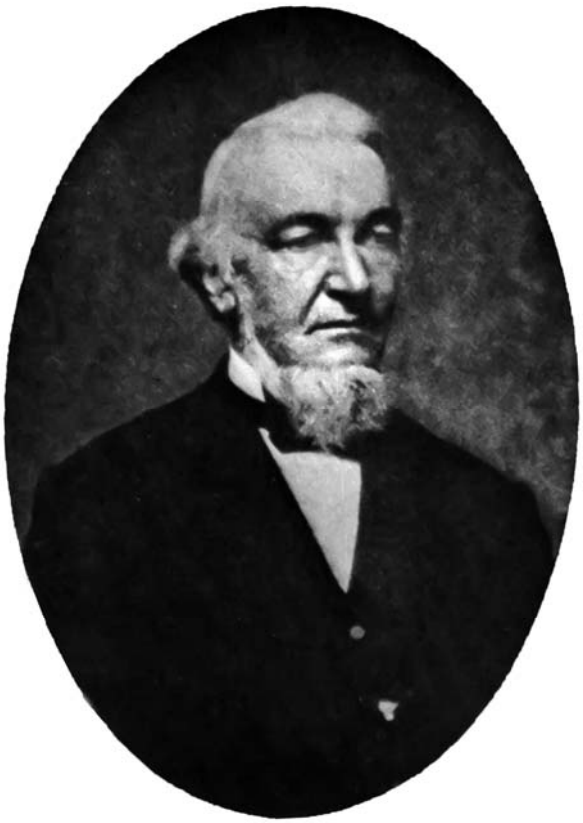
The Connecticut Fish Commission began a large program in 1869 to stock bass in many waters and by 1870 bass had been introduced into five New England states. Bass were transported in the water tank of a locomotive from the Ohio River to the canal basin at Cumberland, Md. in 1854, where they escaped into the Potomac River. Private citizens in Pennsylvania introduced bass into the Susquehanna River about 1869. Undoubtedly, the ease with which bass could be transported allowed innumerable transfers and introductions to lakes and rivers, and to ponds where they were extensively propagated for stocking elsewhere. Other fish introduced into new waters included the walleye, lake trout, brook trout, American eel, alewife, American smelt and lake whitefish.

ORIGIN OF THE AMERICAN FISH CULTURISTS' ASSOCIATION

The founders of American fish culture were, almost exclusively, wealthy and educated men. They could afford the time and expense to pursue what initially was a hobby, but what soon evolved into a lucrative business venture for a fortunate few. As the number of fish culture establishments increased, the highly profitable aspect of selling eggs and fingerling fish diminished. The first organized effort of the fish culturists was intended to protect the lucrative egg and fry market.

In 1870, the federal government was not involved in fish or fisheries, though in the northeastern states scientists and other citizens were expressing concern about the resource. (Their concern would result in federal action in 1871.) Although fish commissions had been established in some states, their financial appropriations were small and their activities largely regulatory. And in 1870, some 200 private persons were practicing fish culture, either as a business or as a hobby.

During the summer of 1870, the Rev. William Avery Clift (for more than a quarter of a century Clift was a regular contributor to the columns of *The American Agriculturist, The Country Gentlemen* and *The New England Farmer;* he introduced the Peking Duck to this country and promoted in many ways the interests of agriculture by introducing or developing improved breeds of sheep, cattle, poultry, fruits, etc. and was an active pioneer in the establishment of artificial fish hatcheries), Fred Mather and J. F. Slack corresponded with A. S. Collins, and Livingston Stone concerning the formation of an association to fix the prices of eggs and fish. Collins, as a partner of Seth Green, was not in favor of setting prices, since as the largest producer of trout eggs, their supply was excessive, and they were already cutting prices. But Collins favored the idea of an organization of fish culturists, as did Stone and Clift.



Reverend William Avery Clift (1817-1890), a founder and first president, 1870-1874, of the American Fish Culturists' Association, predecessor of the American Fisheries Society.

On November 1, 1870, a notice was printed in several eastern newspapers of a meeting of practical fish culturists to be held on December 20 in New York City under the sponsorship of Clift, Collins, Mather, Slack and Stone. The meeting took place in the New York Poultry Society rooms in New York City. Three others answered the call: Dr. M. C. Edmonds of the Vermont Fish Commission, Dr. J. D. Huntington, Watertown, N.Y., and B. F. Bowles, Springfield, Mass. The price of eggs was never discussed. Instead they unanimously resolved to form the American Fish Culturists' Association (AFCA) "to promote the cause of fish culture; to gather and diffuse information bearing upon its practical success; the interchange of friendly feeling and intercourse among the members of the association, the uniting and encouraging of the individual interest of fish culturists." A constitution was adopted, annual dues were set at $3 and officers were elected. On adjournment of the meeting they decided to meet again in Albany, N.Y., on February 7, 1872.

The new organization, eager to advance fishery knowledge, was receptive to suggestions from the interested public. Within a year a lively issue was raised by a "gentleman in St. Louis." He wrote to Livingston Stone, the Association's secretary, that in the course of his extended experience fishing in the southern, western and northwestern states, he had noticed confusion in fish names:

The black bass is called, in the southern states, a trout. The rock bass of the east is called a goggle-eye in the west. The silver perch of the south is called in Missouri a croppie, and in Kentucky by still another name. The pickerel of the north is called a jack in the south.

Stone and his colleagues recognized that ambiguity and confusion of fish names were inconvenient and objectionable. But because the custom was so deeply rooted they had little to suggest as a remedy. They were pessimistic about improvement which was long in coming. (When the confusion and ambiguity finally became too much to bear, the American Fisheries Society ultimately began standardization of the common names of fishes and, if not universally accepted, it is one of its notable achievements.)

The underlying intention of the founders of the American Fish Culturists' Association was to fix the prices of their products, but at the first annual meeting it became apparent that future efforts were to be directed towards the promotion of the public good rather than the furtherance of private interests. Motions to fix prices were made in 1875 and 1876, but neither carried. Fish culture alone was not the sole topic of discussion. At the third annual meeting James Worrall reported on his fishway investigations as Fish Commissioner of Pennsylvania, and Charles Hallock of New York spoke of the need for uniform laws to regulate the fisheries.

By 1875, the Association was showing concern about pollution. Frederick Mather, one of the founders, spoke to the annual meeting in New York City:

From all over the land there is a murmur of complaint about the pollution of our creeks and rivers by manufacturing companies, dye-

ing establishments, saw mills, and the like; and while the general Government, States and individuals are working to re-stock our nearly exhausted rivers, lake and streams, this pollution is allowed to go on unheeded and unchecked.

This subject is new to us, but is well worth our attention. So far, we have bent our energies to producing fish in vast numbers, with but little consideration of the many delicate conditions necessary to their future growth; and in my opinion, if the rivers were as pure to-day as when our forefathers landed on Plymouth Rock, there would be the same immense shoals of salmon, shad and alewives ascending our rivers that there were then, multiplied tenfold by our methods of artificial propagation.

The wide variety of subjects prompted the adoption of a motion in 1877 to organize the meeting into four sections:

1. Methods of Fish Culture and Apparatus
2. Fishery Laws and Fishways
3. Natural History and Aquaria
4. Fisheries

George Shepard Page was born in 1840 in Readfield, Maine. He returned east in the late 1870s where, being a gifted businessman, had a profound influence on the gas and oil industry in the United States during the 20 years he was involved in it. Through his involvement with the gas and coal industries and his activities on Wall Street, Page became a millionaire. Page was also a passionate sportsman. He was the founder of Quassaic Sportsmen's Club in his home state of Maine. He also started and maintained Dunrobin Kennels on his estate in New Jersey and could often be found hunting in the fields with his dogs. Page was a keen fisherman and for a time was president of the Chatham Fish and Game Protective Association and vice-president of the American Fish-Culturists Association. He worked for the protection and propagation of fish and was the main impetus behind the formation of the United States Fish Commission.

It was in fact Page's passion for fishing that led to his involvement with dogs. He was responsible for introducing black bass into England and received a gift of two Scottish Deerhounds from the Duke of Sutherland as a token of thanks. The hounds came from Dunrobin Castle in Scotland, hence the kennel name Page went on to use. He was one of the earliest Scottish Deerhound breeders in the United States.

Page was also a great proponent of education. He believed that public education should be non-sectarian, compulsory and free for every child. When he first moved to his home in Stanley, just outside of Chatham, New Jersey, he noticed the lack of a school and immediately founded one, hiring teachers and supplying materials. He went on to spend thousands of dollars to found a school

George Shepard Page (1840–1892), a member of the Society in 1872, Vice-President, 1874-1881 and 1883-1884, and President, 1882-1883).

for children of the poor. The National Education League of England even invited him to give a lecture on the free public school system of America. George Shepard Page died on March 28, 1892 of a heart attack in his home at the age of 52.

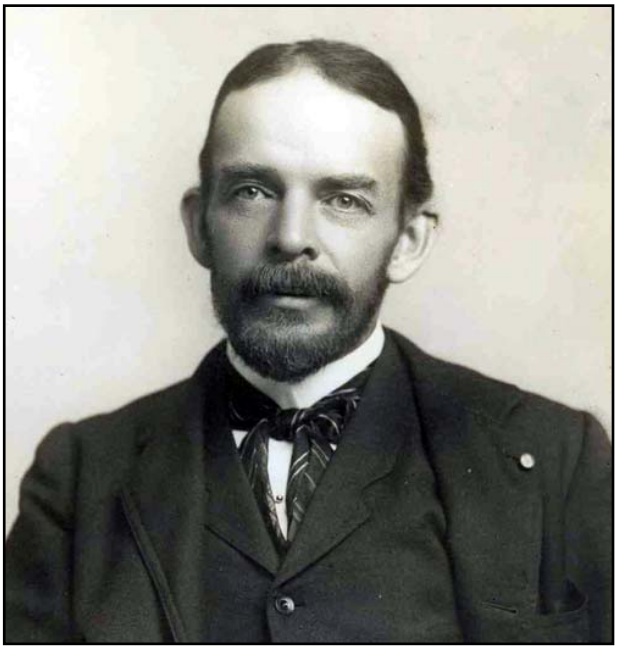
Page was a persistent advocate of broadening the scope of the American Fish Culturists' Association. As early as 1874, he was responsible for amending the constitution to allow "any person" instead of only "fish culturists" to join the Association. Four years later the name was changed to the American Fish-Cultural Association to indicate a broadened outlook. Page apparently was not satisfied with this name and in 1879 he prefaced a paper describing the ravaging destruction by wood boring mollusks with the following remarks.

The name of our Association indicates that its transactions refer solely to the increase of food fishes, and heretofore the papers and discussions have been confined almost exclusively to that department of science; but I have assumed that the information concerning the most destructive of marine animals, and practical appliances for preventing its ravages, would certainly be within our province. As the boundaries of our field of observation and inquiry must rapidly enlarge, permit me to suggest that a change be made in the designation of the Association. Would not "The American Fishery Society" be far more expressive and inclusive? This would correspond to the title of the greatest of the European associations, "The Deutscher Fisherei Verein" of Germany. I deem it of equal importance to instruct our fellow-citizens concerning the vast losses incurred by the unceasing ravages of the destructive denizens of fresh and salt water, as to enlighten them upon the subject of the best modes of propagating trout, bass, shad, and salmon, or restoring depleted public and private waters.

There had already been one change of Association name, though the change was scarcely noticeable. In 1878, the members voted to call themselves the American Fish-Cultural Association instead of the American Fish Culturists' Association. But the subject came up again, this time at the thirteenth annual meeting in 1884. G. Browne Goode proposed the name, the "American Fisheries Association," arguing a closer alignment with similarly named European fishery organizations.

George Brown Goode (1851-1896), was an ichthyologist. In 1872 he started working with Spencer Baird and soon became his trusted assistant. While working with Baird, Goode led research sponsored by the United States Fish Commission and oversaw many Smithsonian displays and exhibitions, for the museum itself and for expositions around the world. Goode effectively ran both the fish research program of the U.S. Fish Commission and the Smithsonian Institution from 1873 to 1887. He was the United States Commissioner for Fish and Fisheries from 1887 to 1888. He authored many books and monographs and wrote more than 100 scientific reports and notes.

After Goode made his proposal for a name change, the president submitted a general request



George Brown Goode (1851-1896).

for the opinions of the members. These opinions, together with a record of the action taken, are summarized as follows:

R. B. Roosevelt [Robert Barnwell Roosevelt, 1829-1906 - was the uncle of President Theodore Roosevelt and the grand uncle of Eleanor Roosevelt], New York Fish Commission, confessed surprise at the proposition to change the name. He did not agree that the proposed name conveyed the purpose of the organization and held that people would regard it as composed of fishermen. "'Fish-Cultural' is a better term. ... I cannot see how anything connected with the study of fish would not come within the limits of a Fish-Cultural Association. . . . The term 'Fisheries Association' would not definitely interpret the aims of this society."

W. M. Hudson, Connecticut Fish Commission, agreed in substance with Roosevelt, but reached an opposite conclusion. "All kinds of fish, lobsters and oysters are described; their anatomy and physiology discussed; their food investigated; their flesh analyzed, and their organizations compared with others. The term 'Fish-Cultural' in all the matters just alluded to cannot be strictly included, and for that reason I believe that 'Fisheries Association' would be more suitable."

R. F. Pike, Connecticut Fish Commission, said that strictly speaking, Professor Atwater's excellent paper ("The Chemical Composition and Nutritive Value of Our American Food Fishes and Invertebrates") would not have been appropriate before an association of persons devoted to cultivating and increasing food fishes. And yet it was one of the most acceptable papers, because the members of the Association have broader and more comprehensive views of the subject of fisheries.

S. G. Worth, North Carolina Fish Commission, stated that "We not only want to propagate fish, but to perfect the system of fishing, and the methods of preparing and marketing them; all of which have direct bearing upon the name by which our Association should be known. The proposed name should be broader and more comprehensive, but I am opposed to calling it The American Fisheries Association. I can suggest nothing better, but there must be some intermediate and appropriate name."

C. B. Evarts, Windsor, Vermont: I somewhat disagree with my friend Mr. Roosevelt. I suggest something covering the same idea, "The Fish Interest Association"—I don't know whether that would be intelligible or not.

L. Stone, U.S. Fish Commission: I think the considerations on both sides are of equal weight. Perhaps I am more sensitive because I drew up the constitution under the old name. If, however, the change is thought to be for the interests of the Society, I don't offer any

Robert Barnwell Roosevelt (1829-1906). He served as a Congressman from New York from 1871 to 1873, and as United States Minister to Netherlands 1888 to 1890. He was an uncle of President Theodore Roosevelt.

objection, but it would be a good plan to let the matter lie for a year, until we have given it more thought.

F. Mather, U.S. Fish Commission, proposed "a name that would embrace the whole purpose of the Association—perhaps The American, Fish, Fisheries, Oyster, Lobster, and Fish- Cultural Association. As a fish-culturist, I do not like to see the idea of fish-culture lost sight of or made to take second place. That was the main purpose of the Association at its birth, and I believe that Mr. Stone and I are the only two original members left. I agree with Mr. Stone's suggestion that the matter die for a year. I object to any change because we are well known by our old name."

T. N. Gill, George Washington University, thought Roosevelt had given a good argument for changing rather than keeping the name, and if the word "association" was retained the organization "would then be on a footing with the American Association for the Advancement of Science, and others."

Theodore Nicholas Gill (1837-1914) was an American ichthyologist, mammologist, malacologist and librarian at the Smithsonian and senior assistant to the Library of Congress, and professor of zoology at George Washington University

H. H. Cary, Georgia Fish Commission, proposed The American Fish-Cultural and Protective Association. "We need protection as much as anything else. There are as many poachers of fish as of game."

Professor Gill aptly summarized the discussion: "The furtherance of the fisheries is the object of this Association and fish-culture is simply a means by which this objective can be obtained. The work of this Association naturally includes a very wide field and the term 'fish-culture' is decidedly too narrow. It seems to me that, if it be desirable to have a name which is expressive of its present aims the American Fisheries Association is decidedly preferable."

Mr. Roosevelt: "I move that the subject lie over for a year, or until the next meeting of the Association."

The President: "Gentlemen, Are you ready for the question? The first vote will be on Mr. Roosevelt's amendment." This was taken and lost.

Mr. Roosevelt: "I recommend the word 'society' instead of 'association.'"

Professor Goode: "I accept this amendment, I and am willing that it should be called 'The American Fisheries Society.'"

The vote on the amendment was taken and it was carried. The name of the association thenceforth became "The American Fisheries Society."

In 1890, a proposal in Congress to change the organization of the U. S. Fish Commission and put its chief and employees under the Department

of Agriculture brought forth a protest by the Society's members at their meeting in May of that year at Put-In-Bay, Ohio. The legislation was described as "directly inimical and prejudicial to the progress and proper consummation of the original intent and present practical and efficient work of the Commission." In short, what the members feared was the possibility of appointments and dismissals of employees for political reasons. The members then voted not only to protest the legislation but also to urge senators and representatives to oppose and defeat such an "obnoxious enactment." The proposed bill was dropped.

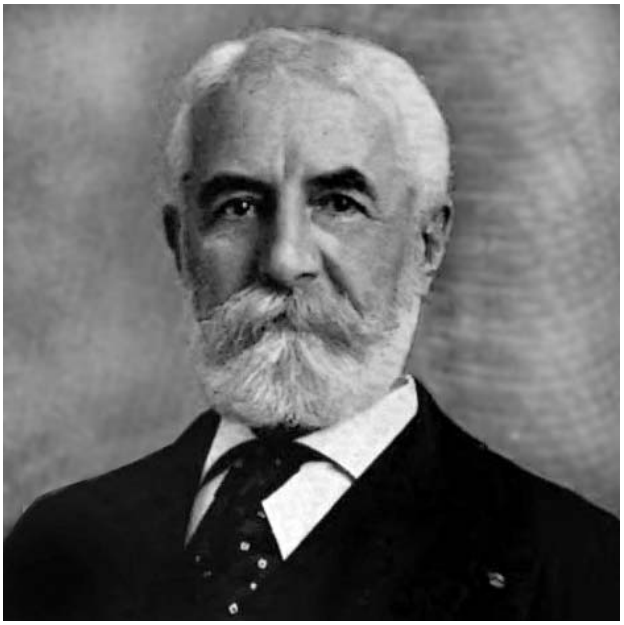
During this period, and perhaps for the first time involving fish and fishing, the subsequently recurring issue of states' rights was aired. Representative Oscar Lapham of Rhode Island had introduced a bill which, if passed, would have done what the Black Bass Act did later; prohibit interstate transport of fish taken in violation of state law. In addition, it would have imposed federal regulations on the mackerel and menhaden fisheries. According to discussion within the Society, a determined lobby was working to get the bill passed.

The stenographer recording testimony before the Merchant Marine and Fisheries Committee was an employee of an association working for passage of the bill, and was described as having been highly selective in transcription of the record. One argument for the bill was the "petty, local nature of these State regulations, conceived in ignorance and brought forth in prejudice. . . ." The concerted effort of certain Society members, with assistance of some state fish commissioners, killed the bill, principally on the grounds of unconstitutionality. There has never since been so close a contest for federal control of fisheries. Though the Lapham Bill itself did not provide for complete abrogation of state control, it seemed clear to many that it was intended as a first step toward nationalization. That first step, of course, was never taken.

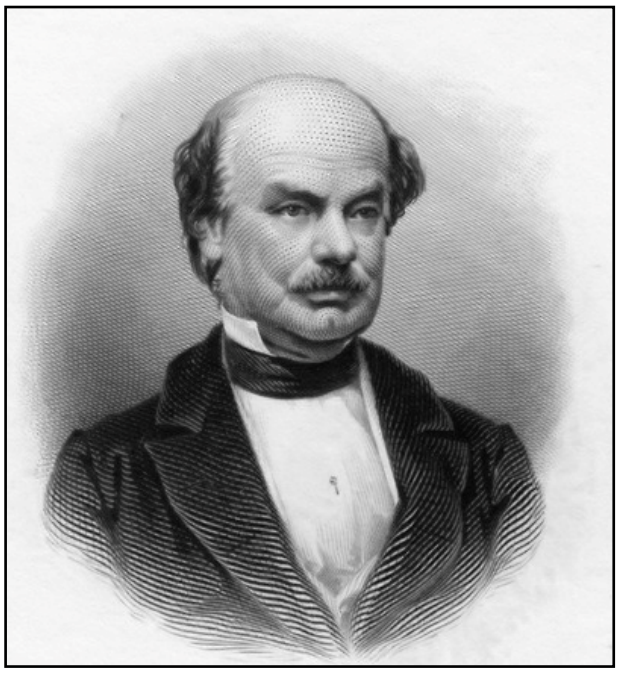
By the end of the Nineteenth Century the Society, though small in numbers, was influential out of all proportion to its size. It was the recognized spokesman for fishery scientists and technologists. It had created an impressive body of literature. It was internationally known and respected, and it helped bring about university instruction in fisheries to educate men and women for the profession.

ORIGIN OF THE U.S. FISH COMMISSION

Federal concern for fisheries originated through the efforts by the Department of State to protect American fishing rights in international waters. It evolved to preserve and maintain the fishery resources from natural and human depletion. Attempts to establish a federal fish culture program began in 1868 when a petition signed by Seth Green and Robert Barnwell Roosevelt of the New York Fish Commission, and F. E. Spinner, United States Treasurer, among many others, requested the Commissioner of Agriculture to apply to Congress for a modest appropriation for the propagation of shad. Green and Roosevelt as individuals



Oscar Lapham (1837-1926) was an American lawyer and politician from the U.S. state of Rhode Island. He served as a member of the Rhode Island Senate and the United States House of Representatives.



Francis E. Spinner (1802-1890) was Treasurer of the United States from 1861 to 1875. He was the first administrator in the federal government to employ women for clerical jobs and he, along with Seth Green and Robert Barnwell Roosevelt , signed the shad petition, the first Attempt to establish a federal fish culture program.

wrote the Commissioner of Agriculture explaining the conditions of the shad fisheries, and stating that if anything of importance was to be accomplished it must be done by the federal government. Also in 1868, the New York Fish Commission, recognizing that cooperation among the states was tantamount to each state solving its problems, called a convention of fish commissioners.

A resolution requesting protection through uniform laws and restoration through propagation was forwarded to the Commissioner of Agriculture by Chairman James Worrall of Pennsylvania. The report of the Commissioner of Agriculture for 1868 pointed out the need for joint state and federal action, but no appropriation materialized.

Had fish culture become a function of the Department of Agriculture, its status today would be altogether different. The result was a federal fish culture agency oriented toward natural resources rather than to the agricultural industry. The precedent was set for the stocking of public waters with fish produced by the government instead of fish purchased from private producers. On February 25, 1871, Ulysses S. Grant appointed Spencer Fullerton Baird as the first Commissioner of Fish and Fisheries for the United States Fish Commission. He would serve in this position until his death.

Already at the age of 27 Baird had an astonishing reputation as a scientist. He had collaborated with European scientists and was personally known and respected in all of the scientific centers in America. His writings were preeminent, and his knowledge of languages and the many fields of science made him respected as an editor. After a delay of three years, the request of Joseph Henry (the Secretary of the Smithsonian Institution) for Baird's appointment as Assistant Secretary was approved in July, 1850. His salary was $1,500, a

Spencer Fullerton Baird (1823-1887).

considerable improvement over the $400 per year he received Professor of Natural History at Dickinson College, Carlisle, Pa.

It had taken three years of active solicitation by Baird and the exertion of considerable influence on the part of a broad spectrum of American science for Baird to obtain a Smithsonian appointment, but it took him a mere 54 days to obtain the approval of both houses of Congress for a new government agency, the appropriation to carry out its programs, and his appointment as Commissioner. During the twenty years between the two appointments, Baird, the scientist, learned well the ways of Washington and the Congress, and became an effective politician in his own right.

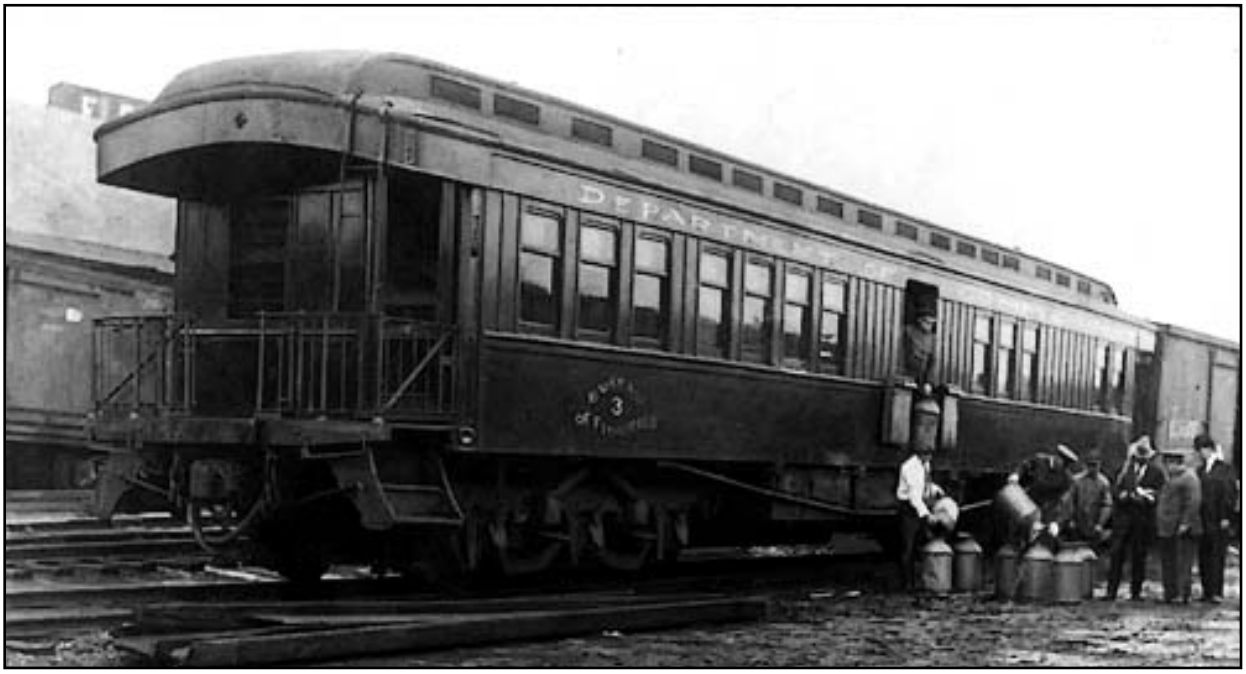
The establishment of the Fish Commission as a separate agency rather than as a part of the Smithsonian set the course of fishery conservation in the United States. As a part of the Smithsonian, the Commission would have been subject to Secretary Henry and dependent upon him for support. As head of an independent agency, Baird was free to lobby on its behalf and direct the course of its programs with no encumbrances other than the Congress.

As passed by Congress, the resolution contained four provisions.

A. The President, with the consent of the Senate, was required to appoint from among the employees of the Government a commissioner "of proved scientific and practical acquaintance with the fishes of the coast," to serve without salary.

B. The Commissioner's primary duty was "ascertaining whether any and what diminution in the number of food fishes of the coast and inland lakes had occurred" and to report to Congress necessary remedial measures to be adopted.

C. The heads of the executive departments were directed to provide "all necessary and practicable aid" to the Commission.



From 1881 to 1947, the U.S. Fish Commission delivered fish to private as well as public applicants throughout the United States on specially designed train cars like this one. The cars had water tanks, aeration devices, cooling systems, and bunks for the attendants, among other things.

D. The Commissioner was authorized to take fish from lakes and coastal waters, regardless of any state law.

The requirement that the Commissioner be a federal employee, experienced in the field of fisheries, was to assure that Baird would be appointed Commissioner. The experience requirement and provision for no salary was intended to prevent the position from becoming political in the future.

The investigation of the inland fisheries was not proposed by Baird, but was included because of the concern for the Great Lakes fisheries and to obtain the support of Midwestern Congressmen, including Senator Zachariah Chandler of Michigan, chairman of the Senate Commerce Committee. The ordering of the executive departments to provide assistance to the Commission was a deviation from the normal procedures of government. Baird fully intended to exploit this provision. He obtained the use of vessels and personnel from several services, and many installations were requested to collect oceanographic and meteorological data. This privilege has not been removed from the U.S. Statutes.

Baird's interest in the collections of the Smithsonian's National Museum of Natural History and his understanding of the required background information necessary to solve the fisheries problems are reflected in the final provision of the resolution which also remains on the U.S. Statutes. It was not his intention to become involved in a dispute with the states over the ownership of fish, but he believed that the Commission needed to function free of the impediments of state laws. Extensive collections of marine plant and animal life would be required adequately to study the ocean environment and enable the prescribing of measures to restore the fisheries; afterwards the collections would be deposited in the National Museum. Baird interpreted the phrase "fish or specimen thereof" to include specimens of any nature and made the most of the opportunity to enlarge the museum collection. The collection cost $4,000 to administer in 1871, but grew so extensively that $163,000 was required 16 years later.

The affairs of the Fish Commission received only a minor part of Baird's attention, particularly while he was director of the National Museum after 1872 and, concurrently, secretary of the Smithsonian after 1878. Outside of his "summer campaigns" to the New England Coast, he conducted affairs of the Commission in the evening hours at his residence in Washington, D.C. In 1875, George Brown Goode, assistant to Baird at the Smithsonian, began to handle most of the administrative affairs of the Commission.

With the new Commissioner in place, the Association sought the assistance of Congress to provide funds for the propagation and introduction of shad, salmon, and other valuable fishes through-

Botany students at Woods Hole, 1895.

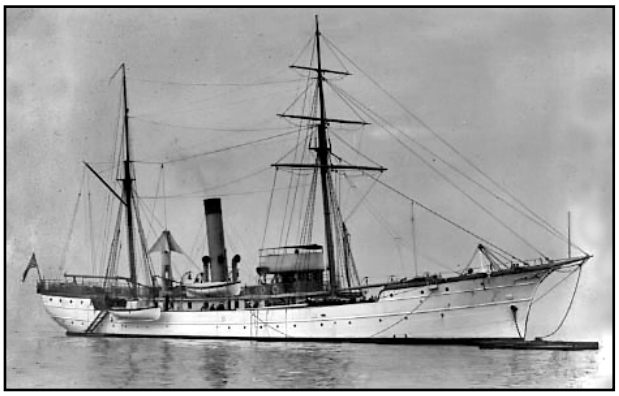
out the country. Congress appropriated $15,000 in 1872 to support these requests, and fish culture by the Federal Government began. Since the Federal Government had no fish culture facilities, The American Fish Culturists' Association asked that the funds be provided to private fish culturists Seth Green and William Clift so they could release shad in the Mississippi River and enlarge Clift's salmon hatchery on the Penobscot River in Maine. The Association also requested that the funds be used to support unspecified work by Livingston Stone on the Sacramento River.

Baird recognized the need for fishery research and established the first Federal fishery research program at Woods Hole, Massachusetts, in 1873. The research program was rather minor compared with the hatchery program and operated primarily during summer when university professors were available for field research. In 1877, David Starr Jordan, a student of Louis Agassiz, with the assistance of Charles H. Gilbert, conducted an extensive survey of the fishes of the Pacific Coast. Similar work was conducted with Commissioner Baird's support, but after his death in 1887, research by his agency received much less emphasis. From 1873 to 1885 the annual budget averaged $70,000 for propagation of fish at Woods Hole, but was less than $4000 for research. Advances in fish culture apparently stagnated even further after the reference book, “A Manual for Fish Culture,” was published by the Commission in 1897. The manual contained descriptions of culture techniques for more than 40 species or groups of finfish, plus lobsters, oysters, clams, and frogs; apparently, in the view of the Commission, it contained all the information needed by fish culturists. At the 1899 annual meeting of the American Fisheries Society, a criticism of the preoccupation with fish culture was made by Hermon C. Bumpus of Woods Hole. Discussing the rise of the U. S. Commission of Fish and Fisheries laboratory there, and its subsequent stagnation and deterioration following Commissioner Spencer Baird’s death, he said:

In the meantime the work of fish-hatching had continued, but only along the old lines and in the perfunctory way that prevails for those who take no vital interest in their work.

I believe that the history of the Woods Hole Station during its dark ages of scientific inactivity will be the history of every station and sub-station that attempts to confine its energies to the merely mechanical work of hatching fish. Close up your drafting room, and your machinist becomes a blacksmith; do away with your schools of design, and the standard of even your so-called practical builder is immediately lowered. More progress has been made in practical medicine during the past twenty-five years than during the previous centuries. Who shall say that the progress is not the direct result of laboratory activity and he application of the scientific method? The scientific and practical work of a fisheries station cannot be divorced.

In 1872, Baird approached Seth Green and W. Clift with respect to rearing shad. Green was really under the gun, as the shad spawning season in New York was about over. Clift, working farther north in Connecticut, where the spawning season began later in the year, had a bit more time. Both men were successful in their endeavors. Green hatched shad eggs for the states of New York and Vermont and provided 55,000 fry to the Commission. The Commission’s fish were stocked in the Allegheny River at Salamanca, New York, and in the Mississippi River near St. Paul, Minnesota.



U.S. Fish Commission Steamer Albatross.

Fish produced by Clift also ended up in the Allegheny River, as well as in the White River at Indianapolis, Indiana, and in the Platte River in Colorado.

The fish culture activities of the U.S. government had developed with amazing rapidity after the establishment of the Fish and Fisheries Commission. By 1874, the Commission was concentrating on shad, alewife, striped bass, salmon (both Atlantic and Pacific), whitefish, and carp. There was also activity with other species. For example. Fred Mather had collected eggs of the black sea bass and fertilized them (a storm terminated that particular experiment). Baird felt that the production and distribution of fish was of extreme importance. He was dedicated to getting the highest possible yields from the nation's waters.

Baird was deeply concerned over providing a source of food fish for the rural areas, particularly in the South where he envisioned that small ponds would provide needed sources of protein. He seriously considered the native species, especially catfish and buffalo fish, but experimentation with the indigenous species had scarcely begun, and rather than waiting until culture methods were available, he looked elsewhere. The culture of carp had been practiced for several hundred years and was a thriving food-producing industry in Europe and Asia. The fish was capable of rapid growth and tolerant of the wide range of environmental conditions found in the United States. Baird, in 1877, stated, "I fully believe that within ten years to come this fish will become, through the agency of the United States Fish Commission, widely known throughout the country and esteemed in proportion."

When he first took steps to propagate carp in 1875, the fish was already established in California and New York. Baird determined that these were either wild or scaled carp, and not the domesticated varieties which had been developed by generations of cultivation in Germany. After two unsuccessful attempts to transport carp to the United States, the German fish culturist Rudolph Hessel arrived at New York in May 1877 with a consignment of 227 leather and mirror carp and 118 scaled carp. Because the Commission lacked pond facilities, the fish were temporarily held at the Maryland state hatchery near Baltimore. Baird made another foray on Capitol Hill and obtained a special appropriation of $5,000 and authority to construct ponds on the grounds of the Washington Monument.

The carp program was modest in relation to the similar shad and salmon programs. Commissioner Baird had learned the value of having constituents request fish through their Congressman. In 1876, one year before the program started, Congressmen had forwarded 3 applications to the Commission; this increased to 20 in 1877 and to 98 in 1878. When the first distribution was made in 1879, the number of applications had reached 324; fish were supplied to applicants in 23 states, most receiving 20 fish. Consignments were also shipped to fish commissions in 9 states. The popularity of the program reached unexpected proportions in 1882 and in his report to Congress Baird took full advantage of it: "This distribution reached applicants in every state and territory in the United States except Montana. Fish were sent into 298 of the 301 Congressional districts and into 1,478 counties. The total number of applicants supplied was 9,872, the total number of fish

The Common Carp.

distributed, 259,000." The freight charge, generally less than $1, was paid by the applicant.

Rather than distributing fry, the Commission raised the fish to a length of 2 to 3 inches, thus greatly increasing their chance of survival. The fish were distributed in the fall when the weather was mild and losses during transit were minimized. Even though the Commission repeatedly warned that carp should not be stocked in waters containing existing populations of other fish, the enthusiasm of individuals and the U.S. and State Commissions saw to it that every body of water imaginable received its share of the young carp. As a result, the naturalization was quickly accomplished. However, early attempts to develop commercial carp culture failed because the fish had little demand in American markets and by 1883, some of the comments received by the Commission were critical of the program.

Thus started repeated attacks and spirited defenses of the introduced carp. As might be expected, the defenders were often representatives of the Commission. Their arguments were on economic grounds (the sales of carp in the big cities) and on angler preference in certain waters of certain sections of the country. There is no evidence, however, that a carp supporter ever converted an unbeliever! In any event, public enthusiasm turned to disapproval, and after 1890 the number of plantings declined and was discontinued in 1896. The success of the carp experiment was forgotten and the criticism of the fish became acute, with farmers, sportsmen and fishery biologists maligning the fish for displacing more desirable species from public waters.

With Baird as Commissioner, the commission sought opportunities to restock rivers with salmon and lakes with other food fish and the depletion of food fish in coastal waters. Baird reported that humans were the reason for the decline of food fish in these coastal areas as individuals with access to shoreline property were using weirs or nets to capture large amounts of fish on the coast, which threatened the supply of fish on the coast. He used the U.S. Fish Commission to limit this human impact through a compromise by prohibiting the capture of fish in traps from 6 pm on Fridays until 6 pm on Mondays. Baird was highly active in developing fishing and fishery policies for the United States, and was instrumental in making Woods Hole the research venue it is today.

Baird's vision with regard to Woods Hole was not fulfilled during his lifetime. To a large extent, this was due to an embarrassing dispute that began in 1885 when an official of the new Administration of Grover Cleveland charged that the Fish Commission's rather elaborate facilities at Woods Hole, which included a residence building and scientific laboratories, far exceeded the intent of Congress in making funds available for a ma-

The Interior of the U.S. Fish Commission's Central Station in Washington D.C. The jars in the background are hatching jars. for eggs. Fish and eggs from all over the world were collected and distributed from this room.

rine fish hatchery. Baird's friends in Congress soon forced this investigation to be dropped, but in the 2 years remaining in his life, Baird was very cautious about undertaking any activity that might be questioned, such as the establishment at Woods Hole of a summer university under the inspiration and guidance of a government agency.

However, a significant part of Baird's dream would be realized in 1888-89 when his long-time friend and summer laboratory associate, Alpheus Hyatt, took a leading role in establishing the Marine Biological Laboratory, an international center for research and education in biology, biomedicine and environmental science in Woods Hole. Although that institution was entirely separate from the Fish Commission, Hyatt suggested that the Marine Biological Laboratory was a direct outgrowth of Baird's educational schemes.

In looking back at Baird's stewardship of the Fish Commission through the first 16 years of its existence, one must be impressed by the continuities between the late Nineteenth Century and our own time. The issues that his agency addressed are familiar ones, including the dynamics of marine populations, efforts to maintain and enhance the productivity of commercial fisheries, direct aid to the fishing industry through improved techniques and exploratory fishing, and finally a vigorous program of basic research. But, in the largest context, Baird perhaps can best be remembered as one of the able institution builders of a century ago who recognized the essential need for universities, museums, and government agencies to support and encourage an American fisheries scientific community that was then in its infancy.

THE PRONUNCIATION OF SCIENTIFIC FISH NAMES

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, December 3, 2016)

Carl von Linné (Carolus Linnaeus) once said,

Nomina si nescis perit et cognitio rerum ("If you do not know the names of things, then the knowledge of them dies too").

The positive result of this dictum was that it simplified the naming of our fishes; The negative result was that it complicated pronouncing their names. Thus, aquarists tended to follow the advice of Julius Caesar,

Tamquam scopulum sic fugias inauditum atque insolens verbem ("You should avoid new and unusual words as you would the cliff's edge").

English (and most other Western-European languages) adopted many words from Latin and Greek throughout history because they - and especially Latin - were the Lingua Franca all through Antiquity, the Middle Ages, the Renaissance and later. In their own time, the classical versions of these languages were, like English today, international languages with a dominant effect on the educational systems and culture of the rest of their world. Just as it is hard to think of a world language today escaping at least some influence from English, so it is hard to think of any western European language that has evaded the influence of Latin and Greek at some time in its history. Remember that at some time in their past, all the modern Romance languages were Latin.

It is not correct to say that "English has both Latin and Greek origins." Origin means starting point and English has Germanic origins. However, English has many more words borrowed from Latin than have other Germanic languages, which it owes to the conquest of England by the Normans in the year 1066. A large percentage of English words have Norman French origins, which in turn had Latin origins. The Normans spoke Norman French, which was still much closer to Latin than modern French, especially in spelling. From then on, French was used as the language of administration for a while, and much of this was incorporated into English even as the influence of Norman culture in England waned.

About 80 percent of the entries in any English dictionary are borrowed, mainly from Latin. Over 60 percent of all English words have Greek or Latin roots. In the vocabulary of the sciences and technology, this figure rises to over 90 percent. About 10 percent of the Latin vocabulary has found its way directly into English without any intermediary.

Words of Greek origin have generally entered English in one of three ways: 1) indirectly by way of Latin, 2) borrowed directly from Greek writers, or 3) especially in the case of scientific terms, formed in modern times by combining Greek elements in new ways. The great majority of Greek and Latin borrowings into English date from after the year 1500. They are mostly "learned" or technical words, though many have languages began with the Renaissance and has continued ever since. Even today, Latin and Greek roots are the chief source for English words in science and technology.

THE ORIGINS OF THE ENGLISH LANGUAGE

The history of English is conventionally divided into three periods usually called Old English (or Anglo-Saxon), Middle English and Modern English. The earliest period begins with the migration of certain Germanic tribes from the continent to Britain in the fifth century AD (although no records of their language survive from before the seventh century) and it continues until the end of the eleventh century or a bit later. By that time

Latin, Old Norse (the language of the Viking invaders) and especially the Anglo-Norman French of the dominant class after the Norman Conquest in 1066 had begun to have a substantial impact on the lexicon, and the well-developed inflectional system that typifies the grammar of Old English had begun to break down.

The following brief sample of Old English prose illustrates several of the significant ways in which change has so transformed English that we must look carefully to find points of resemblance between the language of the tenth century and our own. It is taken from Aelfric's "Homily on St. Gregory the Great" and concerns the famous story of how that pope came to send missionaries to convert the Anglo-Saxons to Christianity after seeing Anglo-Saxon boys for sale as slaves in Rome:

Eft he axode, hu ðære ðeode nama wære þe hi of comon. Him wæs geandwyrd, þæt hi Angle genemnode wæron. Þa cwæð he, "Rihtlice hi sind Angle gehatene, for ðan ðe hi engla wlite habbað, and swilcum gedafenað þæt hi on heofonum engla geferan beon."

A few of these words will be recognized as identical in spelling with their modern equivalents - he, of, him, for, and, on - and the resemblance of a few others to familiar words may be guessed - nama to name, comon to come, wære to were, wæs to was - but only those who have made a special study of Old English will be able to read the passage with understanding. The sense of it is as follows:

Again he [St. Gregory] asked what might be the name of the people from which they came. It was answered to him that they were named Angles. Then he said, "Rightly are they called Angels because they have the beauty of angels, and it is fitting that such as they should be angels' companions in heaven."

The period of Middle English extends roughly from the twelfth century through the fifteenth. The influence of French (and Latin, often by way of French) upon the lexicon continued throughout this period, The loss of some inflections and the reduction of others (often to a final unstressed vowel spelled -e) accelerated and many changes took place within the phonological and grammatical systems of the language. The following typical prose passage is drawn from a work of the late fourteenth century called "Mandeville's Travels." In this extract Mandeville describes the land of Bactria, apparently not an altogether inviting place, as it is inhabited by "full yuele [evil] folk and full cruell."

In þat lond ben trees þat beren wolle, as þogh it were of scheep; whereof men maken clothes, and all þing þat may ben made of wolle. In þat contree ben many ipotaynes, þat dwellen som tyme in the water, and somtyme on the lond: and þei ben half man and half hors, as I haue seyd before; and þei eten men, whan þei may take hem. And þere ben ryueres and watres þat ben fulle byttere, þree sithes more þan is the water of the see.

Although may not have as foreign look to us as Aelfric's prose has, it will not be mistaken for contemporary writing either. However, the number of inflections for nouns, adjectives, and verbs has been greatly reduced in this example, and in most respects Mandeville is closer to Modern than to Old English.

The period of Modern English extends from the sixteenth century to our own day. The early part of this period saw the completion of a revolution in the phonology of English that had begun in late Middle English and that effectively redistributed the occurrence of the vowel sounds to something approximating their present pattern. (Mandeville's English would have sounded even less familiar to us than it looks.)

Although learning Latin and Greek might help you understand a lot of difficult English vocabulary, it has little or nothing to do with the origins and early development of the English language.

HOW DID LATIN BECOME SO IMPORTANT?

The Romans had a different attitude toward colonization and conquest than did the Greeks. The Greeks remained an international class of rulers, dominating trade; they were not averse to military conquest, but they did their best work as economic and cultural persuaders. The Romans had the conquer, dispossess, enslave and, if necessary, sow-their-fields-with-salt mentality. As the Romans conquered the Italian peninsula, Gaul (modern France), Iberia (Spain/ Portugal) and North Africa, they tended to take over from its previous dwellers, plant their own soldiers and colonists there and replace local cultures with their own. As a result, we know almost nothing of many pre-Roman languages from these areas, including Etruscan, Ibero-Celtic, and Carthaginian.

The one language that the Romans never uprooted was Greek, largely because Greek was more widely and better established, had a literary tradition that impressed the Romans and made them envious (in an emulating, not a destructive, way), and was circulated over a wide territory that was heavily populated, urban and economically developed. Even though the Romans conquered most of the former Greek empires - colonizing Egypt for example quite heavily - their Latin language was always an alien thing in the eastern Roman Empire. Hence the early association of Christianity in the first century AD was with a dialect of Greek, not with Latin. When the Roman Empire became officially Christian in the fourth century AD, Latin Christians became committed to the translation and preservation of Greek culture. (Greek Christians, naturally, just kept on preserving their own Greek tradition.)

Obviously Greek culture had a massive effect on Roman identity, but how much did the Greek language change Latin (or the precursor to Latin)? The answer is that it didn't. Resemblances between the Greek and Latin languages are cognate - that is, derived from a common (Indo-European) ancestor - and not the result of one language directly imitating the other.

Other than trivial ad hoc exceptions like loanwords (words adopted by the speakers of one language from a different language), there are two broad exceptions to note:

1. From the third century BC onwards, Roman poets started imitating the poetic rhythmic forms used in Greek poetry, and these eventually superseded native Roman poetic rhythmic forms altogether. In this way the quantitative nature of Greek language (i.e., their verse was composed of "feet," defined by short and long vowels, rather than by stressed and unstressed syllables as in English poetry) caused Roman poets to emphasize quantity in Latin in a way they would not otherwise have done.
2. Greek grammarians literally wrote the book on grammar, and Roman interest in the study of grammar was largely based on Greek models. As a result, the way the Romans conceptualized the formal properties of their own language (parts of speech, morphology, syntax, etc.) was based on categories that had been designed for the Greek language.

It should also be noted that the Ancient Greeks were the first to use a "true" alphabet, that is, one representing both vowels and consonants. Indeed, the word "alphabet" is formed of the first two letters of the Greek alphabet, "alpha" and "beta." Incidentally, the Greeks were equally conscious of the sound, pronunciation and diction of their words. This why the word symphony is spelled with an "m" instead of an "n." Syn, a prefix meaning united, acting or considered together, is the original spelling. But to the Greeks the "n" before the consonant "f" sounded cacophonous!

THE USE OF LATIN OVER THE YEARS

Latin evolved over the years into nine different periods, but only these last four are of significance for aquarists:

(a) **Medieval period (600-1300)**. Latin was used as an official written language in all West-European countries. Its vocabulary absorbed a lot of words from the local languages in order to meet the changed intellectual and social conditions.

Authors: mediaeval chroniclers and theologians as the Venerable Bede, Alcuin, Saxo Grammaticus, John of Salisbury, St. Thomas Aquinas and Pierre de Abellard.

(b) **Renaissance period (1300-1600)**. The humanists tried to revive the grammar and the vocabulary of the Classical Latin language.

Authors: Thomas More, Erasmus of Rotterdam, Giordano Bruno, Tomaso Campanella, Nicolau, Copernicus, some works of Dante Alighieri, Petrarca, Boccaccio.

(c) **New period (1600-1900)**. In this period Latin was gradually replaced in literature and administration by the modern national languages. It was used as an international diplomatic language till the 18th century and as a teaching language in the European universities till the late 19th century. A lot of scientists and philosophers continued publishing their works in Latin.

Authors: Hugo Grotius, Benedict de Spinoza, Francis Bacon, René Descartes, Pierre Gassendi, Thomas Hobbes, John Locke, Isaac Newton, Carolus Linnaeus, Mikhail Lomonosov, Immanuel Kant, Leonard Euler, etc.

(d) **Contemporary period (since 1900)**. Latin remained the official language of the Catholic church, though it was replaced in liturgy by the modern spoken languages. Together with Greek, it is the main source for creating scientific terms.

THE PRONUNCIATION OF LATIN

The pronunciation of Latin becomes much less puzzling once you realize that there are at least four rival ways of doing it. The pronunciations you hear in a biology or astronomy class don't match the ones you learned from your Latin teacher, and guess what? That doesn't mean they are wrong. They just reflect different periods in history. Here's an example of the four main methods using the name, Julius Caesar*:*

1. YOO-lee-us KYE-sahr (Classical Roman)
2. YOO-lee-us SAY-sahr (Continental Europe, France)
   YOO-lee-us (T)SAY-sahr (Continental Europe, Germany
3. YOO-lee-us CHAY-sahr (Church Latin in Italy)
4. JOO-lee-us SEE-zer (English method)

The Classical Roman pronunciation is of course what we use when teaching or seriously speaking Latin (see Appendix III). Its biggest peculiarities are that v is pronounced like English *w*, c like k and ae like English *ai* in *aisle*.

The Classical Roman pronunciation wasn't accurately reconstructed until about 1900. Before that, scholars in every European country pronounced Latin as if it were their own language (note how the French and Germans pronounced Caesar in the Continental Europe method above; the German pronunciation, by the way, is the one used in Old French).

Italian Church Latin is the form of the Latin language used in the Roman Rite of the Catholic Church for liturgical and other purposes. It is distinguished from Classical Latin by some lexical variations, a simplified syntax and Italianate pronunciation.. Italy is the country in which Rome lies, and Rome was the first capital of the empire and later became the center of the Church. Pronouncing Latin in the Italian way, therefore, is not difficult. Here is a list of the most important differences between the Italian and the classical pronunciations:

• the letter groups ae and oe are both pronounced like a long a;
• the vowel letter y (which in Latin only occurs in

Greek loans) is pronounced like a long e;
• the letter h is not pronounced at all;
• the combinations ci and cci and ce and cce are pronounced as the first sounds in chilly and check respectively;
• the combination ti before a vowel is pronounced [tsi], as in natio [natsio].

Hence the pronunciation of Caesar as CHAY-sahr . In his *Latin for all Occasions*, Henry Beard writes tongue in cheek:

If you [pronounce Caesar like CHAY-sah], you are going to take some flak from Latin purists, classics snobs, and other assorted lingo bores, but on the other hand, you're going to get a much better table in the Vatican restaurant.

On the revival of the study of the classics in England circa 1490, when every gentlemen was supposed to know Latin and Greek (in a verse eulogy prefixed to the First Folio, Ben Jonson famously wrote that William Shakespeare had "small Latin and less Greek"; in Appendix II, Innes left out some important details in this quote), the ordinary sounds of the letters as used in English were generally given in pronouncing Latin. No one, of course, claims that the sounds given by this method are the same as those given to the same letters by the Romans of Cicero's time, nor that by it alone an elegant or even a correct pronunciation of English can be acquired. There is no language whose pronunciation can be learned accurately by rule. English is particularly full of peculiarities and exceptions. In any event, the method conforms strictly to the rules of Latin in word structure, length of vowels (i.e., the perceived duration of a vowel sound) and accent, but uses the English sound values of the letters.

One place where this pronunciation is heard is in some of the Latin phrases that pepper legal and philosophical talk. If a case is adjourned indefinitely, the lawyers may say *sine die* (literally "without a day") and pronounce this expression something like **sign-ee dye-ee**. We also usually say *habeas corpus* with the first word sounding something like **hay-bee-ass**, and similarly in the case of *modus operandi* , well known to all lovers of detective fiction, as **mow-des oh-per-and-dye**. The logical terms *a priori* and *a fortiori* are usually pronounced with the first word like the name of the letter A and the last vowel like the word I.

The first person to write about the pronunciation of fish names - and it is based upon the English Method - was Judson Cole in an article, "Pronouncing Fish Names," that appeared in the 1934 issue of *Aquatic Life* (see Appendix I). The second was William T. Innis, two years later in 1936 in the First Edition of his book, *Exotic Aquarium Fishes (*see Appendix II).

Innes noted that it was English botanists who decided to modernize Latin and Greek names by giving these English pronunciations to the vowels but, at the same time, they devised a method of simultaneously indicating the vowels to be accented and whether those vowels take the long or short English sound. The system consists of the use of the French acute mark (′) over the vowel to indicate the short and the grave (`) mark to indicate the long sound. Innes followed this system and each of the species described in his book starts with the scientific name of the fish with these marks over the vowels. (These marks, which simply indicate vowel quantity, are called "macrons.") Thus all of the work had been done for aquarists. S*pléndopleùrus* is pronounced **splen'do-plew"riss** (where the single quote indicates the secondary accent and the double quote indicates the stronger accent) and one does not have to consult a Latin dictionary to find the vowel sounds and then consult rules to place the accents.

Innes claimed that this system had continued and was now in practically universal use in all works or books of science written in English. Unfortunately, however, this is misleading since the pronunciation of a fish name is generally found only

in its original description (and this sometimes a problem; in the Myers and Weitzman 1966 descriptions of *Sarcoglanis* and *Malacoglanis* in the *Journal of Zoology*, these marks are present but are over the Greek, not the Roman alphabet) and then not always (e.g., the description of the new species, *Rivulus degreefi*, in the *Journal of the American Killifish Association* for March/April 2016 lacks the pronunciation for *degreefi*, i.e., **deh-grayph'-eye**).

Innes never actually discussed the rules for placing the accents when vowels were long or short. This is important since the major problem most aquarists have with pronunciation is not with the sounds of the vowels (after all, Americans pronounce vowels differently according to where they live), but where to place the stress. He also omitted how the diphthongs were pronounced. Cole, however, did provide this rules and thus his explanation of pronunciation was superior to that given by Innes.

In Ray Cui's *Phonetica Latinae - How to pronounce Latin*, he writes:

There is a third pronunciation system, the so-call "Anglo-Saxon" pronunciation [Cui refers here to the English Method]. It is often abused among British and American scholars, and has remarkable (and in my opinion, bad) influences. Though about 70% of English vocabularies have Latin origins, the English Language belongs to a different linguistic family from Latin; thus they have completely different phonetic rules. Such pronunciation is definitely incorrect - not even close; thus this method should be prevented.

Cui overlooks the fact that a goodly number of local terms have found their way into scientific names; thus the English method is not the only one that encounters difficulties in pronunciation. In any event, choose the pronunciation system that suits you best. There are no Romans around to take issue with you. I personally use the English method for scientific names but when I am reading Latin (which I do out loud as did the Romans), I use the Classical Roman method.

A METHOD FOR PRONOUNCING SCIENTIFIC FISH NAMES

Lacking the kind of macrons that Innes provided in *Exotic Aquarium Fishes*, we have to start somewhere and I suggest first dividing a word into its syllables, a process called "syllabification." Seneca once said,

Longum est iter per praecepta, breve et efficax per exempla (" To learn by rules is a long road, by example a short and effective one").

Except in obvious diphthongs such as au, oe, ei and eu, every single vowel signals a separate syllable, as in English 'recipe' (three syllables).

Although the following rules - with examples - may look daunting, they usually pop into our heads naturally even if we did not know about them:

1. Two contiguous vowels or a vowel and a diphthong are separated: *Danio*, **Dan-i-o.**
2. A single consonant between two vowels goes with the second vowel: *Colisa***, Co-li-sa**.
3. When two or more consonants stand between two vowels, generally only the last consonant goes with the second vowel: *Girardinus***, Gir-ar-di-nus**
4. The so-called "mute plus liquid" pairs, br, bl, cr, cl, dr, gr, gl, pr, pi and tr are generally counted as single consonants and go with the following vowel: *Pseudotrophius*, **Pseu-do-tro-phi-us**.
5. Counted as single consonants are qu and the aspirates ch, ph, th, and should never be separated in syllabification: *Aphyosemion*, **Aph-y-o-se-me-on**.
6. The syllable is divided after the letter x: *Exodon*, **Ex-o-don**.

Since in Latin a word has as many syllables as it has vowels or diphthongs, this can be used as a first step in checking your syllabification. For example, *Aphyosemion* above has six vowels so its

syllabification is **Aph-y-o-se-me-on**.
With regard to accents, the distinction that will be observed here between syllable weight and vowel length, i.e. between metrically "heavy" and "light" syllables and naturally long and short vowels, is relatively recent. Older books use "long" and "short" indifferently for both syllables and vowels, thereby encouraging mispronunciation.

1. The accent is *never* on the last (ultimate) syllable.
2. The stress in words with two syllables almost always falls on the first syllable (the penultimate): *lèvis*, **lee"-vis**.
3. The stress in words of more than two syllables falls on the penultimate syllable if this is metrically "heavy" (i.e. contains a long vowel, a diphthong, or a vowel followed by two consonants), e.g. *pàleàtus*, **pay'-le-ay"-tus** and *Acánthophthálmus*, **A-kan'-thof-thal"-muss** (the short á at the end of the word is followed by the consonants l and m). It falls on the antepenultimate (third from last) syllable when the penultimate is metrically "light" (i.e. contains a short vowel before either another vowel or a single consonant), *plecóstómus*, **plah-cos"-tah-mus** (the short ó at the end of the word is followed by the single consonant m). This pair of rules is natural for English speakers.

Note A: For the purposes of syllable weight, x always counts as two consonants while qu always counts as a single consonant. (Strictly speaking, a syllable can be light even where it contains a short vowel that is followed by two consonants, provided that those two consonants are one of the so-called "mute plus liquid" pairs, br, bl, cr, cl, dr, gr, gl, pr, pi and tr. However, this is really a question of pronunciation; such syllables can be pronounced either **pay"-tris** or **pah"-tris**, tr making one sound.)

Note B: In a word of three or more syllables a second accent is placed on the second syllable before the principal accent, if that syllable is metrically heavy in quantity (e.g., *Cỳnolèbias* = **Sigh'-no-lee"-bee-as**), or is the first in the word; otherwise it is placed on the third syllable before the principal accent (e.g., *Pólycentrópsis* = **Pahl'-ee-sen-trop"-sis**).

With regard to pronunciation, a long y is pronounced like a long i. However, a short y poses pronunciation problems for English speakers and so it is often pronounced like a long e. *Cỳnolèbias* has the long i and *Pólycentrópsis* has the long e. For example, **Sigh'-no-lee"-be-as** and **Pah'-lee-sen-trop"-sis.**

A related problem involves the name *Bärbus*, meaning "with barbels." In the English system, the a should be pronounced as in hay if it is long or as in hat if it is short, making the pronunciation difficult for English speakers in either case. Innes was forced to define a "Broad ä as in bar," making the pronunciation of *Bärbus*, **Bar"-bus,** more easily pronounceable **(**similarly for *gorämy***, go-rah"-mee)**.

The problem now is that we may not know whether the penultimate syllable is short or long. To find out, it is necessary to consult a dictionary. What kind of dictionary? Well, an ordinary English dictionary will often do the job, although a Latin dictionary is also useful (commonly recommended is *Cassell's Latin English Dictionary* but I prefer the *Oxford Latin Desk Dictionary*). In *Cassell's Dictionary* it states that "where helpful," short vowels are indicated by a breve accent like ă and long vowels are indicated by a straight bar like ā. The *Oxford Latin Desk Dictionary* indicates only the long vowels (with a straight bar), so all of the unmarked vowels are to be assumed by the reader to be short. "Where helpful" is not really a helpful term; the method used in the *Oxford Latin Desk Dictionary* is much better as it leaves no doubt as to the sound of all of the vowels.

One should also not forget the Internet as another source for pronunciations. http://www.personal.psu.edu/staff/l/l/llb/PRIVATE/Verbword.htm, for

example, has a "Piscatorial Verbiphile Pronunciation List" that provides the correct syllabification and the primary accents.

An example is *Pántódon* so it is pronounced **Pan"-tah-dahn,** the accent on the first syllable (note that I sometimes disagree with Innes on his phonetic spelling of short vowels). However, The first step is to consult a dictionary for the suffix "panto" (I'll use my Collegiate Dictionary here). I find that both vowels are short and so using Rule 3 for accentuation (the ó is followed by a single consanant), its pronunciation and accentuation is as above.

Now let's try *Aphyosèmion*. The phonetic spelling with the accent is **Aff-ee-oh-see"-me-ahn**. Again, let's assume that we don't have this information. My Latin dictionaries tell me that in "semion" the e is long and the i is short (followed by a single consonant). As mentioned previously, the short i is frequently a problem in Latin and to ease pronunciation it is often pronounced like a long e. Its pronunciation and accentuation, therefore, is as above.

English speakers often have difficulty maintaining differences in vowel quality in unstressed syllables, where vowels tend to be reduced to a short indiscriminate sound often called a "schwa," and this is especially true when the vowels are short. A short e, for example, may sound like a short a or it may be indistinguishable. Thus, I wouldn't worry about the pronunciation of short vowels unless they are accented. I wouldn't worry about secondary accents either as they tend to come naturally. More important is to get the primary accent on the right syllable, along with the correct pronunciation of the vowel there, be it long or short.

THOSE PESKY PATRONYMS

According to the rules of the International Commission on Zoological Nomenclature (ICZN), species named in honor of people (patronyms) are pronounced as the person pronounces his or her name, and this causes the greatest amount of trouble in pronouncing scientific fish names.

A good example is *Mikrogeophagus ramirezi*. Ramírez is a Spanish surname meaning "son of Ramiro," and is the 9th most common name in Mexico. Its correct spelling in Spanish is with an acute accent on the i, which is often omitted in English writing. According to the ICZN rules, it should be pronounced **rah-meer"-ez-eye** but it is often corrupted into something like **ram-ah-reez"-ee**. Another well-known example is *Apistogramma agassizii*, named after Louis Agassiz of Harvard University, a Swiss-American biologist and geologist regarded as one of the greatest scientists of the 19th century. It should be pronounced **ag"-ah-see-ee-eye** but it is often corrupted into something like **ag-ah-see"-zee**.

The problem here is that we have to know how the person pronounced his name; there are no general rules for this as it depends upon the language used by the honoree. Either (1) the original describer of the species included its pronunciation, (2) the pronunciation is found in articles, etc., (3) the aquarist knows how the honoree pronounced his name (e.g., personal knowledge) or (4), our old friend once again, the Internet. The fourth way is usually the fastest and easiest. For example, take the species, *Julidochromis marlieri*. The species is named Georges Marlier (a Belgian ichthyologist) who pronounced his name **Mar-leh -ay";** so using the site: www.pronouncekiwi.com, the proper pronunciation is **mar-leh-ay"-eye** - not **mar"-ler-eye** or (cringe) **mal"-er-eye**.

Another example is *Apistogramma nijsseni*, named in honor of the highly respected Dutch ichthyologist Han Nijssen who pronounced his name **Nye"-szen**. So using the site www.pronouncekiwi.com again, Nijsseni is properly pronounced **nye"-szen-eye**.

Note that in these examples, save for *agassizii*, the patronym ends in a single i; in *agassizii* it

ends with a double-i, a real tongue-twister. The reason for this is a little complicated for those who are not familiar with Latin grammar but I present it here for the curious. The ICZN Code states that genitive case masculine gender patronyms may be formed in either of two ways: (1) By taking the stem, Latinizing it, and deriving the genitive case; the Code gives as an example, the name Cuvier, which is Latinized to Cuvierius, leading the genitive *cuvierii*; (2) By taking the personal name and merely adding *i*; the Code again gives as an example the name Cuvier, leading to *cuvieri*.

The Code also states that: "The original spelling of a species-group name formed under Subsections (i) or (ii) is to be preserved unless it is incorrect." This is further elaborated in Article 32(b), where it is stated that: "The original spelling of a name is the 'correct original spelling', to be preserved unaltered unless it is demonstrably incorrect as provided under Section (c) of this Article..."

There has been prolonged controversy over whether patronyms should have a single or double-*i* as a termination but as I have just shown, the International Code of Zoological Nomenclature clearly indicates that either a single or double -*i* is acceptable and also that the original spelling should be amended only if there are demonstrable errors. There is no scope for opinions on whether a particular author was or was not competent in Latin in determining the acceptability of original spellings of names. Therefore, we have to live with those double-*i* tongue-twisters!

If you are not satisfied with the English method and wish to use the examples used in this essay with their Classical pronunciation, all you have to do is to replace the sounds, nothing else: the vowels are the same as in modern Spanish or Italian, the diphthongs ae, oe, ei and au sound like eye, oy, ay and ow, respectively, and c is sounded like a k. There are relatively few complications. The gu group is pronounced gw: *lingua,* **leen"-gwah**. Similarly, the group qu is pronounced kw: *aqua*, ah"-kwa.

APPENDIX I

Judson Cole, "Pronouncing Fish Names," in *Aquatic Life*, September 1934.

The shark sucker, which uses the shark for a free taxi, is an impediment to the "taxis" comfort, so I'm told. From conversations with fish fanciers I find the proper pronunciation of the scientific names used for fish quite an impediment also, one as hard to shake off as is the hitch hiker on the shark. Eventually, when the method is determined the shark rids himself of the offender and it is possible for one to overcome the handicaps found in scientific nomenclature of fish once they are defined.

Fish names seem formidable for two reasons: first, they seem to have no reason to exist unless one is versed in at least the rudiments of foreign languages - alive and dead. Most of them, in defense, do have a meaning, changeable seemingly but more or less appropriate to the occasion. The second handicap - usually the stumbling block, is the uncertainty of proper pronunciation.

Scientific names, for the most part, are in Latin. If derived from some other language they are expressed in Latinized form. These then, for their proper pronunciation, depend greatly on their derivation, but the proper pronunciation of Latin, if at hand, will minimize the element of error which always creeps in at this point. The rules which apply in the matter are far more exhaustive in nature than a complete issue of AQUATIC LIFE. This being true we must seek some method, less complicated, to complete our purpose.

Some simple rules, of help, in pronouncing scientific names will suffice in the absence of a reliable information source on the subject. These are not offered to make one a complete specialist on the subject for, it is found that even they (the spe-

cialists), in a mixed audience, find themselves completely on edge because of the way in which their pronunciation is received by many of the company assembled. Fish culturists differ more on matters of nomenclature than on any other point.

Teachers claim there are three distinct methods of pronunciation applicable - all alternative. The Roman method, said to agree with that used by the ancient Romans, finds but little following among the English-speaking peoples because, it is said, we know not how they pronounced their words. In spite of this it has found some following in the schools and, to those who have studied this method, it presents a stumbling block when they attempt fish nomenclature.

The English method conforms strictly to the rules of Latin in word structure, length of vowels and accent but uses the English sound values of the letters. When, by this method, a good Latin scholar has determined the proper pronunciation of a word, we have something concrete to our purpose. Few of us have the privilege of such an authority to check our pronunciation.

The last method depends on the fact that many English words are from Latin derivatives, it regards the words as English and completely forgets the derivation and Latin rules. This is really the vernacular method, characteristic of a locality, and has its followers - who swear by a local pronunciation, regardless of how far wrong it may be. As an example take the word cichlid which in and around New York City is almost invariably, by dealer or fancier, pronounced as chichlid.

The English method, the one preferred by the majority, has each vowel or diphthong determine a syllable with all vowels pronounced which also includes the final one, a, i, or e. The final syllable is generally an inflective ending and needs distinct pronunciation to show grammatical construction, the vowel generally has an intermediate or even long value.

Long a is pronounced as in fate, short a as in fat. At times when preceded by r or h it takes the broad sound as in car. Final a has an intermediate sound while long e is pronounced as he while the short e is pronounced as get; long i as in mite; short i as in mit; long o as in note; short o as in not; long u as in dude; short u as in dun; long y as in type; short y as in lynch. The diphthongs, æ and œ are pronounced like the vowel e. [Author's Note: Cole overlooked another diphthong that crops up often in scientific names, i.e., ei, pronounced like "eye."]

Consonants generally are, sounded soft; r and g like in lice and girl before e, i and y and the diphthongs. Elsewhere their sound is hard like in can and gun. J an involvement of i used as a consonant is always troublesome . Sometimes it is used as alternate of y; at others the correct English pronunciation should be followed as in cognate words.

Ch, ph, th, ps are Greek derivations and cannot be separated in dividing a word into syllables. Ch is pronounced like k, ph like f, ps like s, while th is used the same as in English. Sch is pronounced scholar.

"The position of accent is complicated. The syllables of most importance are the penult or one preceding the last and antepenult or third from last. If the vowel in the penult is long the accent is taken by it, otherwise, it goes back to the antepenult.

More than two accents, in succession, are hard to pronounce. Therefore, a syllable near the beginning, in very long words, receives a secondary accent. A short vowel is indicated by an acute accent, a downward stroke from right to left, while a downward stroke from left to right, opposite from the above, is used to indicate a long vowel. These marks appear over the vowel.

In words from two derivations or roots, the connection is usually made by an o for sake of euphony. This connects the two by smooth transi-

tion when o is accented like in *Hyphessobrycon*. [Author's Note: In his description of *Hyphessobrycon*, Innes pronounced this as **Hy-fess'-o-bry"-kon** but allowed that **Hy-fess-ob"-re-kon** was admissible.)

Sometimes Latin gives undue importance to unimportant letters. This is found in personal names in which certain letters are silent. Less-objectionable is the case when the commemoratives are derived from personal names ending with a silent e.

While the above rules, not intended or proposed as complete, will not make one perfect in all pronunciation of fish names, they may well serve as a guide for a start which will make the names have a sonorous rhythm, both euphonious and attractive.

Much satisfaction will be derived from mastery thus far which will give impetus to still further study.

APPENDIX II

William T. Innes, "Pronunciation of the Scientific Names of Fishes," in *Exotic Aquarium Fishes*, 1936.

As "rare Ben Jonson" expressed it, most of us have "little Latin and less Greek," yet we aquarists would like to be able to acceptably pronounce the scientific names of our fishes.

We have therefore consulted leading scientists and scholars. In the main, all agree. The few differences of opinion occur principally as to which syllables in compound words take the accent.

Generally speaking, there is an accepted standard of pronunciation of scientific names. This, however, is not inflexible, nor without its exceptions. As with all languages, it is influenced by popular usage.

And now a word about the modern system. English botanists, so far as we can learn, were the first large group of scientists to address themselves seriously to this matter. Nearly a century ago they decided to modernize Latin and Greek names by giving English pronunciation to the vowels. At the same time they devised a method of simultaneously indicating the vowels to be accented and whether those vowels take the long or short English sound. The very simple system consists of the use of the French acute mark (′) over the vowel to indicate the short, and, the grave (`) to indicate the long sound. This system proved so satisfactory that it has continued and is now in practically universal use in all works or books of science written in English. The phonetic spellings, just below the marked titles, are for the benefit of those readers who have not acquainted themselves with the system of accents just referred to.

It will be noted that in the phonetic spellings, both single and double accents are used. The double mark shows which syllable takes the stronger accent.

The pronunciation of the vowels, long or short, according to the marks are as in the following words:

Long à as in hay; short á as in hat.
Broad ä as in bar.
Long è as in key; short é as in met.
Long ì as in tie; short í as in hit.
Long ò as in toe; short ó as in top.
Long ù as in cue; short ú as in nut.

Aquarists will be relieved to know that the consonants C and P queerly used in the beginning of such words as *Ctenobrycon, Ctenops* and *Pterophyllum* are silent. They represent Greek sounds which have no English equivalents.

APPENDIX III

Henry Beard, "A Brief Guide to Pronunciation," in *Latin for All Occasions*, 1990.

VOWELS AND A FEW DIPHTHONGS

A is pronounced "ah" as in "father."
E is pronounced "ay" as in "they," but the very common words et (and), est (is) and sed (but) should be pronounced like "bet," "best" and "said," and the very common word ending em should be pronounced like "stem."
I is pronounced "ee" as in "Vaseline," but the very common words id (it) and in (in, on) should be pronounced like "did" and "din."
O is pronounced "oh" as in "go."
U is pronounced "oo" as in "crude," but the very common word endings us and um should be pronounced like "puss" and "room" (with the "oo" sound of "cookbook"), and the very common word ut (how, so that) should be pronounced like "put."
AE is a diphthong (a pair of vowels joined together to form a single sound) pronounced "eye."
AU is a diphthong pronounced "ow," as in "luau."
OE is a diphthong pronounced "oy."

CONSONANTS

B, D, F, H, K, L, M, N, P and Z all sound the same as they do in English.
C always has a "K" sound as in "car."
Ch always has a "K" sound as in "chorus."
G always has a hard "G" sound as in "get."
Gu is pronounced "Gw" when it comes after an "n," as it is in English.
I is a consonant pronounced like "Y" when it is the first letter in a word and it is followed by a vowel. The common Latin word iam (now) is pronounced "YAHM."
Qu is pronounced "Kw," as it is in English.
R can be rolled in a sort of Scottish burr.
S always has a hissing sound as in "moose" or "soda," and some very common word endings sound like this: as = "demi- tasse"; es = "ace"; is = "geese"; os = "verbose"; and us = "wuss."
T always has a hard "T" sound as in "tar." In Latin, the word "ratio" is pronounced "RAH-tee-oh."
V is always pronounced as if it were a "W." What Caesar (KYE- sahr) said after he defeated somebody or other (veni, vidi, vici) sounded as if he had just conquered Hawaii: WAY-nee, WEE-dee, WEE-kee.
X is always pronounced "Ks."
J, W, and Y don't exist in Latin.

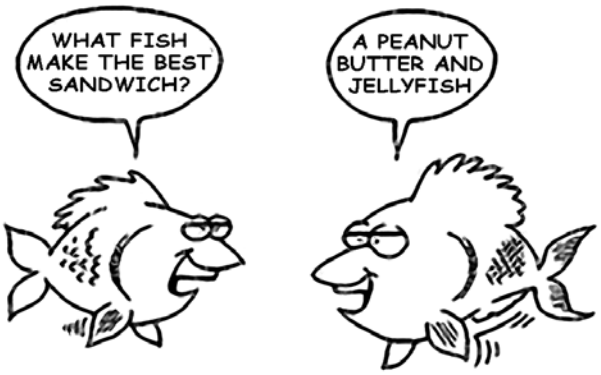
III SYLLABLES

Latin words are divided into syllables in the same way that English words are, but in Latin every vowel or dipthong is a syllable, and every syllable is pronounced separately. If there are two vowels together, and they are not AE, AU, or OE, both vowels are pronounced individually. So, for example, praebat = "PRYE-baht" (ae is a dipthong); speciem = "SPAY-kee-ehm"; and earn = "AY-ahm."

IV STRESS

If a word has two syllables, put the stress on the first one. If it has more than two, put the stress on the second-to-last syllable unless both the second-to-last syllable and the last syllable are vowels. When that happens, shift the stress back one syllable earlier. So, for example, locutionem = "loh-koo -tee-OH-nehm," but lo-cutio = "loh-KOO-tee-oh."

If the second-to-last syllable has an "i" in it and doesn't end in a consonant, the stress is usually moved back one syllable. So, for example, corrigant = "KOHR-ree-gahnt" and dificilissimum = "dee-fee-kee-LEESE-ee-muhm." For the same reason, the very common word aliqui (any) is pronounced "AH-lee-kwee."



A SHORT AUTOBIOGRAPHY

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, February 18, 2017)

Over the years I have had numerous chats with fellow aquarists, where their interest is primarily biographical, over my involvement with the hobby. Sometimes the information requested involved more than just the basic facts like education, work and relationships; sometimes what was asked involved my experience of these life events, including intimate details with an eye to gleaning something of my personality. This is understandable since, to most people, I am mostly a disembodied spirit. Sometimes I am surprised at what I am asked and at other times the tables are turned and they are surprised at what I deliver. This short autobiography, mostly limited to relevancies to the aquarium hobby but not entirely, is designed to fill those gaps not previously widely known.

EARLY YEARS

For starters, I was born on my Great-aunt's farm on January 4, 1929, located in the proverbial boondocks between Budd Lake and Hackettstown, New, Jersey. Although my parents, my brother and I lived in New City, we had stayed over at the farm over the Christmas Holidays when, after being snowed in, my mother went into labor. In those days doctors braved the snow, came to your house and delivered the baby, and this is what happened in my case. I mention this because for all of the years up to entering college, I spent the summers on my Great-aunt's farm where I learned about chickens and pigs (I know the difference between a Poland China and a New Hampshire Red, although I can't really say that information has been solicited much from me over the years) and growing vegetables and fruits. However, since my Great-aunt's farm abutted a forested area, I grew up with an appreciation of nature (and especially how to avoid stepping on copperheads in one's bare feet).

During my early school years we lived near a sound called Pelham Bay; it is not really a bay since it is open to larger bodies of water at both ends, opening onto Long Island Sound and City Island Harbor at the east. Here I collected various marine creatures, including *Fundulus heteroclitus* and other brackish water fishes. I also collected fishes in the Greater New York area such as Dace and small Sunfish, breeding some of them including Sticklebacks and four *Fundulus* species. They were kept in glass jars with no aeration, but water changes were frequent.

After moving back to the City, I once set up a regular tank in the living room at my father's request (he was to regret this later) and populated it with a few local fishes and a slew of tadpoles. One night the tadpoles hatched and jumped out from the uncovered tank onto the floor. Unfortunately, my father came out the next morning and stepped upon them in his bare feet. After picking pieces of frog from between his toes, the tank and

Albert J. Klee - Two Years Old.

all my animals (mostly fish, white rats and mice) were banished to a room in the basement. This was known locally as the "Great Bronx Rodent Migration of 1945."

This was a positive move for me since I could do pretty much what I pleased without my parent's knowing about it. In addition to biology I was also interested in chemistry and I conducted many admittedly dangerous experiments in that basement room. In those days it was easy - even for the youngster that I was - to obtain items like elemental phosphorus, elemental sodium and even potassium cyanide from the well-known chemical supplier, Eimer & Amend, which was then located at the corner of 18th Street and Third Avenue. With the phosphorus (which had to be kept in water) I generated phosphine, a deadly gas (but I burned it as it came out of my retort). The elemental sodium, on the other hand, had to be kept in kerosene. Since it would explode when it came into contact with water, it came in handy for practical jokes, like throwing a piece of it into a water puddle on the sidewalk as pedestrians were passing by. It was a miracle that I didn't burn down or explode the building or myself during these early years.

My last contact with Eimer & Amend came during World War II when my father asked me to procure a small glass still and condenser (legal at that time). During the war, booze was in short supply as distillers converted their production to industrial alcohol to aid in the manufacture of smokeless gun powder and synthetic rubber. My father got a mash going under his bed, using anything that could be fermented, such as raisins, prunes, carbohydrates, etc., and when the time came to distill out the alcohol, I set the whole thing up in the bathtub where there was a supply of running water for the condenser. Unfortunately we only had one bathtub in our apartment at the time, so a strict bath schedule for the four of us had to be adhered to before the process commenced. It is one thing to bum a cup of sugar from a neighbor and quite another to ask to use his bathtub, even though a clean neighbor is a good neighbor.

My interest in foreign languages started when I studied Latin at the Catholic grammar school I attended. Unfortunately, this loused up my classical pronunciation of that language for years afterwards, referring to Caesar rolls rather than Kaiser rolls. My parents were in the habit of speaking German when they did not want my brother or me to know what they were talking about. My Oma (Grandmother on my father's side) lived a block away from us and I visited her regularly and enjoyed hearing her tell me wonderful stories of the "old country." One day I complained about this situation with my folks and, with a smile on her face, said "Well, Albrecht, we must do something about that!" and undertook to teach me how to speak and understand German. I stopped by her apartment every day for lessons and this contin-

Albert J. Klee - Nine Years Old.

ued up to the time I entered High School. By that time I could understand everything my parents said in German, but I never led on that I could, and my Oma never let the katze out of the bag either. Later in life my father took my German accent to task, but I never had the heart to tell him that it was his own mother who taught me!

HIGH SCHOOL AND COLLEGE

At the time there were two prestigious High Schools in the City: Peter Stuyvesant and the Bronx High School of Science, admissions being determined by school grades, an entrance exam and whatever elixirs higher-ups used to make such decisions. I applied, passed the tests and became a Bronx High School of Science student where I majored in pranks. Once, for example, I exchanged the gas tube to the chemistry teacher's Bunsen burner with a tube leading to the water faucet. The bottom of a Bunsen burner has many holes in it for air, set out in a radial pattern, so when he turned it on the water not only got him but the first three rows of my fellow students as well. As an avid reader of detective stories I was never caught, as I knew the value of wearing gloves to conceal fingerprints. I should mention that my father was a great prankster, and drove my mother crazy sometimes with dribble glasses, hand buzzers and plastic flowers that squirted water when one was invited to smell them. This pretty much came to an end, however, when I began slipping exploding loads into his cigarettes. After putting out the fires in his eyebrows and preparing to remonstrate with a belt in his hand, I pointed out that I was just carrying out the old paternal family tradition and from then on, all was quiet on the domestic front

After graduating High School in 1946, I took the competitive admission test for the College of the City of New York and passed that one also, selecting as my major chemical engineering - no surprise there! In my sophomore year we had to take two "elimination" exams since the school's chemical engineering staff and labs could only accept a certain number of students; about 350

New York Public Library Main Reading Room.

students started out in this major but only 32 graduated. Chemical engineering was a five-year course there at the time but by going every summer and intersessions, it could be done in four; I graduated in four years, becoming the first one in my family to graduate from college.

Although the CCNY scholarship included all of my tuition - all I paid was a $5 fee each semester- it did not pay for books and although my family provided my room and board, I needed a source of extra income to make ends meet. In my sophomore year I learned that the main New York Public Library, located at the intersection of Fifth Avenue and 42nd Street (you know, the one with the lions in front of it), was hiring Pages to work the 5 PM to 10 PM shift in the stacks; I applied and was accepted. The library often refers to this as the "Day of Infamy."

The stacks were located below the main reading room (there were seven of them, plus two basement levels) and in the middle was a table where

One of the Library stacks.

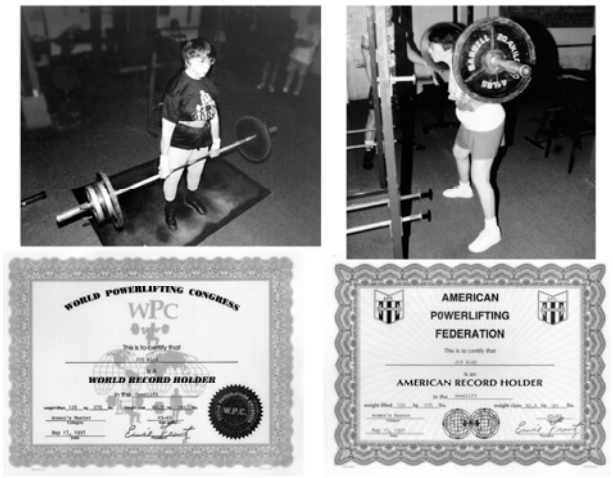
the Page (or Pages) sat waiting and a continuous vertical conveyor belt containing baskets in which books passed to and from the Main Reading Room. When a reader filled out a request slip, it was send down by a librarian to the proper stack through a pneumatic tube where a Page retrieved the books and sent them up to the Reading Room. The slips were time-stamped before they were sent down and also after the books were delivered. At about 9 PM the slips were sent down to Stack 6 where a librarian in charge of the Pages was situated and who averaged the times for each Page.

The lengths of these stacks were extensive and so I brought a pair of roller skates with me to the library one night and broke all records. The skates made a lot of noise over the tiled floors of the stacks, but I only used them when I was the only one assigned to a stack so I was never caught. I also played a lot of pranks while I was at the library, like putting together a false slip that would send a particularly obnoxious Page (he was pretty much of a bully, preying on smaller Pages) down into the bowels of the basement level to retrieve a pile of City Records that not only carried dust on them a quarter of an inch thick, but that weighed so much (each was about three feet in height) that they had to be carried on a cart to a special elevator.

The Page in question - proof that evolution can go in reverse - couldn't retaliate. As a favor to the boxing coach at CCNY (I was a member of the Boxing Club and had a long reach), I once was a sparring partner for Roland La Starza. (La Starza fought 66 professional bouts and won 57 of them, 27 by knockout. He may have come closer than any other boxer to defeating Rocky Marciano.) I had a little discussion with this Page in private and his bullying ceased.

Incidentally, I also did some track at CCNY (I was a miler) and was a member of the Wrestling Club in my freshman year. The latter was a disaster. Wrestlers typically are short and stocky and I was the opposite. As a consequence they would tie me in knots and I got tired of making impressions with my nose in the mats. Unlike Pinocchio whose nose kept getting longer, mine kept getting shorter.

Actually the real athlete in the family was my wife. In 1989 she and I were on an elephant traveling the mountain tops in the Golden Triangle between Thailand and Burma when the neck rope broke loose and the howdah rotated, throwing my wife and me onto the ground. I was stunned but otherwise OK, but my wife broke her left foot and left arm. It took me five days to get her back to the States where she was operated on. Afterwards she rehabilitated at a Sports Medicine center and when that was finished she was advised to continue her therapy at a regular gym. However, the only gym near us was one designed for young men in interested in powerlifting. We knew the coach and he let us use the facilities. The coach had her doing the standard bench presses, squat lifts and deadlifts and noticed she had a facility for the last. He entered her in a deadlift contest and, at age 62, she broke the State record, lifting 255 pounds. Over the next several years she continued to break national and world records in two different powerlifting organizations. Her last contest - at age 69 - she lifted 290 pounds (I have seen her do two replications of 305 pounds in the gym). Not bad for an English teacher!



My wife at work lifting iron at age 67.

Sorry for going off on a tangent (as I am a mathematician I could have gone off on a cosecant, but tangents are more comfortable). In any event, the job at the library was a Godsend for me since after 6 pm things were pretty quiet and I could study and write papers at the Page's desk for four hours each night without much interruption. Pages were paid double time on Saturdays and Sundays, and triple time on Holidays and I took advantage of these opportunities.

THE ORIGINS OF MY AQUARIUM HUMOR

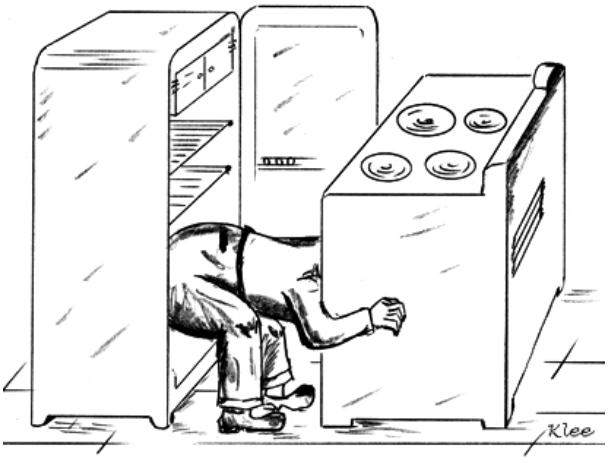
Incidentally, I mention these pranks to show the genesis of my passion for humor in one form or another, although after graduation from college it took a more literary and oral form than physical. Thus I started to inject humor into my aquarium writings and presentations to the extent that I became the hobby's first cartoonist, not that I was the first to draw an aquarium cartoon but the first to draw them (over 120) as a recognizable genre within the hobby. Over the years I have written more aquarium hobby satire than any aquarist living or dead (there are 23 of them in the Second Edition of *The Finny Bone*, satires that is, not expired aquarists). I have included four cartoons in this essay that I did when working for Proctor & Gamble as a statistician.

Sometimes my humor has unintended consequences, one example being my satire on the Yahoo site of the Aquarium Hobby Historical Society of America on the history of plastic bags in the hobby, which I attributed to one "Algernon Fiddle" in the late 1940's. This tale was received by the forum members with laughs but when I followed it up with Fiddle's exploits with undergravel filters, frameless aquariums and electric eels (I have combined these two posts on pages 45-46 of *The Finny Bone*), I got the following response from Alan Fletcher:

Enough fiddle faddle, already. It is getting to be difficult for those of us with only average intellect to distinguish between fact and fiction.

It turned out that Alan was under the mistaken impression that my first post about Fiddle involving plastic bags was a true story and after my second post, he really had trouble figuring out whether I was serious or not. Actually something similar happened to me with a humor column I wrote for the *Lorelei News*, a publication of the Homeowner's Association of Lake Lorelei, a gated community near Cincinnati, Ohio in which I lived. The following appeared in the November 1995 issue:

The Board of Trustees discussed the possibility at last Friday's Board meeting of making every Lorelei street whose name contains an umlaut, one-way. "Something has to be done to relieve the traffic congestion," said one Board member. "Last week a woman with a baby carriage had to wait 6 hours before she could find a break in the traffic to cross Lubeck Road. She was forced to flag down passing motorists and beg for Pampers, talcum powder, and other essentials." The audience in attendance at the meeting quickly arranged themselves into four camps, according to the direction the one-way streets should take. A scuffle broke out between the North/South and West/East groups, and was quelled only after the Lorelei constable resorted to Mace and playing old Lawrence Welk records, the latter quickly emptying the clubhouse.



Definition of a statistician:
On the average he feels just fine!

Unfortunately, one elderly resident of the community thought I was publicizing an actual meeting of the Board of Trustees and had a bout of apoplexy upon reading this, subsequently complaining loudly to the Board for contemplating the idea. I got into a little hot water over that one! In any event, Alan forgave me for fiddling with Fiddle and we have been close friends ever since.

My humor is not of the scathing type, but mostly a matter of satire or quips. The following is an example of the latter; it was sent to Gary Haas (Editor of *The Business Newsletter of the AKA*) just last week after I received his email informing me that I would be dropped from the AKA roster unless I paid my dues:

Gary:
I received your email informing me that my membership expired on 12/31/2015. Some years ago the BOT awarded me a Life Membership. Since I am still alive - barely - evidently I also expired on 12/31/2015. Please correct this paranormal data.
My best,
Al Klee

Gary liked my humor and so "What dreames may come, When we haue shufflel'd off this mortall coile, Must giue vs pawse."

HOW I GOT INTO THE HOBBY

Stack 2 in the Library contained mostly technical books, including those that covered the biological sciences. There were not many calls for books from this section in the late evenings nor was I usually assigned to this stack, presumably because the Librarian wanted to keep a close eye on me to forestall pranks that he suspected I was the mastermind of (I preferred to think of them as "excursions into corporeal humor").

All things were quiet for a few weeks on the prank battlefield so, to my surprise, one evening I was assigned to Stack 2. Things were slow on this stack so I browsed among the books and soon encountered shelve after shelve of books about the aquarium (the New York Public Library at the time was the second largest public library in the United States, and fourth largest in the world). Most of these were in English, a few in German and a smattering of other languages. I saw pictures of Plecostomus and other strange-looking fishes, and also pictures of freshwater fishes sporting fantastic colors, notably killifishes and cichlids, and I marveled that they could be and had been kept in a home aquarium.

I was hooked! I immediately scoured the main fish stores in New York City, looking for some of these fishes and I was successful in obtaining Corydoras, *Apistogramma agassizii*, *Aphyosemion bivittatum* and others that I set up in several aquariums in my room at home. In my spare time at the library I wended my way down to Stack 2, and over time read almost every aquarium book the Library had. During my last two years in college and during the

Albert J. Klee, 1950.

two years that followed, I kept every sort of fish imaginable and by the time I went into the Army in 1952 during the Korean War, I had amassed over 90 tanks in the top floor and in the basement of the house in Cincinnati I had rented after graduation.

During this time I wrote three articles that were published in *The Aquarium*: "Carbon Dioxide in the Aquarium (January 1951), "Geography and Science of the Fundulopanchax Group (December 1951) and "The Fleischmann Aquarium in Cincinnati" (August 1952). Regarding the last, early on I had become a consultant to the Fleischmann Aquarium and in 1952 at the request of the Cincinnati Zoo, I provided them with a formula for artificial sea water. The Zoo had this made up by a commercial chemist and, in order to defray costs, marketed it publically under the name of "Marine Mix," thus being the first artificial sea water mix on the market in this country. I was off to a good start!

THE WAR YEARS

After I was drafted during the Korean War in May 1952, later that year I was assigned to the Officer Candidate School (OCS) in Ft. Riley, Kansas where I was to spend the next 22 weeks. Ft. Riley was in the middle of nowhere and on weekends I was pretty lonely, the only one writing to me at the time being my mother. However, while working as a page at the New York Library, I'd met an assistant stack chief I'd never seen before. Her name was Joy and she worked the day shift so for one hour each day - from 5 to 6 PM - she was my boss. She was an English Literature major with a minor in German at NYU and, since I was a technical type, on the surface it would seem that we had little in common. However, we talked a lot and as the floors were made of marble and hard on the feet, we usually took them off when not retrieving books for the top floor reading room. Thus, I was in the habit of stealing her shoes with her chasing me all over the stack to get them back! A few months later, Joy's parents moved to Lynn, Massachusetts and she followed, transferring to Boston University, and that was that.

At Fort Riley the idea popped into my head that I would write to her, asking how she was and what she was doing. I didn't know whether she was married or going with someone, and the only address I had was her name and her parent's home town of Lynn with no street address. I sent the letter off knowing that it was a snowball's chance in hell that it would ever get to her. Wonder among wonders, her folks finally got the letter (they had moved from Massachusetts to White Plains, New York during this time; God bless the U. S. Post Office!) and forwarded it to her in Mackinaw City, Michigan where she was teaching high school. It turned out that she was neither married nor seeing anyone and, from then on, the letters between us began in earnest, every other day at a minimum.

This went on for two months. Well, I knew what she looked like, I knew something about her personality and she sure could write great letters. So in a moment when I had gathered all of my courage, I proposed by mail. Bear in mind that this was to a woman that I had not seen in five years,

Lt. Albert J. Klee, Company Commander, 501st Chemical Depot Co. Ft. McClellan, Anniston, Alabama.

never had a date with and never even got close enough to for a peck on the cheek!

You can imagine how I was feeling, awaiting her rely. I was lucky I wasn't getting gigged right and left (gigs were demerit marks in OCS) since I hardly knew what I was doing in class or out. Her reply came and I was stunned by her answer. She told me that she had fallen in love with me the day we met and told her mother that "Today I met the man I'm going to marry." In short, her answer was "YES! and this month we will have been married for 63 years.

We decided that she would not renew her contract with her school but would move east to stay with her Grandmother in Jersey City, New Jersey (just across the river from New York City) to be nearer her parents while we hammered out the details of when and how we were getting married. In the meantime, she needed a job and she got one - you guessed it - at the main New York Public Library, this time as a librarian! Incidentally, while she was there she met Ida May Mellen before I did.

My wife had a great influence on me. Among other things, I read all of her college books and discussed English literature with her. She had studied Latin, French and Spanish and, as I have noted, majored in German. Many years later she met Franz Werner in Chicago at an American Killifish Association and I remember Franz clicking his heels together exclaiming "Gnädige Frau!" as I introduced her to him. He was as pleased as all get out when she spoke German with him and had no trouble when *Nothobranchius* and *Aphyosemion* were dropped into the conversation.

So due to my wife, I read Beowulf, Chaucer, Dante, Boccaccio, Aristophanes, Schiller and a host of others I never would have approached on my own, getting a liberal education in the bargain. Furthermore, during the first twenty years of writing about aquarium hobby topics, she edited them or made suggestions before I sent them off to be published; I learned a lot from her about editing as well.

POST-ARMY YEARS

After getting married and being mustered out of the Chemical Corps in 1954 (and glad to say goodbye to handling mustard and nerve gases - I still have the scar on my left arm from a mustard gas - actually a liquid -burn), I secured a summer internship with the Socony Mobil Oil Company in their lube oil refinery in Paulsboro, New Jersey, just across the river from Philadelphia. This filled up the time until, taking advantage of the GI Bill of Rights, I started on my Ph.D. in Chemical Engineering at New York University's uptown campus. I had also secured a Student Assistantship to the Chairman of the Chemical Engineering Department. My wife and I had rented the upstairs of a house in Hillside, New Jersey where she had taken a job as an English teacher in their High School. I had a long bus/subway ride each day to get to school but my thesis advisor was Dr. Robert E. Treybal, one of the country's foremost experts in mass-transfer operations.

During my time at New York University I met

Albert and Joy Klee wedding picture, 1954.

many old-timers in the aquarium hobby such as Hugo Schnell, Aaron Dvoskin and Richard Büttner. Rosario LaCorte lived in Elizabeth, the next town down from Hillside, so we visited him and took a tour through his famous fish room. While at New York University I wrote an article on metals in the aquarium and submitted it to the *Tropical Fish Hobbyist* (TFH) magazine. After several months without receiving even a simple acknowledgement, I submitted it to the *Aquarium Journal* whose editor, James Crawford, immediately informed me that it would be published. The article appeared in the February 1955 issue of the *Journal* but unfortunately it – much to my astonishment – also appeared in the same month in TFH. After this experience I swore that I would never again submit any material to TFH while Herbert R. Axelrod was either its editor or publisher, and I never did. It was, however, the start of a long association with the *Aquarium Journal* and a close friendship with its editor.

When I was about 80% through my first year at NYU my wife became pregnant. I had to find the courses with which to finish with a Master's degree rather than the doctorate I had planned and also to find a job. Unfortunately this was at the end of June and there were no chemical engineering courses scheduled for the summer. I did discover that the Biochemistry Department offered an intensive 6-credit course during the months of July and August (8 hours a day, 5 days a week for two months). This fitted in perfectly with the job I had obtained with the Atomic Energy Commission in Cincinnati where I was due to report in September. The problem was in securing permission to do this.

The Biochemistry Department was OK with it if I could secure the OK from the Engineering Department, the Engineering Department was OK with it if I could secure the OK from the Head of the Chemical Engineering Department, and the Head of the Chemical Engineering Department was OK with it if I could secure the OK from Dr. Treybal, the head of my Doctoral Committee. Treybal was OK with it but there was a catch; I first had to secure the OK from the Head of the Chemical Engineering Department. I was stuck in an endless loop! Having nothing to lose (I figured if they ever caught up with me I would long since be gone), I told the Head of the Chemical Engineering Department that Dr. Treybal had approved it and then worked my way backwards reporting approvals along the way and the loop was broken.

The next two months were pretty rough on me, not really having the necessary prerequisites for the course, but I made it and received my Master's degree in absentia. Treybal thought that the work I had done on my thesis was publishable and together we wrote a paper using my results. It was published in the December 1956 issue of the *Journal of the American Institute of Chemical Engineering* ("Rate of Rise or Fall of Liquid Drops"). Years later, when my son was a chemical engineering student at the University of Cincinnati, I was amazed to find that this paper was the basis for a required experiment in its chemical engineering laboratory. He in effect had to duplicate the results I had discovered twenty years earlier! My son was pretty proud of me and his instructor also was surprised when he learned that the paper was written by the father of one of his students.

"I've got a little data I'd like you to look at!"

THE WRITING YEARS

During the two decades of the 1960s and 1970s I wrote over 600 articles for various aquarium magazines, including *The Aquarium Journal, The Aquarium, All-Pets Magazine, Tropicals Magazine, The Aquarist, Pet Shop Management, Aquarium Illustrated, Killie Notes* and the *Journal of the American Killifish Association* - this does not count the many articles published in foreign magazines - and I was an editor in some capacity of most of them. The bulk of this material - almost 1,000 pages - can be found in the two volumes of my *Anthologica Aquatica* and need not be examined in any further detail. I would, however, like to make some generalizations about this material.

These articles covered a range of topics never equaled before by any other aquarist, dead or alive. I do not claim that my articles were of any particular excellence, just that they were different. They included beginner's topics to those bordering on (or even including) ichthyological material. They also included statistically-based experiments on various fishes, descriptions of old and new species, diseases, nomenclature, travel, collection and water analyses in foreign countries, building of specialized testing equipment such as conductivity, humor, book reviews, genetics, aquarium shop management and history. Some of the topics were unique, such picking pairs of fishes using probability, inducing spawning using the urine of a pregnant woman or introducing aquarists to the word "floccinaucinihilipilificator."

To this end I learned to read and write a number of different languages in addition to the Latin, German and Spanish I already knew; these included Dutch, Danish, Swedish Italian, French and Portuguese. At one time I subscribed to 15 different aquarium magazines in these languages. (I have had formal study in all but Dutch, Danish and Swedish; these I picked up on my own). Thus I have long been interested in linguistics and etymology. In addition to the above, I subscribed to many scientific journals that were of some relevance to the aquarium hobby.

THIS MATTER OF DEGREES

Much to my amusement, I have been known as an amasser of college degrees, but that was not my intention. I have already described my first three - Bachelor of Chemical Engineering, Master of Chemical Engineering and Master of Business Administration - and there is nothing unusual about that. However, the GI Bill allowed for three years at the University level but I had only done two years for the Chemical Engineering and Business Administration degrees, and I wanted to fully utilize all three years. The only way I could do that working full time in Cincinnati was to defer putting in my request for graduation and to continue to take courses. This went along for about two more years, but the Dean of the Graduate School of Business was worried that the school would get into trouble with the Veteran's Administration and kept pressing me to put in my graduation request papers. Finally, he couldn't stand it anymore and put in the papers for me and I graduated with one credit less than two years of full time study (59 credits versus the standard 30 credits). Although I was disappointed, the truth of the matter was that I had difficulty finding any more courses at the University; I had taken almost all of them!

Albert and Joy Klee, 1980.
These were my handlebar mustache days!

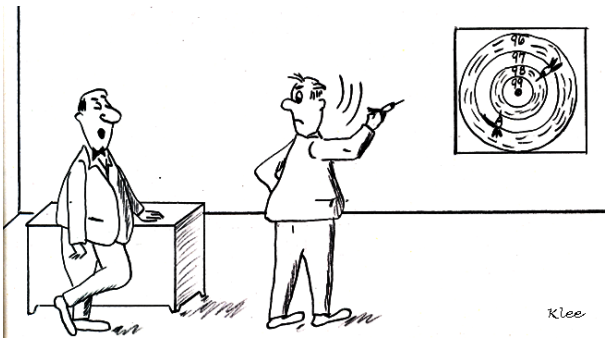
While at NYU a fellow student had introduced me to statistics, in particular least squares curve-fitting, which I used in my thesis. I was the first to use statistics at this level in the Department of Chemical Engineering and it fostered my interest in the subject, leading me to read quite a few statistics books on experimental design and regression analysis. These, however, were "cookbooks" and I had trouble understanding the theory behind them. Nevertheless, while working for the Atomic Energy Commission, I taught my fellow engineers how to plan experiments and fit data to curves, becoming well-known for this, even giving courses at work on these subjects.

Unfortunately for me, I accidentally ingested some uranium oxide while pelletizing the powder. This was to be the feed for a moving bed pilot reactor that was designed to replace the obsolete rotating kiln process used at the time for converting the oxide to the fluoride. This showed up in the urine analysis we had to take each month and I was permanently banned from any work in the plant that involved uranium or its salts.

While I was twiddling my fingers doing some esoteric experiments on fluidized bed reactors in the engineering lab, I was approached by the Plant's Chief Statistician, a good friend of mine. He had just lost his last statistician and offered me the job. This would really be a major career change for me and I had doubts that I could do the job, although he seemed to think I could. I really didn't want the job and so looked for a way to turn him down without hurting his feelings. I devised a plan around a counteroffer that I was sure the company would never accept, i.e., that (1) they would give me time off from work to take a Master's degree in pure mathematics, (2) that they would pay the tuition and the costs of the books required, and (3) that they also would pay me my full salary during this time. Much to my astonishment, they agreed and I picked up degree number four! With this background, I had no difficulty later when things with the AEC slowed down, in obtaining a job with Proctor and Gamble.

I worked at Proctor and Gamble for four years before taking a position with the United States Health Department in the Bureau of Solid Waste Management as a statistician and later as an Operations Research analyst. It was the custom at the Bureau that every year they would send two of their young engineers back to school for one year, and from this they often returned with a Master's degree. One year I criticized this choice, pointing out that the young engineers had just graduated from school and that it was the older engineers that they should be sending back. They compromised and decided to send off one young engineer and one old engineer. I was surprised, to say the least, when the "old" engineer they selected was me (I was in my early forties)! However, I thought it was a good idea since I was getting into more and more areas that needed some academic tweaking, so I planned to take courses at the University of Cincinnati in social psychology, systems analysis and economics. There was no intent for another degree, just coursework relevant to my job.

While at the University of Cincinnati and getting used to being in a classroom again, I recalled a fellow chemical engineer at one of my prior jobs recounting his experiences in going to the highly-ranked Salmon P. Chase Law School in downtown Cincinnati. The school offered a six-year evening program, which lead to a Juris Doctor degree. This provided him with a supplemental income that he practiced out of his home. Xavier University at the time was hosting a sort of law school jamboree where various law schools - in-



"So this is our new random sampling plan, eh, Gridley?"

cluding Chase - discussed their own schools. After these presentations, rooms were made available where interested parties could speak to representatives from specific schools. I attended the one for Chase and was convinced that it was worth a try. I forked over the $20 needed for the LSAT, a half-day, standardized test administered four times each year at designated testing centers and one of them was the University of Cincinnati.

After finishing my first quarter at UC, I found myself one cold December day trudging along the almost deserted campus to the building where the test was to be administered. Along the way I met Dr. Albert J. Simone (almost the same name as mine!), a noted decision scientist and Chairman of the Department of Quantitative Analysis who I had known for several years from various scientific meetings I had attended in the Cincinnati area. Simone immediately tried to talk me out of it, saying that he had a better plan.

The new Chancellor of the University was Warren Bennis, a well-known management expert and proponent of the change agent theory of leadership (a change agent is a person from inside or outside an organization who helps it transform itself by focusing on such matters as organizational effectiveness, improvement and development). Bennis and Simone had put their heads together and had come up with a new kind of degree, i.e., an interdisciplinary doctorate. The idea was to pick three very different areas of study and justify how the degree would be applied in practice. I was very enthusiastic about the concept, having been an interdisciplinary practitioner most of my professional life (my title when I retired from the U.S. Environmental Agency was "Senior Science Advisor"). I signed up and discarded the law school idea, although having paid my $20 I did take the LSAT. (I passed and wrote an apologetic letter to Chase.)

The three areas I picked were Quantitative Analysis as the major (Departments such as these are commonly known as Systems Analysis or Operations Research), Economics (the Economics Department devised a special concentration for me they called "Mathematical Economics") and Political Science, the last two as minors. The Political Science may sound odd but the only class course I took in that department was Comparative Public Administration, which compared government service in various countries and obviously was relevant to my work. The majority of my courses in that department were reading courses, mostly in management theory and also in the statistics unique to public opinion sampling, a special interest of mine. (A reading course is where one meets regularly with a faculty member and discusses assignments made the previous session; since one is quizzed each meeting on the material, one really has to study in these kinds of courses.)

I was forty-one when I started the program, much older than the other students in Quantitative Analysis. Also, I had worked for many years in a research capacity and had many published papers in engineering and scientific journals under my belt, more so in fact than any of my professors. Classwork, therefore, was easy for me and I had the habit of finishing every midterm and final examination much faster than my fellow students. The standard test time at UC was one hour and 15 minutes, and I usually finished in 20 minutes. Thus I acquired a reputation with the faculty as one unlike any other student but I had a lot of fun

Here I am, analyzing fish habitat waters in Columbia, 1966.

in the process. One time after I took an exam in linear programming, the instructor told me that for the first time another student got a higher mark than I did; he got a 98 and I got a 95. When I asked how long he took, he replied "one hour and 15 minutes." I reminded him that I took my usual 20 minutes and he laughed. That was the sort of relationship I had with the faculty.

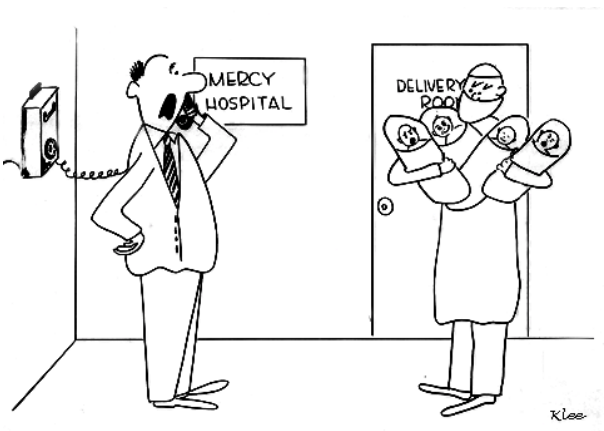
Over time, this even got to be a sort of friendly contest between the faculty and me. On my comprehensive examinations I came across a question in the quantitative analysis section that I'd never encountered before. I solved it with a somewhat obscure technique that I learned during my Master's degree work in pure math and finished the other questions concerned with my two minors. After two weeks and not having heard whether I passed the comps or not, I ask one of the younger fellows on my doctoral committee what was taking so long. He told me that the committee had put their heads together to try to find a question that would stump me, hence the odd question on the exam. Unfortunately, no one on the committee knew the answer and they had spent the time arguing over whether I was right or wrong. They never could decide, so they passed me.

Another incident happened during the oral defense of my dissertation, "Biased estimation as a solution to the multicollinearity problem in multiple linear regression." Doctoral orals are the most brutal of all examinations but I was not particularly concerned because I figured, "who would know more about this topic than I do?" Now for the past year I had been taking a readings course in advanced econometrics and one of the minor things my instructor and I discussed was a certain unsolved problem in the field. We frequently returned to it because by this time, the instructor and I were good friends. The problem interested the both of us and we enjoyed talking together about it.. Neither of us, however, had come up with a solution.

Imagine my astonishment when, after finishing my presentation and ready for the expected grilling, he stood up and presented me with the problem and asked for an answer. I was dumfounded and didn't know what to do since the question had nothing to do with my dissertation. I remembered an old Toastmaster's ploy used when one got an unexpected question and needed time to answer - slowly repeat it or, if one was available, write it on the blackboard. As I was writing it, however, the gleam of an idea came into my mind and when I had finished writing the statement of the problem on the blackboard (I had taken my time) the answer just popped into my head! I suppose it wasn't that unexpected since I had been thinking about it for a year. In any event, Simone jumped out of his seat and yelled, "I told you he could do it!" Yep, the committee had once again deliberately thrown in an irrelevant question to see what I would do.

I finished my dissertation in seven months, the minimum allowable by University rules. The problem then was, since this was an interdisciplinary degree, which of the schools would award the degree? The University mulled this over for a few months and finally decided that it would be the School of Arts and Sciences. I finally got to add a bit of color (orange) to my graduation robes!

I tell this story of my experiences with this degree because the degree was unusual (six tried it but



"Hello Sam? About those probabilities we were discussing a while back…"

only two finished; a Korean exchange student and I) and I thought it might be interesting to readers. It was not meant to show that I was smarter than the average bear by any means. After all, I was older than any of the faculty involved and had twenty years of experience in the real world.

In the introduction to my dissertation I thanked many people, including my wife, to whom I promised this would be my last degree. However, I held Adjunct Associate Professorship rank at both Xavier University and the University of Cincinnati so I was able to take courses at no cost to myself. I took advantage of this and acquired enough language credits for two additional Master's degrees, but in keeping my promise to my wife, I never bothered making it official. I, by the way, never audited a course in my life; they all were for credit. I felt that if I audited a course, I would not apply myself as diligently and would therefore learn less.

AQUARIUM HOBBY HISTORY

I became interested in aquarium history in the early 1950's. However, one doesn't jump into inventing a new genre without doing a ton of research, and this took some years before I felt that I was ready to write about the subject. In the meantime, what did appear in the aquarium magazines almost always concerned goldfish history, only a small portion of the complete picture.

Over a period of close to ten years I amassed a collection of aquarium books and magazines. This was a time when few showed any interest in the subject, save for my good friend, Dr. James W. Atz, the Curator and Dean Bibliographer of the Department of Ichthyology of The American Museum of Natural History. Accordingly, he had a unique opportunity to review the entire literature of ichthyology, including a good many aquarium references as well. Jim loved aquarium history as well as I did and - along with Lee Finley - and I consider these two the most accomplished aquarium historians I have ever known.

Some years before I started writing my history of the aquarium hobby in America, Jim had planned to write such an account and as a title he had intended to use *The Toy Fish*, a term introduced into the hobby by Ida May Mellen over 70 years previously. Because it evoked a certain charm and enchantment that reflected the period covered by my history, without knowing about Jim's plans I used it in the title of my book, *The Toy Fish, A History of the Aquarium Hobby in America - The First One-hundred Years.*

During this time, my work with the U.S. Public Health Service made it necessary for me to travel extensively in the United States and Canada. In every city and town I set foot in, I visited as many book stores - old, new and antique - that I could. In this way I built up quite a collection without spending much money or encountering any real competition with other aquarists. Using the Union List of Periodicals, I tracked down and obtained microfilm of old aquarium magazines that resided in libraries all over the country. Through various sources I also obtained originals of magazines such as *The Aquarium, the Home Aquarium Bulletin, Aquatic Life* and many others.

Dr. Albert J. Klee, Graduation, 1974.

I started writing my history in 1960 but delayed publishing it since I became busy in founding - with Bob Criger - the American Killifish Association and later on in planning, editing and writing for the *Aquarium Illustrated* magazine. (I won't mention the AKA in this essay any further since I have documented my involvement in great detail elsewhere.) The first of what was to become a series was published in the January-February 1964 issue of that magazine under the title, "A History of the Aquarium Hobby in America," and this was continued for a total of eight episodes, the last appearing in the March-April 1965 issue when publication ceased. In November of 1967 I assumed the position of Editor of *The Aquarium*, and in the December issue started the series all over again, finishing the series with the 22nd episode in the September 1969 issue.

Some years later, I gave Ross Socolof my permission to reprint pro bono the history series for the American Cichlid Association, and this was published in 1987. The price of the book was $35 and it sold out in about 90 days, garnering over $7,000 for the ACA. Lee and Aline Finley (mostly Aline) did the physical typing and Lee did the layout. (A minor matter: In their introductory notes they unfortunately erroneously cited the dates of publication of the material in Aquarium Illustrated; for the record I have given the correct dates above.) Ross handled all the printing, binding, sales, mailing and distribution. He also did the cover that contained the caricature of Guy D. Jordan, to whom the book was dedicated.

AQUARIUM HOBBY HISTORY IN EARNEST

After my tenure as Editor of *The Aquarium* - the last issue I edited was December 1971 - I pretty much dropped out of the aquarium hobby to finish my Ph.D., but not completely. I wrote a seven-part article on the guppy in the *Aquarium News* in 1977, an article on the genus *Rivulus* for the *Journal of the American Killifish Association* (JAKA) in 1982, a two-part article on the meaning of "killifish" in JAKA in 1983 and an article on the history of the American Killifish Association in JAKA in 1990.

During this time, however, I was working behind the scenes on a new edition and by 2002 it was completed. I approached the Chairman of the Board of Trustees of the American Killifish Association with the idea of doing with the AKA what had been done with the American Cichlid Association. While this was being discussed, however, Lee Finley wrote to me suggesting that I write a new version, offering to publish it and shouldering all the financial risks. Since this book would be a much more expensive undertaking than the American Cichlid Association version, I decided not to expose the AKA to such a gamble and the book, now titled *The Toy Fish, A History of the Aquarium Hobby in America - The First One-hundred Years*, was published under the aegis of Finley Aquatic Books. For marketing reasons, Lee called it a "Revised & Expanded Edition" but it was, in effect, the second edition of the work. Here I did almost everything: writing it, preparing the layout, providing the captions for the illustrations and preparing the images for publication. My wife helped immensely by editing the text. The book has since gone through two additional editions since and, comparing the Fourth Edition

The largest poisonous snake in the Western Hemisphere, the Bushmaster (*Lachesis muta*), I discovered it in the Peruvian Amazon and brought back to the Cincinnati Zoo in 1964.

with the Second, we have 435/203 pages, 516/ 242 illustrations, 321/119 bibliographic entries and 208,276/75,062 words.

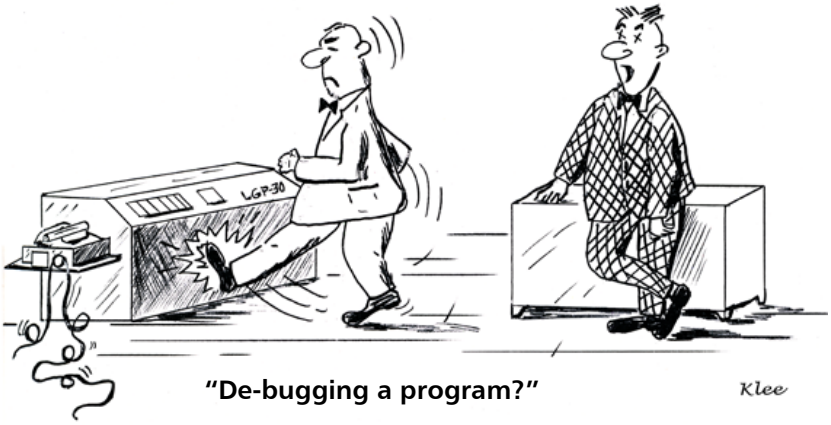
In 2003 I joined the Aquarium Hobby Historical Society of America, a Yahoo Group established just the year before. Yahoo groups - like Facebook groups - allow one to write material to files that are available to group members and I took the opportunity to write quite a number of them. There was an advantage in this in the fact that, unlike an article written for a commercial aquarium magazine, it could be much longer, publishing schedules could be ignored and I was free of editorial excursions into well-meaning but sometimes disastrous editing of my material.

I wrote an article about the Aquarium Hobby Historical Society of America and sent it to TFH but, for some reason, it never was published. It included a picture of Henry Dennison Butler and if the article had been published, it would have been the first image of this important aquarium hobby personage ever seen. I wound up later publishing Butler's portrait in the Third Edition of *The Toy Fish*.

At one point, fearing that if Yahoo foundered this material would be lost, I decided to collect them in a book in pdf format that I referred to as a *Compendium of Aquarium Hobby History Articles*. Later I changed its name to *Essays on Aquarium Hobby History*, using the term Stephen Jay Gould (whom I much admired) favored for his 300 popular articles published in the magazine, *Natural History*. At this writing, *Essays on Aquarium Hobby History* stands at 868 pages, about twice that of *The Toy Fish*.

Printing the second edition of *The Toy Fish* via offset was expensive and Lee barely broke even on the deal. However, I always wanted to do a book on the history of the guppy and in 2003 I wrote the first edition of *The Guppy - 1859-1967*. I did the layout myself and had it printed POD. Print on demand (POD) is a printing technology and business process in which book copies are not printed until the company receives an order, allowing runs of small quantities. POD could only develop after the beginning of digital printing, because it was not economical to print single copies using traditional printing technology such as letterpress and offset printing. In this way I printed other aquarium history books such as *A History of Aquarium Inventions - The First 100 Years, The History of Ichthyology, The Finny Bone and The First Lady of the Aquarium Hobby - Ida Mae Mellen*. For many of these I turned the printing over to Lee Finley who also marketed the book, although I gave the American Cichlid Association the right to publish the Mellen book, the earnings of which went to support the Paul V. Loiselle Conservation Fund.

I have never sought compensation for any of my work, and when I was writing for those various aquarium magazines I was always amazed at getting paid for material I would have gladly submitted just for the joy of writing. To this end I have made available all of my books, large and small, major and minor, freely to all members of the Aquarium Hobby Historical Society of America. As Caecilus Statius (219 -168 BC) - a Roman comic poet, noted for his colorful language, linguistic effects and puns - once said, Serit arbores quae saeclo prosine alteri ("He plants trees which will yield a profit for a later age"). I hope I have planted some for the aquarium hobby.



ANCIENT EGYPTIAN FISH NAMES

by Albert J. Klee

(Aquarium Hobby Historical Society, Facebook Files, May 6, 2017)

To the ancient Egyptians, fish were inextricably connected with the Nile. It is only in two sources from the New Kingdom (18th to the 19th dynasties, 1549 to 1069 BC) that fish from other regions are recognized; the Punt reliefs from the mortuary temple of Hatshepsut at Deir el-Bahri show fish of the East African and Indian coasts and a New Kingdom text lists the names of sea fish (the former is discussed in the Addendum of this essay).

Fishing and fowling scenes illustrate the importance of fish as a source of food. This is also shown by the recorded fish names noted in Figure 1 for the payment of fish for the workers at Deir el-Medina, an ancient Egyptian village that was home to the artisans who worked on the tombs in the Valley of the Kings during the 18th to 20th dynasties of the New Kingdom. We know the hieroglyphics for the eighteen fishes shown at the top; the thirteen below them are known only from the hieratic text of this record, a sort of shorthand used for commercial purposes where the hieroglyphics would take too long to write. However, without the aid of named drawings or textual references that do more than merely record names, little can be done to identify them or other fish that are mentioned in ancient Egyptian texts.

The place of fish in mythology in ancient Egypt was limited. Certain species enjoyed cult worship and were mummified, such as *Lates niloticus* (see Figure 2) and two species (the *ỉn.t*, i.e., *Tilapia* and the *ɜbḏw*, Figures 20 and 21, respectively) were depicted in the heavenly Nile guiding the boat of the sun-god Rē barque in its hazardous journey across the sky, warning of the approach of the Apophis serpent during the underworld voyage. Figure 3 shows an antelope-headed solar barque with a fish leading Horus, who is representing the sun god, sitting on the four pillars of the Firmament. The *ʿḥɜ* fish (Figure 20) and the

Figure 1: Fish eaten by the ancient Egyptians.

ỉn.t were of particular significance, being guarantors of rebirth after death. One species (*ỉtnw*) was especially associated with the fish goddess - Hatmehit (Figure 4) - of the city of Mendes located in the eastern Nile delta.

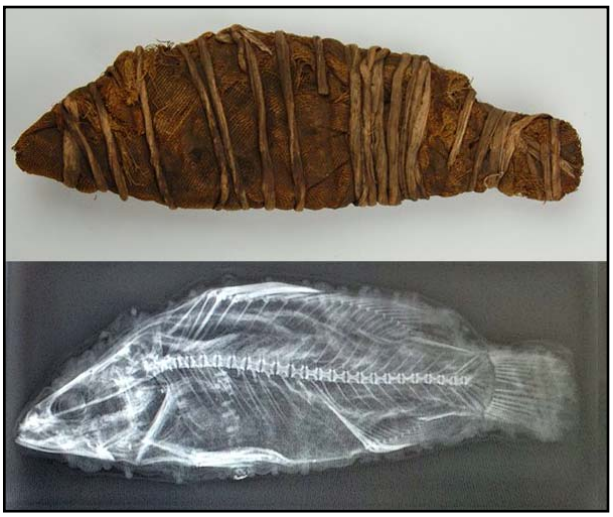


Figure 2: A *Lates Niloticus* mummified.

Figure 3: A tilapia guiding the boat of the sun-god Rē in its hazardous journey across the sky to the underworld.

Figure 4: The fish goddess, Hatmehit.

In ancient Egyptian times, there was a city located about 100 miles south-southwest of Cairo, Per-Medjed (later renamed Oxyrhynchus or "sharp-nosed"), named after the medjed, a species of elephant fish of the Nile River worshipped there as the fish that ate the penis of Osiris (Figures 5 and 6 bottom).

Another city in which a fish was worshipped was "Latopolis" (a city about 34 miles south of Luxor). It was named Latos. The fish actually was the Nile perch, *Lates niloticus*, the largest of the 52 species that inhabit the Nile and abundant in these stretches of the river in ancient times (Figures 5 and 6 top). It appears in sculptures among the symbols of the goddess Neith, associated by the ancient Greeks as Pallas-Athene, surrounded by the oval shield or ring indicative of royalty or divinity. West of the town is a Ptolemaic-Roman cemetery containing great numbers of *Lates niloticus*, mummified either by nature or by art. Cemeteries of the same fish, unassociated with human remains and dating from times at

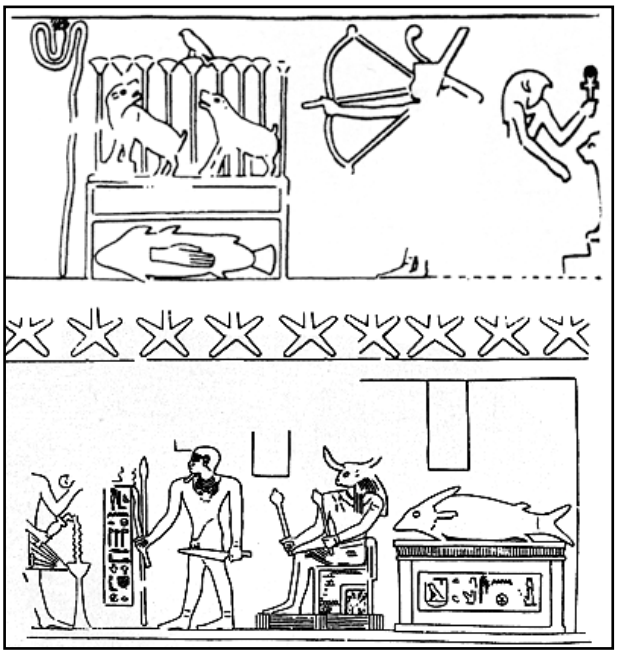

Figure 5: From the Temple of Hibis. Top: Latos. Bottom: Oxyrhynchos.

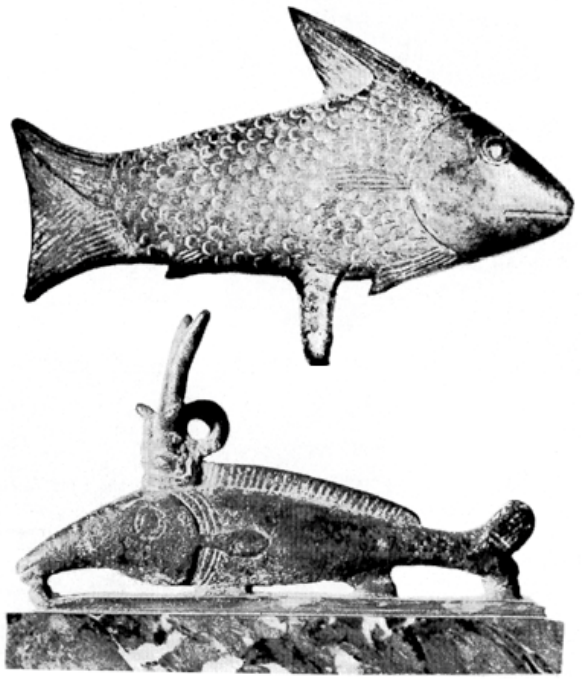

Figure 6: Top: Latos. Bottom: Oxyrhynchus.

least as remote as the 18th or 19th dynasties, have been found elsewhere in Egypt. Oddly enough though, the fish worshiped at Latopolis does not appear portrayed among the symbolic figures that adorn the walls of it temples.

The Temple of Esna in Latopolis conveys a sense of the importance which the Ancient Egyptians placed upon their places of worship. All Egyptians who entered the confines of an Egyptian temple were required to comply with the strict rules regarding ritual purity. According to inscriptions carved on the walls of the Temple of Esna, those who entered this temple were expected to fastidiously cut their fingernails and toenails, remove other body hair, wash their hands with natron (a natural occurring salt), be dressed in linen (they were forbidden from wearing wool), and not to have had sexual intercourse for several days.

Although it is unlikely that the ancient Egyptians were fully aware of all the particular tilapia traits, without doubt the species of Egyptian *Tilapia* were then as now famous for an unusual form of rearing its young where the female tilapia carries her young in her mouth after hatching, thus sheltering them from harm. While more understood as a regenerative power, this unusual trait led Egyptians to exaggerate aspects of tilapia fertility, imagining this as a powerful rebirth tropism, a biological phenomenon indicating the growth of an organism in response to an environmental stimulus.

Like modern fish aquaculture, Egyptians also farmed tilapia in closed ponds along the Nile, and this fish had its own special hieroglyph character, *ỉn.t*, in texts. *Tilapia* were often found in tombs as offerings to the deceased (Figure 7) and its image was also worn as an amulet or on necklaces, not only on pregnant women, but later also sewn into shrouds for the afterlife.

It is possible that tilapia were connected with Bastet, originally a lioness warrior goddess of the sun throughout most of ancient Egyptian history,

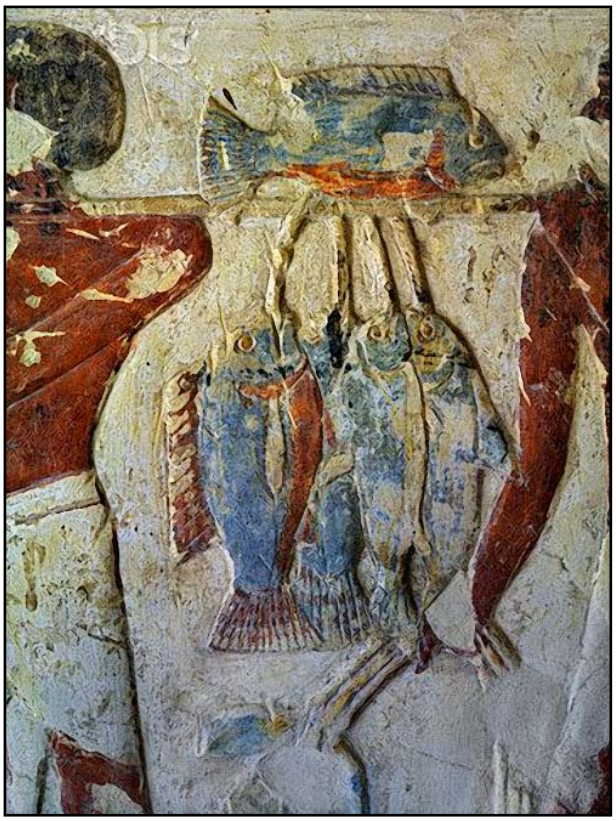

Figure 7. Tilapia being carried to a tomb as an offering to the deceased.

but later changed into the cat goddess that is familiar today. The wooden object A in Figure 8 found in the tomb of *Ḥ^{c}bḫnt* in Deir el-Medina could point to such a relation. On its top point, where one would expect a sacred animal or a divine symbol as in the well-known images B and C, are a quadruped and a fish. The relatively high trunk, the long red dorsal and the tail fin that terminates in a nearly straight edge, argues against identifications with *Barbus bynni* or *Lates niloticus* proposed by some, but rather clearly for a tilapia. The attitude of the animal and the position of its ears as well as its overall formation show clear characteristics of a cat. Although a clarifying inscription does not exist, one can scarcely fail to see that we are looking at the two animals sanctified, and to which the owner of the tomb saw himself especially connected for some reason.

In an article titled "The Fishes and Fishponds of Ancient Egypt" (Klee, 2016), I described how the Egyptians kept fish in ornamental ponds in their gardens, using the tombs of Rekhmire and Nebamun to illustrate their usage in this regard. More to the point of this essay, however, in another article titled "Our First Aquarium Cichlid" (Klee, 2005), I showed that the title fish in question was most likely *Tilapia nilotica* or *Tilapia galilaea*, based upon the bones of fish species from excavations in Egypt (Boessneck, 1988). These were archeological investigations related to cultural studies that, in contrast to the antiquarianism of classical archaeology, were concerned with the explanation of cultural processes such as foods eaten and animals domesticated or farmed. The number of species so found using this approach totaled forty four.

The problem with this type of analysis is that an examination of bones by themselves does not provide the Egyptian names of these species, since these are available only from their hieroglyphs and written language. An exhaustive treatise on fish in ancient Egypt (Gamer-Wallert, 1970) included a lexicographical study of some 70 individual fish names. Also, fifteen names that have recently come to light should be added to Gamer-Wallert's work, making a total of 85 species, more than twice identified from the excavations. However, unless a hieroglyph shows a drawing and a name associated with it, we have no idea of what fish is meant by the Egyptian name alone.

HOW THE EGYPTIANS CLASSIFIED ANIMALS

Research since the 1950s into folk biosystematics (i.e., prescientific man's classification of his biological universe), has indicated a considerable degree of consistency in the ways in which societies categorize the animals with which they are familiar.

The most inclusive category, which corresponds to the English word "animal," is seldom named in pre-scientific classificatory systems, even if the category is perceived, i.e., there may be no single term for plant or animal in a language, although plants and animals are never confused. The next most inclusive categories are almost always named. These life form groups are mammal, bird, fish, reptile and insect.

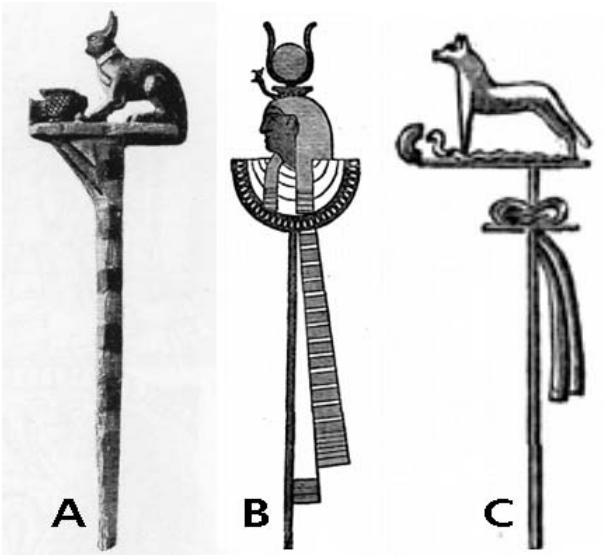

Figure 8: A is the wooden standard found in the tomb of *Ḥ^{c}bḫnt* in Deir el-Medina. For comparison, B and C are typical standards.

Work done on these life form terms suggests that these categories are universally recognized, although not all need be named. The life form classes most commonly named are those focusing on birds, fish and snakes. The next most commonly named class focuses largely, but seldom exclusively, on insects (it may comprise, however, other small creatures such as worms or frogs). The mammal class is encoded last of all, probably because of the greater visibility and (economic) importance of mammals to man; the distinction horse/pig may be as significant to man as fish/bird.

No work has been carried out previously on zoological classifications in ancient languages, though various studies of animal names in Greek, Latin, Akkadian and Hebrew do exist. Despite the disadvantages of using a "dead" language as a data base (there can be no truly objective way of checking evidence, which in itself is distorted by chance of survival) it is of interest to see how closely the ancient material corroborates the modern.

The Egyptians employed a system of five-fold classification, i.e. man, mammal, bird, fish and snake to categorize all living things. The divisions perceived by the Ancient Egyptians within the animal kingdom, might be expressed as follows:

(a) Things which walk (mammals, not including mankind and sometimes excluding cattle);
(b) Things which fly (birds; also bats and certain insects);
(c) Things which swim (fish; also crocodiles, turtles, hippos);
(d) Things which crawl (snakes; also scorpions, lizards).

RECENT RESEARCH INTO ANCIENT EGYPTIAN FISH NAMES

Ingrid Gamer-Wallert is a German Egyptologist who, in 1962, received her doctorate at the University of Munich with a dissertation on the palm trees in Ancient Egypt. In 1962/63 she received a travel scholarship from the *German Archaeological Institute*. She did post-doctoral research in 1968 at the University of Tübingen, writing "Fishes and Fish cultures in Ancient Egypt." Afterwards, she worked at the *Tübingen Atlas of the Near East* (an epochal bilingual German/English collection of geographical and historical maps and scholarly publications on the Middle East), and for many years served as its second spokesperson. She taught as a Professor of Egyptology at the *Egyptian Institute* of the University of Tübingen and from 1990 to 1994 she was its vice-president. Among other things, she was involved in many excavations in Egypt.

Her exhaustive treatise on fish in ancient Egypt (Gamer-Wallert, 1970) included a lexicographical study of some 70 individual fish names and this essay will use this work as a starting point. Figures 10A and 10B from the tombs of *Ṯy* and *Mrrwkꜣ* in Saqqara, show two drawings of fishes in a net below their fishing boats. The 56 numbered fish images are identified (see the bottom of Figure 10B. An additional 32 species included as known to the Ancient Egyptians according to Gamer-Wallert are shown in Figure 11.

THE DIFFICULTIES IN TRANSLATING EGYPTIAN ANIMAL NAMES

Egypt provides unique evidence on the existence and naming of an ancient fauna. Reliefs and paintings, especially those of the Old (3rd to the 6th dynasties, 2686 to 2181 BC) and Middle (11th to the 12th dynasties, 2134 to 1069 BC) King-

Figure 9: Egyptian fish pendant, Middle Kingdom, circa 1878-1640 BC.

doms, illustrate a diverse mammal, fish and avifauna. The hieroglyphic script itself, representing a number of basic sounds with the figures of animals, provides an insight into the importance of the animal world for the ancient Egyptians not offered by other languages.

The use of an ancient language as the basis for any study entails specific problems. Texts (for Egypt there are two: hieratic and demotic) are inevitably limited in number and can be preserved from sometimes widely differing dates and provenances. Dialectal variations may be

undetectable or easily misinterpreted. A word's meaning may change dramatically over a decade, yet translations may rest on only a few records scattered over several centuries. Deduced meanings cannot be checked by asking native speakers.

The search for translations of animal names in the face of these difficulties has often led to the comparison of Egyptian words with those of other languages, notably the Semitic ones, Coptic and, via Coptic, Greek and Arabic. One should be aware of the dangers of being influenced by one's

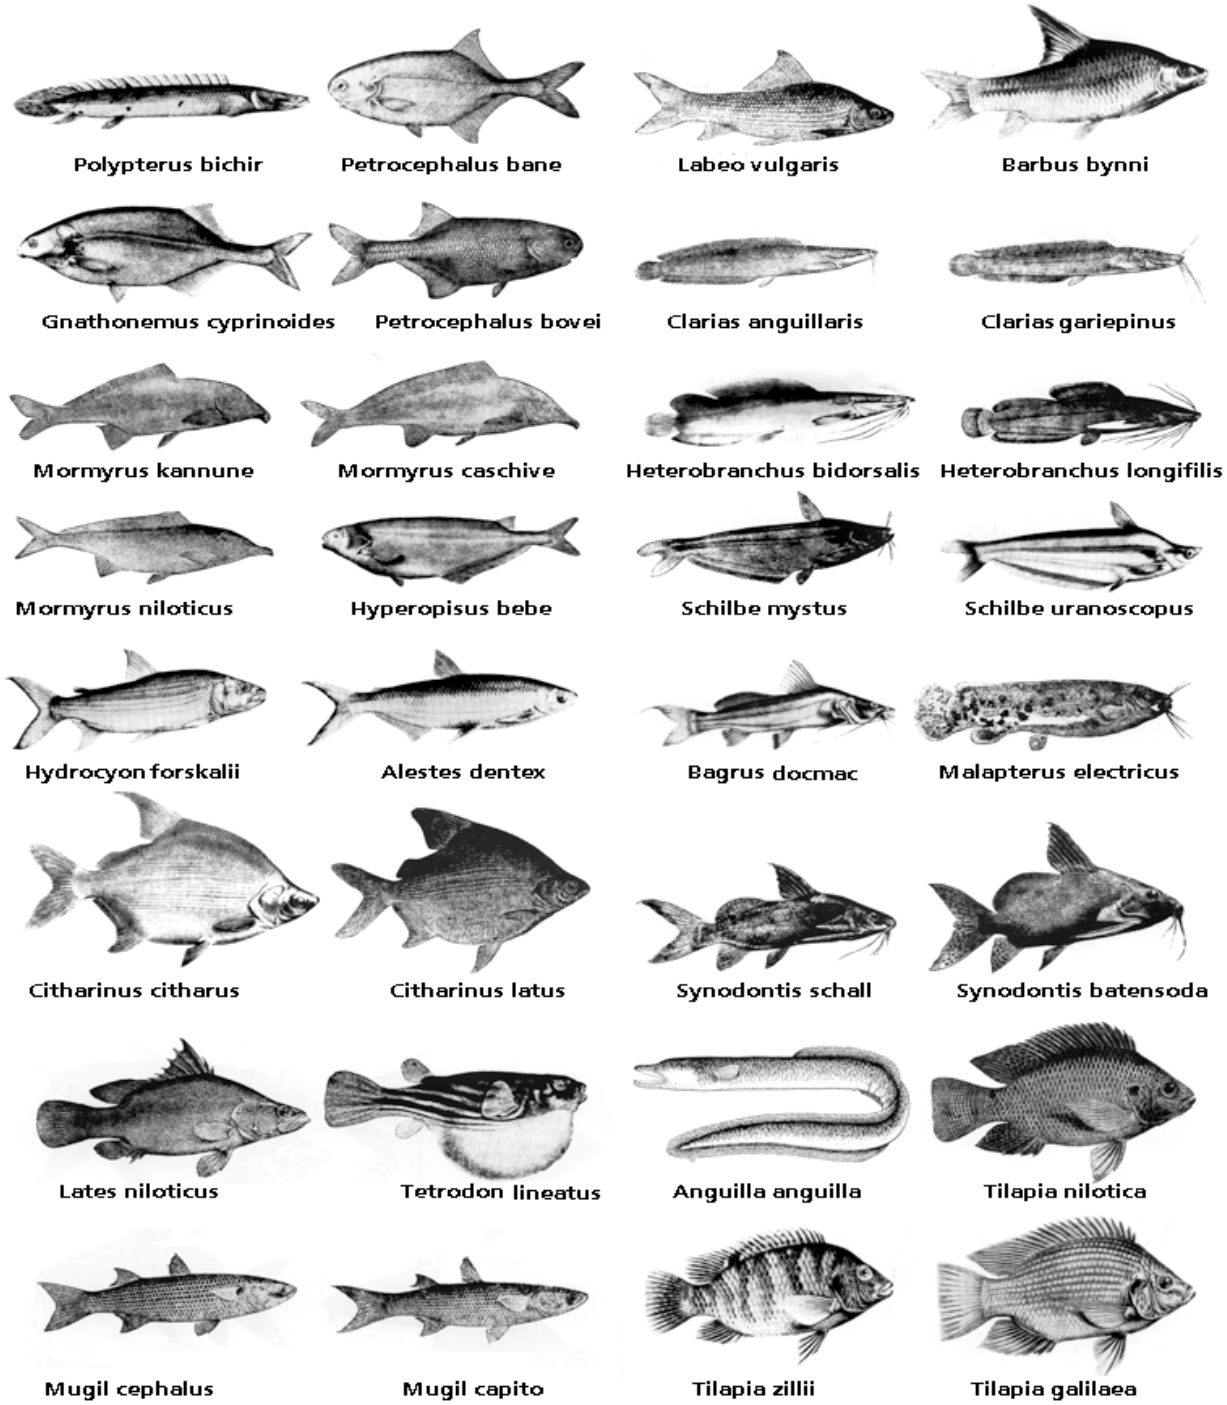

FIGURE 11

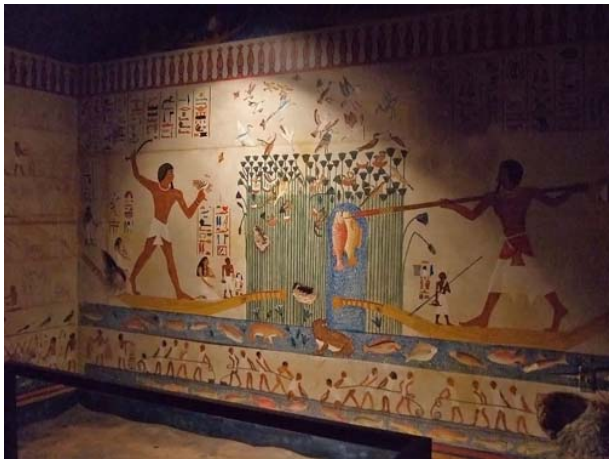

Figure 12: Examples of paintings at Beni Hasan, an Ancient Egyptian cemetery site located approximately 12 miles to the south of modern-day Minya in the region known as Middle Egypt, showing birds and fishes not depicted or named elsewhere.

own culture when attempting translations and the same can be said of the influences of other - even ancient - cultures. The relationship between these languages is extremely complex (and inadequately researched) and simple comparisons do not take into account these complexities, although they may be of some use when all other evidence is lacking.

There is a certain element of chance at work in the preservation of records in any ancient language. Egyptian literature of a religious nature far outweighs other texts surviving from ancient times, and! this will inevitably have restricted the type and number of animal names to have been preserved. Many fish names must have been used which are not to be found in the extant texts. The highly specialized body of medical information contains many terms unknown from other sources and the same can be said of the unusual tomb paintings at Beni Hasan which show birds and fishes not depicted or named elsewhere (see Figure 12). These examples indicate that other specialized texts (had they survived) would also reveal their own specific terms. Many names are found largely, if not solely, in descriptions of kings or gods; obviously not all animals are suitable for such comparisons.

The Egyptians divided the animal kingdom into classes of beings, they did not develop the systematic analysis of the modern Linnaean classification. The animals drawn and named were those of greatest significance; for example, cattle were frequently shown and were assigned a great variety of names but the zoologically vast class of insects received little attention.

In many instances fishes were depicted accompanied by their names, though in some cases it is obvious that the wrong name has been chosen. In other cases, especially when a word is but infrequently confirmed, it can be difficult to decide whether the association of picture and name is to be trusted. In yet other cases the representation itself may be unhelpful, either because it is badly drawn by an inept artist or so stylized that the fish is unrecognizable. In general, the Egyptians did not draw animals purely out of scientific curiosity (the Beni Hasan paintings mentioned above seem to be a notable exception) and this should be borne in mind when interpreting the tomb scenes.

THE ANCIENT EGYPTIAN LANGUAGE

Ancient Egyptian literature was written in the Egyptian language from ancient Egypt's pharaonic period until the end of Roman domination. It represents the oldest body of Egyptian literature. Along with Sumerian literature, it is considered the world’s earliest.

Hieroglyphs were very time consuming to create, so the Egyptians developed a cursive script called hieratic in the early years of hieroglyphic use. The characters of the hieratic script were based on the hieroglyphic symbols, but they were simplified and little resembled their hieroglyphic origins. Hieratic was used for the bulk of writing done with reed pens and ink on papyrus. In the 7th century BC the Egyptians began using a script called demotic, which was even more simplified than hieratic. After this point hieroglyphs continued to be used in carved inscriptions on buildings, jewelry and furniture, but hieratic was used for

- **For everyday use, a script form of hieroglyphics evolved called *hieratic*.**
- *This is from a letter written about 1790 BCE.*

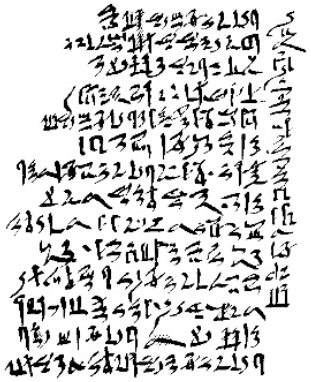

Figure 13: Hieratic Writing.

religious writings, and demotic for business and literary texts. Figure 13 shows an example of hieratic writing.

Writing in ancient Egypt - both hieroglyphic and hieratic - first appeared in the late 4th millennium BC during the late phase of pre-dynastic Egypt. By the Old Kingdom, literary works included funerary texts, epistles and letters, hymns and poems, and commemorative autobiographical texts recounting the careers of prominent administrative officials. It was not until the early Middle Kingdom that a narrative Egyptian literature was created. This was a "media revolution" that was the result of the rise of an intellectual class of scribes, new cultural sensibilities about individuality, unprecedented levels of literacy and mainstream access to written materials. However, it is possible that the overall literacy rate was less than one percent of the entire population. The creation of literature was thus an elite exercise, monopolized by a scribal class attached to government offices and the royal court of the ruling pharaoh. However, there is no full consensus among modern scholars concerning the dependence of ancient Egyptian literature on the sociopolitical order of the royal courts.

Middle Egyptian, the spoken language of the Middle Kingdom, became a classical language during the New Kingdom when the vernacular language known as Late Egyptian first appeared in writing. Scribes of the New Kingdom canonized and copied many literary texts written in Middle Egyptian, which remained the language used for oral readings of sacred hieroglyphic texts. Some genres of Middle Kingdom literature, such as "teachings" and fictional tales, remained popular in the New Kingdom, although the genre of prophetic texts was not revived until the Ptolemaic period (4th century BC to 1st century BC). Popular tales included the "Story of Sinuhe and The Eloquent Peasant," while important teaching texts included the "Instructions of Amenemhat and The Loyalist Teaching." By the New Kingdom period, the writing of commemorative graffiti on sacred temple and tomb walls flourished as a unique genre of literature, yet it employed formulaic phrases similar to other genres. The acknowledgment of rightful authorship remained important only in a few genres, while texts of the "teaching" genre were pseudonymous or falsely attributed to prominent historical figures.

Ancient Egyptian literature has been preserved on a wide variety of media. This includes papyrus scrolls and packets, limestone or ceramic ostraca (pieces of broken pottery or stone - most often limestone - used as notepads as they were a cheaper and more plentiful option than papyrus which was costly and time consuming to make), wooden writing boards, monumental stone edifices and coffins. Texts preserved and unearthed by modern archaeologists represent but a small fraction of ancient Egyptian literary material.

HIEROGLYPHICS

Hieroglyphic writing, which we find on the temple walls and in tombs, is the writing everybody "knows." It is a monumental form of writing which is engraved into stone, even if painted examples exist, notably within tombs. However, etymologically, "hieroglyph" simply means "the engraving of sacred characters."

There are three main groups of glyphs:

1. Pictograms: Stylized pictures that represent

the drawn object. For example, an image of a fish represented a fish.

2. Phonograms: Reused pictograms that represent the sound of the object originally depicted. An example in English is the verb "can" being represented by a picture of a tin can. Some phonograms represented the sound of one consonant, some two and others three.

3. Determinatives: Pictograms can convey meaning about an object, or something related to that object. For example, a pictogram of writing equipment can mean "scribe," "writing" or "to write." To clarify which of these is meant within the context of a certain passage, a determinative sign is added. In my example of writing equipment, when the word "scribe" is intended the determinative of a man is placed after the original pictogram. When "writing" or "to write" is meant, a determinative of a papyrus scroll is added instead. Determinatives then, are the signs, which are placed after a pictogram or phonogram in order to clarify the meaning.

Here is an example of determinatives using the word freight. While the F, R and T in freight sound the normal way, the G and H are silent and the E and I make one sound (long A). There are 7 letters in the word, but only 4 sounds (F, R, long A and T) are heard. So to spell freight with hieroglyphs, you'd use the symbols for those 4 sounds shown in Line 1 in Figure 14. Four different sounds are used to say freight, so four symbols or hieroglyphs are needed to write it the Egyptian way. No more, no less.

Egyptians often used only hieroglyphs for consonant sounds to write their words. Therefore, ignoring the vowels you could now spell freight like Line 2 in Figure 14.

But that's the same way you would spell fort and ferret without vowels. So how do you know which word it's supposed to be? You would have to look at the word in the context of the rest of the sentence to figure it out. Or, you could rely on a special silent hieroglyph, i.e., a determinative.

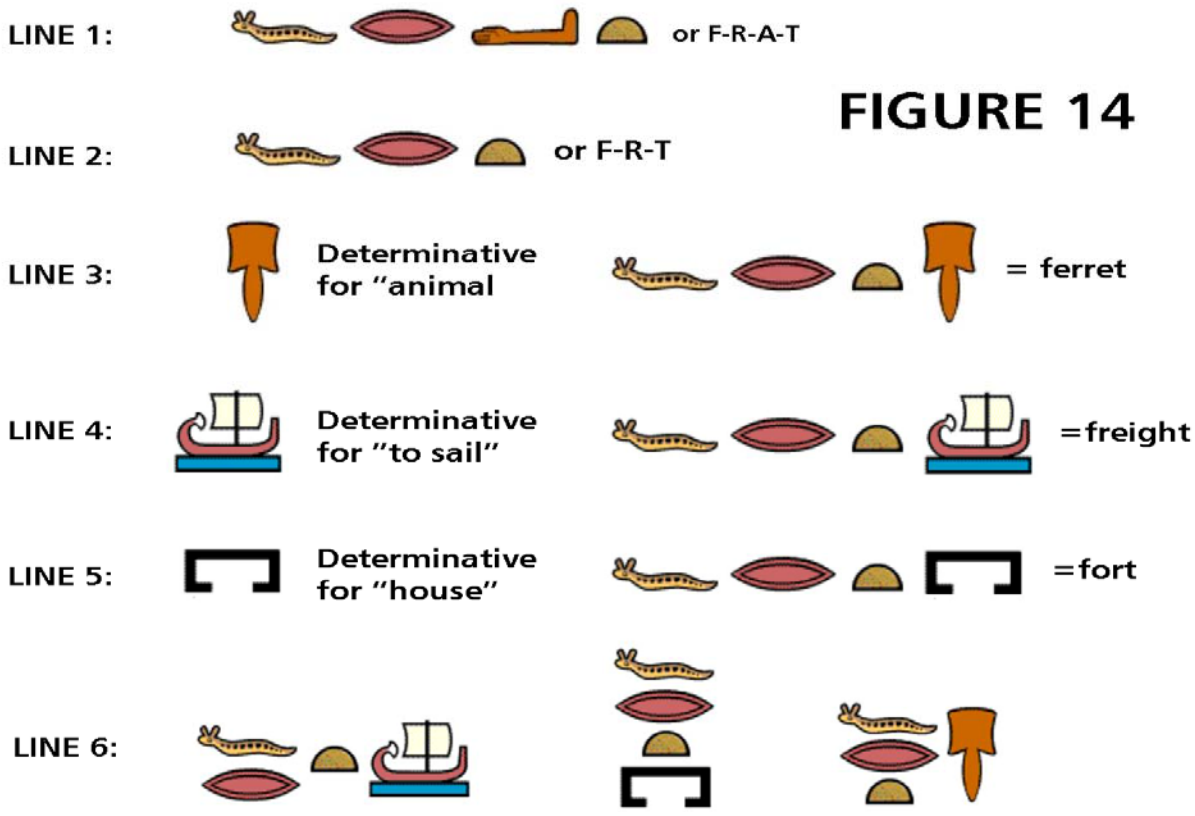

FIGURE 14

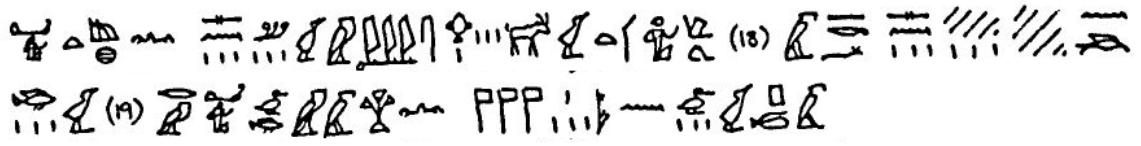
Determinatives were added at the ends of words to give the reader a hint about the general meaning. You could use these determinatives to clarify the meaning of F-R-T as shown in Lines 3, 4 and 5 of Figure 14.

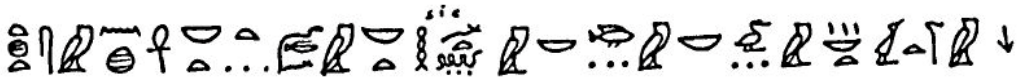
The three components are not found in every word. There are words which are reduced to a pictogram or which are only composed of phonograms. On the other hand, a determinative never exists by itself. They are only written with phonograms. Determinatives are not usually a factor in fish names since they usually have a pictogram to indicate that a fish is meant.

Hieroglyphs could be arranged in both columns and rows, and the direction in which they were read depended upon how they were rendered. This flexible writing system allowed the ancient Egyptians to effortlessly integrate writing with art. In fact, the boundary between art and hieroglyphs appears non-existent!

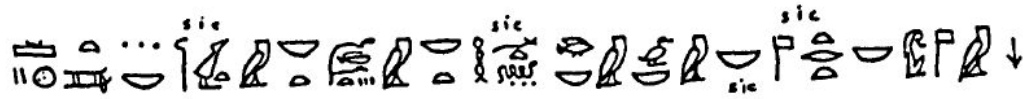
Although the task of reading hieroglyphs from the right direction may seem daunting at first, there is a simple trick that will allow you to easily identify the correct direction from which to begin. Find a figure with a head and start reading toward the front of its head. As you can see, when the figure is facing to the left, begin reading from the left, toward the face on the right. If they are facing to the right, begin from the right and toward the face. An example is Figure 15, which shows three selections mentioning fish from "The Book of the



"I have not driven small cattle from their herbage. I have not snared birds for the gods' harpoon tips. I have not caught fish of therir (lagoons)."



"But every creature likewise that shall die, the whole of them together - even all quadrupeds, all fowl, all fish, all snakes, all worms - living or dead - they are yonder, having passed on, after all the worms have finished (their work)."



"The deceased rots when he has gone to the Shu, as do gods, goddesses, all fowl, all fish, all snakes, all worms, all quadrupeds, the whole of them together."

"The deceased rots when he has gone to the Shu, as do gods, goddesses, all fowl, all fish, all snakes, all worms, all quadrupeds, the whole of them together."

Figure 15: Examples of hieroglyphics mentioning fish from The Book of the Dead," an ancient Egyptian funerary text.

Dead," an ancient Egyptian funerary text, used from the beginning of the New Kingdom to around 50 BC. It was written by many priests over a period of about 1000 years and consisted of a number of magic spells intended to assist a dead person's journey through the Duat, or underworld, and into the afterlife.

Another feature of the Egyptian writing system that you might have noticed is "group writing." Rather than placing hieroglyphs side-by-side, they were arranged in order to reduce empty space: taller signs stand alone, while smaller signs are stacked on top of each other. For example, Line 6 of Figure 14 shows three ways freight, fort and ferret could have been written.

TRANSLITERATION AND THE ALPHABET

Although we have the glyphs that provide us with the pronunciation of the name of the fish (and hence its name), this is not particularly useful since what is needed is a process that facilitates the publication of texts where the inclusion of photographs or drawings of an actual Egyptian document is impractical. The three writing systems, hieroglyphs, hieratic and demotic, while very decorative, are difficult to represent on an internet page and are not very useful to the ordinary reader. Thus we want to convert the glyphs into alphabetical symbols that can be understood and written, either by hand or by using a font. The problem is that although we have the pronunciation glyphs, we do not know how they were pronounced and there are no ancient Egyptians around to help us.

In the field of Egyptology, transliteration is the process of converting (or mapping) texts written in the Egyptian language to alphabetic symbols representing uniliteral hieroglyphs or their hieratic or Demotic counterparts. This process facilitates the publication of texts where the inclusion of photographs or drawings of an actual Egyptian document is impractical. The symbols in the alphabet are called "uniliterals," because they can be represented by a single symbol. There are also biliterals and triliterals, which are represented by two and three symbols, respectively. Figure 17 shows the Egyptian alphabet with its unilateral hieroglyphs and a description of each glyph with its transcription and pronunciation.

It should be emphasized that transliteration is not the same as transcription. Transcription seeks to reproduce the pronunciation of a text. For example, the name of the founder of the Twenty-second dynasty is transliterated as šš*nḳ* but is transcribed Shoshenq in English, Chéchanq in French and Scheschonq in German. Due to the exact details regarding the phonetics of ancient Egyptian not being completely known, most transcriptions depend on Coptic for reconstruction or are theoretical in nature. Egyptologists, therefore, rely on transliteration in scientific publications. Also, the three writing systems, hieroglyphs, hieratic and demotic, while very decorative, are difficult to represent on an internet page and are not very useful to the ordinary reader.

Transliteration gives the reader some idea of how the words may have been pronounced, but nobody really knows how ancient Egyptian, in any of its historical versions, sounded. One of the difficulties is the complete absence of the representation of vowel sounds in the hieroglyphic, hieratic or demotic system. This has resulted in a plethora of ways of how to transcribe Egyptian texts. The god Amen for instance is also represented as Ammon, Amon, Amun, Imen etc. If there are no historical clues, "e" is used as default vowel.

As important as transliteration is to the field of Egyptology, there is no one standard scheme in use for hieroglyphic, hieratic and demotic texts.

Figure 16: An Egyptian Oxyrhynchus amulet, Late New Kingdom, circa 1150-350 BC.

Some might even argue that there are as many systems of transliteration as there are Egyptologists. However, there are a few closely related systems that can be regarded as conventional. Many non-German-speaking Egyptologists use the system described by Egyptologist Sir Alan Gardiner in 1954, whereas many German-speaking scholars tend to opt for that used in the *Wörterbuch der Ägyptischen Sprache* (Erman and Grapow 1926–1961), the standard dictionary of the ancient Egyptian language. In the scheme introduced by Jan Buurman et al. in 1988, known (in shortened form) as the *Manuel de Codage*, all transliteration characters are taken directly from the English alphabet. However, there is a growing trend, even among English-speaking scholars, to adopt a modified version of the method used in the *Wörterbuch* and this is what I use in this essay. A comparison of the *Wörterbuch* with the *Manuel de Codage* is shown in Figure 18.

A DICTIONARY OF THE EGYPTIAN LANGUAGE

The *Wörterbuch der Ägyptischen Sprache* (*Dictionary of the Egyptian Language*), abbreviated Wb in bibliographic references, is a large German-language dictionary of the Egyptian language published between 1926 and 1961 by Adolf Erman and Hermann Grapow. It is a comprehensive work encompassing 3000 years of linguistic history, including Old, Middle and Late Egyptian as well as hieroglyphic inscriptions of the Classical Greco-Roman period. The dictionary contains approximately 16,000 headwords in five main volumes, two secondary volumes, and five volumes of primary source references. It is therefore the largest and most complete printed dictionary of Ancient Egyptian in existence.

Begun in 1897 as a research project at the Prussian Academy of Sciences in Berlin, the dictionary is also known as the "Berlin Dictionary." Interrupted by both World Wars I and II, the first volumes were published in 1926 and the final volume released in 1961. An example of a page from the Dictionary is shown in Figure 19. The first column contains the transliterated name of the entity. The left-hand hieroglyphic column contains the usual orthography of the word, which is usually also the phonetically correct and the old form. The right-hand hieroglyphic column presents important deviations. In the middle column, the occurrences, meanings, etc., of each word is mentioned. The selection outlined in red shows the transliterated name as *rꜣ-ḏꜣ* and the German text in English is "A type of fish (noted as forbidden food in several regions)."

It will be noted that the fish pictogram differs between the first and second hieroglyphic columns. As I mentioned previously, the ancient Egyptians integrated writing with art so at times, a pictogram might vary in design for the same fish. It also should be noted that the *ꜣ* and *š* in the *Wörterbuch* are often written as two half-circles in the former and a caret or a short vertical line over the s in the latter.

CURRENT PROBLEMS IN IDENTIFICATION

Note: In this section after their Egyptian names I have placed in square brackets the volume of the *Wörterbuch* and the page number on which the fish name is to be found. Also, in Figures 20 and 21 I have shown a number of the entries from the *Wörterbuch* for many of the fish names that are discussed in this section.)

Only a few of the fish names preserved from ancient Egypt are readily translatable (see Figure 20), though even in these cases it is usually not possible

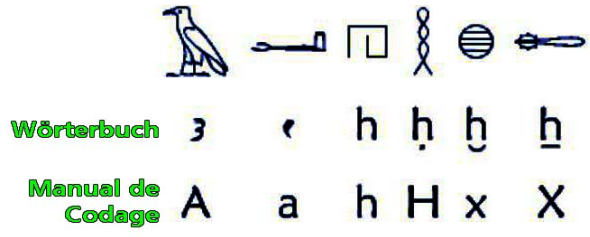

Figure 18: A comparison of the Wörterbuch with the Manual de Codage symbols.

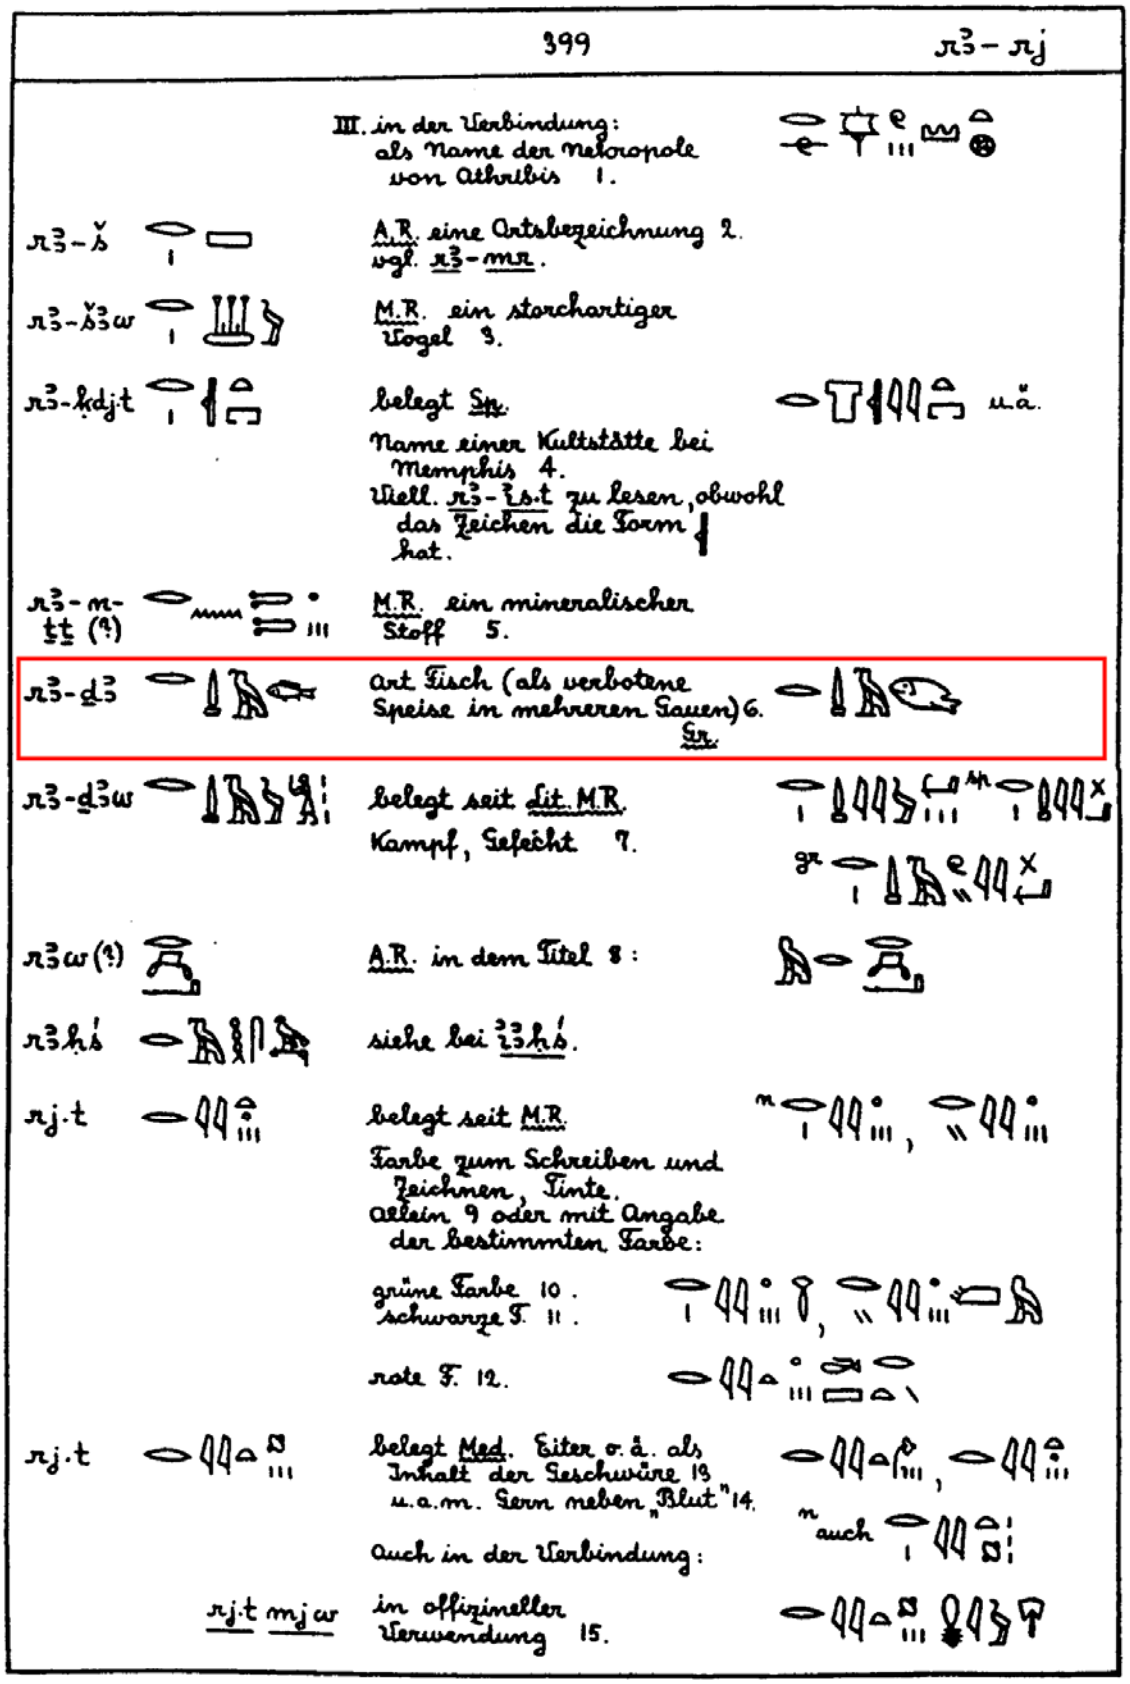

Figure 19: A page from the Wörterbuch.

to identify down to the species level. These include the Nile Perch, *Lates niloticus,ʿḥɜ* [Wb I, 217]; *Clarias* sp., *nʿr* [Wb II, 209]; *Synodontis* sp., *whʿ* [Wb I, 350] var. *ḥwʿ*; and *Tetraodon lineatus, špt* [Wb IV, 453]. The names of these fish are found in lists of fish names and in the medical texts and occasionally elsewhere.

The Grey Mullet has been recorded as the determinative of three words - *ḥbɜ, ḥskmt,* var. *ḥỉslkt,* a*nd bq* - as well as being used as a phonetic sign [*ʿḏ*]. (*ʿḏ* itself is confirmed as a fish name.) Two other fish were common as phonetic symbols and can been identified from the hieroglyphs as members of the genus *Sarotherodon* or *Tilapia,* and *Mormyrus*; these are *ỉn.t* [Wb I, 92] and *ḫɜt* [Wb II, 359] respectively.

Three further fish names were identified by Gamer-Wallert as designating members of the genus "*Tilapia*" (*Sarotherodon/Tilapia*); these are *wḏj* [WB I, 399], also written *wɜḏ* [WB I, 268], *dšrw* [Wb V, 492] and *ỉmskɜ* [WB I, 88].

Both *wɜḏ* and *dšrw* are mentioned together with another fish, *ɜbḏw* [Wb I, 8] in place of its usual companion the *ỉn.t,* and it has been suggested from this that the three terms were synonymous. *Wḏ* appears also in a hymn to Ramesses VI and in association with the baboon. *Dšr* occurs in association with Horus.

A fish named *w3ḏ-nfr* is depicted on an ostracon from Deir el-Medina; only the hind part remains, and shows a tail fin shaped like those of the *Sarotherodon/Tilapia* genera. It was this, together with the pattern on the tail, which prompted Gamer-Wallert to regard *wɜd* as synonymous with *ỉn.t*. The *wɜd* is elsewhere described as being red, though its name suggests that it was green. That a "green" fish should be described as red would, according to Gamer-Wallert, suit the shimmering colors of *Tilapia.* Keimer (1938) also believed this to be the case, noting the variety of the color of the stones on which figures of *Tilapia* were made. However, both *ỉn.t* and *w3ḏ* appear together in another text, which suggests that the words denoted separate species (or at least different types). In any case an early text gives *wɜd* a different determinative from *ỉn.t*. *ʿImskɜ* appears in parallel with *wɜd* and *ỉn.t* and cannot, therefore, be entirely synonymous with these.

Despite being depicted mummified in the tomb of Khabekhnet (Theban Tomb No.26, Figure 22) *ɜbḏw* has resisted identification. It is partly obscured in the tomb scene by the figure of Anubis who is attending to its mummification; only the tips of the dorsal and anal fins and its tail are visible. It is described in the accompanying text as

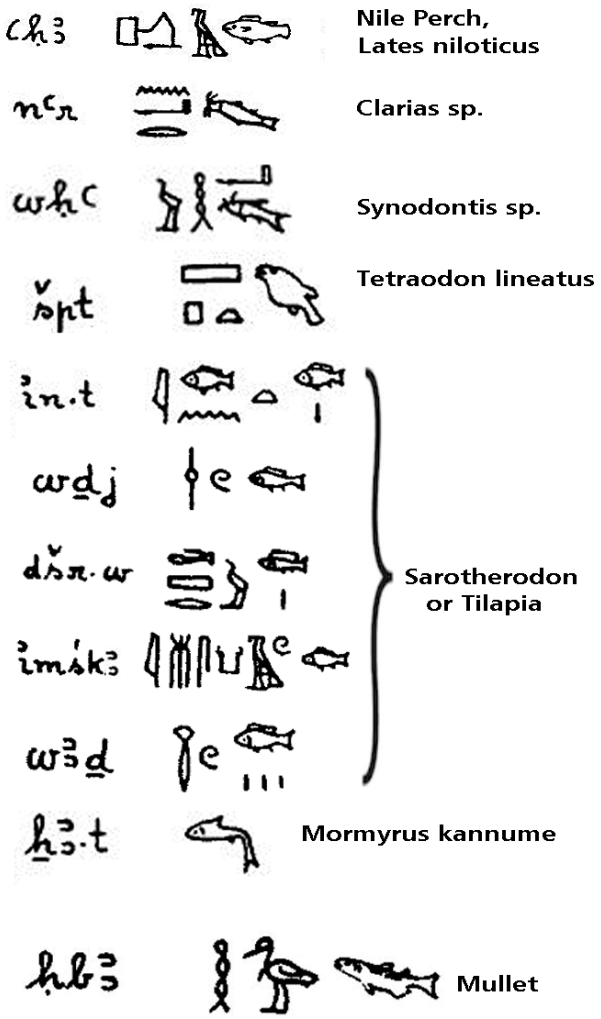

FIGURE 20

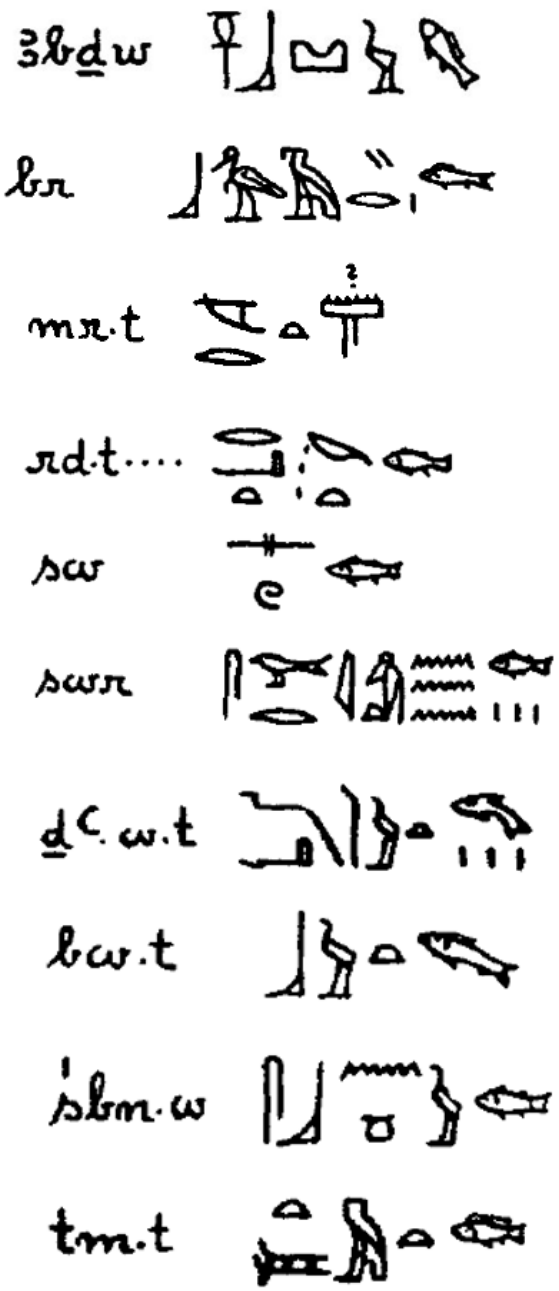

FIGURE 21

the "*ꜣbḏw* of lapis lazuli"; elsewhere "*ꜣbḏw* of gold" is a more common descriptive name.

The original translation of *ꜣbḏw* from a comparison with the Coptic and Arabic terms for "turtle." Many texts, however, mention the *ꜣbḏw* (alone or with the *ỉn.t, dšr* or *wꜣḏ*) as accompanying the bark of Rē, and representations of this scene show two types of fish guiding the boat. In scenes showing the deceased tomb owner spearing fish the *ỉn.t* fish is accompanied by the Nile Perch, *Lates niloticus,* but the name of this fish is *ʿḥꜣ,* and it clearly differs from the *ꜣbḏw* of Khabekhnet and the second fish of the solar bark drawings in having a rounded rather than a slightly indented tail.

The problem of the identification of *ꜣbḏw* was addressed at some length by Gamer-Wallert who rejected various species as being different in some degree from that fish as depicted: *Labeo niloticus, Barbus bynni, Schilbe mystus, Polypterus bichir* (a suggestion of Ebers, 1889), *Lates niloticus, Petrocephalus sp*. (because of the characteristic lip of this fish), *Mugil sp*. (though this remains a possibility). This difficulty in identifying the *ꜣbḏw* with any known species has led to the suggestion that the *ꜣbḏw* was a purely mythical beast. It was closely associated with Rē, Amun (because of this it has been identified as an eel), Horus and other deities and is found in magical texts. Nevertheless it also appears in a number of rational texts - on ostraca and on weights. A further text states that this fish should not be eaten on certain festival days, and it was used in medicine, as well as in magico-medical remedies. *ꜣbḏw,* therefore, evidently denotes a real fish.

As mentioned above, the mullet has been named as the fish which determines the words *ḥbꜣ,*

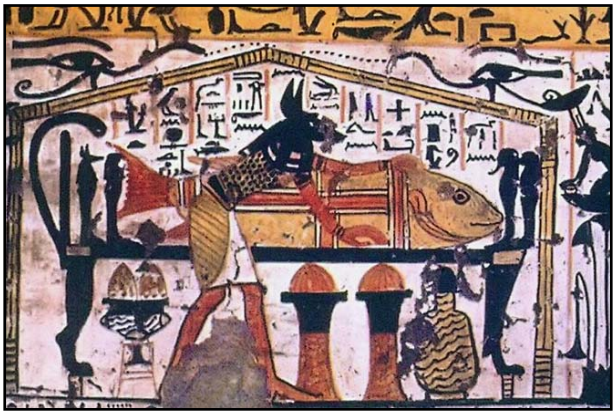

Figure 22: Wall painting of a mummy depicted as the fish, *ꜣbḏw*, Tomb of Khabekhnet, Deir El Medina, Western Thebes.

ḥskmt, a*nd bg* and writes the phonetic group *ʿḏ*. Another fish, *br* [Wb I, 465], has also been identified as this fish by comparing the Coptic and Arabic terms for "mullet." As one text records *br* as a marine fish, this may be possible. (Likewise the New Kingdom term *sɜr*, (cf. Arabic *šɜl*, *Synodontis schall*) was held to denote the fish originally called *whʿ*.)

This profusion of terms apparently denoting the same fish has received considerable discussion. Edel (1961, 1963) presumed that, in the Old Kingdom, *ʿḏw* was a generic term for mullet, with *bg, ḥbɜ* and *ḥskmt* denoting the three species *M. cephalua, M. capito* (now *Liza ramada*) and *M. auratus*. In the Middle and New Kingdoms, he believed *ʿḏ* was the only definite term for the genus *Mugil* (the terms *ḥbɜ* and *ḥskmt* are found only in the Old Kingdom), though he presumed that *br* was a "spezielle Bezeichnung" for a type of mullet. This opinion was also accepted by Gamer-Wallert.

In two New Kingdom Texts both *br* and *bg* appear together in addition to the *ʿḏ* and would, therefore, seem to denote different types of fish (cf. *ỉn.t, wɜḏ* and *ỉmskɜ* above). Whether they denoted different genera, species or subspecies is difficult to say. The deduction of the meaning of *br* via Coptic and Arabic is by no means a certainty, and *bg* written in an Old Kingdom relief showing a market scene may not refer to the fish (a mullet) being handled. It is not impossible that *ʿḏ* designated both the genus and the most abundant (typical) species as is the case in other languages. If the three words did all refer to the same species this would constitute a rare case of "overdifferentiation" (a phenomenon described by anthropologists from modern primitive languages in which animal categories are subdivided further than the species in Linnaean classification) in the ancient Egyptian zoological nomenclature, paralleled by the earlier examples of *ʿḏ, ḥbɜ* and *ḥskmt*. This practice was recognized by Keimer (1938) in modern Arabic, in which he noted different words for fish which had spawned and those which had not, for larger and smaller fish, and for males and females.

ʿỉtn is frequently found and was associated with the deity of Mendes, Hatmehit, "Foremost of Fish." The word was considered a miswriting of

Figure 23. Fishing scene, painted relief, Mastaba of Princess Idut, Old Kingdom, 6th Dynasty.

ỉn.t by Montet (1928) in a study of various texts of the Ptolemaic Period, though earlier examples are provided by the Cairo Calendar (an ancient Egyptian calendar with a 365-day year) and the Papyrus Sallier IV (a hieratic literary text in the British Museum). The term also appears in a passage relating the evil deeds of Seth and is recorded in another text among the fish of the *wꜣḏ-wr*.

The texts written on the walls of the temple of Edfu in Upper Egypt, the Cairo Calendar text and the Papyrus Sallier IV text all associate the *ỉn.t*-fish with the city of Busiris (= Mendes), and the Papyrus Sallier IV and the Calendar text mention also the deity Hatmehit. The nome sign (ancient Egypt was divided into autonomous city-states called "nomes") for the Medesian nome shows a fish which has been identified as a dolphin, and the text numbering the *ỉn.t* among the fish of the sea has been taken to support this proposal. Engelbach (1988), on the other hand, compared the fish of this sign with the fish which determines the word *bwt* and the *ḥꜣ*-fish (*Mormyrus sp.*) and concluded that the fish of Mendes was the same as that determining the word *bwt*, the fish often called "Schilbe" in Egyptological literature (probably *Schilbe mystus*. though *Eutropius niloticus* is also possible].

A further few fish names have been deduced from words which show fish determinatives, notably *bwt* [Wb I, 453] though from the texts quoted it is difficult to tell whether it was the fish and not some other taboo food which was meant; *srḳ* (not in Wb as a fish determinative); *sbnw* [Wb IV, 89] var. *bsnt* [not in Wb] and *bs* (not in Wb as a fish name).

Two words originally believed to be fish names are *pḥ* and *tmt* [Wb V, 306]. However, these should be understood as "hind-part" and "whole" respectively, and the following fish hieroglyph in the texts read *rmw* "fish." This is also the case with *pꜣḫnt*, recorded by Gamer-Wallert as the name of a fish. It appears to be a personal name with (in some cases) the "seated man" determinative not written; the fish sign following must in all cases be read *rmw*, as other examples from the ostraca show.

Finally, a number of fish names which have recently come to light should be added to Gamer-Wallert's work; most of them occur so seldom that they cannot be identified:

ỉtn [Wb I, 145]
ỉmt [not in Wb]
ỉrṯ [not in Wb]
bꜣy [not in Wb]
mrt [Wb II, 105]
rdt [Wb II, 469]
sw [Wb III, 426]
swr [Wb III, 429]
šᶜt [not in Wb]
sṯpw [not in Wb]
šdy [not in Wb]
kwỉꜣ [not in Wb]
ḏᶜwt [Wb V, 535]
sꜣ [not in Wb]
ḥꜣ [not in Wb].

Figure 24: Bowl with fish and lotuses, New Kingdom, 1450–1400 BC. Sometimes called "marsh bowls," they usually alluded to concepts of fertility via aquatic imagery.

ADDENDUM: THE PUNT FISHES

The time to the end of the Old Kingdom must have been a period of restless observation and exploration. At that time, the essential knowledge of the morphology of a fish was acquired in Egypt. The first attempts at devising a system for classifying the rich world of fishes were made and important observations were made on the specific characteristics of the biological behavior of certain species.

Significant new ichthyological knowledge presented itself again in the 18th dynasty. Egypt was now on the way to becoming a world power and its kings pushed with their armies far over the northern and southern borders of the country. Egypt's horizon was widening, and hand-in-hand with it, a whole new interest in foreigners, their inhabitants and also their flora and fauna was awoken.

Recall the onomastics (the study of the history and origin of proper names, especially personal names) that have been written down since the Middle Kingdom, in which the "names of all things that have existed" were recorded in a kind of inventory. Thutmosis III did the same in recording the foreign plant and animal species which he had encountered in his campaigns, and which he had inscribed in the walls of Karnak. But this was not the first time in Egypt. Foreign animal species were to be seen on the Theban west bank in the terrace temple of Queen Hatshepsut, the immediate predecessor of Thutmosis III. As part of the report of her expedition to the land of Punt, this queen had her scribes record the plants and animals in relief that, unknown in the Nile, had been encountered by the Hatshepsut on her journey south: giraffes and baboons, to name but a few, and strange fishes that had not appeared in the great fish representations of the Old Kingdom.

Unfortunately, the most exact reproduction of nature had long since passed in the New King-

dom. This was true with the Punt reliefs. One cannot help getting the impression that the artist, in his endeavor to picture these new alien types for an Egyptian, was only too fond of his own imagination and influenced with a certain exuberance of the far-traveled. From this point of view it is understandable why, in contrast to the fish specimens of the private tombs of the Old Kingdom, a systematic investigation of the Punt fishes was missing until recently. From just a glance at these fishes, one can see among them representatives from tropical seas, such as found in the diverse group of coral fishes. It is, therefore, natural to look for the natural models in the Red Sea and south of it.

Figure 25 shows four of the actual images of the Punt marine fish in the temple. Figure 26 shows all of the images, in outline form, of the Punt marine fish pictured on the walls of Queen Hatshepsut's terrace temple - the ones denoted by the integers from 1 to 17 - and for comparison, living representatives - the figures with decimal places - that are close to the represented fish. The four with question marks refer to pictured fish for which no living representatives have been suggested; in place, fish families have been proposed.

The Land of Punt was an ancient kingdom. A trading partner of Egypt, it was known for producing and exporting gold, aromatic resins, blackwood, ebony, ivory and wild animals. The exact location of Punt is still debated by historians. Most scholars today believe Punt was situated to the southeast of Egypt, most likely in the coastal region of modern Djibouti, Eritrea, northeast Ethiopia, Somalia and the Red Sea littoral of

Figure 25: Images of the Punt marine fish pictured on the walls of Queen Hatshepsut's terrace temple.

Sudan. However, some scholars point instead to a range of ancient inscriptions that locate Punt in the Arabian Peninsula. It is also possible that the territory covered both the Horn of Africa and Southern Arabia.

Thus the question that has always interested the viewer of the Punt reliefs, and which has given rise to bitter controversies in research, is the more precise geographical position of that mysterious country. No one has been able to find any essential support in the fish presentations, but clearly there are clearly definite species with a narrowly restricted area of distribution. From the standpoint of the Egyptologist the most important conclusion reached by ichthyologists does not permit us to locate the Land of Punt. According to their unanimous opinion, these marine fishes belong to the Indian Ocean, Red Sea fauna. We can only say with certainty that the Punt fishes were not present in the Egyptian pharaonic time (i.e., from the 1st Dynasty in 3000 BC to the 32nd in 30 BC).

Figure 27: From the tomb of Mereruka, a vizier to the Pharaoh Teti (2323 BC). Fish species include: Tilapia, eels, puffer fish, catfish, elephant fish, mullet, carp, Nile perch, upside-down catfish and moonfish (a citharinid).

A HISTORY OF THE IMPORTATION OF THE GOLDFISH INTO WESTERN EUROPE AND THE UNITED STATES

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, June 10, 2017)

The following excerpts are examples of the assertion that the goldfish arrived in Portugal in the year 1611. If true, this would mark the first importation of the goldfish into Western Europe.

In William Yarrell's "History of British Fishes" (1836) he writes:

THE GOLD CARP.

The date of the first introduction of the Golden Carp, or Gold and Silver Fish, as they are more frequently called, is differently stated by authors: 1611, 1691, and 1728, are each recorded as the particular year in which they were first brought over… A correspondent in Loudon's Magazine of Natural History, vol. iii. page 478 [September 1830] considers "that they were probably introduced into Portugal at an early period, after the people of that country had discovered the route to the East Indies by the Cape of Good Hope, as they appear to be now completely naturalised there, and abound in many of their streams, whence they are brought to us by trading vessels from Lisbon, St. Ubes, &c. in large earthen jars, and may be had at a very easy rate before they get into other hands. They have also been introduced and naturalised in the Mauritius by the French, where they now abound in fishponds and streams, and are served up at table as agreeable food, with the other fresh-water fishes, to the brood of which they are thought to be very inimical, by destroying their spawn and young fry."

The correspondent cited by Yarrell was J.T. Cork and his letter was dated March, 1829. In François de Schaeck's "Histoire du Poisson doré" (1893) he wrote:

It is believed that this fish was brought to Europe at the end of the seventeenth century. Madame de Pompadour received the first copies which were introduced into France. But soon they abounded there. For the culture which was practiced throughout the south, especially in Portugal, succeeded admirably, and supplied the whole of Europe.

In William Houghton's "British Freshwater Fishes" (1895) he wrote:

The date of the introduction of these "sportive" fish into England is uncertain; 1611, 1691, and 1728 are each recorded as the year in which they were brought over; it was not, perhaps, till the year 1728 that Goldfish became generally known, when they were brought over in large numbers and presented to Sir Matthew Decker, Lord Mayor of London, who distributed them to various friends over the country. The Goldfish appears to have been introduced into Portugal at an early period ; it is now completely naturalised in many of the waters of that country, and a great number of these fish, so commonly exposed for sale in the well-known glass globes of the London and other dealers, have been and are now, I believe, brought into England by trading vessels from Lisbon and other Portuguese towns. In France the Goldfish is said to have been unknown till the days of Louis XV., whose mistress, the Marchioness de Pompadour, had received some as a present.

In Hugo Mulertt's "The Goldfish and its Systematic Culture with a View to Profit" (1883) he wrote:

The first introduction of the goldfish into Europe is variously dated, the years 1611, 1691 and 1728, A. D., each having claims for that honor; it may be said also that the variety introduced was the poorest and cheapest the Chinese had.

The first seen in France, however, were those imported for the famous Madame de Pompadour. Soon afterwards they became quite common, as it was found that they throve well in the waters of Southern Europe, especially in Portugal, where they sprang from a few small fish, said to have escaped from a vessel newly arrived from China. In that country they are now considered a delicacy for the table. It was not long until several streams in the neighborhood of Lisbon absolutely swarmed with them, and it is from this source that all Europe became stocked with them.

In Gustave Loisel's "Histoire des Ménageries de L'antiquité à Nos Jours" (1912) he wrote:

About the year 1500 the small goldfish was introduced into Japan from the town of Sakai, which was then the principal port of the Empire. From there it spread throughout the country, where Japanese women and children love it today as much as in China. It then appeared in England in the year 1611, then came to Portugal, where it was very much in favor during the whole of the eighteenth century, in France, where fashion was prescribed by the Marquise de Pompadour, and finally in Germany and Italy, This last country being the only one, we believe, where the breeding of this fish and some of its varieties is now being carried on in Europe.

With this list of references it is not surprising that the idea that Portugal received its first importation of the goldfish in 1911 has persisted up to modern times [see Zhong-ge (1984), Brunner (2005) and currently Wikipedia, often a font of erroneous aquarium hobby history]. In addition to the 1911 date, many of these references specifically mention that the goldfish quickly established themselves in that country and were the source of importations to other Western European countries.

TRACKING DOWN THREE DATES: 1611, 1691 and 1728

James Petiver (1665-1718) was a London apothecary, a fellow of the Royal Society, and a member of London's informal Temple Coffee House Botany Club, famous for its study of botany and entomology. A collector of examples of natural history, his extensive collection became known as the Museum Petiverianum. He was especially anxious to ensure that his collection would facilitate further research and, in the period 1696 to 1709, produced a steady stream of material designed to alert fellow scientists to new discoveries.

He engaged the captains and surgeons of ships to bring him specimens, enabling them to select proper objects by printed directions that he distributed among them. By these means his collection became so valuable that, sometime before his death, Sir Hans Sloane offered him four thousand pounds for it (about $907,000 in today's currency). After his death, it was purchased by Sloane, and some of it is now in the Natural History Museum in London where it is frequently resorted to for the sake of ascertaining obscure synonyms, his plates being so generally cited by Linnæus but in many instances insufficient to express the precise object intended.

In Petiver's 1711 edition of his **"**Gazophylacii Naturae et Artis" ("The Treasury of Nature and of Art" - the book was written partly in English and partly in Latin, although he was not very proficient in the latter) there are illustrations of two goldfish brought alive from China (Figure 1). As the plate was on sale in 1706 (a common practice at the time), it is reasonable to assume that the

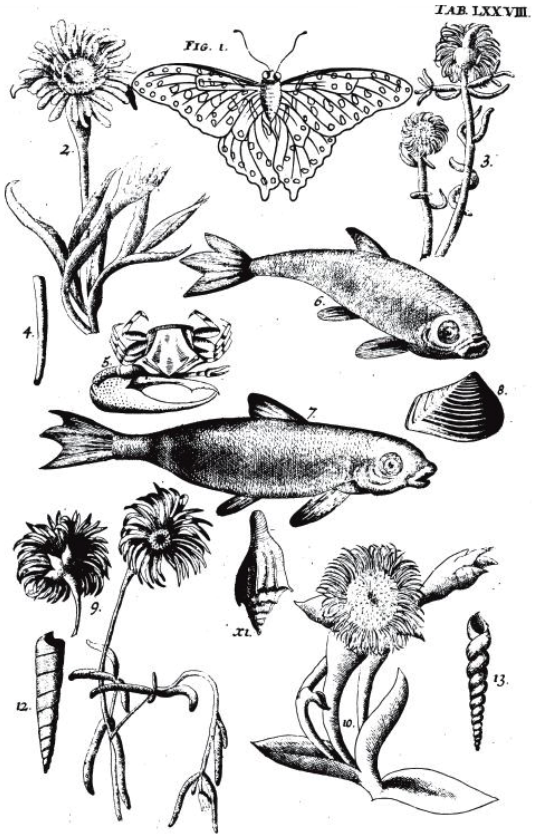

Figure 1:
A Plate from Petiver's 1711 edition of his *Gazophylacii Naturae et Artis*.
Numbers 6 and 7 are the goldfish bright back alive from China.

fish were in Petiver's possession in 1705, thus inducing Hervey and Hems (1968) to consider this date as marking the first importation of the goldfish into England.

In Edwards' "A Natural History of Birds" (1751), in the section "The Gold-Fish from China" there appears the following footnote:

His Grace the late Duke of *Richmond* had a large *Chinese* earthen Vessel full of these Fish, brought alive to England. I drew some of them for his Grace, who permitted me to make Draughts for myself, with Leave to make them Publick. The first Account of these Fishes being brought to *England* maybe seen in *Petiver's* Works, published about *Anno* 1691. See his *Catalogue*, 186, *Piscis Chin. Caudâ argenteâ*, Plate 78, Fig. 6. and *Catalogue* 187, *Piscis Chin. Caudâ aureâ*, Plate 78, Fig. 7. They were not generally known in *England* till the Year 1728, when a large Number of them were brought over in the *Houghton Indiaman*, Captain *Philip Worth*, Commander, and presented by him and *Manning Lethieullier*, Esq; to Sir *Matthew Decker*. Since which Time they have been propagated in Ponds by several curious Gentlemen, in the Neighbourhood of *London*. They may be esteemed a Domestick Fish; they vary infinitely in their Colours and Marks, as do all Domestick Animals; they have been propagated and greatly increased in the Island of St. *Helena;* from whence they are now brought by all our *India* Ships that touch there. They keep them in small Ponds and Basons in *China*, for the Amusement of the Ladies, and other curious Persons. Those propagated with us are generally of a deader Colour than what are brought from *China*, or St. *Helena*. In a few Years it is probable, we shall have them in our Rivers. The last Author that has mention'd this Fish is *Linneus*. See his *Fauna Sveciae*, published at *Leyden*, 1746. See his Figure of it, *Tab*. 2. Fig. 331, which is like it, but seems fore-shorten'd, which makes it appear thick and short. He calls it *Cyprinus pinna ani duplici, cauda trifurca, exoticus, Piscis aureus Chinensium*.

Edwards, however, states (erroneously) that Petiver's book was published about 1691 instead of MDCCXI (1711). Hervey and Hems (1968) postulate that Edwards made the simple mistake of transposing the X and the C to produce MDCXCI (1691). In any event, along with the reference to the importation of the goldfish into England in 1768, Edwards is responsible for two of the three most common importation assertion dates of the goldfish into Western Europe in the literature - 1691 and 1728. This information was copied by Pennant (1776):

They were first introduced into England about the year 1691, but were not generally known till 1728 when a great number were brought over, and presented first to Sir Mathew Dekker, and by him circulated round the neighborhood of London, from whence they have been distributed to most parts of the country.

Marcus Elieser Bloch (1723-1799) was a physician who began to devote himself to ichthyology at the age of 56. Bloch was no stranger to the goldfish, having described a subspecies, Carassius auratus gibelio in 1783 (and known variously as silver crucian carp, golden carp, crucian carp, goldfish, giebel, prussian carp, common goldfish, wild goldfish, silver crucian, brown goldfish, and giebel carp). Bloch also wrote a book titled, "Naturgeschichte der ausländischen Fische ("Nature story of Foreign fishes"), 1785-1795. In his "Oeconomische Naturgeschichte der Fische Deutschlands" (1785), he states:

At present goldfish are esteemed not only in England, Holland and Denmark, but also in different cities of Germany. They were brought to the first country in the year 1611, and in 1728 they were already widely known.*
******Penn.* **Britt. Zool. III, p. 374.**

Thus he also credits Pennant but in his dates makes the error of recording the latter's 1691 as 1611, thus introducing the last of the three most common importation assertion dates of the goldfish into Western Europe into the literature: 1611, 1691 and 1728.

THE PORTUGAL ASSERTION

As I have shown at the beginning of this essay, one of the most common assertions is that the goldfish arrived in Portugal in 1611. We know that the 1611 date is a typographical error, but when was the goldish imported into Portugal? In Carlos Almaça's "Fish Species and Varieties Introduced Into Portuguese Inland Waters" (1995) he discovered that in the zoological literature, the goldfish was first mentioned as found in Portugal by Vandelli in his 1797 book, "Florae et Faunae Lusitanicae Specimen," under the scientific name *Cyprinus auratus* and the common name "Peixe da China" (suggesting a probable introduction into Portugal from China).

The goldfish was not mentioned in Baptista's prior 1789 account, "Ensaio de huma descripçao, fizica e economica de Coimbra, e seus arredores." If, as many of the assertions claim, streams in the neighborhood of Lisbon absolutely swarmed with them, certainly Baptista would have mentioned these goldfish. This suggests that the introduction of the goldfish to Portugal occurred sometime between 1789 and 1797, and not 1611.

It is now time to explore dates earlier than 1705 for the importation of the goldfish into Western Europe.

THE FIRST IMPORTATION OF THE GOLDFISH INTO WESTERN EUROPE

The following entry made by Samuel Pepys in his diary on May 28, 1665 is well known among aquarium hobby historians:

Thence home and to see my Lady Pen, where my wife and I were shown a fine rarity: of fishes kept in a glass of water, that will live so for ever; and finely marked they are, being foreign.

Aquarists have tried to pin down the fish in question, the first being William Alford Lloyd in 1876 and, much later, Cristopher Coates. Lloyd stated:

The Chinese kept gold and silver carp for amusement long before they were introduced into Europe during the second half of the seventeenth century. It was probably some such fish as these which are alluded to by Pepys in his Diary…, and doubtless vegetation grew, and was encouraged to grow, in the glass and porcelain vessels in which these household pets were kept, and so constituted them in some measure as "Aquaria."

For two reasons, however, this view was not held by all aquarists: (1) Some could not believe that the goldfish was introduced into England as early as 1665 and (2) others could not believe that goldfish could live in a glass of water for an extended period of time in the England of that era. In their 1968 book, "The Goldfish," Hervey and Hems write:

It is unlikely that these fish were goldfish, and Dr. C. W. Coates, of the New York Zoological Society, has expressed what he calls the 'educated guess' that the fish were Paradise Fish (*Macropodus opercularis*), which is finely marked in the sense that the word 'finely' would be used by a seventeenth-century writer, and which by reason of its supplementary breathing organ, would be able to live for a very long time in a small container. Certainly, at this time, goldfish were not generally known in England; for Willughby (1635-72), old Izaak Walton (1593- 1683), and others do not mention them, especially, they are not mentioned by John Ray (1627 -1705) in his *Synopsis Methodica Piscium*, posthumously published in 1710.

Note: It should be noted that although Coates had no doctorate, earned or honorary, he let the assumption go uncorrected on a number of occasions. Coates was a mediocre aquarist at best but an excellent publicist for The New York Aquarium. He was best known for his work with electric eels, the exhibits drawing thousands of visitors to the Aquarium who were enthralled by the sound and the voltages produced by the eels that were seen and heard by the electronic equipment Coates had devised.

In my essay, "The Mystery of Lady Pen's Fish" (2016), I refuted all of these objections so I won't repeat the details here. However, I would like to cite the following from Dr. Malcolm Peaker's blog (zoologyweblog.blogspot.com) that appeared shortly after my essay was published on Facebook. Dr. Peaker, by the way, is a Fellow of the Royal Society and a former Vice-President of the Zoological Society of London.

Dr. Albert J Klee has published an essay in which he questions what has become the standard dogma for the identity of Lady Pen's fish. He has shown that goldfish were imported into Europe earlier than claimed by Hervey and Hems and that the Paradise Fish first arrived much later. He also notes the close ties between Lady Pen and family in the Netherlands, where goldfish arrived with the Jesuit, Martinus Martini, in 1653. He, and I, see Coates's point about survival in a small vessel to be irrelevant. Even large goldfish have survived for decades in small goldfish bowls. I knew of one which had been in the family for twenty or more years; the water was changed every day.

The only real description of the fish was in Pepys's 'finely marked'. Klee points out that this could have meant any number of things, not just in the sense of 'with fine markings'; attractively distinctive might just as well have been Pepys's meaning. Indeed he could have described any of his lady friends as 'finely marked'.

I have never been content with the notion that Lady Pen had Paradise Fish. While they are relatively hardy and would have survived indoors during a London summer they are not that hardy. Lady Pen must have had the fish before Pepys and his wife visited their neighbours on 28 May (7 June in the present, Gregorian, calendar) and had they been sent from the Far East would have had to have survived at least part of the European winter and spring. That winter and spring were known to have been exceptionally cold, as those seeking the cause of the outbreak of The Great Plague of London in that year, recorded and noted. English houses were, and some still are, unless within a few yards of an open fire, freezing cold in winter. Too cold, I would suggest, for Paradise Fish but not for goldfish.

Figure 2: The goldfish pictured in Edwards' *A Natural History of Birds*, 1751

Peaker's last point really puts the paradise fish theory to rest. With regard to Pepys's "finely marked," I draw reader's attention to the four Kinyu-type goldfish images taken from Edward's 1751 book and shown in Figure 2. Clearly these goldfish could easily be described as finely marked.

All that remains now is to show that goldfish were imported into Western Europe prior to Pepys' visit to Lady Pen. In my Yahoo Aquarium Hobby Historical Society of America group post Number 1465 dated May 13, 2004, I first reported the following:

It is of some interest to note that in 1643, Jesuits established themselves in Hang Zhou, China, where their church was located close by a "local farm of red fishes." This took the fancy of a man known only by his last name of Martini, who took an interest in the fish and brought back 10 of them to Holland.

The following is from Addendum II in my 2016 Pepys essay after I had uncovered additional information about Father Martini Martini:

In 1650 the superior of the mission sent Father Martini to Rome in order to explain and defend the missionary approach encultured of China Jesuits. Chinese customs that are not contrary to the Christian faith were respected and even encouraged by the missionaries, but that was not the view in Europe, especially by the Franciscans and Dominicans. The travel was long and dangerous. The route passed through the Philippines on the way to Amsterdam where he arrived on August 31, 1653. In Amsterdam, Antwerp, Vienna and Munich he met with printers and prepared the edition of three important books including his famous *Novus Atlas Sinensis China*. He finally arrived in Rome in the spring of 1655.

We now have a very definite date for the first importation of the goldfish into the Western Europe, i.e. August 31, 1653. Finally, I would like to quote the following excerpt from Martini's *Description Géographique de l'Empire de la Chine*:

The mountain of Cinking is near Changhoa, where there is a lake, which, although not being the greatest, occupies three hundred acres of land. It is famous and renowned for the small golden fish within it, and because their skin shines between lines edged in gold, the Chinese have named this effect Kinyu. The whole back is like strewn with gold dust and they are no longer than a finger. They have a tail with three points, sometimes two, sometimes it is simpler and a little large; they are curious to see. The Chinese make much of their existence and feed them with great care in their houses and in their pleasure gardens, in vessels that are made just for this purpose. The great Lords give them some time to eat from their hands and often play with them as if the fish knew their masters, and they show that they like the pleasure and diversion they receive, when they honor their presence. When

they have all the right markings that the Chinese desire, one of these small fish is worth two or three gold crowns.

This is probably the first reference to the Kinyu (also known as Chin-yü; in Japan it is Kingyo) or common goldfish in a Western publication in addition to providing an explanation of the name. Martini does not indicate that the locals bred these fish found in the lake but he does mention that the more prized (because of their markings) were kept by the Chinese in their houses and in their garden pools.

THE FIRST IMPORTATION OF THE GOLDFISH INTO THE UNITED STATES

The following is an account of the goldfish kept in the ponds of Col. Godfrey Malbone (1695-1768), a wealthy Newport, Rhode Island merchant. Malbone was one of the chief Newport merchants of the 1700s. He settled in the town about the year 1700 and from there engaged in successful enterprises, including fitting out privateers in 1740 during the French and Spanish war. Malbone was a rough, bold, sea-faring man, ready to trade in slaves or rum, and to send privateers to the Spanish Main. He is best known for financing the construction of Trinity Church in 1725. The following is from *Harper's New Monthly Magazine*, August 1854:

Noble mansions, spacious and elaborate gardens, arose and adorned the island and the town. The country-house of Col. Godfrey Malbone, which was commenced in 1744, was famous as the finest residence in the colonies. It was built of stone, two stories high, with a circular stair-ease leading to the cupalo [*sic*], the cost of which was reputed to be equal to that of an ordinary dwelling-house. The house was within a mile of Newport, and the farm of six hundred acres sloped gently toward the bay. According to tradition, this garden was elaborately laid out; ranges of banks and terraces alternated with plots of flowers, and hedges of shrubbery, and groups of rare trees; silver and gold-fish swam in artificial ponds; while over this mingled beauty the eye swept across the bay to the blue line of the opposite shore, or saw the sea flashing over the rocks and cliffs at the entrance of the harbor."

Malbone, by the way, had an underground tunnel built down to the sea from the house so as to receive contraband goods without paying customs duties on them. The house was completed no later than 1747 (Charles Pym Burt wrote to Malbone from London in 1747: "**It gives me the deepest Concern, to find that your new Habitation proves so very disagreeable to you, but I hope you will soon be reconciled to it."** Assuming that the grounds were completed at the same time Malbone took possession and moved in, 1747 marks the earliest reference to goldfish in America.

In Job Baster's "*Natuurkundige Uitspanningen, behelzende eenige waarneemingen, over sommige zee-planten en zee-insecten, benevens derzelver zaadhuisjes en eijernesten*" (1762-1765), he writes:

Some of these Fishes were sent from China on a British Ship to the Island of St. Helena. From here the first goldfish in England were brought in 1728 by Philip Worth, Skipper of the East Indian Ship, *The Houghton* , and presented to the well-known Merchant, Sir Mathew Dekker. Since then, they have come across on various ships, and in fish ponds in England they were bred and sent to Europe where they became known.

Although Hervey and Hems question the 1728 date because the records show that *The Houghton* sailed from England only at the end of 1728 and did not return until 1730, it is most likely that the goldfish received by Malbone were later bred in England from this source.

ADVENTURES IN AQUARIUM HOBBY HISTORY RESEARCH

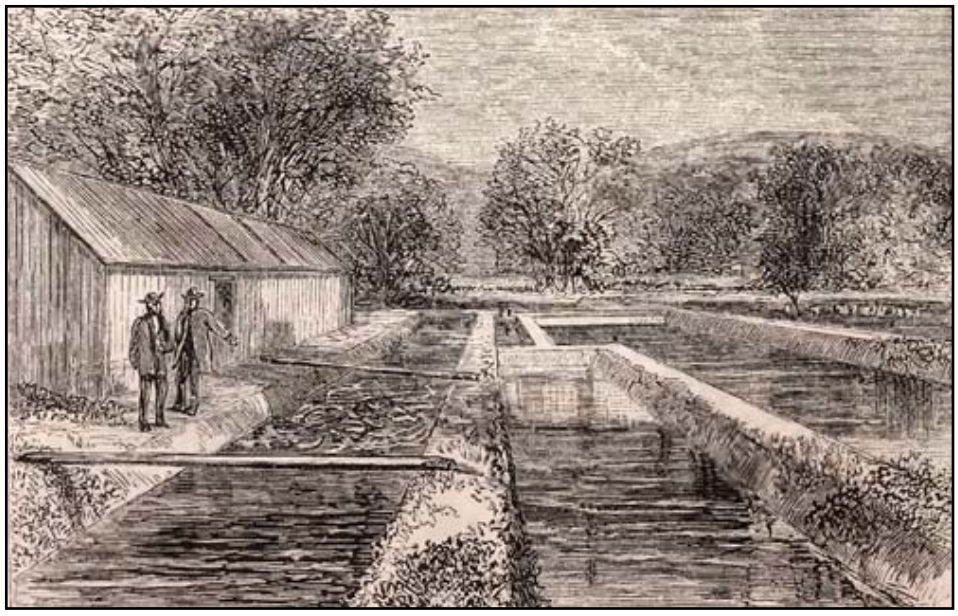
By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, July 15, 2017)

I have always preferred doing research by starting from the most recent documentation to the oldest. For one thing, the most recent documentation usually has a pretty good bibliography providing me with references that I never knew existed. A good example is my recent essay on ancient Egyptian fish names. I started with a doctoral thesis awarded to Belinda Ann Wassell in 1991, titled "Ancient Egyptian fauna - a lexicographical study." Although it did have a small section concerning fishes, it did not examine the derivation of names, which was my major objective. However, it did reference Ingrid Gamer-Wallert's 1970 doctoral dissertation, "Fische und Fischkulture im Alten Ägypten." I ordered a copy from Germany and found that it was just what I was looking for, plus the fact that it had an extensive bibliography that I also found useful.

Another example but with a slight twist was my search for the first horticulturist to use the word aquarium, since this was the genesis of the word used by Warington to refer to his invention of the flat-sided tank or the aquarium as we aquarists know it today. Because I knew that the origin of the world was Roman, here I reversed my usual procedure and started with Cato the Elder around 160 BC. This, however, came to naught since at no time did the Romans use aquarium or its cousins in the sense of a container; rather, it was either meant as water or a place (but not a vessel) that held water. (Klee, 2015). Thus I returned to my usual system and started with the plans for the aquarium of the Marquis of Whiteknights published in 1806. It was safe to assume that the word was used in the 1700's so I doggedly consulted a long list of horticultural dictionaries written (mostly in German and French) of that century. After drawing a number of zeros, I finally hit pay dirt with Carl Linnaeus' 1742 *Hortus Upsaliensis* (Klee, 2014).

In February of 2014, a member of the Yahoo *Aquarium Hobby Historical Society of America* asked if they knew who first used beef heart as a fish food and I decided to try for the answer, thinking it would be fast and easy. A number of the members of the forum were quite certain that it was either the *Bureau of Fisheries* or the *American Fisheries Society* no but documentation was offered by them.



The Troutdale Fishery Fish Ponds, Bloomsbury, New Jersey , 1838.

I decided to start in the 1920s and found the following from M.C. James's "More about fish food" (James, 1928):

At least 35 different items were being fed as the 1920s were ending. Included were sheep plucks and liver; beef heart, spleen, and lungs; pig liver, milts, plucks, hearts, and lights; horse and cow meat; fish meal; salted and fresh salmon; condemned canned salmon; herring and other species of fresh fish; middlings; red dog flour; beans (including pinto and soybeans); and cod liver oil. Less frequently used food items included blood, boiled eggs and potatoes, milk (including buttermilk), shrimp, shrimp heads, and fish processing waste.

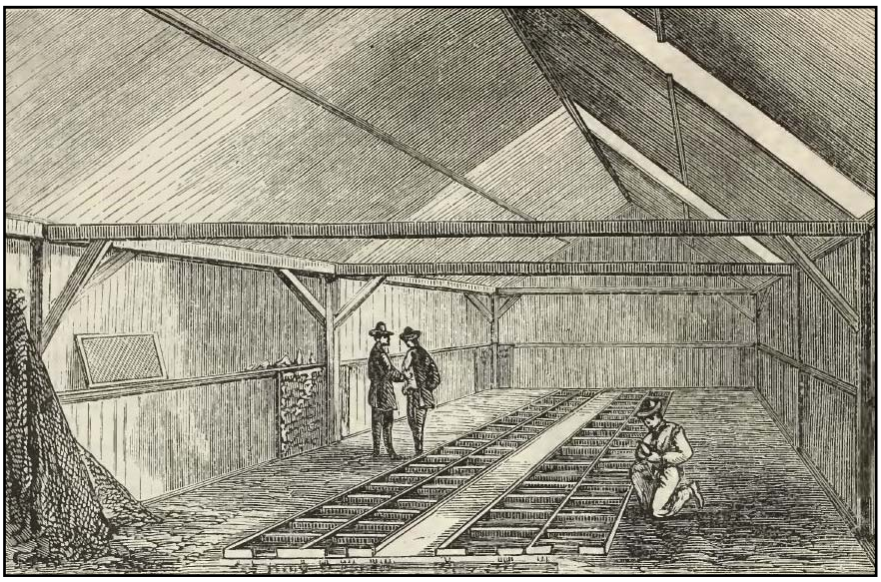
Then I found the following from the *Bureau of Fisheries Service Bulletin, Department of Commerce,* Washington, No. 46, March 1, 1919:

Liver vs. Heart as Trout Food.
An interesting experiment has just been undertaken at the Wythevllle (Va.) station in the feeding of beef liver and beef heart to young rainbow trout. In each of two 14-foot troughs 10,000 fish just ready to take food were placed. The water temperature for the first 30-day period was approximately 55° F., and a flow of about 7 gallons per minute was maintained. All the fish included in the experiment were selected from the same lot and their treatment in the troughs was identical in every way with the exception that those in one trough were fed on heart and those in the other trough on liver.

The results of this experiment were that the rainbow trout fed on beef heart suffered less mortality and also gained slightly in weight as compared with those fed on beef liver.

This, however, did not answer the question since fish farming in this country started in the 1800's and surely beef heart was used then. I then consulted Fred Mather's "Modern Fish Culture in Fresh and Salt Water" (Mather, 1900), and found that he had mentioned beef heart in two places. (Note: Among other things, he was Superintendent of Fish Culture at the New York Aquarium from 1876 to 1879, working under Henry Dennison Butler.) In preparation for his book, Mather constructed a questionnaire and distributed it in the summer of 1891. One of the questions involved a trout epidemic and the following was one of the answers received:

Six years ago, about the same disease appeared among my trout from April to July. In June they died in great numbers, from twenty-five to thirty every night, and I was discouraged. One day I saw that a great many more would die and thought that the cause might be from feeding stale beef hearts. I stopped feeding for ten days and then began giving them live minnows, and in a week's time the mortality stopped and I have lost very few trout since. *Albert Rackow, Elmont, Long Island.*



The Troutdale Hatching-House.

Since the responses to the questionnaire were received in 1891, Rackow was feeding beef heart in 1885.

Incidentally, Rackow thought the problem might be in the stale beef heart he was feeding at the time. In 1891 he was actively feeding a combination of beef heart and minnows to his trout. The response to the questionnaire as to what trout farmers fed included the following:

Albert Rackow, Elmont, Long Island, N. Y., says: "'I feed my trout on beefs' (sic) hearts and minnows; growing 8,000 trout every year, and it pays a profit."

These reports led to a spirited discussion on the Forum of the merits of feeding beef heart to aquarium fish. This, however, was not relevant to the member's question. However, remembering that long list of horticultural dictionaries written in the 1700's that I perused without success when searching for the origin of the word "aquarium," I decided to look a bit more. The book I found was published in my own back yard, "A Helping Hand for Town and Country; An American Home book of Practical and Scientific Information" (Draper and Croffut, 1870):

When they are two months old they should be fed occasionally with curds, or beef's heart, or liver minutely hashed. Toss this to the fish a little at a time, so that they can catch and devour it before it reaches the bottom of the trough; no more should be given than the fish will eat, because if any is left it will settle on the bottom and foul the water, and the fish will sicken and die.

At this point I ceased my beef heart investigations, only to revive them three years later. My next finding was an article on fish culture in America that appeared in *Harper's New Monthly Magazine* (Shanks, 1868):

The best substance for this purpose is beef's heart, chopped into minute fragments, sifted through a fine wire sieve, mixed with water, and fed to the fish by means of a small syringe of about one ounce capacity.

Care must be taken that no more be placed in the trough than can be immediately devoured; but at the same time the fish should be fed until he is thoroughly satisfied. Nature made the trout a true cannibal, and he cannot eat too much for his own good. It is for reasons of cleanliness - as absolutely necessary to fish as food - that too much food should not be put into the boxes. If it is not immediately eaten it soon fouls the boxes and kills the fish.

The problem with the Draper/Croffut and Shanks references is that although the dates are useful, neither helps in identifying the person who first used beef heart. Certainly it was not the authors. Lyman C. Draper was Secretary of the Wisconsin Historical Society and W.A. Croffut - along with

Securing the Trout Eggs.

his coauthor - was the author of “The History of Connecticut” and a series of biographies of American pioneers. William Franklin Gore Shanks (1837 -1905) was war correspondent for the *New York Herald* (1861–65) and subsequently joined the *New York Tribune* where during this time he was imprisoned for refusing to divulge the name of a writer of an article in the paper. Besides his contributions to periodicals, he published: “Recollections of Distinguished Generals” (1865)"; “Bench and Bar” (1868); and a play, “A Noble Treason” (1876). None of these three men were fish culturists themselves and therefore not responsible for the introduction of beef heart as a fish food..

The farther back one goes into the literature, bibliographies are less often found so I decided to bite the bullet and to examine the following seven books, arranged in order of publication, to learn what these pioneering fish culturists had to say about feeding (Stone and Slack are tied for fifth place)

1. FRY 1854
2. GARLICK 1857
3. NORRIS 1868
4. GREEN 1870
5/6. STONE 1872
5/6. SLACK 1872
7. GREEN and ROOSEVELT 1879

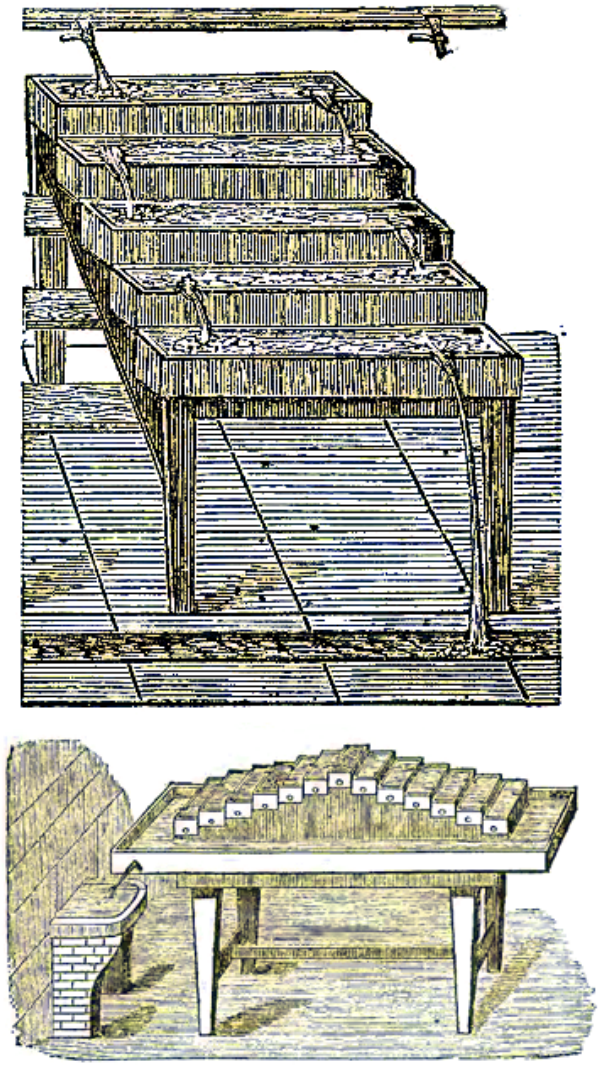
The following are the relevant excepts from each of these books:

1. FRY 1854

As early as 1849, as appears by a memoir on the domestication of fish and the formation of ponds, I had proved by actual experiments, that very young fish could be fed upon the raw flesh of domestic animals, hashed, and that they would thrive and grow rapidly on this diet.

The operation of reducing muscular raw flesh to minute fibrous particles, small enough to be readily swallowed by exceedingly little fish, is one that demands considerable time; and the further difficulty of separating and properly dispersing in the water the compact mass of flesh resulting from this operation, led me to seek some more expeditious mode of feeding.

To Mr. Chantrant, under whose charge is the hatching apparatus of the College of France, is due the idea of replacing raw by cooked meat. This substitute has had all the success I hoped for, and has enabled me to feed easily, and at small expense, and to bring up in a space 55



Top: A single flight of hatching boxes. Bottom: A double flight of hatching boxes. The water enters from a two-inch pipe directly from the hatchery spring into the boxes and from the last box into a trough on the floor.

centimetres long, 15 wide, and 8 deep, as many as 2,000 young salmon at once. The muscular flesh of boiled beef, which, by being pounded, grated and cut, is reduced to particles proportioned to the size of the little animals it is to nourish, flesh reduced to that state that it will stick together in a mass but can be with greatest ease separated into the smallest particles, I have found, up to this time, the most suitable food for very young fish just beginning to feel hunger.

2. GARLICK 1857

It has been ascertained that the lean flesh of animals, when boiled, is an excellent article of food for young fish, or even old ones. As the young fish are very small, it is necessary, to hash it up into very fine particles, or they will not be able to swallow it; in fact, it should be pounded or grated very fine, but as they increase in size, it may be given, in coarser particles. The flesh of other kinds of fishes, where they are plenty, would be an excellent substitute for the flesh of animals, either cooked or uncooked; I think this kind of food, preferable to any other.

3. NORRIS 1868

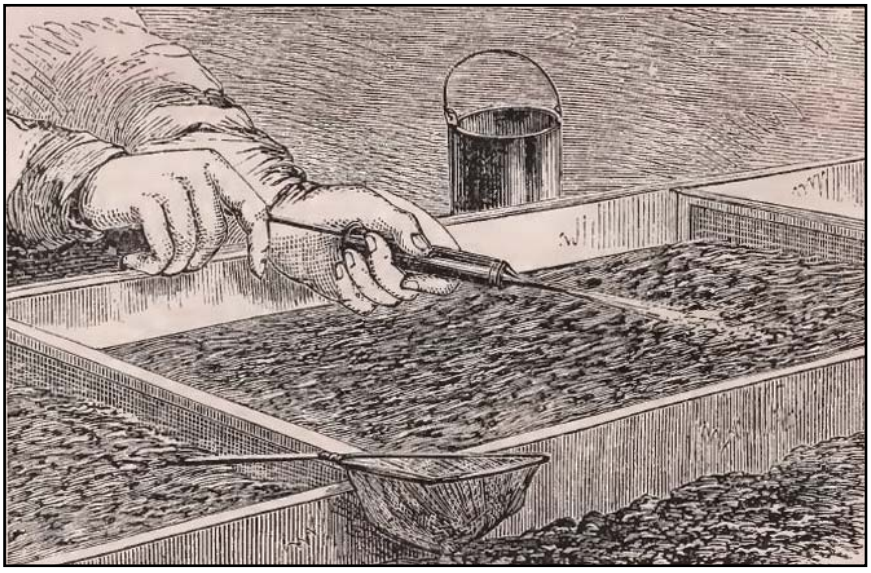
Four or five different kinds of food have been recommended. Liver or lean meat boiled hard and grated ; the yolks of eggs boiled hard and reduced almost to a powder; raw liver chopped fine with a long sharp knife; fresh or coagulated blood; fresh shad or herring roe, raw or boiled; thick milk or bonny-clabber (In Irish Gaelic, bainne clabair means 'thickened milk.' In English, the equivalent word is bonnyclabber), and curds.

4. GREEN 1870

In this country we pursue a cleaner method. The pluck of animals killed (that is the lights and liver) is obtained from the butchers. This food can be obtained fresh at least once or twice a week in most localities and kept fresh by means of an ice house. We feed meat to them raw. They have never been used to cooked food in their natural state and we do not see that it is any better tor them. The lights (lungs) should be given to the larger fish as it cannot be chopped so fine as the liver and is more apt to hang in strips or strings. The liver which can easily be cut into small pieces may be fed to the smaller fish.

5/6. STONE 1872

I think the best food for them at first is liver, and curd made from sour milk, mixed in about equal proportions, or, still better, with two parts liver and one part curd. The young fish at this age, as may be supposed, can take only the finest particles of food. The curd, therefore, should be made as fine grained and moist as possible. The liver should also be reduced to the smallest possible particles. This is accomplished in various ways, but the way that I have found the most satisfactory and the most expeditious is to grate the liver on a common tin lemon-grater or cheese-grater. You must be careful to have the holes small enough at first to admit only very fine parti-



Feeding the Young Trout.

cles; they should not be over one tenth of an inch in diameter.

5/6 STACK
To be discussed later.

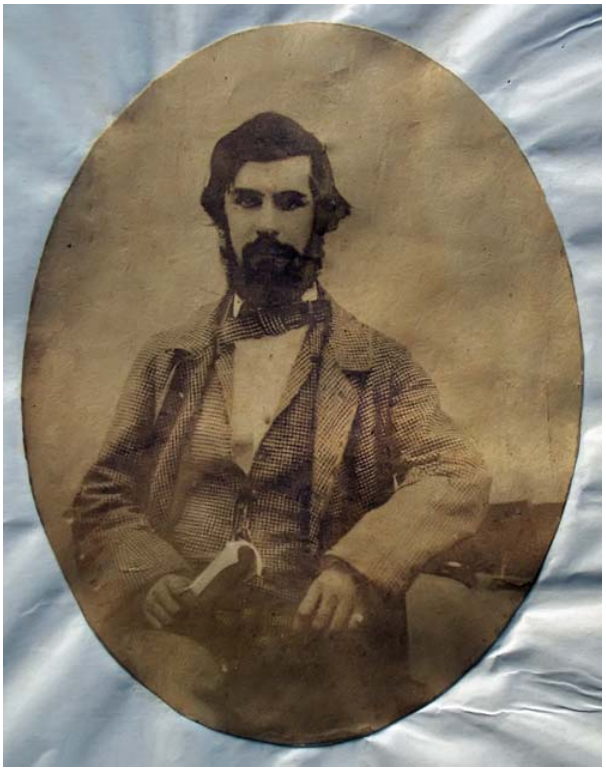
7. GREEN and ROOSEVELT 1879
It is supposed that a trout is very fond of grasshoppers, but the trout in one of our ponds which we have fed for a long time with beef lights, will not look at grasshoppers, and will turn up their noses at the fattest and juiciest worms, while the trout fresh caught out of the stream, which we have put in a pond by themselves to educate, will for weeks refuse the daintiest bits of lights and liver. Hunger will after a time drive them to change their food; but with the young ones we cannot wait for this, as they will die off before they learn. As the fish grow older and stronger more food must be given to them; when six months old, a bowl full of liver will answer for a thousand. While the fish are young, feed often; six or eight times a day for the first two or three months; three times a day will do after three months until they are a year old.

As can be seen from these excerpts, six out of the seven authors did not mention the use of beef heart as a food. It is now time to say more about John Hamilton Slack.

William Henry Fry, Theodatus Garlick, Thadeus Norris, Seth Green, Livingston Stone, R. Barnwell Roosevelt, Fred Mather: these are well-known names in American fish culture. But John H. Slack? Although he was author of *Practical Trout Culture* (1872), a founder the *American Fish Culturists' Association*, a deputy U.S. fish commissioner, and a key player in a nationwide campaign to introduce nonnative species to new waters, few know much about him. In my own essay, "The Early History of American Fisheries" (Klee, 2016), I gave him but brief mention twice. I intend to remedy this omission now.

JOHN HAMILTON STACK

John Hamilton Slack (1834-1874) was born and raised in Philadelphia. His family seems to have been reasonably prosperous and after graduating from the Department of Arts of the University of Pennsylvania in 1856, he made a tour of Europe, Northern Africa and the Nile. Upon returning in July, 1857, he was elected a member of the *Academy of Natural Sciences of Philadelphia*. During the same year he presented valuable specimens of Egyptian natural history and antiquities, for which the thanks of the *Academy* were formally returned. The next year he presented for publication a paper, which appeared in the *Proceedings* under the title " Catalogue and Notes on the Egyptian Antiquities in the Museum of the Academy." In the spring of 1850 he graduated from the Medical Department of the University, and at once applied himself to the practice of his profession and the study of natural history. From this time until his removal from the city he was an active and enthusiastic worker in the *Academy*. His name appeared in the *Proceedings* as a constant contributor to the museum and library, and also as the author of three papers on



John Hamilton Stack (1834-1874).

Mammalogy, the most important of which was a monograph of the Prehensile-tailed Quadrumana of South America. Slack was elected Librarian of the College of Physicians in December, 1864, and served until December 31, 1867.

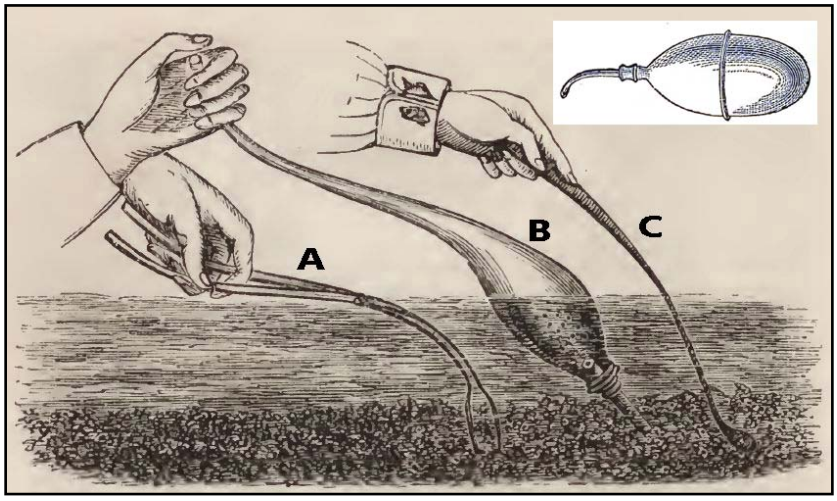
He was a gentleman of unusually varied attainments, a true Renaissance man. Although he was most devoted to the natural sciences, he exhibited an active interest in literature and art. His obituary says he was "a painter of some ability" but he also possessed talents as a musical composer which, if cultivated, would have secured him a wide-spread reputation. As it was, his arrangement of "Home, Sweet Home" was a favorite in thousands of Victorian parlors and rendered his name familiar to thousands who knew nothing about his life-work. he was also an amateur printer who, on a home press, produced handmade volumes of prose and poetry in a "sumptuous style."

Slack was struck by pisciculture as practiced in Egypt but he also was a fisherman and so it is reasonable to assume that he patronized the Philadelphia tackle shop of rod maker and angling *eminence grise* Thaddeus Norris. "Uncle Thad," also known as "the American Walton," was a generation older than Slack. The companionable Norris enjoyed the company of younger anglers, and at some point it is likely they struck up a friendship. At the very least we know they were acquainted.

Norris was interested in the developing science of fish culture and looking for suitable property for building a hatchery. He found just such a place near Bloomsbury, New Jersey. Norris later recorded that he started the hatchery in May 1866 and sold it sixteen months later "in an uncompleted condition to Dr. J. H. Slack."

In the summer of 1867, Slack took possession of 169 acres bordering the lower Musconetcong, in a valley of gently rolling farmland and neat stone houses. Troutdale Ponds, the hatchery itself, took up several acres adjacent to the river. Its outstanding natural feature was a limestone spring gushing a thousand gallons a minute of pure 50-degree water, winter and summer. The spring fed into the single pond dug by Norris and stocked with a few hundred anemic trout. These "died by dozens," wrote Slack in a recollection of his first year of on-the-job training, while "our spawn from want of proper knowledge of the theory of impregnation, and the sickly condition of our parent fishes, perished by thousands." Thousands more washed away in a flood, and thieves absconded with the few healthy adult fish.

Slack persevered. Setting out immediately to make improvements, he added more ponds, with raceways connecting them, and a hatching-house for fertilizing and incubating eggs. On a rise overlooking the hatchery, he built a handsome two-story frame house for himself, his wife and their two small children; two more children soon followed. In the spring of 1868, everything was



Early instruments for removing dead eggs and debris. A is a pair of pincers with pointeds blades; B is a pipette, while C is a scoop to be placed beneath the egg, whch I to be thrown out by a sudden turn of the wrist. Although these worked they were slow and by no means sure. Slack replaced then with the rubber bulb device shown in the inset.

ready in Troutdale. By now, three ponds nurtured a thriving population of trout segregated by size.

In the wake of pell-mell commercial development following the Civil War, states began creating fisheries commissions to promote conservation. New Jersey's was established in 1870, with Slack and fellow physician Dr. Benjamin P. Howell of Woodbury, New Jersey, as charter commissioners. In their first annual report, the New Jersey commissioners noted that the river appeared to be "suitable habitat" for Atlantic salmon and would be stocked with a thousand fry "hatched by the artificial process." The state legislature hadn't authorized funds for stocking, and the commissioners stated they would be doing this at their own expense. Soon enough, however, they found a reliable underwriter in the federal government. Slack and several other hatchery owners had recently founded the *American Fish Culturists' Association*, which successfully lobbied Spencer Fullerton Baird at the newly established *U.S. Commission of Fish and Fisheries* to sponsor a national stocking effort, for which Congress appropriated $15,000.

Troutdale was a busy place. It had become New Jersey's de facto state "hatching house," not only for Atlantic and Pacific salmon but for "salmon-trout" (sea-run brook trout) and landlocked salmon, two other species the fisheries commission introduced into state waters. The hatchery was also raising smallmouth bass and brook trout for private stockings, and watercress for sale in urban markets. Slack was a key player in a nationwide campaign led by Baird to introduce nonnative species to new waters. It was a vast ecological exercise with profound consequences - mainly positive - for American fisheries. To cite just one example, today's Delaware River supports a diverse mix of native and nonnative species: American shad, striped bass, shortnose sturgeon, and brook trout (all indigenous); and smallmouth and largemouth bass, rock bass, walleye, bluegill, muskellunge, channel catfish, European carp, and brown and rainbow trout (all introduced, mostly in the second half of the nineteenth century).

Between 1870 and 1875, Slack's operation raised more than 170,000 Atlantic salmon fry and released them into the Musconetcong and other Delaware tributaries; this was in addition to 154,000 released into the Raritan and two other New Jersey watersheds. During this same period, Troutdale also hatched 450,000 Pacific salmon fry from fertilized eggs shipped from California on the new transcontinental railroad. Most of these (265,000) were deposited in the Delaware, with the rest going to other eastern rivers.

Slack and others in the vanguard of the fish-culture movement viewed the introduction of salmon as eminently worth trying, and for a time it looked like their grand experiment might succeed. Mature salmon were first observed in 1875 and the numbers steadily increased through 1878. 1879 had a good run, but regrettably, the experiences of that year were not repeated. In 1880 just a few adults were recorded, and in 1881 a few were reported but not confirmed. The experiment was a failure.

In the spring of 1873, Baird named Slack a deputy U.S. fish commissioner, an appointment expanding his responsibilities beyond the borders of New Jersey. His immediate assignment was assisting shad-hatching operations in North Carolina and Virginia and escorting a shipment of

The "American Chopper," used by Slack to cut his beef heart.

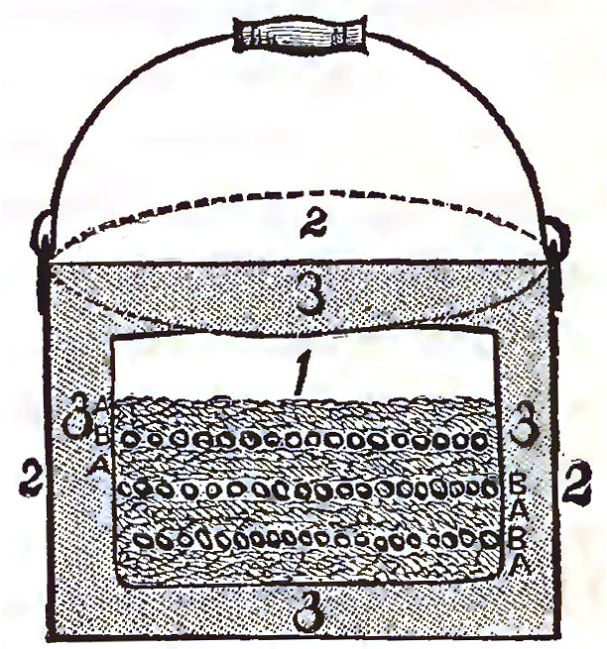
15,000 shad fry to western Pennsylvania for deposit into the Monongahela River, a tributary of the Ohio. The Monongahela fry were hatched at a seasonal station on the Delaware River at Lower Black Eddy, a stretch of slack water near Point Pleasant, Pennsylvania, about 30 miles from Troutdale. In honor of his boss, Slack named the station Camp Baird.

The next year Slack and his shad team set up camp on June 25. They had a good run of fish and by June 29 had hatched 100,000 fry. Slack dashed off a note to colleagues at the *Academy of Natural Sciences* urging anyone curious about "the modus operandi of impregnating and hatching spawn" to join them. Whether anyone did isn't known. What we do know is that Slack departed camp on July 2, leaving an assistant in charge, and went home to Troutdale. Probably he was sick, for on July 3, according to a subsequent account, he took to bed, "prostrated . . . by a violent attack of Pleurisy," an inflammation of the lining of the lungs often associated with pneumonia. Presumably by telegraph, he stayed in touch with Camp Baird until it ceased operations on July 13, having hatched 530,000 fry. By then Slack was gravely ill. He lingered another six weeks and died on 24 August 1874, a month shy of his fortieth birthday.

In his time, John H. Slack was a prominent figure in what can rightfully be called the heroic age of American fish culture. We can marvel at his efforts, however wrongheaded, to establish salmon in rivers where nature never intended them. He might have achieved the stature of his contemporaries Livingston Stone, Seth Green and Fred Mather if he hadn't died young and bet on the wrong fish. In 1875, a year after Slack's untimely death, Stone shipped the first eggs of California rainbow trout to Green's hatchery in Caledonia, New York, with more following in 1878. A few years later, Mather began raising brown trout imported from Germany and Scotland at the New York State hatchery in Cold Spring Harbor. By the early twentieth century, rainbows and browns were thriving in much of the eastern united States. Had he lived, Slack would doubtless have been involved in the introduction of both species, and we would recognize him today as a central player in the history of American fisheries. Instead, he is mainly a footnote, a man who pursued a quixotic quest that was bound to fail.

The following is taken from Slack's 1872 book:

A beef's heart or kidney is taken, and with a sharp knife cut in pieces about an inch square. If heart is used, all skin, arteries, valves, and other fibrous portions which cannot "be readily cut are rejected. The pieces are then moistened with water and chopped to a pulp. This was formerly done with a hatchet and Knife - a work of no small labor. We now accomplish it by means of the "American Chopper." A pound of heart can be cut by this in about seven minutes sufficiently fine for the smallest trout. Should any coagulated blood be found in the heart, it may be thrown into the chopper with it. Yet, still some minute fragments of fibrous tissue may remain, and to remove these, as well as to be



Slack's device for Eggs packed for egg transportation.
A = moss; B = spawn; 1= spawn box; 2 = tin kettle; 3 = sawdust.

sure that all the meat is chopped sufficiently fine, the pulp is mixed with water and washed (not rubbed) through a fine wire sieve of twenty-eight threads to the inch. By this means all fragments over about one-fiftieth of an inch in diameter are retained and may be returned to the chopper for further comminution.

In Merritt's 2011 biography of Slack, he noted: **In the spring of 1868, a Harper's Weekly correspondent visiting Troutdale found everything in order.** The "correspondent" was, of course, William Shanks. The mystery is now solved. John Hamilton Slack, in 1838, was the first known American to use beef heart as a fish food.

The Troutdale Transit Tank, invented by Slack. The can is constructed of heavy galvanized sheet iron ; to the outside is attached an air-pump, communicating by means of an india-rubber pipe with a tube leading to the bottom of the can, which terminates in a nose similar to that of a watering-pot pierced with minute holes. By simply working the handle, air is driven in, and being divided into fine bubbles by the nose, completely aerates the water, restoring the oxygen consumed in respiration by the fishes.

PDF SECURITY FOR AQUARIUM HOBBY ORGANIZATIONS

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, August 11, 2017)

File security has been with us since the beginning of personal computers. The simplest kind was to move a tab on a floppy disk to prevent overwriting any of its files. Another was to set the file to read only, which protected them from accidental or unauthorized changes. Things haven't changed much since the natal days of the home computer, except that they have gotten more complicated and security more difficult.

WHAT IS A PDF FILE?

In 1991, Adobe Systems' co-founder John Warnock outlined a system called "Camelot" that evolved into what is now known as the Portable Document Format or PDF. While Adobe Systems made the PDF specification available free of charge in 1993, it was a proprietary format, controlled by Adobe, until it was officially released as an open standard on July 1, 2008. It was published by the International Organization for Standardization as ISO 32000-1:2008, at which time control of the specification passed to an ISO Committee of volunteer industry experts. In 2008, Adobe published a Public Patent License to ISO 32000-1 granting royalty-free rights for all patents owned by Adobe that were necessary to make, use, sell, and distribute PDF compliant implementations.

The PDF file format is used to present documents in a manner independent of application software, hardware and operating systems. Each PDF file contains a complete description of a fixed-layout document, including the text, fonts, graphics and other information needed to display it. In other words, it is a file that will look the same on the screen and in print regardless of what kind of computer or printer someone is using and regardless of what software package was originally used to create it. Problems that are caused by fonts that are not installed on the viewer system are unknown when using this format, the files are very small and their content can be stored compressed. Thus, it is a convenient, cheap and effective solution for distributing digital documents, hence its widespread use by aquarium hobby organizations.

PDF files can be created in a number of ways. On my computer I have four programs that I use to create them. One is Microsoft Word. In Word I enter my text and include figures and tables as required along the way. When finished, I print the file using a PDF printer driver (this is one of the printer options that comes up when you hit the PRINT button) and the resulting file has the PDF extension. Another program is Adobe Photoshop. I enter the text, figures and tables as I do in Word but in this case when finished I use the "Save as" command and save it as a PDF file. The other two are pdf creation/editing programs, Adobe Acrobat and Nuance Power PDF.

When you create a PDF file it cannot be easily edited or changed in any way (one reason is that it is compressed to save space). However, you can add to it and the additions can be easily edited or changed. Look at it this way. The elements of PDF file you just created - text, images and tables - are embedded on a single layer and combined as one entity. However, in a PDF editor you can add other layers, notably headers, footers and watermarks, and these can be edited and changed easily. Headers and footers are areas where you can insert the date, time, page numbers, and more to top and bottom margins

of each page in a document. Watermarks are a pattern of bits inserted into a digital document that typically identifies on each page the file's copyright information (author, rights, etc.). (The name comes from the faintly visible watermarks imprinted on stationery that identify the manufacturer of the stationery). The purpose of digital watermarks is to provide copyright protection for intellectual property that is in digital format.

The problem is that ANYTHING in a PDF file CAN be edited with a PDF editor. Large areas such as watermarks, headers and footers can be whiteouted digitally, and individual text can be deleted, changed or added to the file.

WHY DO AQUARIUM HOBBY ASSOCIATIONS NEED PDF SECURITY?

There are two - but not necessarily mutually exclusive - main reasons:
(1) The organization wants to restrict the use of the material to members only, and
(2) The organization wants to sell the material either as a way to recover the cost of producing it or as a means of income.

With regard to the latter, some of these materials involve a massive amount of the member volunteer work that supports these organizations. The pilfering of this revenue could not only be crippling in obtaining volunteers to do this kind of work in the future, but it could affect the financial future of the organization as well. In any event, for whatever reason the security of these widely used PDF files needs to be protected.

PDF BUILT-IN SECURITY

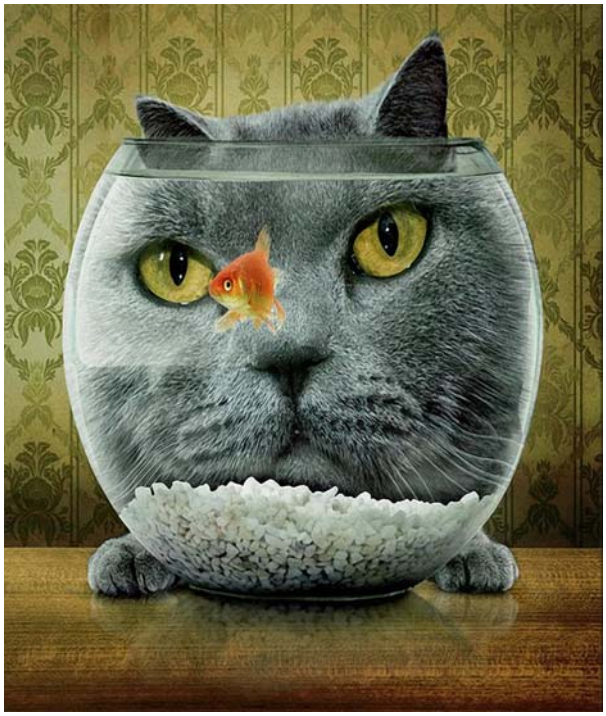
PDF documents offer two basic types of PASSWORD security:
(1) A USER PASSWORD (also referred to as an open password) is required to open the file for viewing.
(2) A PERMISSIONS PASSWORD (also referred to as an owner or master password) is required to change any security settings, such as prohibiting changing the document, printing, copying or extracting text. Note: If a restricted file is copied, the file will generally have "(SECURED)" added to the name of the file, e.g.,

Newsletters, 2010-2017, American Mudskipper Association.pdf (SECURED).

PDF password cracker tools fall into two major categories:
(1) Tools that recover the user password, and
(2) Tools that remove the permissions password in restricted files, allowing full access to the file.

In the first category, the Brute Force Attack is the most widely known password cracking method. This attack simply tries to use every possible character combination as a password. The number of possible combinations (and therefore required time) grows rapidly as the length of the password increases and this method quickly becomes useless. The table shows the time required for the Brute Force Attack depending on the password length and used character set. It is assumed that the attack is carried out on a single computer and the brute force speed is 500 000 passwords per second.

This kind of security, however, is not relevant for aquarium hobby organizations; it is used by the



PASSWORD LENGTH	CHARACTER SET			
	Lowercase letters	Lowercase Letters & Digits	Both Lowercase & Uppercase Letters	All Printable ASCII Characters
5	Instant	2 min.	12 min.	4 hours
7	4 hours	43 hours	23 days	4 years
9	4 months	6 years	178 years	44,530 years

owner of the file to protect it from being accessible to or stolen by others who have access to the computer that holds the file.

In the second category, the tools that remove the PDF permissions password allowing full access to the much easier. Here one is not looking for the correct password but only the place in the file where the permissions password is located. Since one doesn't even need to know the password to remove it, even a 20-character password with upper and lower case letters, numbers and all ASCII characters (e.g., #, $, &, etc.) is worthless in this regard.

WATERMARKING AND RESTRICTIONS

Since the purpose of digital watermarks is to provide copyright protection for intellectual property that is in digital format, some organizations have used them and they do provide some security. For one thing, it is difficult to sell or even give away a document when it is watermarked for a specific owner. Infringement of copyright is almost always specifically mentioned on the CDs that contain these documents, for example,

Issued to Paul Fishfinger 7/31/2017
Copyright © American Mudskipper Association 2017

If this is done, there is really no need to place any further restrictions on the CD, such as prohibiting copying, printing or extracting pages.

It has been traditionally assumed that including a user-name watermark such as in this example in a PDF file secures the file. Now there are two types of people in this world: (1) those who would never copy an organization's material and give or sell it to another, and (2) those who would. Anyone in the former group would not try to break security, so any discussion about security would be of academic interest to them at the most. Anyone in the latter group would persist until they found a way to break this kind of security. Once broken, the watermark could then be removed manually. THUS, ADDING A USER-NAME WATERMARK TO A FILE IN THIS WAY IS HARDLY ANY SECURITY AT ALL.

PDF CREATOR/EDITORS

The three best of these programs from a 2015 re-

view of ten of them (in order of decreasing rank, i.e., 9.95, 9.4 and 9.00) were: Adobe Acrobat ($300), Nuance Power PDF Advanced ($98) and Foxit Phantom PDF Standard ($78). (These prices will, of course, vary.) Although Acrobat is the standard, you don't have to pay the high Adobe Acrobat price. The Nuance Power PDF Standard, which has all the features that an aquarium hobby organization would need, can be found for as little as $65 on Amazon.com. Indeed, this is the PDF creation program I use, having replaced my old Adobe Acrobat Version 9. In this white paper I will refer to it simply as "Power PDF."

Note that not all PDF editors fully support and respect settings made by other editors such as watermarks, headers, footers and restrictions that are made after the basic pdf is created. Therefore it is best when using an editor to use it only on pdf files that do not contain post PDF creation settings made by any other program.

A SOLUTION

There is a solution that has been available for some time and it is difficult to break, especially for long files. PDF programs since the time after Acrobat version 9 have had the ability to flatten and merge elements within pdf files. PDF files are generally constructed as layers, with the main layer containing the text and images of the document and secondary layers such as headers and footers and watermarks.

To "flatten" a PDF file means that a selected secondary layer in the file will become seamlessly imbedded throughout the document. In Power PDF, watermarks can be protected by embedding them in the file by doing the following:

1. After constructing the watermark go to the "Advanced Processing Menu" and select "Layers" (see Figure 6).
2. A little wrench icon with a down arrow appears; right click on the arrow and select "Flatten Layers." Wait until Power PDF finishes doing this on all pages of the file.
3. The watermark can now only be removed page by page in a PDF editor, a daunting task for large files.

Incidentally, the process is extremely fast; on my computer a 1,000 page PDF file took Power PDF 20 seconds to install the watermark and 18 seconds to flatten and embed it in the file.

HEADERS AND FOOTERS

The header is a section of the document that appears in the top margin, while the footer is a section of the document that appears in the bottom margin. Headers and footers generally contain additional information such as page numbers, dates, an author's name or footnotes, which can help keep longer documents organized and make them easier to read. However, they can also be used to display the same type of security information that the watermark is intended to do and thus a footer is helpful in showing an additional security warning such as, "COPYING OF THIS FILE OR ANY PART OF IT FOR DISTRIBUTION IS A CRIME!"

There is, however, a catch; they cannot be embedded like watermarks and thus they can easily be removed manually. However, one can prepare a watermark that contains, for example,

Issued to Paul Fishfinger 7/31/2017
Copyright © American Mudskipper Association 2017

at the top, and the following at the bottom

COPYING OF THIS FILE OR ANY PART OF IT FOR DISTRIBUTION IS A CRIME!

We've met!

POWER PDF AND WATERMARKS

Power PDF allows only one watermark per file but there is no limit on the number of lines in the watermark. A left click on "Watermarks" in the Home Menu brings up a thumbnail view of all the watermark lines on the left side of the screen. A red plus sign at the top of the thumbnails enables you to add a watermark line, name it and set type properties and position of the line. When this is done, Power PDF creates a new thumbnail with that name. Note that a double left click on a thumbnail enters the line into the file, and a right click brings up a list of options, the most important being "Apply" and "Edit."

It is important to note that when a watermark line is edited, the old line must first be removed, otherwise the edited line will be written right over the old one. It might be supposed that the options "Remove Watermark from Document" or "Delete" will do the job but the first will remove ALL the watermark lines from every page of the document and the second will remove the line AND its thumbnail. The line must be removed therefore by other means to be shown shortly.

A FLOWSHEET FOR SENDING THE FILES TO MANY RECIPIENTS

First, create a copy of the file to be secured and add the water mark with name of the first recipient. In this example I have used a single-page pdf file dealing with the origin of plastic bags in the hobby. Figure 1 shows the file and the various Menu headings of Power PDF.

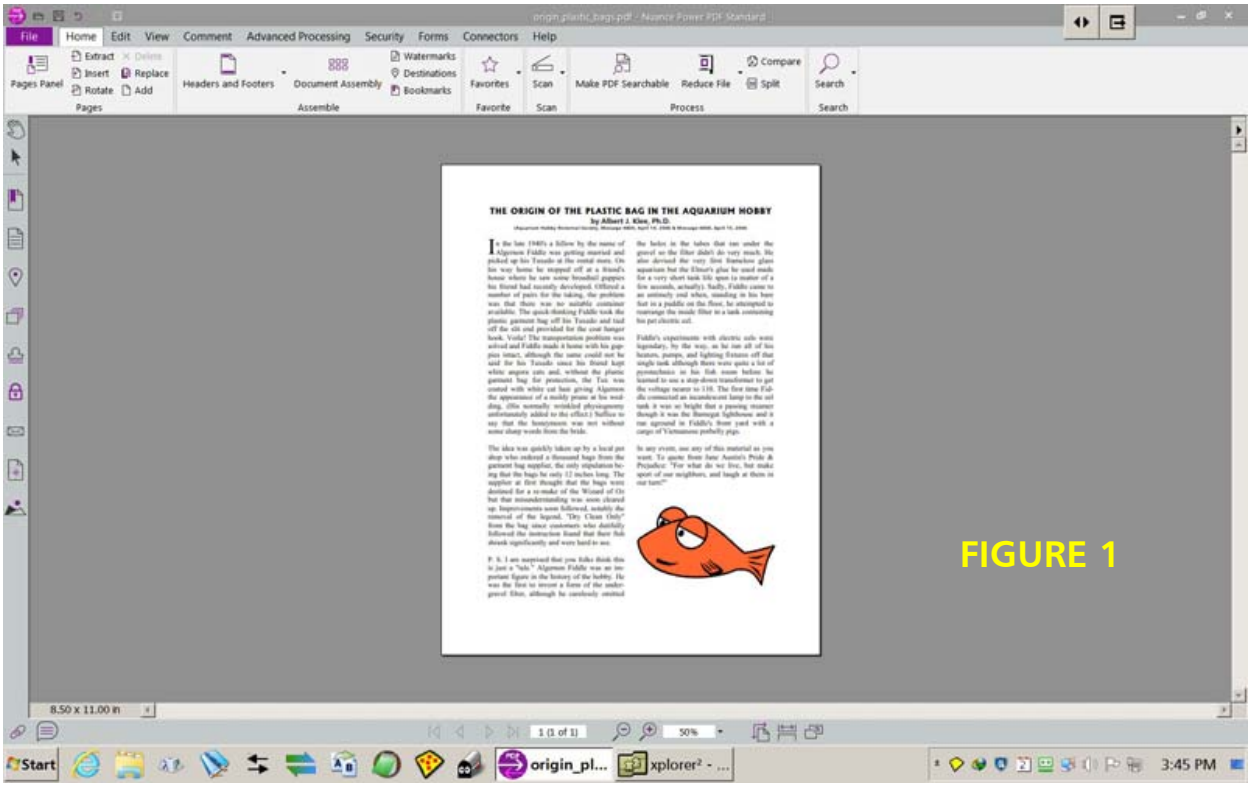
1.In HOME, click on WATERMARKS. A section to the left opens up with a red plus sign and a wrench image at the top (Figure 2).

2. Click on the red plus sign. A "Create Watermark" dialog box opens up and you are ready to create the first watermark and its thumbnail. (Figure 3).
3. In the Title box type LINE1.
4. In the Properties Text box type in the first line of the watermark,

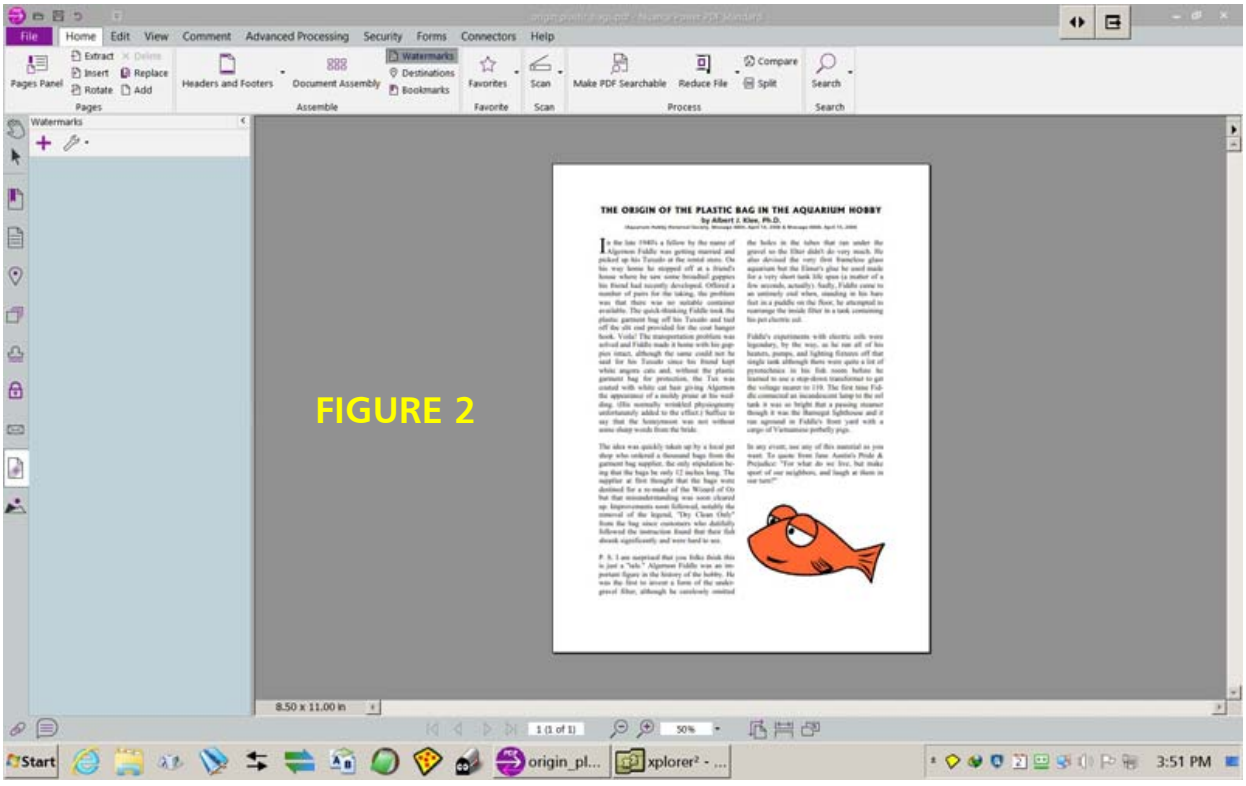
Issued to Paul Fishfinger 7/31/2017.

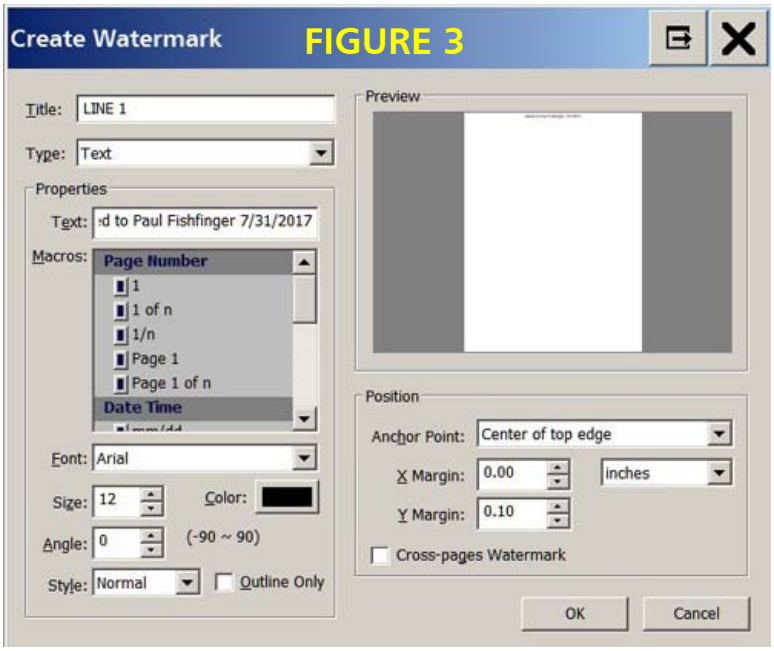
Use the Font, Size, Color and Style boxes to set the type.
5. In the Anchor Point box select "Center of top edge."
Use the Y-Margin box to place the line vertically (0.10 in this case). You can use the scroll wheel, the arrow in the box or just type it in.
6. Click OK.

7. Repeat this for the **Copyright © American Mudskipper Association 2017** line and the **COPYING OF THIS FILE OR ANY PART OF IT FOR DISTRIBUTION IS A CRIME!** line, titling them Line 2 and Line 3, respectively. For Line 3 set the Anchor Point box to select "Center of bottom edge" so one doesn't have to scroll down almost a full page. (Note: In this file I used Y-Margins, in inches, of 0.10, 0.25 and 0.07, respectively for Lines 1, 2 and 3.)



8. Right click on the Thumbnail for Line 1 and left click on “Apply.” An “Apply Watermark” box will appear. Make sure all pages are selected and left click OK. Wait until the application of the watermark is finished. The file is now watermarked with Line 1.





9. Repeat for Line 2 and Line 3. You now have a 3-line watermarked file (Figure 4). Save this file under the name MASTER.PDF and copy it (in two or more locations) in case anything goes wrong.

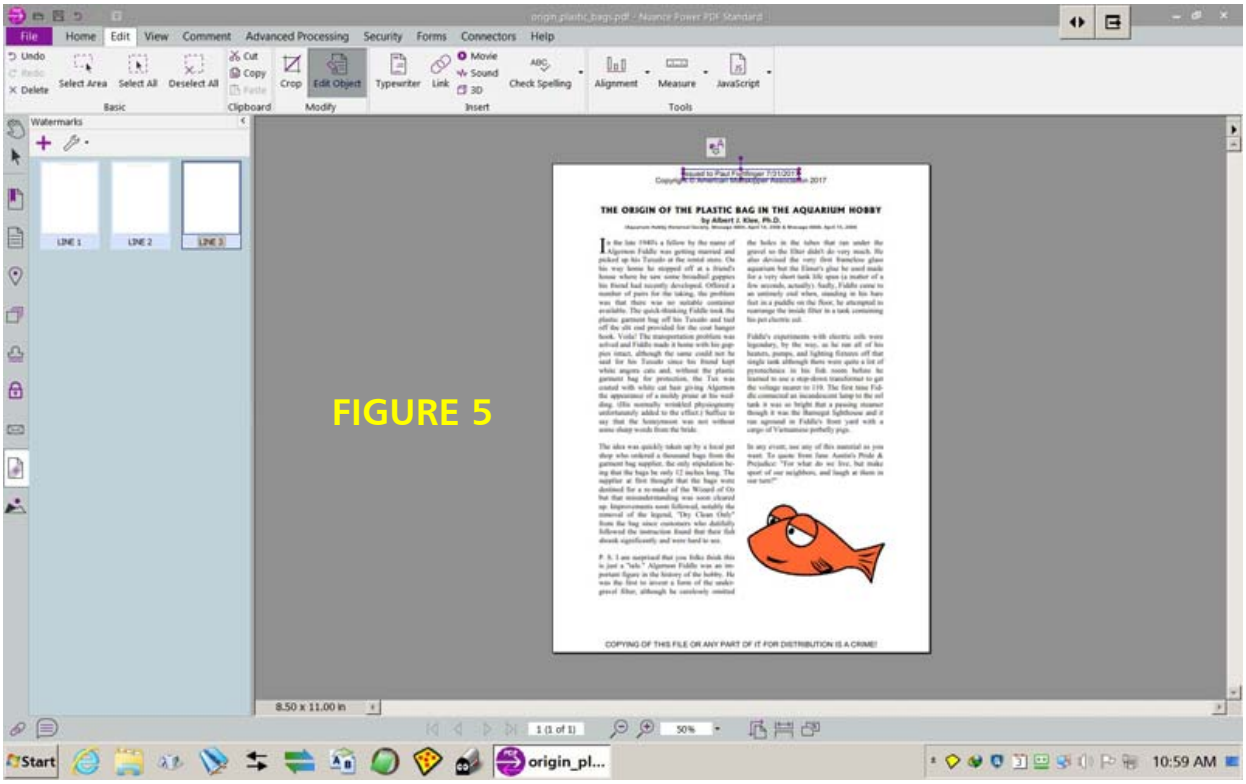
The flowsheet procedure now is as follows:

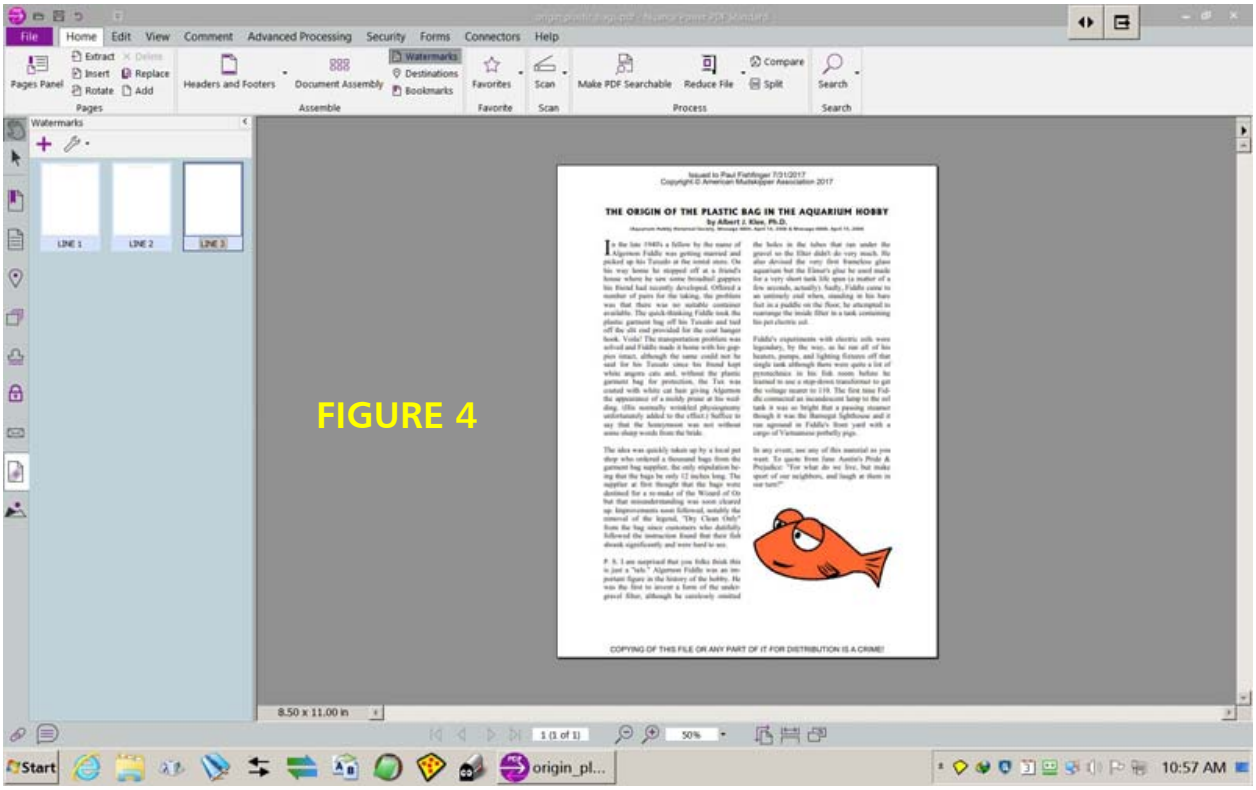
1. Copy the Master.pdf file to a different folder and rename it to describe what it contains, e.g., **Newsletters, 2010-2017, American Mudskipper Association.pdf**.

2. Under the Edit Menu select Edit Object and the cursor changes to an arrow. Place it over LINE 1 in the watermark and left click. A box now surrounds Line 1 (Figure 5). When you see the crossed arrows, right click and select Cut. The first line in the watermark is now deleted, leaving the other lines unchanged.

3. Under the Home Menu select Watermarks and right click on the first line thumbnail and select "Edit." Change the name to the new recipient and click OK. Right click on the thumbnail and select "Apply." Wait until the application of the watermark is finished.

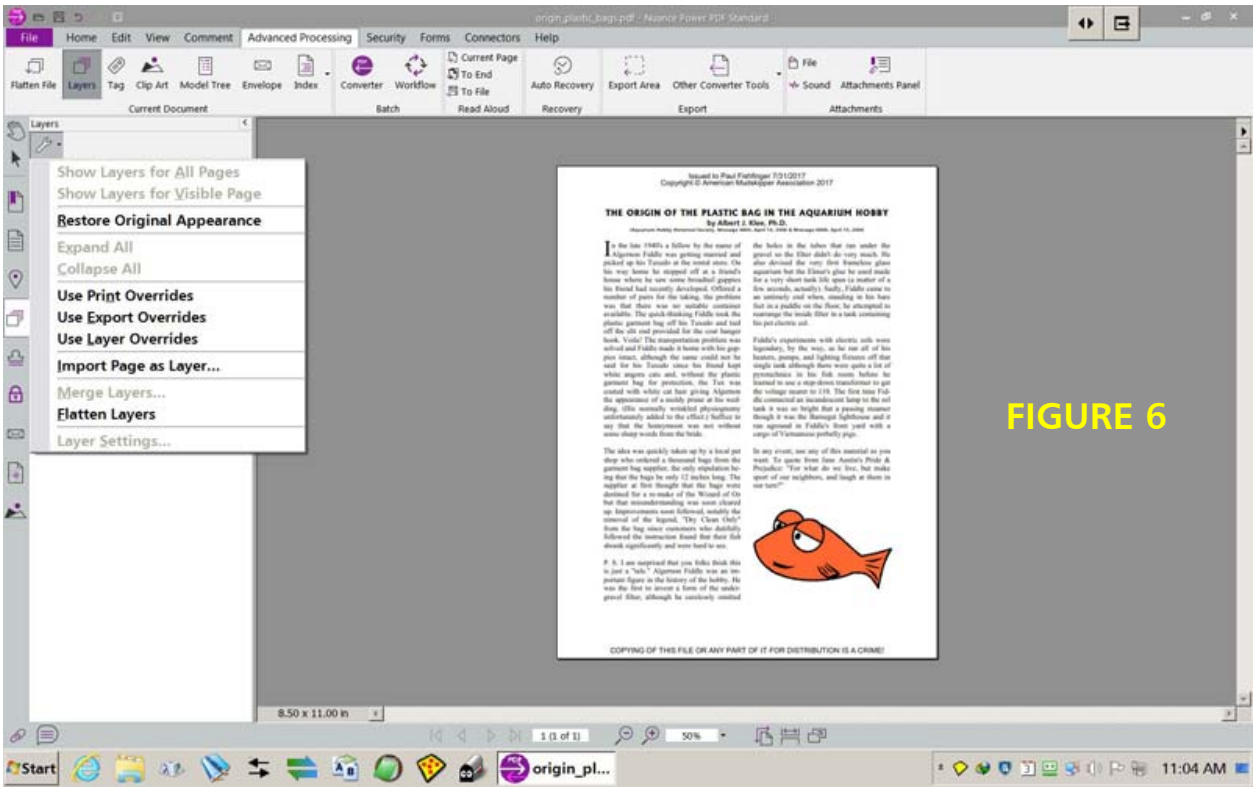
4. Under the ADVANCED PROCESSING Menu select Layers. A box opens up at the left with a wrench at the top left corner. Left click on the wrench and then left click on "Flatten Layers" (Figure 6).





5. Save this file and either send it to the recipient or burn it to a CD and send it. Now go back to Step 1 and stop when all recipient files have been written.

Although this flowsheet may look complicated, it is actually very quick and simple once one has tried it. It is usually not necessary to refer to it again after doing it three or four times.



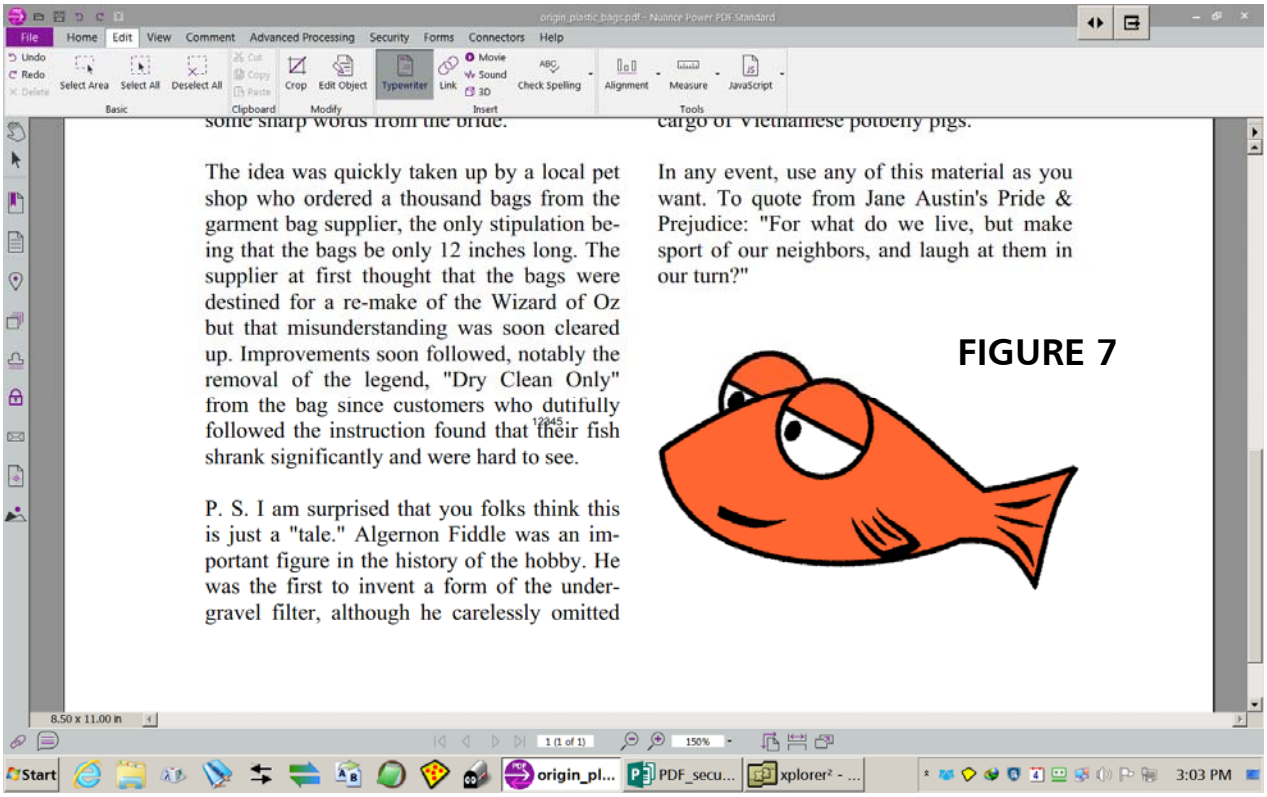


FIGURE 7

EMBEDDING THE USER NAME

Embedding the user name in such a way that it is not easily detectable is another security measure, especially suited to large files. This is done as follows:

1. In Power PDF select a page in the document.

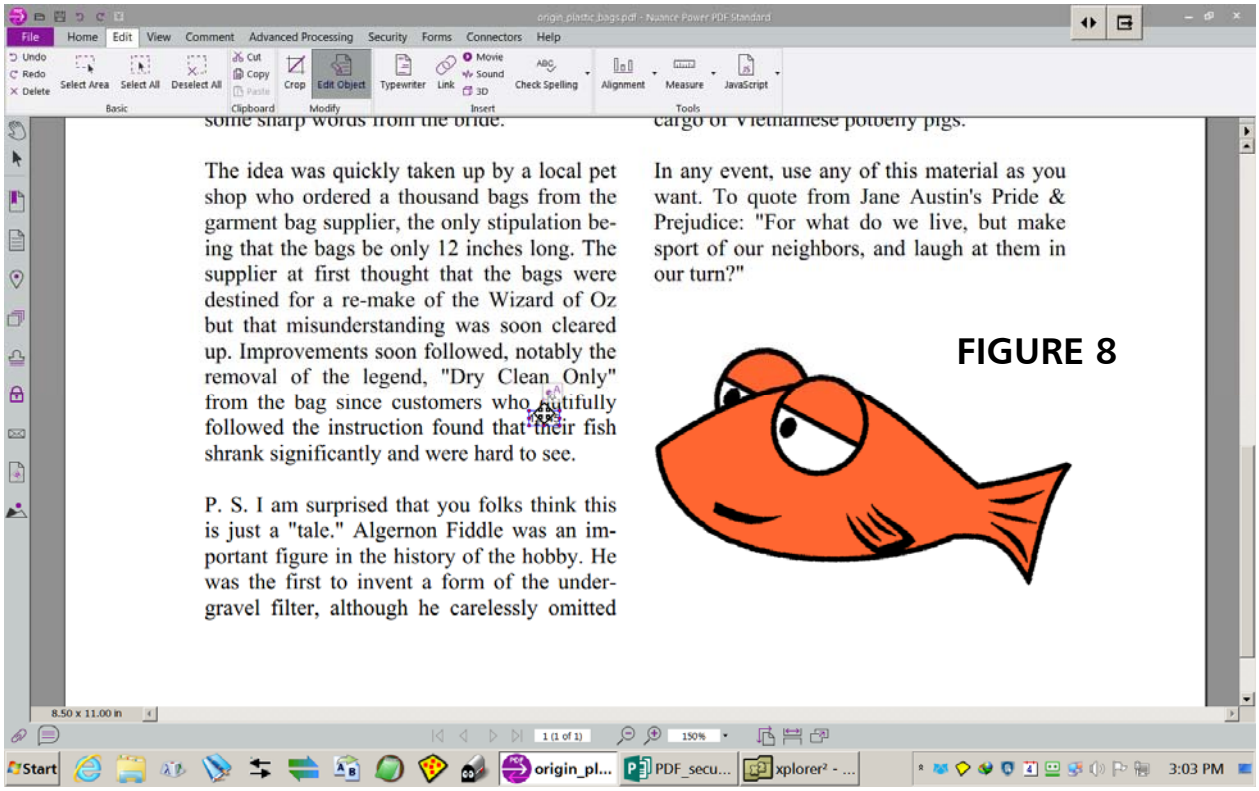

FIGURE 8

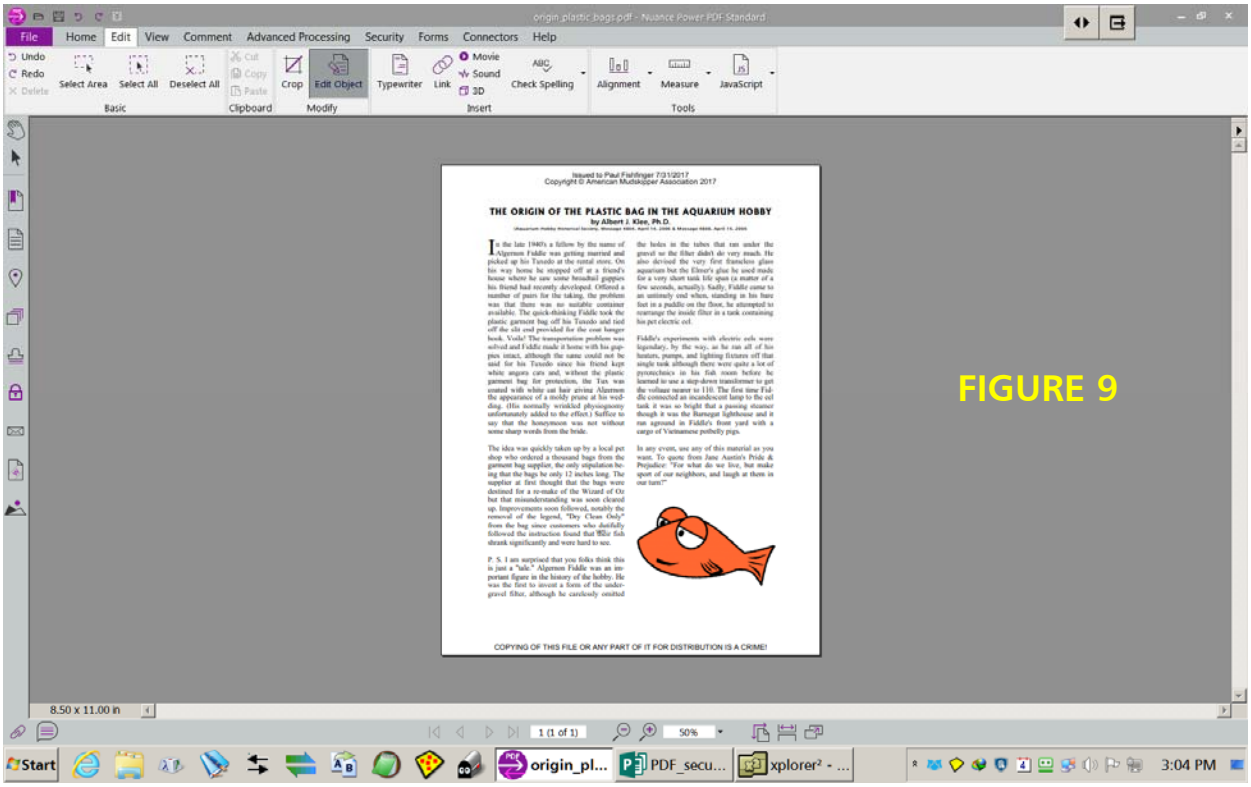

2. Under the Edit Menu select "Typewriter."

3. Move the cursor anywhere and left click.

4. Enter the code used to ID the user (I have used "12345."). In Figure 7 the fish's nose is pointing to it.

5. Under the Edit Menu select "Edit object." Move the cursor on the text just created left click and a box now appears around the text. Right click within the box and select "Properties" and then the "Text" tab. Select Arial at a 6 point type size and close the Properties box.

6. Place the curser within the box (it turns to a cross - Figure 8) and move the text it anywhere on the page you like. You can also use the Control plus arrow keys (small movements) and Shift plus arrow keys (very small movements) to move the box. If the arrow keys are used it is not necessary for the cursor to be in the box.

7. Under the Advanced Processing Menu, click on Flatten File, check "Select All" and click on "OK." Figure 9 shows that it is difficult to spot the code, especially if it is buried in an image in the file.

The code is now in the file and the organization can retrieve the user's name even if the watermark is removed. The organization must keep a record of the page the code number is on, although for simplicity this can be the same for all recipients. It also should keep quiet about it. However, an interesting ploy is simply to announce in the watermark that the name is embedded in the file without actually doing it. The thief will waste his time trying to find it! It is an additional signal that the file may be traceable to its original owner, another deterrent to illegal distribution of the file.

HIGH SECURITY IS EXPENSIVE

Unfortunately, having a watermark that is difficult to remove is no guarantee that the file will not be given away or sold. There is always a market for "hot goods" sold by a thief and commercial companies go to great - and expensive - lengths to minimize this.

There are three main approaches that can be taken to provide a high security for documents:

1. User-independent authorization systems: These are systems where files are downloaded and are authorized for offline usage by either: device

identification, which requires prior registration of the device; or by entry of an authorization code that is checked on a central system (does not require prior registration).

2. User and/or device-dependent systems: These are systems where each person downloading a document must be pre-registered on a centrally managed service, and then each publication they are permitted to view is centrally enabled for them.

3. Online-based systems: Approaches 1 and 2 assume the files are to be downloaded and read offline - no host connectivity is required after the initial stage of downloading and enabling. In many ways a simpler alternative is a hosted service, where the files are kept centrally (i.e., in the "cloud") and displayed via a browser.

Note that all of these systems require a "central system," a "centrally managed service" or a "hosted service," all of which are expensive and which must be maintained 7 days a week, 24 hours a day.

An example of the most common system employed commercially today is activation. These activation schemes work by creating a unique value or ID for each user, based on the user's hardware configuration and the product serial number, though this is implemented differently by different vendors. Microsoft, for example, sends a single combined value, while Macrovision, the maker of the popular Digital Rights Management (DRM) product SafeCast, sends two separate values: the serial number and a number representing the hardware. The user information is transmitted via the Internet (or telephone) to a vendor's activation server, which receives the value, records it in a database and sends back a unique activation code that unlocks the user's product.

Depending on the vendor's implementation, unique hard drive or Registry identifiers are stored on users' machines. There is no way around this, since the key to the process relies on checking user licenses locally each time the application runs. Macrovision's SafeCast stores the values in several areas to make cloning more difficult and to protect legitimate users from accidentally wiping out their license files. (One area is an unused portion of a PC's boot track 0. While this sounds clandestine, an ID stored in that location is less likely to be deleted inadvertently than a file or Registry entry would be.) Clearly no aquarium hobby organization could afford to implement any of these systems.

CONCLUSION

Placing other restrictions on the file, such as changing the document or printing, copying or extracting text is a waste of time since they can be removed without any special knowledge needed by an unprincipled user and are irritating to a legitimate user. In short, the best solution for creating recipient files is, starting with an unsecured PDF file, adding a user-name watermark, flattening all layers, saving the file under a different name and sending it or burning it to the recipient's CD. Change the user-name in the first watermark line and repeat for as many new recipients you have. I also recommend embedding the user name (in code) and not advertising that this is being done.

JOSEPHINE WHITE (1916-1973)

Our First African American Aquarist of Note

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, September 2, 2017.

Josephine White was born Josephine Harris in Abbeville, South Carolina on March 15, 1916, her father being a farmer with a large family. Josephine had five brothers and three sisters and of the nine children, Josephine was the youngest. Not much is known about her early age but at the age of 18 she married Charley White, who lived in the small town of Due West, about 12 miles away from Abbeville. She had four daughters in quick succession, all one year apart (in the 1940 census they were: Betty, age 5, Nellie Mae, age 4, Dolly, age 3 and Jessie age 2). Unfortunately, Charley died shortly after Jessie was born and Josephine was a widow with four children to support. Coming from such a large family, it is supposed that they provided some additional support.

TOP: The location of Abbeville County in South Carolina. BOTTOM: The locations of Abbeville and Due West in Abbeville County, South Carolina.

The year 1940 was still in the Great Depression era and she listed her occupation as laundress and her prior year income, in today's currency, about $1200. The depression was interrupted by World War II and since men were scarce, women were in jobs in factories supporting the war effort. It is possible that Josephine moved from South Carolina - perhaps with one or more of her brothers - to take a job in one of these factories or else to do laundry or other household tasks for those in those jobs. In any event, she obtained a Social Security number during this time while living in Illinois.

In 1951she met Victor White (no relation) and were married shortly afterwards. Victor was born in September 1903 in Hutchinson, Kansas, about 36 miles from Newton and was about 13 years her senior. In 1953 she had a son, Walter, and at that time Josephine, her husband, son and four daughters were living together in Newton. I met Victor and found that he was a pleasant and friendly fellow. Walter, by the way, over time developed a keen interest in his mother's hobby.

Oxen pulling a wagon heaped with cotton bales into early Abbeville, South Carolina.

Josephine was now a "housewife" and for the first time had the time and money for a hobby. How she became interested in tropical fishes is not known but it is clear that it started sometime in the early 1950's. Her interest in the aquarium was broad, as attested to the fact that she was a Charter Member of the American Killifish Association in December 1961. In addition to being an accomplished breeder of such fishes as angels, rams, a variety of tetras (including the black phantom and the emperor), barbs, discus, bettas, killifishes and African frogs, Josephine White had that rare ability to communicate to her fellow aquarists the knowledge her years of experience in the hobby has accumulated. Some time back, the Duluth Aquarium Society collected a number of Josephine's articles and produced a booklet of her work. Other aquarium societies have followed this idea of publishing a collected work of a single author, but Josephine was the first author to be so honored. Her last article, titled "Aquariums for Show and Pleasure," appeared in the June-July 1972 issue of *Northwest Aquaria*, a publication of the Greater Seattle Aquarium Society (after her death, it was reprinted in the July-August 1974 edition. See Addendum).

Josephine often traveled over 125 miles just to attend an aquarium society meeting. She was frequently asked to judge fish shows, and she traveled all over this country on such duties. She was Vice-President of the International Betta Congress, and was on its Board of Directors. She also created the marble and piebald betta varieties. Josephine was a religious person and played an active part in her local church. In one exchange involving the question of whether a fish can or not, she remarked, "Well, I was right again. I told you all things are possible by the grace of God."

EPILOGUE

Josephine White died in November 1973, a few months shy of her 58th birthday (her husband died ten years later, at the age of 80). She was born poor, black, with little formal education and forced to raise her four children alone after her first husband (also poor, black and with little education) died. She worked at menial jobs until she remarried, but had a warm-hearted personality and a positive outlook on life. That she was highly intelligent I can attest to personally, and her many accomplishments support this observation as well.

I often wonder what Josephine would have become if she had the opportunity to go to college. Over the years I have known many people who have been educated at expensive universities with no apparent effect whatsoever. Josephine White would not have been one of them. Someone a long time ago asked me who I thought was the most interesting person I had come across in the aquarium hobby. It was supposed that I would answer that it was William T. Innes, but the question was who was the most interesting, not who had the greatest effect. My answer then was Ida May Mellen. That still holds, but if I had to choose a second place, it definitely would be Josephine White.

ADDENDUM: AQUARIUMS FOR SHOW AND PLEASURE

By Mrs. Josephine White

(From the June-July issue of *Northwest Aquaria*)

Now is the time to start planning your aquariums for the oncoming show. A well planned aquarium can and will be a pleasure to all who see it at home or in a show. Smaller aquariums present some problems one does not have in larger aquariums; but for those who have only smaller aquariums or want to show them this should in no way be a stumbling block. Regardless of the size of the aquarium it must be very clean inside and out, so start with a clean, empty aquarium, making sure the back glass is quite dry.

START WITH A GOOD BACKGROUND

First, let us consider the backing for the aquarium. This I believe is very important. The fish shops have several different kinds and brands of crystal paint and sprays and both come in a wide choice of colors to suit everyone's preference. Since these paints have very toxic fumes, application of them should be done outdoors or in another room as far away from the fish as is possible, so the fumes will not be picked up by the pump and pumped back into other aquariums. Painting should be done in the early morning or cool of the evening or in a cooler room, then let dry where direct sun does not shine on it. This gives best results. Follow the directions on the container of paint carefully, starting at the top of the aquarium and working to the bottom. The brush paints can be poured from the bottle across the top of the glass with the aquarium tilted at an angle, and working this from side to side until the paint reaches the bottom by this motion. This gives the effect of hills and valleys and is most attractive. Choose your color carefully, as 1ight or bright colors do not compliment all fish. Since this may be done several weeks ahead of time for the show, and you may not be certain just what fish will be shown in it, it may be wise to choose a color that will show all fish to the best advantage for your background.

OTHER BACKGROUND SUGGESTIONS

Some people do not like to paint the backs of their aquariums. In this case, there are several choices both in material and color. Florist’s paper that is used to wrap flower pots works very well. Recently a contact paper especially for aquariums was introduced in the shops. Colored foil, such as is used in gift wrappings, also makes nice backings and may be taped to the back of the aquarium for easy removal when desired. Aluminum foil should seldom be used. Light reflects onto the back washing all color from the fish and gives a glaring effect.

PLANTS CAN SERVE AS BACKGROUND

For those who do not want a backing of any kind on their aquariums there is another method: Planting very thickly across the back with *Vallisneria, Myriophyllum, Ambulia, Anacharis* or *Cabomba,* taking care all plants are tall enough to reach the top at least and if longer look very nice laying on top of the water when seen from the top. Planting thickly prevents seeing through the aquarium. The plants require a lot of light and some will do poorly if used in fresh water. It is best to use well-aged water, or better still, clean, clear, filtered aquarium water.

FILTER SYSTEM IS IMPORTANT FACTOR

I like to set up aquariums at least two weeks before a show... this takes planning but pays off best in the end. Remember dirty gravel causes cloudy water. Always wash gravel well and sterilize. This should be done to filters, rocks and driftwood. The bit of green color that may cling to some rocks and wood gives a very pleasing effect. Filters should be carefully chosen to be sure they are large enough for the aquari-

um used so the water will clear in the shortest length of time, and remain clear. Sub-sand filters or outside filters are best for use in shows, since they take little room in the aquarium and are more easily hidden. But if you do not have either of these, a corner box filter may be used. Regardless of the type of filter used, the filter box and/or stems should be hidden as much as possible with tall plants, rocks, driftwood or a combination of these, attractively arranged.

GIVE SOME THOUGHT TO YOUR GRAVEL

Gravel can be piled up high and held in place with rocks and stones, giving a shelf effect that is most attractive. Remember to keep all rocks, stones and plants in proportion to the size aquarium used. Best results in any and all set-ups require more gravel than is normally used, and this should be piled high at the rear of the aquarium and slope to the front, and may be quite shallow in the center, near the front. This too, helps bring the fish to a more central area, making them easier to be seen. Gravel should be chosen with care; all fish do not show well over just any kind or color of gravel. Gravel that is more natural on color works best in most cases and should be medium size.

SET UP IN ADVANCE IF POSSIBLE

I have found that an aquarium set up well in advance looks more natural. Things seem to settle in place, plant roots work into the gravel, preventing unsightly roots from showing and this gives time for any changes you may feel will improve the overall picture. Every time the aquarium is seen for the first few days you may decide to make a few changes. Be sure all roots are buried as deep as possible; then pull the plant up (gently so as not to bruise the leaves) until the crown of the plant rests just at the top of the gravel. In larger aquariums some of the plants may be planted in small glass dishes or plastic dishes or flower pots and buried in the sand. Never lay rocks and stones on top of the gravel; these should be buried at least an inch (if at all possible) in the gravel so they will not give the effect of being just dropped in as an afterthought. A portion of driftwood should be buried for the same reason. All rocks, stones and driftwood should be chosen to give a pleasant color contrast. Plants used may be contrasting shades of green but not too startling and should be pruned to remove all defects in the leaves. This may make for a smaller plant, but two or more plants may be held together by lead weights at the crown base to make a better shaped plant. When we are dealing with smaller aquariums, any driftwood used must be small.

POSITION PLANTS CAREFULLY

Plant the taller plants for the background as close to the rear of the aquarium as possible and around the filter or filter tubes (to hide them) and around the two back corners first. One corner may be planted thicker than the other. Remember no two settings in nature are exactly the same. A stone or rock may be placed in this corner so it will extend out into the unplanted area and very low plants arranged near the end of this to give the effect of new plants just starting to grow there. Small Cryptocorynes, Dwarf Vallisneria or small clumps of moss may be used for this. The opposite side should be planted with a larger plant, commonly called a center plant. This plant should not be placed in the center of the aquarium, but somewhat off-center. A few small rocks may be used at the base of the plant if desired, but do not make the aquarium appear rock-happy. Sword plants, Spatterdock, Temple Plant and Cryptocorynes or Radicans work very well for this. Remember the planting should be placed so there is an open area in the center of the aquarium so the fish will tend to swim in this area where they are more easily seen. Caves can be arranged for the fish that like this type of set-up. Construct them so the fish will feel secure and hidden, yet are not hidden from the viewer. Fish must feel secure to show best. Cover the gravel and plants with newspaper or paper- towels and fill the aquarium about three-fourths full; then remove the paper. This prevents the sand or plants from washing out of place.

TAKE GOOD CARE OF THE FISH

The fish you plan to use in this set-up should be chosen carefully according to size, color and sex, being certain they are as near perfect as possible, and placed in separate aquariums. If this cannot be arranged, place them with fish that will not nip or pick on them, or in any way cause damage or death.

FEED THEM WELL AND OFTEN

For healthy fish, feed the best food possible at least two times a day. Remember too many fish make a busy aquarium that is hard to view and the fish can and will get scrappy if they must fight for food, thus spelling trouble.

DON'T TEAR DOWN

At set-up time, siphon out the water from the set-up aquarium (into clean containers) down to the top of the gravel. Do not move the plants or rocks. Just cover with clean paper and the aquarium is ready to move to the show. Net the desired fish into a container with enough water from the aquarium they were in to completely fill the aquarium to be set up. This will lessen the shock of putting fish into different water. Keep the number of fish used on the conservative side.

Artificial plants are best used with plant-eating fish and usually not in combination with live plants. Artificial flowers should never be used in any case. Divers, hutches and ceramics should be used only in novelty set-ups. Burping clams, shells and things of this type should never be used in "natural" set-ups.

Below are a few suggestions for fish that can be used in two to five gallon aquariums. These are mature fish or very nearly mature, as all show fish should be, to show their best.

FISH	No. for 2 Gal.	for 5 Gal.
Killifish:		
Lyretails, Gardeneri, Rachovi & small Killies)	pair	1 pair
Blue Gularis (larger)		2 pairs
Guppies	1 pair	2-3 pairs
Platies, Moons or Variatus	1 pair	2-3 pairs
Tetras, Danios (Neons, Cardinals, White Clouds, Zebras, Spotted & Leopard Danios & any small species)	2 pairs	3-4 pairs
Swordtails		1 pair
Ramirezi	1 pair	2 pairs
Badis badis	1 pair	2 pairs
Other dwarf cichlids		1 pair or trio
Barbs	1 pair	2 pair or 6 fish (males and females)

LARGE TANKS REQUIRE MORE OF EVERYTHING

Larger aquariums will, of course, need more plants, sand or gravel, rocks, longer and larger pieces of driftwood, where this is used. Larger aquariums, from ten gallons up, allow much more room for more attractive planting and ideas, as well as larger fish. Care should be taken not to have the rocks too large or too numerous, or a rock-heavy appearance is given.

SAME PRINCIPLES APPLY

Bank the gravel from the back to the front. I like to use nearly twice as much gravel for a show set-up than is normally used. This allows for deeper planting of the plant roots and the rocks can be buried easier. Select the best filter possible for the size of the aquarium. The larger the filter the faster it will clean the water after the aquarium has been set up. If an inside filter is used this may be partly hidden in the deeper gravel, giving good results. Arrange the gravel and background plants to hide the filter or any filter tubes as much as you possibly can and as attractively. Using larger aquariums will also permit you to use the larger varieties of plants. Since most shows last only a few days and the fish used in these aquariums are frightened and upset in most cases from being moved, care should be taken that the corners are filled so they will not hide in them. Vallisneria makes a nice background plant in any aquarium and there are several choices in this: a giant, corkscrew and regular...as well as *Sagittaria, Cabomba, Myriophyllum* and *Anacharis* which can be used but they are not rooted plants and should be weighted down and buried deep so they do not float up.

USE ROCKS AND PLANTS TOGETHER

Shale and rock ledges can be built against the rear glass, across part or all of the back, or in one corner if desired, filling in any spaces with gravel for stability and to keep the fish from hiding or being trapped there. One of the most attractive setups I have seen was a shale ledge in one corner over and around the filter. The filter tube came just above the highest ledge of shale; this gave the effect of water trickling down from a mountain stream. Mudskippers were shown in this set-up and the water level was naturally lower than in most cases, so the fish could get out of the water on a ledge when they wanted to. The gravel sloped to the opposite corner that had a beautiful rock with low plants at its base. Needless to say, this set-up took a great deal of planning and time. The aquarium was of fifteen gallon size and very attractive. Where a center plant is used this could be larger and there are several good varieties to choose from: Sword plants, Lace plants, Radicans, Cryptocorynes (some of these have large, broad leaves, Spatterdock, Temple plants and Water Wisteria al 1 make nice center plants. None should be planted to the very center of the aquarium but rather back and off-center so none of the leaves will touch the front glass. These plants are all different in shades of color and texture and will add interest to any aquarium. Small plants of most of these and especially Cryptocorynes are very attractive planted around the base of a rock.

LEAVE ROOM TO SWIM

Whatever the choice of plants and planting, leave an open swimming space in the front of the aquarium for the fish so they can be seen in the open. Larger aquariums need larger plants, but too many plants tend to hide the fish, and detract from the total effect.

NATURAL PLANTS ARE BEST

If plant-eating fish are to be used in the aquarium, it is permissible to use artificial plants. An aquarium can be made attractive with the use of larger rocks and driftwood, which are found in the natural habitat of the fish.

TOO MANY FISH

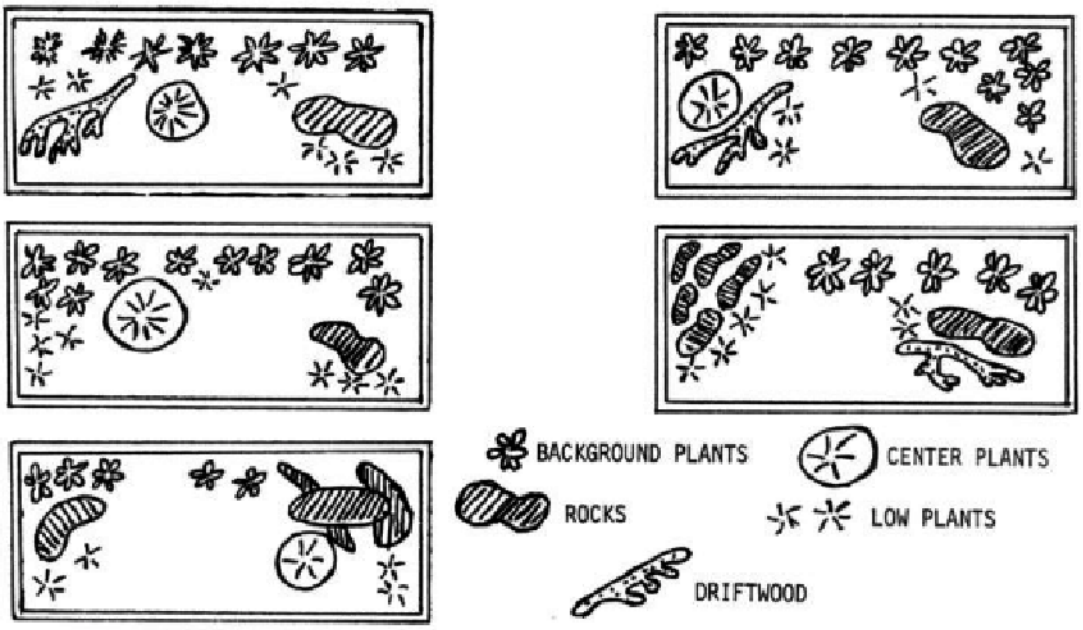
Large fish may be displayed to a better advantage in large aquariums. It is better to display one good pair of fish than a group where one may be old, lazy, injured, sick or deformed, or have torn fins from overcrowding, all of which can take valuable points from a good pair of fish.

SELECT TANK TO FIT FISH

The size and the number of fish to be shown in each aquarium should be one of the most important points in the selection of the size of aquarium used. Naturally larger bodied fish such as Piranhas, Oscars, Discus, Severums and Chocolate Cichlids, to name a few, should be shown in aquariums of at least 25-gallon size.

DON'T PUT SINGLES IN COMMUNITIES

In community set-ups, all fish should be compatible, and two or three of a kind should be shown. Large and small fish do not go well in a community aquarium (such as mature Angels and Neons). If only one of a kind is available...even though it be a perfect specimen...it is best not included.
I hope that the following "top-view" drawings will help give ideas on possible aquarium set-ups.



Josephine White was an avid breeder of Discus in the 1960's.

THE CULTURAL ASPECTS OF THE WARINGTON/GOSSE AQUARIUM ERA, 1850s-1860s

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, November 30, 2017)

In Stephen Jay Gould's book, *Leonardo's Mountain of Clams and the Diet of Worms*, and more specifically in his essay within titled "Seeing eye to eye, through a glass clearly," he remarked that although the owner of any respectable Roman villa could look down upon the animals in his fishpond - and similarly the simple bowl had also allowed the contemplation of a fish or two in the more direct, edge-on, eye-to-eye orientation (through glass, or some other transparent medium that did not always come easily or cheaply) - these precursors were not aquariums in the technical sense for they lacked the defining feature: a stable community of aquatic organisms that can be viewed, not from above through the opacity of flowing waters with surface ripples, but eye-to-eye and from the side through transparent glass and clear water.

According to Gould, a fishbowl presented a temporary display, not a stable community. The water quickly goes foul and must be changed frequently. The concept of an aquarium, on the other hand, relied upon the principle of sustained balance among chemical and ecological components - with plants supplying oxygen to animals and plants removing the carbon dioxide generated by the fish, fish eating the growing plants, and snails (or other detritus feeders) scavenging the wastes and devouring any algal film that might grow on the glass walls.

Since the word "aquarium" owes its usage in the aquarium hobby to Linnaeus and the gardeners and the horticulturists that came after him and can be applied to any artificial body of water that contains fish, I disagreed with Gould (and therefore devised my "Four Stages of the Aquarium Hobby") but not with his conclusion that "**… we only learned the "natural" way to see marine life when the invention of the aquarium permitted us to see through a glass clearly, and to examine a brave new world face to face."** In Figure 1, for example, Johann Scheuchzer's marine fishes are portrayed from the top-down vantage point of a shore-bound observer. This was a common portrayal in the 1700s. In Figure 2, in the first edition of Louis Figuier's - the Carl Sagan or David Attenborough of his day - *The Earth before the Flood* (1863), the top image depicted Devonian sea creatures cast up on the beach. In the bottom image from the fourth edi-

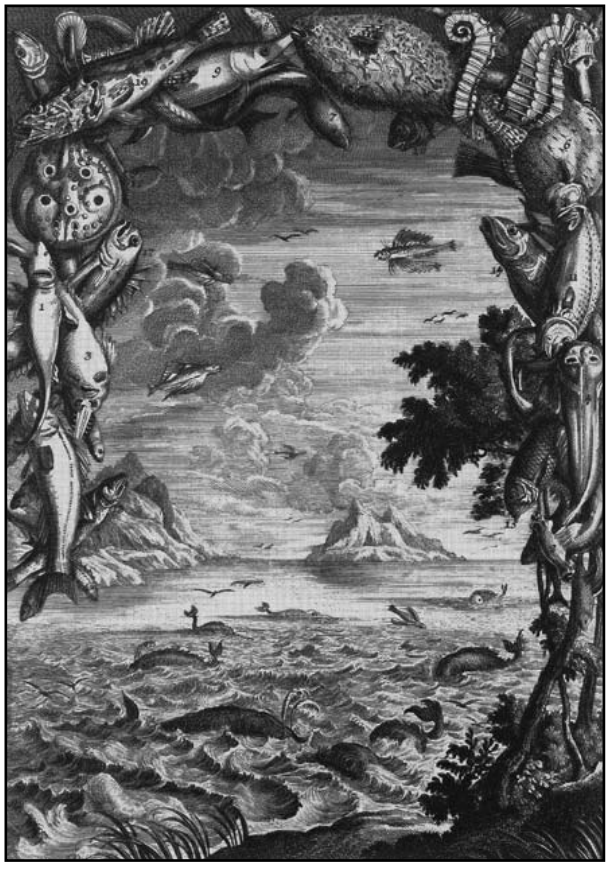


Figure 1: Scheuchzer's marine fishes as seen on the surface of the ocean and as a framing garland are portrayed from the top-down vantage point of a shore-bound observer. This was a common portrayal in the 1700s.

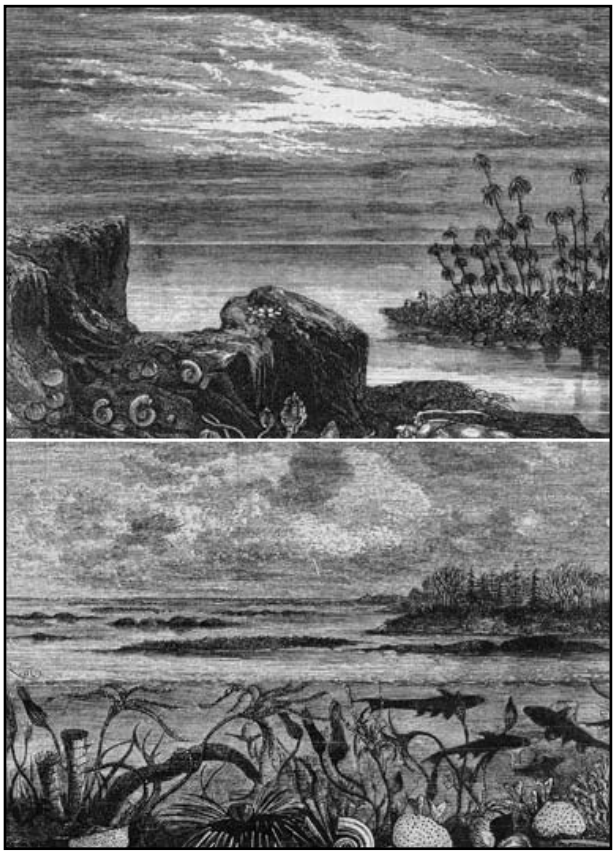

Figure 2, Top: In the first edition of Louis Figuier's "The Earth Before the Flood" (1863), this image depicted Devonian sea creatures cast up on the beach. Figure 2, Bottom: In the fourth edition (1865), a post-aquarium perspective or straight-on view is evident.

tion (1865), a post-aquarium perspective or eye-to-eye view was evident.

Until the middle of the eighteenth century, naturalists had been mainly interested in the physiological description of fish and this could easily be carried out from the study of a corpse. However, the study of the behavior of aquatic beings requires one to be able to observe them living in their natural environment, the water. At the turn of the eighteenth and nineteenth centuries many naturalists were therefore looking for a specific technical device capable of keeping marine organisms of all kinds alive for an extended period of time, the aim being to reconstitute as closely as possible the natural environment of fish. In the past, several modes of conservation and observation of aquatic flora and fauna had been implemented with varying degrees of success, such as the fish pond and the simple jar. Thus was born the "balanced aquarium," the proof of principle demonstrated by the chemist Robert Warington and the naturalist Philip H. Gosse in the early 1850s in England. The intention of the promoters of the aquarium originally was not to confine this invention to the scientific world alone, but to disseminate it widely to the population as a whole so that it could study life underwater, and also to observe and admire it. This resulted in two types of construction: the private aquarium, owned by private individuals, and large public aquariums.

It is interesting to ask what, in the cultural behavior of this period, determined this "moment" of the aquarium, its rapid rise and then its rapid decline (it lasted at about as long as the hoop skirt). To what extent had the aquarium become, in the hands of young women of good society, an ornamental object, a fashionable requirement and then a delegation to the commonplace? How did the aquarium, on a larger scale, enter the early stages of a pictorial culture based on the renewal of visual aids. How was this invention ambiguous because it represented, on the one hand, an undeniable mark of the progress of science and of the superiority of man over nature, but on the other hand, a world dominated by progress and nascent capitalism as well as a moral guide bringing the viewer closer to nature?

THE FIRST AQUARISTS: WOMEN AND THEIR DAUGHTERS

In his 1856 book, "Rustic Adornments for Homes of Taste," Shirley Hibberd extolled the invention of devices - rustic adornments - that allowed home-dwellers to cultivate nature within domestic walls. Hibberd's book contained successive chapters on all forms of indoor natural displays, from fern cases to aviaries and floral arrangements, but he devoted his opening chapter to the great craze that defined his decade of the 1850s - the establishment of aquariums in homes seeking approbation for being with the times. **"I commence,"**

Hibberd writes, "**with the Aquarium, which, for its novelty, its scientific attractions, and its charming elegance, deservedly takes the first place among the Adornments of the House**."

Although the initial intention of the inventors of the aquarium and naturalists in general was to introduce this new apparatus of study to a very large part of the population as part of a wider project of scientific popularization and dissemination of natural history to amateurs, in spite of these democratic intentions the main actors of the fashion that surrounded the aquariums were largely from the wealthy classes. For them, the aquarium was a new and expensive curiosity, the most beautiful object in a parlor. The aquarium took on the status of all the fashionable rarities which, since the eighteenth century, had invaded the collections of the wealthy.

Yet what marks the originality of this new invention, and which explains more precisely its ascent at this precise time, is the role it played with the women of such classes. Parallel to the vast movement of interest of women for natural history, many of them, such as Jeanne Power de Villepreux or Anna Thynne, had directly participated in the scientific research which preceded the establishment of this kind of aquarium. Subsequently they were, more than men, passionate about the aquarium, and were the first to participate in the fashion movement that accompanied the newly-introduced device. In other words, speaking to the lady of the house, if you did not have one of these aquariums in your home, your dwelling was behind the times and out of fashion.

It should be mentioned that what happened in England during this time occurred in lockstep with what was happening in France. The French have two phrases, *outre-Manche* and *d'outre-Manche* meaning "across the channel (or in Britain)" and "from across the channel (or from Britain), respectively. *Outre-Manche* in France, for example, this was evidenced by the publication of numerous articles dedicated to the aquarium in newspapers intended for this type of public, particularly in the 1860s such as *Le Journal des Demoiselles* , *Le Magasin des Demoiselles* and *Le Magasin des familles*. In these articles, any girl of good family was advised to have an aquarium in their living room (Figure 3).

The place of women in the enthusiasm for these ornaments of a new kind can also be linked to their position in the domestic sphere. Women at the turn of the 1850s and 1860s tended to take better care of their homes. In some cases, special attention was paid to decorating in order to match or enhance the husband's position. Through its feminine interest, the aquarium gradually lost its purely scientific status, becoming an object that was above all, decorative. Articles from the periodicals cited above highlighted the ornamental aspect of the aquarium, populated by movements and animated by the always changing colors of the fish (Anon, 1860):

The aquarium is placed in front of a window: a ray of sunshine arrives, makes the water

Figure 3: Young women around an aquarium, *The Journal of the Demoiselles*, p. 257, August 1864.

sparkle, sparkle the scales of the sea bream, blossom the beautiful flower of the aquarium; a sparrow comes to drink, flies take a bath: life and what it brings with it of pure, gay, fresh and charming, bursts thus under this ray of sun, and ready to this corner of your room a charm that will never give to it the sumptuous furniture nor the most wonderful object of art.

Even a scientist such as Pierre Carbonnier, who specialized in aquaculture and had a Quai du Louvre (a wharf located along the Seine River) aquarium shop in Paris, explained the success of his aquariums to his wealthy clients (Carbonnier, 1864):

The aquarium has become almost a piece of furniture of luxury and amenity, and has found its place in apartments of the rich, even in their lounges, next to their elegant planters.

In the hands of the mistresses of the houses of the 1860s, the aquarium was not a laboratory apparatus, but a pure trinket of distinguished interiors. The aquarium was often perceived as a painting, a composition of forms and colors, always recreated by the movements of plants and aquatic animals in the tank. Descriptions of aquariums revealed this image, which tended to reinforce the ornamental character of the aquarium, representing it, through its "plastic beauties," as a "beautiful lantern,"(Rufz de Lavison , 1863), a source of splendor and beauty in a rich interior. Thus remarks the young girl of the *Diary of the Demoiselles* when she speaks of her fish (Anon, 1861):

Mine - I told you that everyone possessed at least one - is charmingly vivacious; its scales shine in the sun like gold; the fine fins, of which I admire the minute details, when they do me the honor of remaining at rest, seem to be hands of extreme delicacy, which bear it in every direction.

A NEW VISUAL SPECTACLE

In Philip Gosse's *The Aquarium* (1856), Plate I (Figure 4) is an image of a wrasse drawn by Gosse - he was a consummate draftsman - and hand-colored by him. The lithographic publishing house founded by Michael Hanhart (1788–1865) in London produced outstanding chromolithographs. Using a complex layering of tint stones, Hanhart produced elaborate works unique for their coloration and tonal values. The technique involved the use of multiple lithographic stones, one for each color, and was extremely expensive when done for the best quality results. Depending on the number of colors present, a chromolithograph could take even very skilled workers months to produce. Hanhart was the one Gosse chose for the Wrasse Plate and for the numerous other colored plates (pasted in the book) in the book that depicted life undersea. These plates stunned the readers of Gosse's books including artists of all sorts and their various schools.

There were, of course, paintings that included goldfish bowls before the Warington/Gosse 1850s -1860s aquarium Era. Figures 5 and 6 were painted in 1829 and 1833, respectively, and not surprisingly both are still lifes. The Giusti painting, however, in comparison almost appears modern. Figure 7 was painted in 1835 by Samuel F. B. Morse, who introduced the daguerreotype to America and also invented the telegraph and the code that bears his name. This, however, was a family portrait and the goldfish within is merely one in the set of background objects. Figure 8 was painted in 1856 by Jonathan Eastman John-

Figure 4: The first Plate in Gosse's 1856 "The Aquarium."

Figure 5: "Still Life, Game and Hanging Snipe with Goldfish in a Bowl (Dead Game)," painted in 1829 by Benjamin Blake (1757–1830). Blake worked for most of his life in London, producing small, gem-like larder and game pieces redolent of country life.

Figure 6: "Stilleben mit Aquarium Umstellt von Sommerblumen und Vogel sowie Schmetterling" (Still life with aquarium surrounded by summer flowers and bird and butterfly), painted by Salvatore Giusti (1773-1851) in 1833.

Figure 7:
Mrs. Richard Cary Morse and family. Richard was the brother of F. B. Morse (1791-1872) who made this painting in 1835.

son. It is a rather dreary image - the paint is peeling off the wall and the girl is clearly not happy- and as the title of the painting indicates, it is just one of the girl's pets. None of these figures have

Figure 8: "Girl and Pets," painted in 1856 by Jonathan Eastman Johnson (1824-1906), an American painter and co-founder of the Metropolitan Museum of Art, New York City.

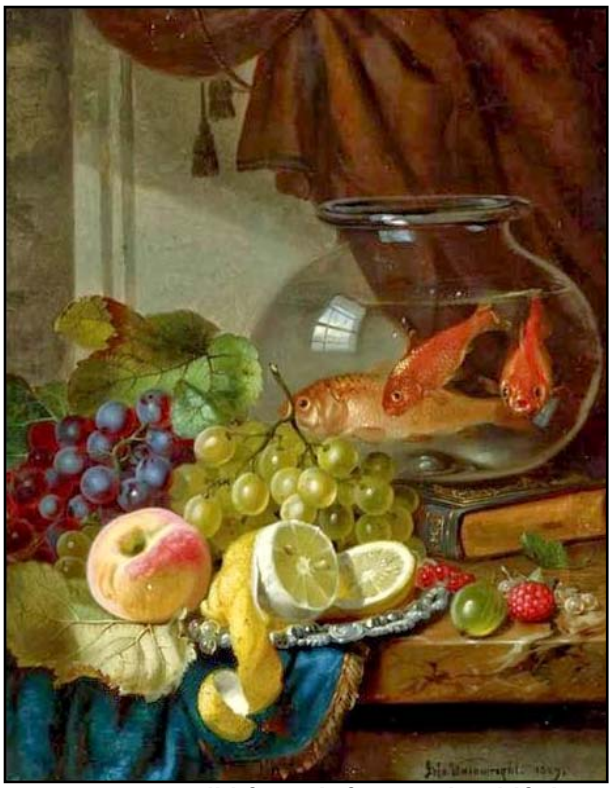

Figure 9: "Still life with fruit and goldfish in a bowl on a ledge, by John Wainwright (a popular British painter) in 1859.

Figure 10: "Fishbowl Fantasy" by Edward Ashton Goodes (1832-1910), painted in 1867. Little is known about this artist except that he lived in Philadelphia and exhibited at the Pennsylvania Academy of the Fine Arts between 1855 and 1868. He was known for his opulent still life, marine and landscape painting.

anything to do with the aquariums of the Warington/Gosse Era of this essay. Two that do, however, are shown in figures 9 and 10. Both are still lifes and like Gosse's Wrasse they are characterized by stunning color and excellent draftsmanship.

The picture in Figure 11 painted in 1864 by Sir John Everett Millais, was quite different from what had preceded. Here was a goldfish bowl but it was a major element, not just a bit of background. Just as important, it contained two human figures, young girls in this case. When a human is involved with an object in a painting - like the girl on the right who seems to be looking at the fish bowl - the viewer is involved as well. The viewer asks questions such as, is she interested in the color, the motion or the behavior of the fish, or does the fish bowl remind her of something quite different?

THE AQUARIUM HOBBY ICON EMERGES

Goldfish in art is a potentially fascinating subtheme. An icon is an emblem, symbol, sign or representation that stands for its object by virtue of a resemblance or analogy to it. A succinct aquarium hobby icon would contain one or two aquarists (three's a crowd and would detract from the fish bowl), one aquarium and one fish. All items must be significant elements of the image and the human must be looking directly at the aquarium (the painting by Perugini in Figure 12, for example, violates this requirement). Following an old photographer's adage, "less is more," the items should occupy most of the painting (photographers often do this by reaching for a longer focus lens so that the subject fills the frame; examples are shown in Figures 13 and 16).

Figure 11: "Leisure Hours," painted in 1864 by Sir John Everett Millais (1829-1896), an English printer and illustrator who was one of the founders of the Pre-Raphaelite Brotherhood. The group's intention was to reform art by rejecting what it considered the mechanistic approach adopted by artists who succeeded Raphael and Michelangelo.

Unfortunately, the Millais painting is not an aquarium hobby icon since it is not clear that the girl on the right is looking directly at the aquarium. Although it looks as if she might, there is too much ambiguity to state this with certainty. Figure 12, on the other hand, painted in 1868 by William Daniels, has all the elements that meet these requirements and is a textbook example of the aquarium hobby icon. The aquarium hobby icon, by the way, need not be drafted with the precision of a Gosse. Figure 13 shows painstaking draftsmanship whereas in Figure 14 the artist has relaxed the draftsmanship and the lines are just brush strokes but still fairly distinct. This brings us to Impressionism. This was a 19th-Century art movement that had its origins in the Warington/Gosse Era. It is characterized by relatively small, thin yet visible brush strokes, an emphasis on accurate depiction of light in its changing qualities, ordinary subject matter and unusual visual angles. It originated with a group of Paris-based artists whose independent exhibitions brought them to prominence during the 1870s and 1880s.

Figure 13: "The Goldfish," painted in 1892 by Thomas Benjamin Kennington (1856-1916). He was an English genre, social realist and portrait painter, and a founding member of the New English Art Club and the Imperial Arts League.

Figure 12: "The goldfish bowl," painted in 1868 by William Daniels (1813-1880). Daniels was a distinguished painter of the Rembrandt school and one of the greatest geniuses that ever reflected honor on Liverpool, the city where he was born.

Figure 14: "Lady with goldfish bowl," circa 1890, painted by Julian Russell Story (1857-1919), an American artist born in England.

Figure 15: "Goldfish Bowl," painted by Robert Gemmell Hutchison (1860-1936) circa end of the 1800s. He was a Scottish landscape artist, specializing in coastal scenes and belonged to the school of British Impressionism.

Figure 16: "The Goldfish," painted in 1892 by Thomas Benjamin Kennington (1856-1916). He was an English genre, social realist and portrait painter

Aquarium hobby icons that were painted by well-known Impressionists are shown in Figures 15, 16 and 17. The last painting shows Impressionism taken to an extreme (it is one of my favorites among the Impressionists). These paintings of the aquarium hobby icon continued well into the Twentieth Century when they were replaced by more modern art approaches of no real use as icons of the aquarium hobby. (One of the problems with all of the arts is that they are frequently populated by those who have absolutely nothing to say.)

THE RISE OF THE PUBLIC AQUARIUM

As was previously discussed, most marine scenes prior to the Warington/Gosse Era portrayed ordinary marine organisms as having been washed up on a shore in the foreground of a landscape seen from a human viewpoint. In effect, the aquatic

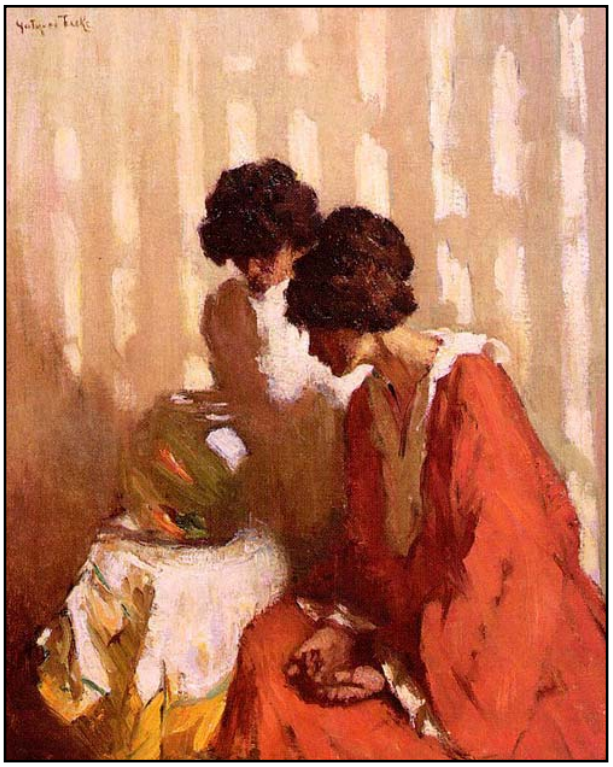

Figure 17: "The Goldfish," painted by Gertrude Fiske (1878-1961) in 1914. An American Impressionist Painter, although she traveled abroad, she preferred living and working in New England. She earned a reputation of a leading woman painter in Boston and won over eighteen prestigious awards. In 1930 she achieved full Academician status at the Boston Museum School.

world from which most fossils were derived was depicted only from the outside. This was difficult for the public and perhaps for most scientists also, to imagine a viewpoint that was not only pre-human but also subaqueous, until mid-century when the aquarium craze made the underwater world generally accessible for the first time in the form of the public aquarium. It was natural for scientists then to visualize the public aquarium as an institution constructed according to a scientific logic of the exhibition of species, as in an aquatic museum.

In 1841 Nathaniel Ward set up an aquarium for fish and plants in a large earthenware vessel. In this miniature lake, the water of which was never changed but kept in a constantly pure state by the action of the associated plants, the animals lived in a healthy condition for many years. This aquarium gave James Scott Bowerbank (both he and Ward were members of the Microscopical Society of London and knew each other) the idea of taking a large glass jar, in which he placed sticklebacks, minnows, snails and plants of *Valisneria,* and covering it with a piece of glass. It was this jar of Bowerbank's that attracted the attention of David Mitchell, then the Secretary of the Zoological Gardens of the Zoological Society of London and gave him the idea for the public aquarium that was opened in 1853 in the Zoological Gardens in Regent's Park. This was a modest undertaking, as shown by the building and its interior (Figure 18). Some of the tanks were built into the wall on the left side and many were merely situated on tables in the middle of the room. Both Robert Warington

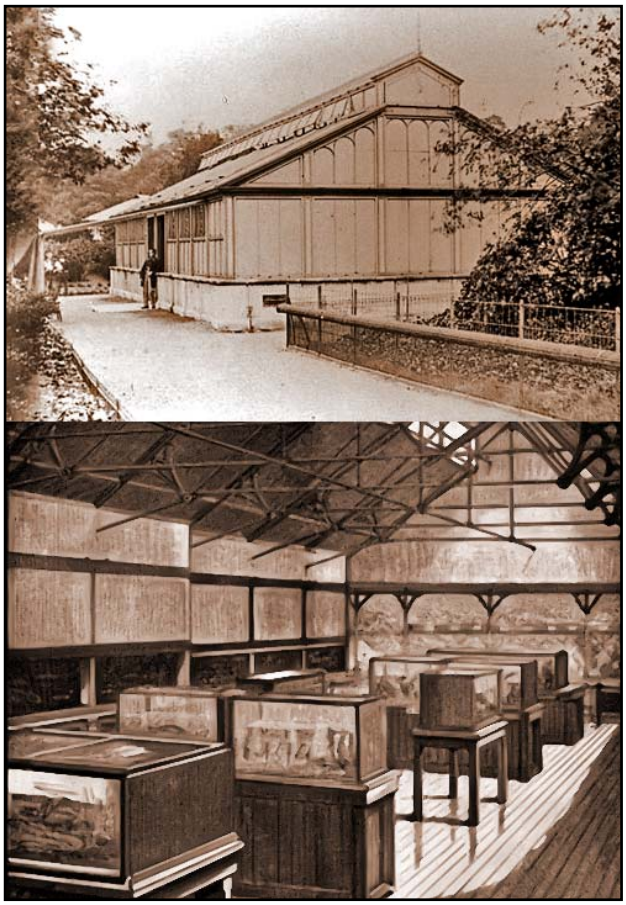

Figure 18: Top - Exterior of the Regent's Park Aquarium. Bottom - Interior.

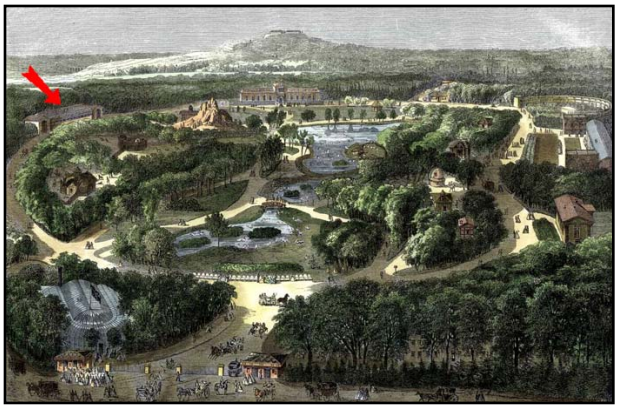

Figure 19: The Jardin d'Acclimatation. The red arrow points to the Aquarium.

(freshwater) and Philip Gosse (saltwater) helped design and implement the aquarium and both were scientists, chemistry and botany, respectively.

In France, the creation of the Jardin d'Acclimatation was the result of an accordance between an urban project and a scientific ambition. As part of the "remodeling" of Paris, the Emperor Napoleon III wanted to give Paris a landscaped park designed according to the model of English gardens. At the same time, the famous zoologist, Isidore Geoffroy Saint-Hilaire, was looking for a place to show a wide variety of animals because the other parks available were filling up. In 1854, he founded la Société Impériale Zoologique d'Acclimatation (the Imperial Zoological Acclimatization Society), which rapidly counted among its members three thousand eminent personalities of the sciences, arts and industry. The objective of the Society was to create a garden favoring the introduction, adaptation and domestication of animal species (Figure 19).

In 1858, the city of Paris granted the Company a 37-acre concession in the Bois de Boulogne. On the initiative of the Emperor and his wife, Eugenie de Montijo who actively supported the project, the concession area was increased by 12 acres. On Saturday, October 6, 1860, less than two years after the beginning of the work, Napoleon III, in the company of the Empress, inaugurated le Jardin Zoologique d'Acclimatation (the Zoological Garden of Acclimatization) in the presence of many prestigious guests including Jacques Offenbach, Prosper Mérimée, Hector Berlioz, Alexandre Dumas and Théophile Gautier. Three days later, the Garden, open to the public, began its long adventure.

Designed by the British engineer William Alford Lloyd, the Jardin d'Acclimatation's aquarium (fourteen glass and illuminated tanks housed in a 130 feet long and 33 feet wide building - see Figure 20 Top) was, according to Lloyd, "the largest, the most beautiful and the most complete of all those made so far. It is, after all, the most modern, since it has a system of re-oxygenation of water." Louis Figuier celebrated this "product of contem-

Figure 20: Top - The Jardin d'Acclimatation Aquarium building. Bottom - Interior of the Aquarium.

Figure 21: Exposition Universelle d'Art et d'Industrie de 1867.

porary science," which fulfilled the triple function of "natural museum, study cabinet and moral theater." He never tired of the ballet of fish (Figure 20 Bottom) and made the following statement: "Few shows are as varied, so picturesque; there are few who give material to as many reflections and which reveal to us better the inexhaustible fertility of the resources of nature."

A few years before the invention of the cinema, the aquarium represented a device of a new kind capable of producing varied images. It could be compared to a new kind of optical machine, such as the kaleidoscope or panorama, as a producer of images but also, depending upon the reactions of the spectators and the reconstructions of the journalists, as a source of illusion, even hallucination. Aquarium spectators were imaginatively projected to the bottom of the oceans. Théophile Gautier (1811-1872), a French poet, dramatist, novelist, journalist, and art and literary critic, recounted his impressions during his visit to the aquarium of the Jardin d'Acclimatation (Gautier, 1996):

After a few minutes, the illusion is complete. The feeling of proportion is lost. As for the fish, penetrated with light, they are of a fairy-like translucency. If they approach the invisible barrier that the glass opposes them, one would say that they are going to leave the frame outside their element.

If the goal of science was to instill a learning of aquatic science into visitors, then these two aquariums (Regent's Park and that of the Jardin d'Acclimatation) were on the right path. However, this was not to be. Their descendants gradually became the pretext for a debauchery of grandiose staging, suitable not to instruct but to impress the viewer. The evolution is clear when we compare the Aquarium of the Jardin d'Acclimatation, which was of reasonable size, contained selected species and in limited number, and the marine L'Aquarium de Paris that followed it.

In 1867, seven million people came to see France's answer to the challenge of the 1862 *London International Exhibition* (Figure 21). Eleven years after the first *Great Exhibition* of 1851, the British had proved to the world that it was no easy matter to repeat a resounding success. Napoleon III decided, seven years after the first French *Exposition Universelle*, that the French could and should again surpass the efforts of their ancient rival and sometime ally.

Figure 22: L'Aquarium de Paris.

L'Aquarium de Paris was arranged in the disused quarries near the prior Universal Exhibitions of Paris. The aquarium site, underground, was made up of old quarries that had served to shelter a part of the cavalry of the Emperor. The original aquarium was partly built in the open and partly built underground by imitating a cave with imitation concrete rocks. It was arranged in eighteen aquariums set between the pillars of the old galleries, on the circumference of two concentric ellipses whose gigantic and fairy-like setting harbored the most bizarre species (Figure 22). In the latter case, for example, a room was built underground so that the visitor found himself surrounded by tanks as if he or she were under water. This complex and costly arrangement was the most popular among the public because it responded to the aspirations for the grandiose which preoccupied Parisians at the time. The installation of a reservoir suspended above the visitors was not the only effect put in place for this purpose: long stalactites fell from the ceiling, resembling those that one could see in caves and all was plunged in darkness and silence (Figure 23). Several testimonies highlighted this supernatural staging, the following being an example from Ognier's "Souvenirs of the Universal Exhibition of 1867":

There is a moment when we cannot help feeling a certain tremor; in fact, instead of being between heaven and earth, we find ourselves between the earth and the water seen above and in which move fish of various species.

On the other side of the channel, things were not going well either. The Public Aquarium situation there, however, was very different from that in France. Thirteen commercial public aquarium ventures took place in Britain between 1871 and 1888 (see Table I - Note: The Regent's Park and Plymouth Aquariums were not commercial ventures). These were simply commercial speculations, money-making shows originated by joint-stock companies with a view to profit only. Scientific instruction or popular information were with their projectors only incidental considerations, and held no part, or only a very small part, in their inception.

William Alford Lloyd maintained that no aquarium pure and simple would pay its way, even in a very large town or city, unless its cost was limited (in current dollars) to about $348,000, and its annual expenses restricted to $58,000. He calculated that, allowing a sum of $75,000 as interest on the capital sum, the total receipts would require to be $17,400 per annum, or about $244 a day, which would represent forty two persons at $5.80 each This presented a rather dark aspect to enthusiasts and scientists of Natural History, for at the prevailing prices of building materials and the high rate of wages paid at the time, only a very indifferent aquarium could be erected for the sum named. At Rothesay, a small pleasure town on the river Clyde, it was found that the $580,000 subscribed for the erection of an aquarium was an insufficient sum, and the

Figure 22: The stalactites of L'Aquarium de Paris.

Figure 24: Royal Westminster Aquarium.

capital in consequence had to be been more than doubled.

To "pay," a really great Aquarium had to be something more than an aquarium; or, if not that in itself, it would be required to be a portion of some greater exhibition, as in the case of the Crystal Palace, where the Aquarium was but a small part of the larger building. The Aquarium attached to the Crystal Palace cost about $1,400,000, exclusive of the ground on which it was erected, and Lloyd felt sure that it never would have been remunerative but for its being an accessory of the greater building. The cost of erecting the Aquarium in the Jardin d'Acclimatation in Paris, although it contained only fourteen tanks of small size, was $483,000. The average number of visitors to the Parisian institution was about 450,000 annually, but it never paid any dividend.

Some of these new public establishments in Great Britain quickly failed: that in Manchester became a Catholic schoolhouse as early as 1877, whilst in 1880 the Aquarium at Tynemouth, having cost $9,562,900, was closed and sold at auction for just $3,125,800. Clearly, these were risky ventures, but some did prosper: Brighton's Aquarium, ideally situated on the promenade, was close to the Palace Pier and offered brass bands, organ recitals and a roller-skating rink. It certainly needed to be successful, having cost $15,398,000 to erect. The Royal Westminster Aquarium (Figure 24), an even more elaborate structure, had required $23,154,000 to build and was alarmingly costly to maintain, employing a 300 regular and a further 700 occasional staff.

The Era, September 12, 1885) noted a gradual lapse from the Royal Aquarium's original intent and knew precisely where to point the finger:

In all cases where a corporate body provides the capital, a dividend is expected, and to pay this it has been found necessary to abandon the lofty ideals propounded in the prospectus issued to the public when the Aquarium was in an embryonic stage.

Culture did not pay. In perpetual financial trouble, and with a dwindling public, the Westminster leviathan thus degenerated from a (prospective) temple of learning into a glorified freak-show, albeit a highly enterprising one (Sherson, 1925):

The fish, though few in number, were on view for some time; in fact, I think that one or two lingered on to the very end twenty-seven years later, in 1903 – but I have always wondered whether anyone went to look at them and if the water was ever changed!

[Note: William Alford Lloyd had been hired to design and build the aquarium, but later ceased his association with The Royal Westminster Aquarium:

There are few things more trying to that great virtue, patience, than a large public aquarium, especially in its preparation, before it is ready for the reception of animals. It is to this lack of patience on the part of the directors of the Royal Westminster Aquarium, and to their absolute refusal to allow me to have proper engineering assistance during its construction, and to general mismanagement, that its present confused state, and its unsatisfactory condition in every way, is due. On this account I re-

Figure 25: The dead whale at the Aquarium.

signed my post of adviser to the society, as I found it useless to advise when advice was recklessly disregarded.]

To continue Sherson's report:

The Royal Aquarium, in short, was intended to be a sort of Crystal Palace in London within easy reach of Charing Cross, a covered-in promenade for the wet weather, with the glass cases of live fish thrown in. In truth, the attractions of the place soon began to be very 'fishy' indeed. Ladies promenaded there up and down without the escort of any gentleman friend (till, maybe, they found one) and the appeal of the management to sensation lovers was very wide indeed. Bare-backed ladies dived from the roof or were shot out of a cannon, or sat in a cage covered with hair and calling themselves 'Missing Links'. Zulus, Gorillas, Fasting Humans, Boxing Humans and Boxing Kangaroos, succeeded one another in rapid changes, and failed in time to attract.

Another talking point, a beluga whale, was introduced to the Aquarium in 1877, but it quickly expired amidst accusations of maltreatment:

When once the animal was safely deposited in the tank its surroundings were fully as favourable as those of most other creatures when deprived of their natural liberty. The supposed marks of ill-usage on the dead body were the consequences of the eels in the tank having after its death nibbled the edges of its fins (*The Times*, October 3, 1877).

In 1880 Agnes Beckwith put the redundant whale tank to good use by treading water in it for 30 hours to equal the record set by Matthew Webb in 1875. Alongside the performing fleas (1878), bulls that climbed ladders and rolled on their backs (1883) and packs of wolves (1887), more familiar members of the animal kingdom also found celebrity; cat and dog shows, for example, were a popular attraction during the 1880s.

From time to time, the morals of the clientele who frequented the Aquarium were called into question. Drunks, thieves and prostitutes mingled with the sight-seers and their continued presence led to the London County Council refusing to recommend the renewal of the license in October 1889. After much debate in the Press, it was eventually conceded that the Aquarium was no better and no worse than many similar establishments and the license was renewed.

Thus the Royal Aquarium was not the prestigious exhibition space and educational forum initially envisaged. It was not the renowned concert venue originally hoped for, it was not the well-loved variety theatre hinted at in its ever-changing programs, it was not even an aquarium: it was in fact a circus fairground given unnatural permanence by its pretentious surroundings. Fairs and circuses are by their very nature transient novelties and in this re-

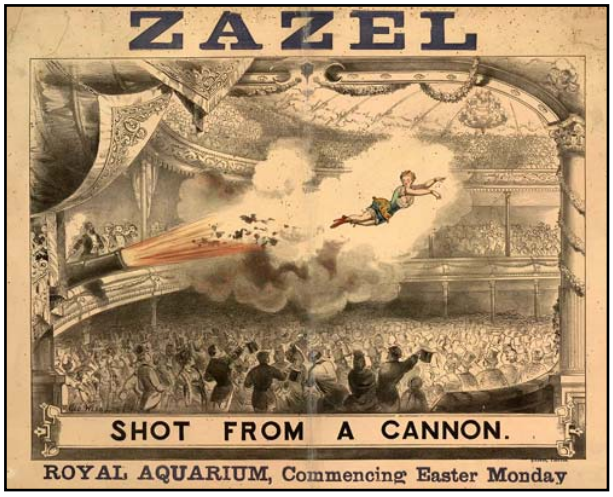

Figure 26: One of the attractions at The Aquarium.

The Aston Aquarium, Birmingham	1879
The Marine Biological Association of the United Kingdom Aquarium, Citadel Hill, Plymouth	1888

spect it is truly remarkable that the place managed to survive for twenty-seven years.

In Table I, only the Regent's Park Aquarium and the aquarium of The Marine Biological Association in Plymouth were non-commercial ventures. The Marine Biological Association of the United Kingdom was founded in 1884 at a meeting of the Royal Zoological Society "…for the purpose of establishing and maintaining Laboratories on the Coast of the United Kingdom, where accurate researches may be carried on leading to the improvement of Zoological and Botanical Science and to an increase of our knowledge as regards the food, life-conditions and habits of British Food-Fishes and Molluscs." This, it was hoped, would lead to a better understanding of the marine environment and the impact of fishing on this environment, which would in turn help to inform better policy-making and legislation which would help manage the fishing resources. The laboratory would have state-of-the-art facilities, including tank rooms and apparatus for the circulation of seawater. The MBA was to be governed by a Council that was headed by a President and the Director was responsible for the day-to-day running of the Association. Thomas H. Huxley was elected its first President and William Henry Flower was elected its first Director.

Plymouth was chosen as the site for its laboratory and aquarium because of its rich flora and fauna. They readily accepted the site under the Royal Citadel offered by the War Department as it was possible to maintain direct salt-water contact. Construction of the building, which was constructed of Devon limestone, commenced in 1887 and the world renowned headquarters of the Association was opened on Saturday June 30th 1888 by Professor (later Sir) William Henry Flower (1831-1899). Flower was director of the Natural History Museum and president of the Zoological Society of London from 1879 to 1899. In 1882 he was awarded the Royal Medal of the Royal Society. Flower was also a leading authority on the arrangement of museums. He insisted on the importance of distinguishing between collections intended for the use of specialists and those designed for the instruction of the general public, pointing out that it was as futile to present to the former a number of merely

Figure 27: The Marine Biological Association of the United Kingdom Aquarium, Plymouth.

Figure 28:
Sir William Henry Flower (1831-1899).

typical forms as to provide the latter with a long series of specimens differing only in the most minute details. His ideas, which were largely and successfully applied to the museums of which he had charge, gained wide approval, and their influence entitles him to be looked upon as a reformer who did much to improve the methods of museum arrangement and management.

The Laboratory of the MBA opened on Plymouth Hoe (referred to locally as the Hoe; this is a large south-facing open public space in the English coastal city of Plymouth) on June 30, 1888. A tank room on the ground floor became the first Plymouth Aquarium and was serviced by underground reservoirs that held up to 100,000 gallons of seawater, which was continually being cleansed and pumped back into the tanks.

Initially, access to the Aquarium was free, but as the rooms developed into a larger and more sophisticated aquarium throughout the twentieth century, the MBA introduced a small fee. In spite of this, it continued to attract hundreds of visitors daily. Through this, the Association met its charitable objective of sharing with the public the knowledge gained through its research activities: the aquarium provided a literal window into the local marine environment. However, it had taken almost a half-century after the start of the Warington/Gosse Era before these goals of the scientific community were realized.

THEOLOGY AND THE AQUARIUM

For many years a large body of British public opinion held to the absolutist view that the sole account of the early history of the earth that could possibly have any validity whatever was that to be found contained within the covers of the Bible. A wordy pamphlet-war long continued in this vein, and at the same time, just because it was their own special subject that had given rise to this terrible debate, those naturalists who found the claims of evolution difficult to reconcile with their religious beliefs experienced an agonizing conflict. Unlike others, they could not honestly deny the evidence or fail to comprehend its overwhelming suggestiveness. Their only refuge was to seek for some flaw in the accepted interpretations, whether doctrinal or scientific, and propound a comforting alternative or else to postpone all decision, hoping that the theory would be disproved or that some champion of the theologians would come forward with a palatable compromise.

Not all naturalists found the facts of evolution spiritually dismaying, and those who did reacted in different ways. There was no recognizable “line” on the matter in natural history circles. If anything, because of the closeness of naturalists to the controversy’s raw material, the spectrum of attitudes among them was even wider than in general. Most of those who grappled with the issues concentrated on the metaphysical or theological aspects; the naturalists, almost alone, could not avoid prolonged and fierce disputes over the scientific ones as well. We can, however, compare the writings of two gentlemen who wrote both about aquarium matters and religion - Philip Henry Gosse and the Reverend Charles Kingsley.

Figure_29: Philip Henry Gosse with his son, Edmund.

First, let's set the record straight as to the character of Philip Gosse. After his father's death, Edmund Gosse published anonymously a Victorian biography, *Father and Son* (Gosse, Edmund, 1907), a book that has never gone out of print in more than a hundred years. The reaction of readers to Philip Gosse's personality and character as represented in *Father and Son* has included phrases such as "scientific crackpot," "bible-soaked romantic," "a stern and repressive father," and a "pulpit-thumping Puritan throwback to the seventeenth century."

However, even a modern editor of *Father and Son* has rejected this portrait of Philip Henry Gosse on the grounds that his "writings reveal a genuinely sweet character." The biographer of both Gosses, Ann Thwaite (Thwaite, 1984), has established just how inaccurate Edmund's recollections of his childhood were, that Edmund indeed, as Henry James remarked, had "a genius for inaccuracy." Although Edmund went out of his way to declare that the story of *Father and Son* was "scrupulously true," Thwaite cites a dozen occasions on which either Edmund's memory betrayed him - he admitted it was "like a colander" - or else he changed things deliberately to make a better story. Thwaite argues that Edmund could only preserve his self-respect, in comparison to his father's superior abilities, by demolishing the latter's character.

In *The Aquarium*, Gosse argued that corallines were "**a City… of myriad individuals sharing a common life, and reflects that heavenly Jerusalem where happy spirits in resurrection bodies collectively form the Church of the living God, the Bride of Christ. The pleasure we take in the rock pools, which seem to be almost immune from the consequences of the fall… is a type of the pleasure we shall someday take in all of nature."**

As Edmund Gosse noted, his father had long complained that natural history had become "a science of dead things," a study not of living organisms in their natural environments but of dried, stuffed, preserved - and consequently deformed and distorted - specimens. To Gosse, clearly the existence of a living God, actively caring for his creation and leaving signs of its fate, could be better seen in living creatures, and the aquarium made that possible. To see creatures "in their proper haunts" was to see them "with their beauty of form and brilliance of color" - and to know how beneficent God had been in providing us with such pleasure even among the lowest creatures in the most unlikely places. In the months following his wife Emily's death, Gosse worked with remarkable diligence on a book that he viewed as the most important of his career. He believed that he had discovered a theory that might neatly resolve the seeming contradiction in the age of the earth as presupposed by Charles Lyell, with the Biblical account of Creation, which suggested that the world was 6,000 years old. Lyell (1797-1875) was a Scottish geologist who, following deistic traditions, favored an indefinitely long age for the earth, despite geological evidence suggesting an old but finite age. He was a close friend

of Charles Darwin, and contributed significantly to Darwin's thinking on the processes involved in evolution.

Gosse started to more formally organize his anti-evolutionary ideas shortly before the writing of *Omphalos*, his attempt to reconcile the Church and Science. His popular writing about marine organisms always had a touch of the theological about it, but in the summer of 1857 he published a series of collected essays from the magazine *Excelsior* under the name *Life in its Lower, Intermediate, and Higher Forms*. The title makes Gosse's belief in a created hierarchy clear, and of its contents his son would later write;

These essays were slight, and the religious element was quite unduly prominent, as if vague forebodings of the coming theory of evolution had determined the writer to insist with peculiar intensity on the need of rejecting all views inconsistent with the notion of a creative design. This book entirely failed to please the public, who had now for so many years been such faithful clients to him; with the scientific class it passed almost unnoticed.

In 1857, two years before the publication of Charles Darwin's *Origin of Species*, Gosse published *Omphalos: an Attempt to Untie the Geological Knot* and thereby created what has been called the Omphalos hypothesis. Gosse's book was an attempt to rescue Creation itself from the perceived threat of science denuded of Christian authority. Gosse fervently believed that God's word and works were in accord, but if there was any conflict between the two it was because naturalists had been looking at the world in the wrong way.

Gosse attempted to mend the increasing tear between a literal reading of Genesis and the facts of geology in a very peculiar way. If you found the skeleton of an extinct animal, Gosse proposed, you would naturally assume that the bones must have given form to an animal that lived at some distant period. But what if you were mistaken? What if, instead, the bones had been created already in place in the ground and had never been clothed in flesh and blood?

For Gosse, fossils were just components of the earth that implied history without actually possessing it. God, in other words, had created the world "already in progress." The first plants and animals were all adults, ready to reproduce "after their kind" and bearing the marks of age that they would be expected to bear. This rule applied to the first humans, too; Adam and Eve had been created with navels even though they had never actually been connected via an umbilical cord to a mother during gestation. Creation carried with it the illusion of time, and Gosse believed this could reconcile the "lost worlds" of geologists the scripture he loved so dearly. Naturally, he rejected any suggestion that life evolved.

Figure 30 shows a mammoth as restored in Gosse's *Omphalos*. In Gosse's view of history, however, such a scene never actually existed. According to him, the bones of the mammoth existed in the earth from the time of Creation and had never given form to a living animal. In what Stephen Jay Gould has called "glorious purple prose," Gosse argued that if one assumed creation *ex nihilo* ("out of nothing"), there would necessarily be traces of a previous existence that had never actually oc-

Figure 30: The Mammoth image from Gosse's *Omphalos*.

curred. *"Omphalos"* is Greek for "*navel*," and Gosse argued that the first man, Adam, did not require a navel because he was never born; nevertheless he must have had one, as do all complete human beings, just as God must have created trees with rings that they never grew. Thus, Gosse argued that the fossil record might also be evidence of life that had never actually existed but which may have been instantly formed by God at the moment of creation.

That Gosse published *Omphalos* two years before *On the Origin of Species* was no accident. As suggested by his son, by the mid-1850's Gosse had become very concerned about ideas that life had evolved. *Vestiges of the Natural History of Creation*, anonymously published in 1844, had popularized the *idea* of evolution even if it failed to convince naturalists of a mechanism by which it could be affected To Gosse, such theorizing was the equivalent of barring God from having anything to do with the world the Almighty had created.

Omphalos would fare even worse upon its release later that year. Even the later writings of his son, Edmund, are tinged with regret that Gosse could not restrain himself from speculating on the natural "philosophy" that Darwin and other naturalists were more adept at handling. (Interestingly, though, Gosse would later exchange numerous letters with Darwin about orchids in 1863. Neither evolution nor *Omphalos* entered the conversation.) Gosse, however, felt that he was more than qualified for the job. The people had to be told that God still lived in Creation, and Gosse fully believed that he could provide the ultimate answer that would put an end to what he saw as idle speculation over trilobites and rock formations. The overly florid and pompous nature of his prose underlined his confidence.

The general response was, as the *Westminster Review* put it, that Gosse's theory was "too monstrous for belief." Even his friend, the novelist Charles Kingsley, wrote that he had read "no other book which so staggered and puzzled" him, that he could not believe that God had "written on the rocks one enormous and superfluous lie for all mankind." Journalists later sniggered that God had apparently hidden fossils in the rocks to tempt geologists to infidelity. *Omphalos* sold poorly and was eventually rebound with a new title, *Creation*, "…in case the obscure one had had an effect on sales." The problem was not with the title, however, and in 1869 most of the edition was sold as waste paper. Gosse's reputation was ruined and the sales of his books declined.

Charles Kingsley (1819-1875, Figure 31) was a priest of the Church of England, a university professor, social reformer, historian and novelist. He was particularly associated with Christian socialism, the working men's college, and forming labor cooperatives that failed but led to the working reforms of the progressive era. Kingsley was born in Devon, the elder of two sons of a clergyman. He studied at King's College London and the University of Cambridge, graduating from the latter in

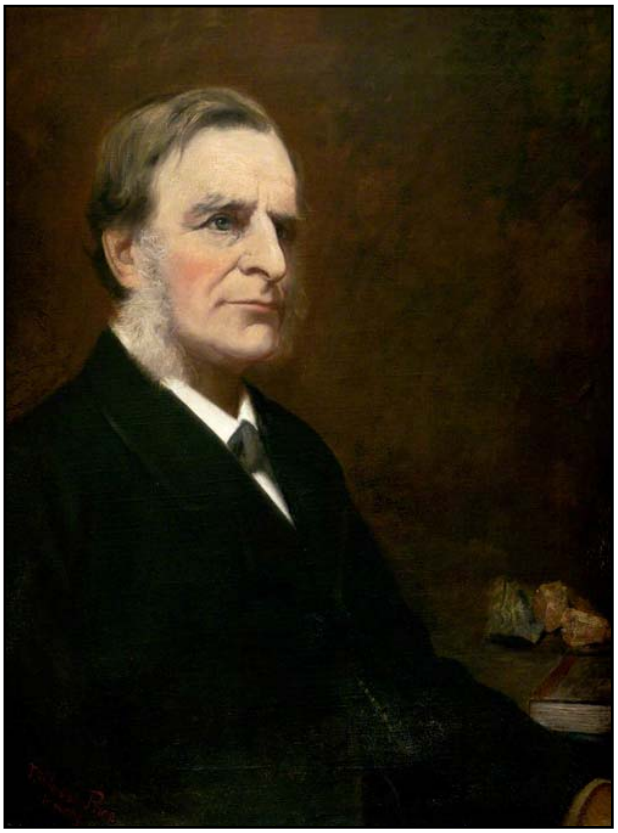

Figure 31: Charles Kingsley (1819-1875).

1842. Kingsley chose to pursue a ministry in the church and starting in 1844, he was rector of Eversley in Hampshire. In 1859 he was appointed chaplain to Queen Victoria, in 1860, he was appointed Regius Professor of Modern History at the University of Cambridge and in 1861 he became a private tutor to the Prince of Wales. In 1869 Kingsley resigned his Cambridge professorship and, from 1870 to 1873, was a canon of Chester Cathedral and in 1873 he was made a canon of Westminster Abbey.

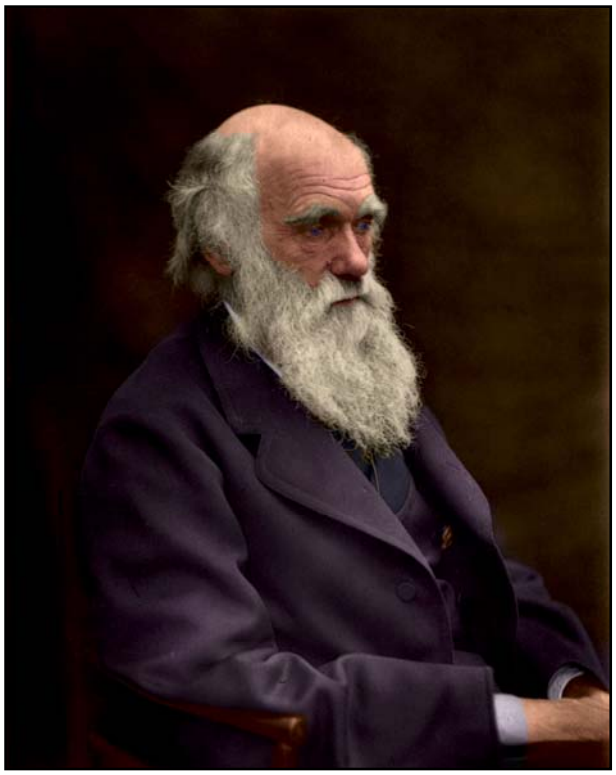

Figure 32: Charles Darwin (1809-1882). With the publication of *On The Origin Of Species*, the established Western view that creatures had been created independently by a God, and indeed the whole supernatural explanation of the universe, suddenly had competition. At first, denunciation by the likes of Bishop Wilberforce was complete. But religious views gradually adapted, through Philip Grosse's theory that fossils had been planted by God to give the earth a coherent history, to today's position where most theists have found accommodation with the idea of natural selection.

Kingsley took a keen interest in science and saw no problem in reconciling his religious faith with Darwin's theory of evolution by natural selection. Kingsley read a review copy of Darwin's *The Origin of Species* in 1859 before it had even been published and became a friend and correspondent of Darwin's in the 1860s. *On The Origin Of Species Kingsley* stated that it was "just as noble a conception of the Deity to believe that He created primal forms capable of self-development," and quotes from his letter were used in every edition of *On The Origin Of Species* until the last in 1872.

Kingsley would be one of the first clergymen to write in support of Darwin's *Origin of Species.* He was sympathetic to the idea of evolution and was one of the first to praise the book. He had been sent an advance review copy and in his response of November 18, 1859 (four days before the book went on sale) stated that he had "long since, from watching the crossing of domesticated animals and plants, learnt to disbelieve the dogma of the permanence of species." Darwin added an edited version of Kingsley's closing remarks to the next edition of his book, stating that:

A celebrated author and divine has written to me that "He as gradually learnt to see that it is just as noble a conception of the Deity to believe that He created a few original forms capable of self-development into other and needful forms, as to believe that He required a fresh act of creation to supply the voids caused by the action of His laws."

Kingsley's love of natural history did not result in a written work until the mid-1950s when he spent the winter of 1853-54 at Torquay while his wife recovered from the ill-effects of living in their damp Rectory home at Eversley. Here Kingsley became enthralled by marine biology. He spent hours on the shore collecting specimens, kept a daily journal, and sent off sea beasts, shells and seaweeds to Philip Henry Gosse in London, with whom he had started to correspond. The fruit of these Devon sea-coast explorations was a series of

articles in the *North British Review for November 1854*, subsequently published as *Glaucus: or Wonders of the Sea Shore* (Kingsley, 1859). The name *Glaucus* refers to the fisherman in Ovid's *Metamorphoses* who turns into a half-man, half-fish creature and goes to live in the sea.

In the opening of *Glaucus* Kingsley asks the reader to picture their six week seaside holiday, which he paints as lackluster, idle and unfulfilling. He goes on to exhort the reader to try the wonders of rational recreation, to learn a little about the wonders of the shore and to marvel at God's handiwork. The exploration of the shore that he narrates to the reader begins with examples from the Devon coastline, namely the landscape of Torquay and Paignton. He loved the seaside and had, quite literally, no time for the idle pursuits of most other holidaymakers:

Follow us, then, reader, in imagination, out of the gay watering-place ... along the broad road beneath the sunny limestone cliff ... to the sea marge; for yonder lies, just left by the retiring tide, a mass of life such as you will seldom see again.

In *Glaucus*, Kingsley addressed the Victorian father on summer holiday, appealing to the notion that even leisure time should be spent in the pursuit of something profitable. Instead of reading another silly novel or engaging in "ineffectual attempts to catch a mackerel," why not "try to discover a few of the Wonders of the Shore" that are there "around you at every step, stranger than any opium-eater dreamed?" Natural history was not only a fascinating field of study, it had "become nowadays an honorable one," pursued by dukes and princes. "Nay," Kingsley declared, "the study is now more than honorable, it is (what to many readers will be a far higher recommendation) even fashionable." Natural history books were "finding their way more and more into drawing-rooms and schoolrooms" and knowledge of the subject was no longer "considered superfluous." Kingsley insisted that the study of natural history led to happiness, as an understanding of nature lifted the individual outside his petty world to a realm of higher meaning.

In Kingsley's opinion, fathers had a responsibility to teach natural history to their children. This "age offers no more wholesome training, both moral and intellectual, than that which is given by instilling into the young an early taste for outdoor physical science." The training provided by natural history was especially important for "middle class young men," the "frightful majority" of which were "growing up effeminate, empty of all knowledge but what tends directly to the making of a fortune."

Kingsley often quotes Gosse when it comes to finding and capturing marine specimens and keeping them in aquaria. He also remarks on Gosse's color plates in *The Aquarium*:

Those who have never seen one of them can never imagine (and neither Mr. Gosse's pencil nor our own clumsy words can ever describe them) the gorgeous colouring and the grace and delicacy of form which these subaqueous landscapes exhibit.

Advances in printing technology at this time made it possible economically to reproduce and disseminate such color images among the new and rapidly growing middle and working class populations. By the 1850s lithography was the cheapest and fastest way to achieve commercially viable color prints, but a close inspection of the plates in *Glaucus* re-

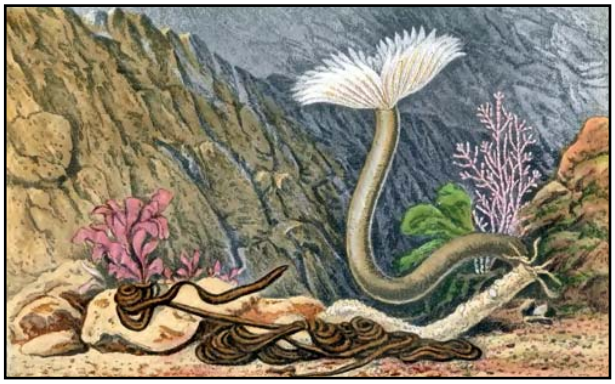

Figure 33: A plate from *Glaucus*.

veals etching, aquatint engraving and wood engraving, i.e., a combination of intaglio and relief printing. The best color prints were achieved by printing from multiple wood blocks engraved on the end grain of a hard wood like box. As this was a labor intensive process and a less versatile medium, George Baxter (1804-1867) developed a more commercially viable method of combining intaglio and relief processes that allowed for the artistic effects and versatility of finely inked lines and etched tones in metal to be had in combination with colors printed from wood.

Kingsley coined the term "Pteridomania" (Fern Madness) to describe the Victorian's fern obsession that started in the 1840s. He viewed this Victorian craze for collecting ferns as a wholesome activity to be encouraged, and expanded to include all aspects of natural history, thus serving both as a means of keeping families and friends engaged in industrious pursuits while on vacation, and united in awe of the wondrous works of God. He also satirized the mania as follows:

Perhaps you smile, in answer, at the notion of becoming a "Naturalist" and yet you cannot deny that there must be a fascination in the study of natural history, though what it is is as yet unknown to you. Your daughters, perhaps, have been seized with the prevailing "Pteridomania," and are collecting and buying ferns, with Ward's cases wherein to keep them (for which you have to pay), and wrangling over unpronounceable names of species (which seem to be different in each new Fern-book that they buy), till the Pteridomania seems to you somewhat of a bore; and yet you cannot deny that they find an enjoyment in it, and are more active, more cheerful, more self-forgetful over it, than they would have been over novels and gossip, crochet and Berlin-wool. At least you will confess that the abomination of "Fancy-work" - that standing cloak for dreamy idleness (not to mention the injury which it does to poor starving needlewomen) - has all but vanished from your drawing-room since the "Lady-ferns" and "Venus's hair " appeared; and that you could not help yourself looking now and then at the said "Venus's hair" and agreeing that nature's real beauties were somewhat superior to the ghastly woolen caricatures which they had superseded.

Kingsley didn't see science as in opposition to the holy word of God, but instead praised scientists who, rather than twist the facts to suit the Bible or the Bible to suit the facts, continued their research with faith that God could take better care than anyone else of His own everlasting truth:

But it is a question whether Natural History would have ever attained its present honours, had not Geology arisen, to connect every other branch of Natural History with problems as vast and awful as they are captivating to the imagination. Nay, the very opposition with which Geology met was of as great benefit to the sister sciences as to itself.

For, when questions belonging to the most sacred hereditary beliefs of Christendom were supposed to be effected by the verification of a fossil shell, or the proving that the Maestricht [a city in the southeast of the Netherlands**]** ***homo diluvii testis*** [an extinct species of giant salamander] **was, after all, a monstrous eft, it became necessary to work upon Conchology, Botany, and Comparative Anatomy, with a care and a reverence, a caution and a severe induction, which had been never before applied to them; and thus gradually, in the last half century, the whole choir of cosmical sci-**

Figure 34: Plate 2 from *Glaucus*.

ences have acquired a soundness, severity, and fullness, which render them, as mere intellectual exercises, as valuable to a manly mind as Mathematics and Metaphysics.

But how very lately have they attained that firm and honourable standing ground! It is a question whether, even twenty years ago, Geology, as it then stood, was worth troubling one's head about, so little had been really proved. And heavy and uphill was the work, even within the last fifteen years, of those who steadfastly set themselves to the task of proving and of asserting at all risks, that the Maker of the coal seam and the diluvial cave could not be a "Deus quidam deceptor" [God who is sometimes a Deceiver] **and that the facts which the rock and the silt revealed were sacred, not to be warped or trifled with for the sake of any cowardly and hasty notion that they contradicted His other messages.**

When a few more years are past, Buckland and Sedgwick, Murchison and Lyell, Delabêche and Phillips, Forbes and Jamieson, and the group of brave men who accompanied and followed them, will be looked back to as moral benefactors of their race; and almost as martyrs, also, when it is remembered how much misunderstanding, obloquy, and plausible folly they had to endure from well-meaning fanatics like Fairholme or Granville Penn, and the respectable mob at their heels who tried (as is the fashion in such cases) to make a hollow compromise between fact and the Bible, by twisting facts just enough to make them fit the fancied meaning of the Bible, and the Bible just enough to make it fit the fancied meaning of the facts.

But there were a few who would have no compromise, who laboured on with a noble recklessness, determined to speak the thing which they had seen, and neither more nor less, sure that God could take better care than they of His own everlasting truth; and now they have conquered; the facts which were twenty years ago denounced as contrary to Revelation, are at last accepted not merely as consonant with, but as corroborative thereof; and sound practical geologists - like Hugh Miller, in his "Footprints of the Creator," and Professor Sedgwick, in the invaluable notes to his " Discourse on the Studies of Cambridge" - are wielding in defense of Christianity the very science which was faithlessly and cowardly expected to subvert it.

As I have mentioned, Kingsley saw no problem in reconciling his religious faith with Darwin's theory of evolution by natural selection:

Let us speak freely a few words on this important matter. Geology has disproved the old popular belief that the universe was brought into being as it now exists, by a single fiat. We know that the work has been gradual; that the earth

> **"In tracts of fluent heat began,**
> **The seeming prey of cyclic storms,**
> **The home of seeming random forms,**
> **Till, at the last, arose the man."**

And we know, also, that these forms, seeming random as they are, have appeared according to a law which, as far as we can judge, has been only the whole one of progress, lower animals (though we cannot say, the lowest) appearing first, and man, the highest mammal, "the roof and crown of things," one of the latest in the series. We have no more right, let it be observed, to say that man, the high-

Figure 35: Plate 6 from *Glaucus*.

est, appeared last, than that the lowest appeared first. Both may have been the case; but there is utterly no proof of either, and as we know that species of animals lower than those which already existed appeared again and again during the various eras, so it is quite possible that they may be appearing now, and may appear hereafter, and that for every extinct Dodo or Moa, a new species may be created to keep up the equilibrium of the whole. This is but a surmise, but it may be wise, perhaps, just now, to confess boldly, even to insist on, its possibility, lest the advocates of the "Vestiges of Creation" theory should claim the notion as making for them, and fancy, from our unwillingness to allow it, that there would he aught in it, if proved, contrary to Christianity.

Kingsley commented on *Omphalos*, treating Gosse lightly in his criticism, something unusual for him:

It is with real pain that I have seen my friend Mr. Gosse, since this book was written, make a step in the direction of obscurantism, which I can only call desperate, by publishing a book called "Omphalos." In it he tries to vindicate what he thinks (though very few good Christians do so now) to be the teaching of Scripture about Creation, by the supposition that fossils are not the remains of plants and animals which have actually existed, but may have been created as they are and where they are, for the satisfaction of the Divine mind; and that therefore the whole science, not merely of paleontology, but (as he seems to forget) of geognosy [now superseded by the term geology] **also, is based on a mistake, and cannot truly exist, save as a play of the fancy.**

It seems to me that such a notion is more likely to make infidels, than to cure them. For what rational man, who knows even a little of geology, will not be tempted to say - If Scripture can only be vindicated by such an outrage to common sense and fact, then I will give up Scripture, and stand by common sense ? For my part, I have seen no book for some years past, which I should more carefully keep out of the hands of the young. I am sorry to have to say this of the-work of a friend, both because he is my friend, and because there are thoughts therein, about the creative workings of the Divine mind, which however misapplied, are full of deep truth and beauty, and are too much forgotten now-a-days. But, as Aristotle says where he differs from Plato, "Truth and Plato are both my friends; *but it is a sacred duty to prefer Truth*."

It is one of the greatest ironies that I have ever encountered in my research into the history of the aquarium hobby that these two great men - Gosse and Kingsley - came to their downfalls because of religion. In the January 1864 issue of *Macmillan's Magazine*, Kingsley published a review of an anti-Catholic History of England by J.S. Froude. In the review Kingsley gratuitously attacked John Henry Newman by writing,

Truth, for its own sake, had never been a virtue with the Roman clergy. Father Newman informs us that it need not, and on the whole ought not to be, that cunning is the weapon which Heaven has given to the saints wherewith to withstand the brute male force of the wicked world which marries and is given in marriage. Whether his notion is doctrinally correct or not, it is at least historically so.

Figure 36: Plate 10 from *Glaucus*.

To translate into modern parlance, Kingsley basically said: “All priests are liars and Newman is the worst.”

John Henry Newman (1801-1890) was an Anglican priest, poet and theologian and later a Catholic cardinal, who was an important and controversial figure in the religious history of England in the 19th century. Originally an evangelical Oxford University academic and priest in the Church of England, Newman then became drawn to the High-Church tradition of Anglicanism. He became known as a leader of, and an able polemicist for, the Oxford Movement, an influential and controversial grouping of Anglicans who wished to return to the Church of England many Catholic beliefs and liturgical rituals from before the English Reformation. In this the movement had some success. In 1845 Newman, joined by some but not all of his followers, officially left the Church of England and his teaching post at Oxford University and was received into the Catholic Church. He was quickly ordained as a priest and continued as an influential religious leader, based in Birmingham. Kingsley hated Newman, as many Anglicans did; they never forgave him for leading the Oxford Movement on the path to Rome. (Newman converted to Roman Catholicism in 1845, and was ordained a priest two years later.) Kingsley hated Roman Catholicism, too, for many reasons, and he associated it with Mediterranean effeminacy and indolence. Rome’s insistence on celibacy in its priests particularly infuriated him.

Newman regarded Kingsley’s reference to him in the review as a gross slander. He might have let it pass, but he had endured years of obloquy and the review touched a nerve; he was not willing to be called a liar. So he demanded an apology from Kingsley and got a half-hearted one. Disputants issued pamphlets, Newman’s being far more effective than Kingsley’s, but Newman remained unappeased. He was quick to take offence, but only when it was loudly given. Although Kingsley had been “furiously carried away by his feelings,” the quarrel could not end there, because Newman deemed the insult an equal reflection on Roman Catholicism, the church as an institution and the priesthood. A pamphlet was not enough. He decided that the slander called for a larger response.

Newman’s definitive response was his masterpiece, *Apologia pro Vita Sua* (A Defense of One’s Life, 1864), a book in seven parts, the first two and the seventh being answers to Kingsley, the remainder a history of his religious opinions from boyhood to 1845. The book was written as rapidly as possible in six weeks with Newman writing standing up sometimes as long as 22 hours straight in order to get his story before the public. He said “it was "the most arduous work I ever had in my life" in "one of the most terrible trials I ever had." The reviews of the book (and these included those by members of the Church of England) were universally favorable, and its sales were enormous. His reputation was restored and heightened and indeed, even his constant financial worries were over.

Kingsley had crossed swords with an opponent too strong for him and was no match for his adver-

Figure 37: John Henry Newman (1801-1890).

sary's subtle skill. Kingsley disgraced himself in scholarship and truth by calling Newman a liar and failing to bring up a single instance of his lying; his reputation never survived the blunder.

AN "UNJUSTIFIED EMENDATION"

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, February 3, 2018)

This story starts with the download of a book from the Smithsonian Library that had been donated to the U. S. National Museum by Dr. George Sprague Myers on September 30, 1935. In 1914 the Vereinigten Zierfisch-Züchtereien (United Ornamental Fishbreeders), a commercial consortium of aquarists in Rahnsdorfer Mühle and previously in Conradshöhe, both districts of Berlin, published the 352 page book, *Exotischen Zierfische in Wort und Bild* (Exotic ornamental fishes in Words and Pictures). The organization described itself as being the "Main Headquarters for imports with the biggest selection, and rarest fish novelties and aquatic plants." The book - over 100 years old - apparently is quite rare, the only known copy being that held by the Smithsonian Institution's National Museum, Division of Fishes, although copies from this Institution are available from various sources here and in Germany since it is in the public domain and one may freely copy and distribute it as no entity (individual or corporate) has a copyright on the body of the work.

GEORGE SPRAGUE MYERS (1905-1985)

Myers was born in Jersey City, New Jersey. He developed an early interest in vertebrate zoology, accumulating aquariums in which he kept species of exotic and native fishes. His first article on aquarium fishes was published at the age of fifteen; this was in 1920 when he was a Junior in High School. Around this time Myers began frequenting the American Museum of Natural History in New York City, seeking advice on natural history questions. As a result, he became a volunteer assistant at the museum from 1922 to 1924. At the museum he came under the influence of its ichthyology and herpetology staff including G. K. Noble, Karl P. Schmidt, John T. Nichols, Eugene W. Grudger, John Tee-Van, Charles M. Breder and others.

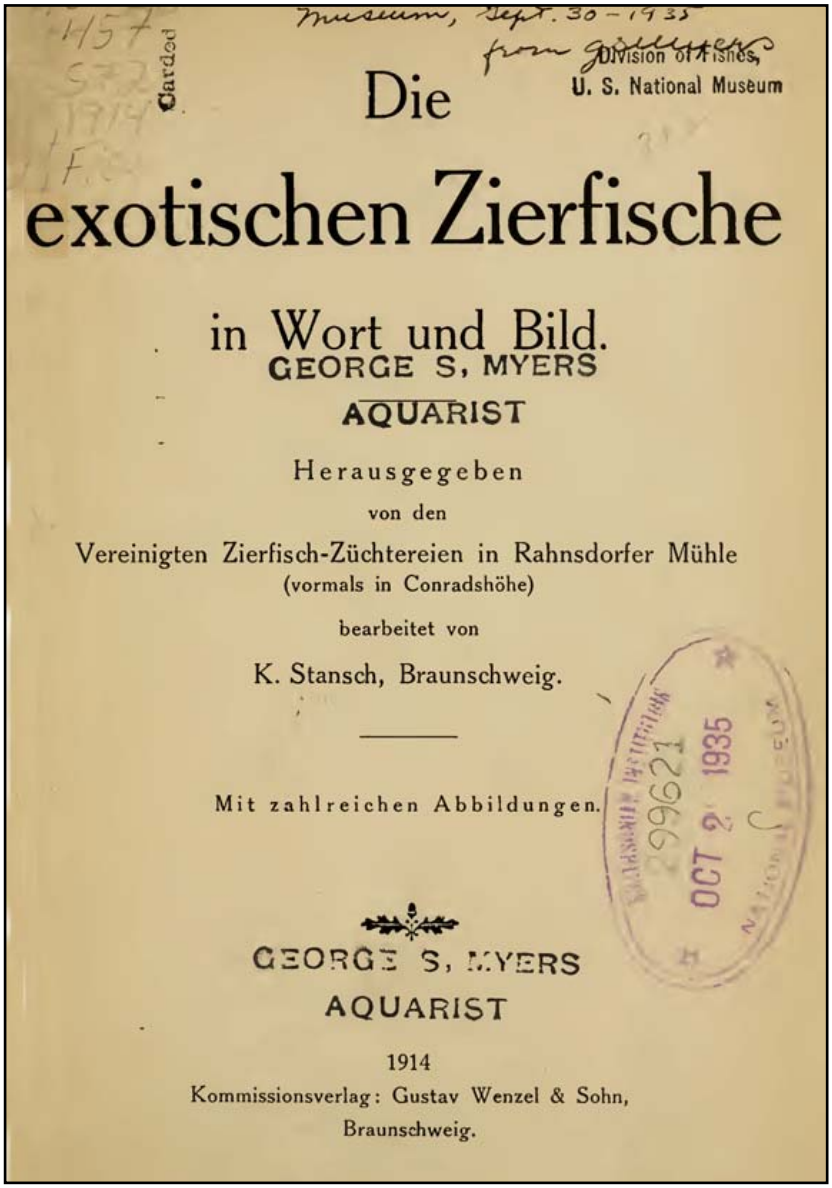

Figure 1: The inside cover page of George Myers' copy of *Exotischen Zierfische* showing two of his "George S. Myers Aquarist" stamps.

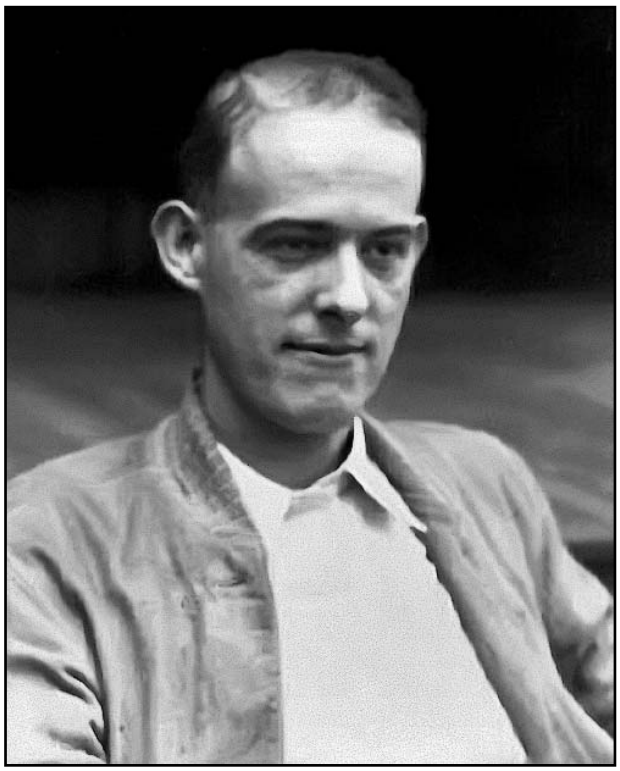

Figure 2:
GEORGE SPRAGUE MYERS (1905-1985)

In 1924, Myers was introduced to Carl H. Eigenmann, who invited him to attend Indiana University and offered him a part-time curatorial assistantship working in the fish collections. Under Eigenmann's guidance, Myers further developed his interest in the systematics of South American fresh-water fishes. He remained there until 1926, when Eigenmann fell ill and moved to California. In that year, Myers was contacted by David Starr Jordan about continuing his ichthyological studies at Stanford University. He accepted Jordan's offer and received an assistantship in the university's Natural History Museum. Myers' education was influenced by an outstanding group of systematic zoologists gathered together by Jordan. John O. Snyder, Edwin C. Starks, Harold Heath, G. F. Ferris and Albert W. C. T. Herre each played a role in shaping his career. Myers received the A.B. degree in 1930, the A.M. degree in 1931 and the Ph.D. degree in 1933. His dissertation was entitled, "The Classification of the African Cyprinodont Fishes, with a Discussion of the Geographical Distribution of the Cyprinodontidae of the World," an indication of his early interest in killifishes.

Myers began his professional career at the United States National Museum (USNM), where he was appointed Assistant Curator in charge of the Division of Fishes in 1933 and it was shortly afterwards that he turned his copy of *Exotischen Zierfische in Wort und Bild* over to the Smithsonian Library. He was an important advocate of modern ideas of fish evolution and was instrumental in developing the most widely accepted system of classifying the world fish fauna as primary freshwater, secondary freshwater, peripheral or marine. Much of his biogeographical research tended to give credence to the theory of continental drift based on evidence derived through observations of primary freshwater fishes.

Myers was a prolific writer and his bibliography included over six hundred titles on ichthyology, herpetology, biogeography, the history of systematic zoology and museum practices. He was also an accomplished editor. From 1932 to 1960, he served as associate editor of William T. Innes's *The Aquarium* and was scientific editor of all nineteen editions of Innes's *Exotic Aquarium Fishes*. He was also the founder and editor of the *Stanford Ichthyological Bulletin*, 1938-1967, and editor of *The Aquarium* Journal, 1952-1954. Older members of the American Killifish Association will remember that he was a good friend of this organization as it often called on him for help in identifying unknown killifishes and in providing assistance in killifish classification.

The book in question is definitely not a pristine copy, since page after page is stamped with the legend, "George S. Myers Aquarist," suggesting that he was in his early teenage years when he procured his copy. Furthermore - and what is of most interest to us here - he frequently corrected the scientific names of the entries throughout the book and occasionally even translated common names from German into English, but especially so in the section on egglaying cyprinodonts. In his copy of the book, his most frequent correction in the killifish section was his changing *Haplochilus* to *Aplocheilus* and in this essay I explore the reasoning behind it.

JOHN McCLELLAND (1805-1883)*

McClelland was a British medical doctor, born in Ireland, and had interests in geology and biology. He was a Member of the Royal College of Surgeons in London and entered the East India Company's Bengal Medical Service in 1830. From an early date, the East India Company's settlements and factories in the East were provided with medical officers. It was not until 1764 that The Indian Medical Service (IMS) was constituted. The service was, from the beginning, divided into three branches, the Bengal, Madras, and Bombay covenanted "Establishments." Its first duty was military as the Medical Department of the Indian Army for both European and native troops, and while its members might be lent to the Civil Department for civil employment, they were always liable to be recalled to military duty. In 1858, after the suppression of the Indian Rebellion or Mutiny of 1857, the Government of India was transferred from the Company to the Crown but the IMS was kept under much the same conditions as before.

One advantage of the IMS to its members was always the great scope available for different tastes, scientific and literary, as well as professional. Hence some of them distinguished themselves as Civil and Political Officers, Oriental Scholars and men of Science. In his history of the IMS, Dirom Crawford (1907) listed five areas in the last named. Under Natural History this included Francis Day, a pioneer ichthyologist who described more than three hundred fishes in his two volume work on *The Fishes of India* in 1878. Under Geology, McClelland was mentioned as one of the three most noted. (Crawford did not include a separate heading for ichthyology). This explains how McClelland was able to do research in addition to that of a military surgeon.

In 1835 McClelland, along with Nathaniel Wallich (a major figure in the history and development of Indian botany) and William Griffith (another well-known botanist), was sent on a mission (Tea Committee) to identify if tea could be grown in northeastern India. One field that McClelland felt might provide evidence for or against the success of tea cultivation was natural history. The more similar the terrain and the flora and fauna were to the tea-growing areas of China, the better the odds in favor. It was in this context that the expedition surveyed and collected birds and to some extent, mammals. Specimens were obtained and sent, with McClelland's report, to the Court of Directors of the East-India Company in 1837 along with drawings expressly made by local artists. McClelland had good evidence for close to 170 bird species, and this total shows just how remarkable McClelland's work was. In its day this was a very considerable sampling of the avifauna of what was then called Assam.

McClelland made preliminary identifications, which appear on the drawings, and provided written descriptions but he was aware of his limited experience as an ornithologist and requested that the Court of Directors have his collection examined by an expert and revised to take account of the most up-to-date information.

Thomas Horsfield (1773-1859) was an American physician and naturalist who worked extensively in Indonesia, describing numerous species of plants and animals from the region. At the time, he was a curator of the East India Company Museum in London, and the Court of Directors asked Horsfield to revise McClelland's material. To this end, he presented a paper to the *Zoological Society of London* (Horsfield, 1840) that appeared to

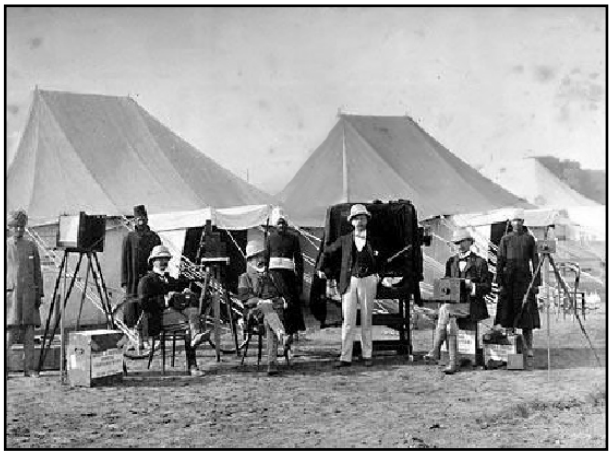

Figure 3:
Members of the Indian Medical Service, 1860.

***Because so little is known of McClelland, I have expanded this section on him to include the results of my researches into his life while he was in the Indian Medical Service.**

Figure 4: THOMAS HORSFIELD (1773-1859).

cover both McClelland's investigations and his own revisions of the mammals and birds. This paper contained the descriptions of 26 new birds, 22 of which figure in the McClelland drawings. Horsfield wrote:

"Mr. McClelland then expresses his desire that his Descriptive Catalogue, before publication, should be revised in England, in order to prevent the introduction of mere nominal species, and to conform the nomenclature to the latest discoveries in science" and continued "the only object has been to secure to Mr. McClelland the discoveries he has made."

There has been some confusion over the attribution of authorship in the names of taxa described in the Horsfield paper that do not have any attribution. In the paper there are cases where the new name is accompanied by a Latin diagnosis (written by Horsfield) *and* by an English vernacular description set within quotation marks and attributed to McClelland. Other cases either have no quoted text from McClelland or the text quoted does not include any description. What is needed therefore is a consistent method for crediting all the new names. Dickson (2003) recommends crediting to Horsfield those names, where no descriptive text by McClelland is included, and by crediting all others to McClelland as it combines consistency of logic with a minimum of change.

McClelland was appointed 1836 as the secretary of the "Coal Committee," the forerunner of the Geological Survey of India (GSI), formed to explore possibilities to exploit Indian coal. He was the first to propose hiring professional geologists for the task. He was also involved in surveys of forests and his reports led to the establishment of the Forest Department in India.

Although not a botanist he edited the posthumous botanical Works of Griffith and also wrote *The Geology of Kumaon, Calcutta*, 1835; *Reports of the Geological Survey of India for 1843 to 1846*, and *Medical Topography of Bengal and the Northwest Provinces, W.P.*, London, 1859; and

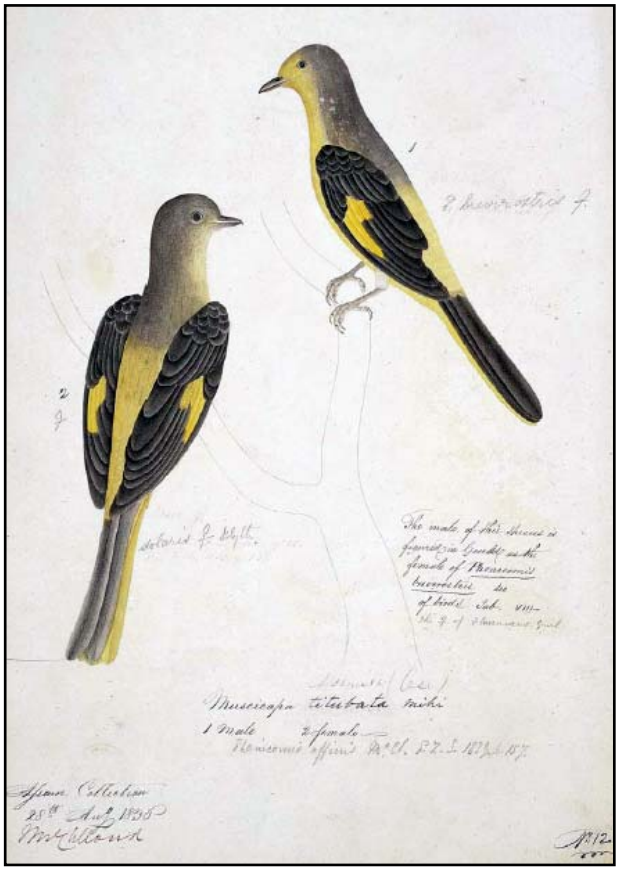

Figure 5: McClelland's paintings of two minivets named *Phoenicornis affinis* McClelland in Horsfield (1840).

Figure 6:
WILLIAM SHARP MACLEAY (1792-1865)

edited the *Calcutta Journal of Natural History* from 1841 to 1847. Scientific studies on Assam fishes were first made by McClelland who happened to visit the upper Assam being attached to a mission of Bengal Medical Service during 1835-36. He described 138 species covering various localities of India including Assam and published in 1839 a memoir on Indian Cyprinidae in the second part of the 19th volume of the Asiatic Researches. McClelland is commemorated in the name of the mountain bulbul, *Ixos mcclellandii* and a venomous snake, *Sinomicrus macclellandi*. In his work as an ichthyologist he described many species and several genera of fish, among them *Schistura*, a genus of fish in the family Nemacheilidae native to the streams and rivers of the southern and eastern Asia.

An ardent Quinarian, his devotion to its principles led to his difficulty in getting his monograph on Ganges fishes accepted by the Asiatic Society of Bengal. The British Civil Servant and entomologist William Sharp Macleay developed the Quinarian system of classification in his *Horæ Entomologicæ*, published in two parts in 1819 and 1821, and William John Swainson's work on ornithology gave wide publicity to the idea. For two decades, the Quinarian system was widely discussed in Britain and influenced such naturalists as Charles Darwin, Richard Owen and Thomas Huxley.

Macleay developed his system under the shaping influence of two pressures: (1) the insistence by followers of Linnaeus on developing artificial systems at the expense of the natural system and (2) the apparent tension between the continuity of organic nature and the failure of linear classification schemes (which continuity seemed to require). Against what he perceived as a dogmatic indolence on the part of the Linnaeans, Macleay developed a philosophy of science in which hypotheses that exceeded the available evidence should be proposed and subjected to severe tests. He also developed a novel comparative anatomical methodology, the method of variation, to aid in his search for the natural system. Using this method, he developed an intricate system that showed how organic nature could be continuous without being linear.

Macleay thought that nature was arranged in patterns of five. So there were 5 classes of animals in the natural world (Figure 7). Each class, such as birds, was comprised of 5 orders, and each of these orders contains 5 families, etc. What made

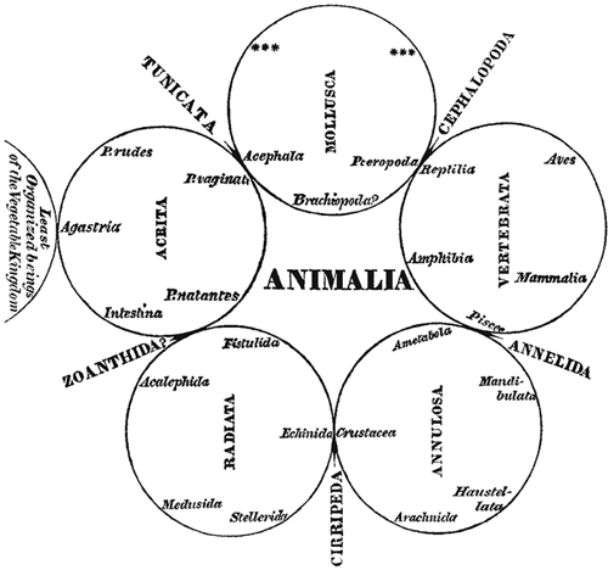

Figure 7: Part of the Quinarian system the classification of animals. The asterisks in the Mollusca represent missing groups that were expected to remain to be discovered.

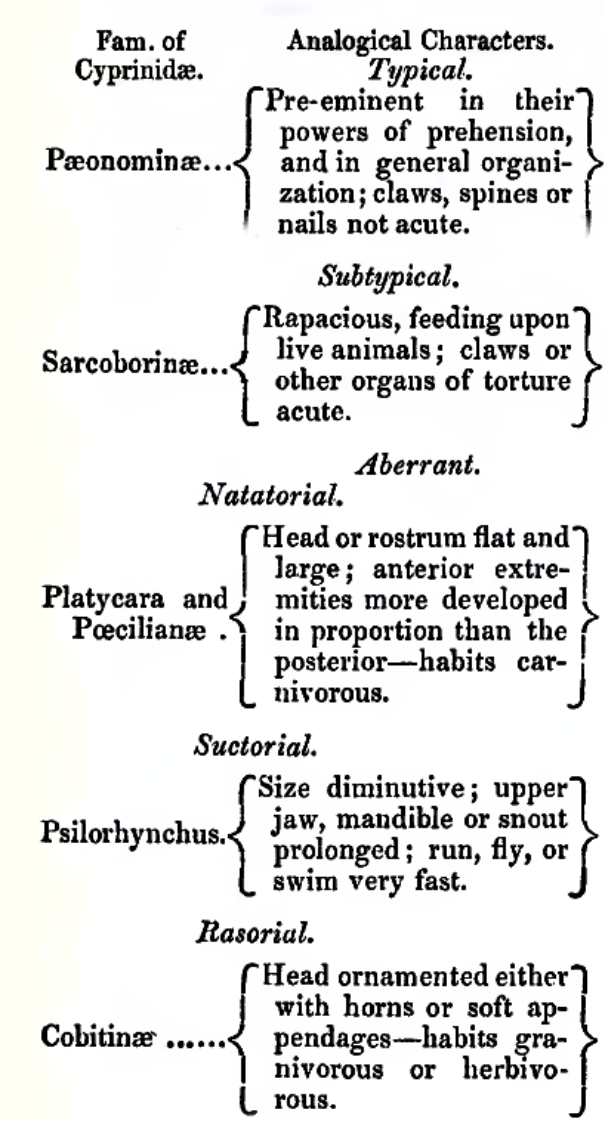

Figure 8: McClelland's Quinarian classification of the Cyprinidae into five subfamilies. Although circles were favored by Macleay, squares, triangles and straight lines were used as well to show the circularity.

the Quinarian system, as it was called, distinctive was its method of graphic display. Macleay would depict the five orders of birds as five circles, arranged in a larger circle with each smaller circle just touching. The five families would then be distributed around each of the five small circles. Where a family on one circle touched a family on another, there was judged to be an affinity. Families that were in corresponding spots in different orders were said to have be analogous.

Quinarianism was not widely popular outside the United Kingdom and it became unfashionable by the 1840s. The system had opponents even before the publication of Charles Darwin's *On the Origin of Species* (1859) that paved the way for evolutionary trees.

In his 1839 monograph on Indian *Cyprinidae,* the family at that time consisting, among others, of carps, barbs, loaches, aquarium livebearers and killifishes (McClelland, 1841), McClelland applied quinarian methods to the family and his classification is shown in Figure 8. McClelland appeared to be the only one at the time who unreservedly adopted quinarian views but fortunately, the Asiatic Society of Bengal did agree to publish his monograph.

In 1839 McClelland took the family *Pœcilianae* and, on the basis that although the members of the family were closely allied the numbers of their branchial rays differed, established the following six subgenera:

1. *Pœcilia*
2. *Lebias*
3. *Aplocheilus* (new)
4. *Fundulus*
5. *Molinesia* and
6. *Cyprinodon*

The misspellings are McClelland's and all six were considered genera by subsequent ichthyologists.

McClelland placed three members in his new subgenus: *Aplocheilus chrysostigmus*, *Aplocheilus melastigmus* (actually an *Oryzias*) and *Esox panchax*, the last named by Hamilton in 1822 and which McClelland considered therefore as *Aplocheilus panchax*. He named *Aplocheilus* on the basis of eleven characters but only four were correct and were not sufficient to characterize the subgenus; this was done by Valenciennes in 1846. McClelland did not specify a type species for his genus so this was done by the Dutch ichthyologist Pieter Bleeker in 1863 who named *Aplocheilus chrysostigmus* as the type species. This was actually directly opposite to what he had intended to do since *Aplocheilus chrysostigmus* is a synonym of *Aplocheilus panchax*.

Although I have chronicled McClelland's errors in his establishment of *Aplocheilus*, I should mention that one of Dey's conclusions in his 1984 "Ichthyological Developments in Assam During Nineteenth Century" was that although the occurrences of fishes in India dates back to three millennium BC (Hora, 1956) and that the first writer was Bloch in 1785, it would seem that the scientific attempt on the fishes of Assam that was initiated by Hamilton in 1814 and 1822 with 16 species was truly elucidated by McClelland in 1839.

In 1861, Northern India was visited by a devastating epidemic of cholera. In consequence of these terrible losses, the Government of India appointed a special Commission on August 31, 1861, commonly known as the "Cholera Commission." The Commissioners appointed were five in number: John Strachey, Esq., Civil Service, President; Dr. William Linton and John McClelland, Inspectors-General of Hospitals; Lt. Colonel J.C. Gawler, Officiating Deputy-Adjutant General, British Forces; and Major Patrick Stewart, Bengal Engineers.

They were instructed to investigate the circumstances under which the epidemic of cholera attacked the European troops in the North-Western Provinces and the Punjab; to place upon record all facts of interest that they could discover; to ascertain, so far as might be practicable, the causes which aggravated the virulence of the disease; to point out how those causes might have been prevented or avoided; and to endeavor to draw from the history of the past useful lessons for the future. It was no part of their duty, however, to inquire into the causes in which an epidemic of cholera has its origin, nor to investigate the pathology or treatment of the disease.

When the Indian Mutiny broke out in 1857, Florence Nightingale offered to leave for India immediately if there was anything she could do. Her services were not required but she became interested in the sanitary conditions of the army and the people there. She became familiar with many facets of Indian life and demanded that there should be improvements in health and sanitation there. From her work, a Sanitary Department was established in the Indian government.

Nightingale was anxious to receive the Cholera Commission report but it was delayed, prompting her to criticize it without seeing it. On November 10, 1863 she wrote: "As to the 'cholera commission' report, it is obvious they are ashamed to send it," and "We know its history. We know that there were evils which accumulated under McClelland, that it is a divided report - part of the commission refused to sign it - and that they are ashamed of the state of things and keep it close." On December 26, 1863 she wrote: "Allusion is made in Dr. McClelland's paper to the report of the Cholera Commission. This report never reached us here. All we have heard is that it is the report of a minority and that one of the ablest sanitary men in the British service, who was a member, refused to sign it (she is referring here to Dr. Linton). For some cause it has given offence."

Strachey, however, explained why the report was delayed and refutes their (Linton and Gawler) criticism of the report. Major Stewart was compelled to leave India on public duty before the completion of the Report but he was present with the Commission during the whole of the inquiry and that portion of the Report which concerned

Figure 9: JOHN STRACHEY (left) and his Brother Richard in 1876.

the special measures to be adopted for the prevention or mitigation of future attacks of Cholera was nearly finished before Major Stewart left the country. However, Strachey and McClelland were authorized to say that he concurred in the recommendations made by them therein to the Government.

The following was written by Strachey:

The duty of drawing up the Report of the Commission fell to me, although, as I need hardly say, the duty of writing upon such a subject was not one that I was likely to think agreeable. My task was not made easier by the fact that the Inspector General of Her Majesty's Hospitals in India was a Member of the Commission [i.e., Linton], and that he was little inclined to admit the shortcomings of his Department. Dr. Linton withdrew from the Commission at Agra, never took any part in its proceedings in that Circle, and never visited Morar, regarding which place the chief question is raised.

We hope that we may be pardoned for saying that serious criticism of this joint Minute of Dr. Linton and Lieutenant Colonel Gawler is hardly possible. It is not worthwhile to expose in detail its mistakes and misrepresentations and contradictions. If the reasons for the opinions given in the Report have not been sufficiently justified by the facts that have been already stated, nothing that could now be added could make the truth clearer. Regarding general conclusions of importance, Dr. Linton and Lieutenant Colonel Gawler hardly say a word, and there is nothing to show whether they adopt them or reject them. Very nearly the whole of their Minutes, except those portions which refer to irrelevant matters, is taken up with the defense of persons or departments whose misconduct or in competency has been exposed in the Report, and with attempts to show that nobody was to blame for anything that happened.

Linton's character was made clear by the following paragraph that appeared in his Report:

There is one point to which I wish to call attention. While the disease was at its height, a large number of men were daily required to attend on the sick and to rub their cramped limbs. This duty exposed to the utmost risk many men who would otherwise have incurred much less danger of infection; and the mortality was thus so much increased, though unavoidably, that I think it would on future occasions be advisable to entertain a number of Natives for such duties, rather than unnecessarily risk the loss of so many European lives.

On November 17, 1863, Nightingale had changed her mind about McClelland and the report:

Let me add that, when I said what was thought of the "cholera report" by the medical officials here (in my last) it was merely as such. The forty-eight hours' reading of it, which I have had since, show me that it con-

Figure 10:
FLORENCE NIGHTINGALE (1820-1910). Nightingale was at first very critical of McClelland and the Commission Report but later had a change of mind and praised them.

tains an amount of' valuable information and makes disclosures such as we have never had, nor made, in our report. But its recommendations are not equal to what we in this country should consider necessary from experience. However it is a great step in advance to have had such a report, although I can easily understand why it should offend army medical officials…

The apparent reason why Dr. Linton would not sign the Cholera Commission report and why it has created so much ill feeling in the Army Medical Department is that *one Indian medical officer, Dr. McClelland, and one civilian, Mr. Strachey, have not only exposed fearlessly the sanitary defects of the stations, for on this all parties may be agreed, but because they have criticized rather severely the measures and treatment adopted for the sick by the royal army medical officers.*

On September 14,1863 Major H. K. Burne, Officiating Secretary to the Government of India, Military Department, sent a letter to Strachey and the following is a quote from it:

The Report of the Commission appointed to inquire into the causes and history of the Cholera Epidemic of 1861 in Northern India, of which you were President, having been laid before Government with the subsequent correspondence on the same subject, I am directed to convey to the Commission, - especially to yourself and to Dr. McClelland, whose labors were prolonged considerably beyond the period over which those of the other Members extended, - the warm acknowledgments of the Government of India for the zeal and earnestness with which the inquiries were conducted, and the patience and care with which the varying results of the investigation have been compared and practical conclusions drawn for future guidance.

McClelland had been promoted to Officiating Principal Inspector General, Medical Department, in 1862 and was promoted to Principal Inspector General in 1863. After retiring from the Bengal Medical Service in 1867, he was knighted and became Sir John McClelland. By then he was married to a Scottish woman, Sophia Rosina, who was younger than him. They had a 5 year old son, John Gordon McClelland, who was born in Hampshire (the southern coast of England) in 1865. In 1871 he was living in Surrey (southeast England), and was listed in the census as a retired surgeon. McClelland died in St. Leonards (east Sussex on the south coast of England) in 1883 at the age of 82. Sophia married Henry Edward Swaine in Tunbridge Wells in 1884 and it is interesting to note that despite remarrying after his death in 1883, Sophia was buried in the same grave when she died, less than two years later.

McClelland made a number of observations during his lifetime that I find interesting, especially the first of the following two:

The number of species and groups are now so much multiplied in every department of natural history, that detached descriptions are daily diminishing in value; and besides, it is so easy to make a new genus if not required to show our reason for doing so, that we need not be surprised that it should now have become a regular trade, and that many acquire a temporary fame with the unthinking part of mankind by the practice.

Writers on natural history in the present day may he divided into three classes; first, those who recognise no rules but such as appear to be laws of nature, and taking nature as their guide, form their views according to the result of observations which are not confined to external characters, but embrace all that

Figure 11: ***Sinomicrus macclellandi.***

concerns natural objects [i.e., Quinarians]. The second class consists of naturalists who pursue the easier course of following authorities, but their works consist chiefly of technicalities derived from external characters indiscriminately applied to genera and species; their higher groups are consequently constructed according to rule rather than nature. The third class comprises describers of species, whose books are only remarkable for their size and expense. Nor can I altogether overlook upon this occasion another class of persons, who, though they are not naturalists, and scarcely even allow us to call them writers, yet exercise but too often an influence in societies detrimental to the objects of such institutions and the real advancement of science.

LOUIS AGASSIZ (1807-1873)

One of the great scientists of his day, and one of the "founding fathers" of the modern American scientific tradition, Louis Agassiz remains something of a historical enigma. A great systematist and paleontologist, a renowned teacher and tireless promoter of science in America, he was also a lifelong opponent of Darwin's theory of evolution. Yet even his most critical attacks on evolution have provided evolutionary biologists with insights.

Agassiz spent his early years in some of the most distinguished schools and colleges in Germany and he had the good fortune to be made early a student of the two great languages of ancient times. He became familiar, by reading them in their native Greek, with the high thought and reasoned truth and graceful style of Plato, and the accurate observations and descriptions of Aristotle. He also read the best Latin authors and wrote the language with great ease. Significantly, he was dogmatic in their usage.

Over the period from 1842 to 1847, Agassiz assembled his *Nomenclator Zoologicus* (1,564 pages and in Latin), which listed all of the names of the genera of animals. It was in two parts: I, the Supplemental List and II, the Universal Index. The first part contained 15,939 entries established previous to 1880 and the second part about 80,000 entries, also up to 1880 and which included all names in the first part. In the Universal part published in 1846, Agassiz listed the genus *Haplochilus* as a replacement for *Aplocheilus*. Each genus in the *Nomenclator* takes up only a single line, citing the name of the genus, the author of the name and the year named, and an indication in the group it belongs to such as Pisces, Aves, etc. (all this is heavily abbreviated).

What is astonishing is that these two names are, as far as their Greek roots go, identical. Aplo and haplo mean the same in Greek, i.e., simple or plain, and cheilus and chilus both mean lips. This is merely a matter of spelling and ichthyologists and other zoologists have been using the different versions for years without any demurral. Ichthyological examples include *Aplocentrus* (one of Rafinesque's "apparently a mythical" species of fish based on a purely imaginative drawing that Audubon prepared as a hoax) and *Haplochromis* (common aquarium cichlid), and *Balantiocheilus* (the Bala shark) and *Chondrochilus* (ray-finned fish in the family *Cyprinidae*). This, however, is merely a matter of how one prefers to spell these roots and Agassiz disagreed with the spelling of McClelland's *Aplocheilus*; it was not up to his own exacting standards.

Figure 12: LOUIS AGASSIZ (1807-1873)

The entries for *Aplocheilus* and *Haplochilus* in the *Nomenclator* are:

° Aplocheilus *M'Clel.* Pisc. 1839. (*Scr.* Haplochilus).
* Haplochilus — (*V. Aplocheilus MClel.*) Pisc.

Agassiz indicated that names in the entry with the superscript circle ° needed to improve in spelling and writing, and names in parenthesis in the entry with the asterisk * were faulty and must be abandoned. Although this was a poor reason for designating a new genus, many ichthyologists followed Agassiz's admonition and *Haplochilus* was widely used for quite a number of years but it was later criticized as being an "unjustified emendation" and thus nothing more than a synonym, hence the changes George Myers made in *Exotischen Zierfische.*

FRANCIS HAMILTON (1762-1829)

Since the *Aplocheilus/Haplochilus* fiasco started with Hamilton's *Esox panchax*, I'll say a little bit about some problems with his own name and discuss Hamilton's life in greater detail. Francis Hamilton was a Scottish physician born at Branziet, in Stirlingshire in 1762. He was the third son of Dr. Thomas Buchanan of Spital (the name derives from a shortened form of "hospital" dedicated to St. Bartholomew) - who afterwards succeeded as heir of entail to the estate of Leney in Perthshire - and Elizabeth Hamilton heiress of Bardowie near Glasgow. As a younger brother he was, of course, destined to a profession. He chose that of his father, and after the finishing the elementary parts of his classical education with considerable credit at the Grammar School of Glasgow, he commenced his medical studies at the University of Edinburgh.

Glasgow college has always enjoyed a high reputation for literature and ethics but, with the exception, perhaps, of the department of anatomy, its fame as a medical school has never equaled that of Edinburgh. During the latter part of the eighteenth century especially, the capital enjoyed a reputation for medical science scarcely inferior to that of any medical school in Europe. Its degrees were eagerly desired by students from all parts of Great Britain and from many parts of the continent, and its diploma was available in almost every part of the world as a powerful letter of recommendation. Hamilton was anxious to secure for himself the advantage of pursuing his professional studies under the eminent professors, who, at that time, more than sustained the high reputation which Edinburgh college had already acquired. Here he remained till he received his degree in 1783.

He soon after was appointed assistant-surgeon on board a man-of-war, a situation from which he was afterwards obliged to retire on account of ill health. He then spent some years at home in the country, his health being so bad as to disqualify him for all active exertion until 1794 when he received an appointment as surgeon in the East India Company's Bengal service. In the course of his medical studies, Hamilton had paid particular attention to botany and its cognate branches of natural science, and during his visit to the Birman Empire, he had an opportunity of making some valuable collections of the plants of Pegu, Ava and the Andaman Islands, which together with several interesting drawings, he transmitted to the

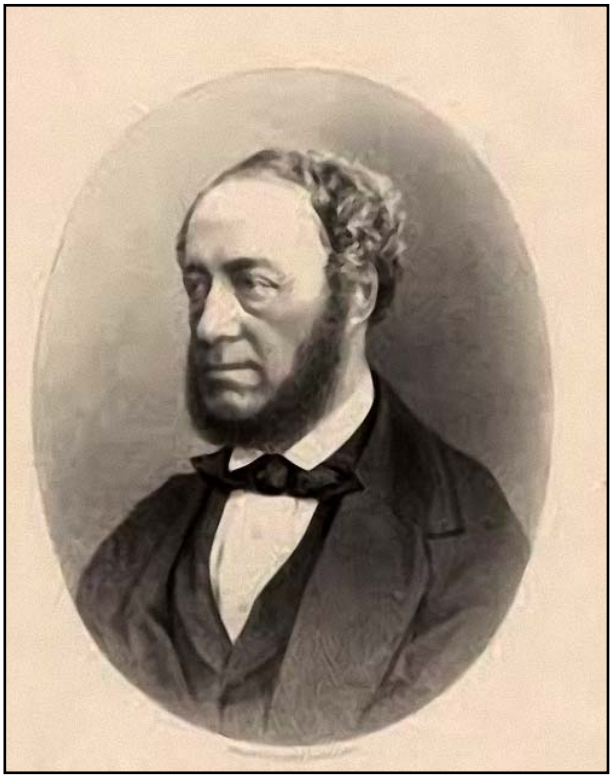

Figure 13: FRANCIS HAMILTON (1762-1829)

Court of Directors (the Minutes of the Court of Directors formed the central record of the deliberations and resolutions of the East India Company), by whom they were presented to Sir Joseph Banks. On his return from Ava, he was stationed at Luckipoor near the mouth of the Burrampooter, one of the major rivers of Asia, a trans-boundary river which flows through China, India and Bangladesh, where he remained two years, principally occupied in describing the fishes found in the neighborhood.

In 1798, he was employed by the board of trade at Calcutta on the recommendation of the Superintendent of the botanical garden, to visit the district of Chatigang (in Bangladesh) and its neighborhood, which formed the chief part of the ancient kingdom of Tripura. These extensive and well-watered districts of India beyond the Ganges afforded him a wide and rich field for pursuing his favorite study. The numerous specimens which he collected in this interesting country were also transmitted to Sir Joseph Banks, and added to his collection. Part of the following year, Hamilton spent in describing the fishes of the Ganges, of which he afterwards published an account.

Although killifish fanciers cannot really blame Hamilton for the *Aplocheilus/Haplochilus* fiasco, snakehead lovers have been annoyed by his error in *Ophicephalus*, a snakehead genus erected by Bloch in 1793. In the same publication that listed his *Esox panchax* ("An account of the fishes found in the river Ganges and its branches, 1822), Hamilton described seven species of snakehead under the generic name of "*Ophiocephalus*," a spelling error caused by the letter o that he had inserted in Block's *Ophicephalus*.

In 1800, he was employed by Marquis Wellesley, then Governor-general of India, to examine the state of the country that the company's forces had lately conquered from the Tipu Sultan (ruler of the Kingdom of Mysore) together with the province of Malabar. On his return to England in 1807, he published under the patronage of the Court of Directors the results of his inquiries in the Carnatic and Mysore districts. This work, "Travels in the Mysore" and extending to three large quarto volumes, were illustrated with maps and drawings and contained much valuable information concerning the agriculture, laws, customs, religious sects and history of India generally and particularly of the interior dependencies of Madras.

In evaluating his work the Edinburgh reviewers observed (*Edinburgh Review*, vol. xiii. Oct, 1808; 18 pages!), "Those who will take the trouble to peruse Dr. Buchanan's book will certainly obtain a far more accurate and correct notion of the actual condition and appearance of India and of its existing arts, usages and manners than could be derived from all the other books relating to it in existence...everything the author has seen is described perspicuously, unaffectedly and beyond all question, with the strictest veracity."

Soon after Hamilton had finished his survey of the Mysore country, he changed the scene of his labors from the south to the northeast of Hindustan, being appointed in 1802 to accompany the embassy to Nepal. In the course of this journey and his subsequent residence in Nepal, he made large additions to his former collections of rare plants. It was during this period also that he collected the greater part of the materials for his "History of Nepal," which he published in 1818 some years after he had retired from the Company's service. On his return from Nepal he was appointed surgeon to the Governor-general, and he employed such leisure time as he had for the study of natural history in superintending the menagerie founded by the Marquis Wellesley and in describing the animals which it contained. Undoubtedly India owed much to

Figure 14: ***Tetractenos hamiltoni.***

Hamilton and it would have been happier, both for her native population and her merchant princes, had her government been always entrusted to men of such practical capacity and unblemished integrity.

In 1805, Hamilton accompanied his patron (Wellesley) to England and in the following year was again sent to India by the Court of Directors for the purpose of making a statistical survey of the territory under the Bengal Presidency of Fort William, which includes Bengal Proper and several of the adjoining districts. With this laborious undertaking he was occupied for upwards of seven years, after which he returned to Calcutta and, in 1814, became Superintendent of the Botanical Garden. But he was now exhausted with long, continued exertion. His services had been liberally rewarded by the East India Company and an independent and honorably acquired fortune relieved him from the necessity of encountering any longer the hardships incident to his former mode of life, viz., among tribes half-civilized and often somewhat less than half-friendly, and exposed to the malignant influence of the Indian climate He naturally wished to enjoy the close of a busy life, free from the responsibility and uneasiness of public service, in some peaceful retirement in his native land.

While he was preparing for his voyage home, he was deprived, by the Marquis of Hastings, of all the botanical drawings which had been made under his inspection, during his last stay in India, and which he intended to have deposited with his other collections in the library of the India house. This circumstance he greatly regretted, as he feared that the drawings would thus be totally lost to the public. "To me," says Dr. Buchanan, in a paper which was published among the *Transactions of the Royal Society of Edinburgh*, "to me, as an individual, they were of no value, as I preserve no collection, and as 1 have no occasion to convert them into money."

In deciding that Hamilton's papers should be retained in India, it may be presumed that the object was that they should there be rendered more useful to the country than they could be in England. As McClelland remarked, "It could scarcely have occurred to the Marquis of Hastings that these works would be consigned to oblivion, and the author in consequence superseded by his successors."

However, although they seem to have been withheld from Hamilton himself, drawings from his original collection of unpublished figures of fishes somehow found their way to the Royal Botanic Gardens, Kew (Hamilton was professedly a botanist) and then into Hardwicke's *Illustrations of Indian Zoology* (1830-35) without any acknowledgement to point out from where they were derived. Major-General Thomas Hardwicke (1756-1835) was an English soldier and naturalist who was in India from 1777 to 1823. He collected numerous specimens of natural history and had them painted by Indian artists and from which many new species were described. Several of these species are named after him.

On returning to England he collaborated with the zoologist John Edward Gray to publish *Illustrations of Indian Zoology*. Hardwicke, however, did not credit the original artists in any of his plates. McClelland suspected that many of the fishes in *Illustrations of Indian Zoology* were originally done by Hamilton and copied by Hardwicke's engraver. He went to the Kew Gardens and found this was so. For example, in Plate 86 of *Illustrations of Indian Zoology* (Figure 17), the upper figure is *Cyprinus angra*, Ham., a pirated figure disguised under bad coloring and named "*Cyprinus Hamilto-*

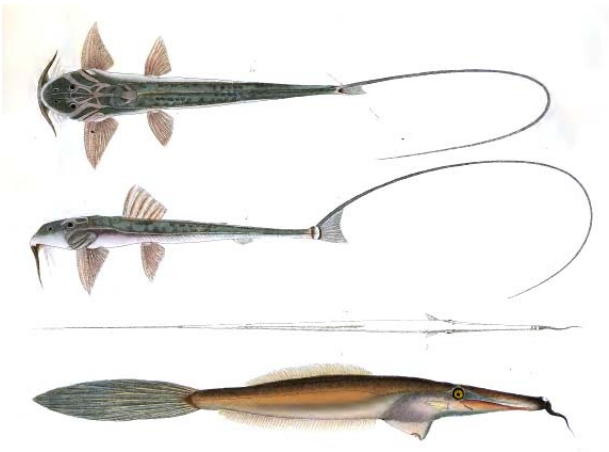

Figure 15: Two of Hamilton's drawings, *Hypostomus sisor* (top) and *Sisor Rabdophorus* (bottom).

Figure 16: Major-General *Thomas Hardwicke* (1756-1835)

nii, Gray" and the lower figure is *Cyprinus goha*, Ham., its coloring much exaggerated. There are two figures of each species, so that this plate had been taken wholesale from Hamilton. As McClelland noted (McClelland, 1841):

Although Buchanan was professedly a botanist his researches appear to have extended to all branches of natural history except entomology. His volumes on Gangetic Fishes, published at his own expense, under the disadvantage of being deprived of the greater part of his figures, are the only part of his zoological labours that are known, yet his inquiries in other branches of zoology were equally extensive, and equally entitled to publicity. It now appears that two quarto volumes of MSS., written with his usual erudition, have been retained in the library of the Botanic Garden since 1815; while every periodical that has since appeared deprived him of some portion of those claims to priority which his papers ought to have secured to him had they been placed in proper hands, or deposited in an institution where their existence could have been known or appreciated.

Such an injury to the advancement of information resulted from an oversight in an ordinary public office, the circumstance would excite less surprise but that the works of a naturalist should be so treated in a public institution expressly intended for the promotion of science, is so unaccountable to me, that I cannot presume to express an opinion on the subject. But as the case stands, perhaps the best remedy that can now be applied, injustice to Buchanan as well as to others who are still engaged in scientific pursuits, would be to give a complete edition of his labours, botanical and zoological, to the public; at the same time it is right to say, that no atonement can now make amends for the injury that has been inflicted on Buchanan as a naturalist, or for the time that has been lost in allowing others to go over unnecessarily the ground which he investigated, instead of beginning where he left off.

On his arrival in England in 1815, he presented to the Court of Directors his collection of plants and

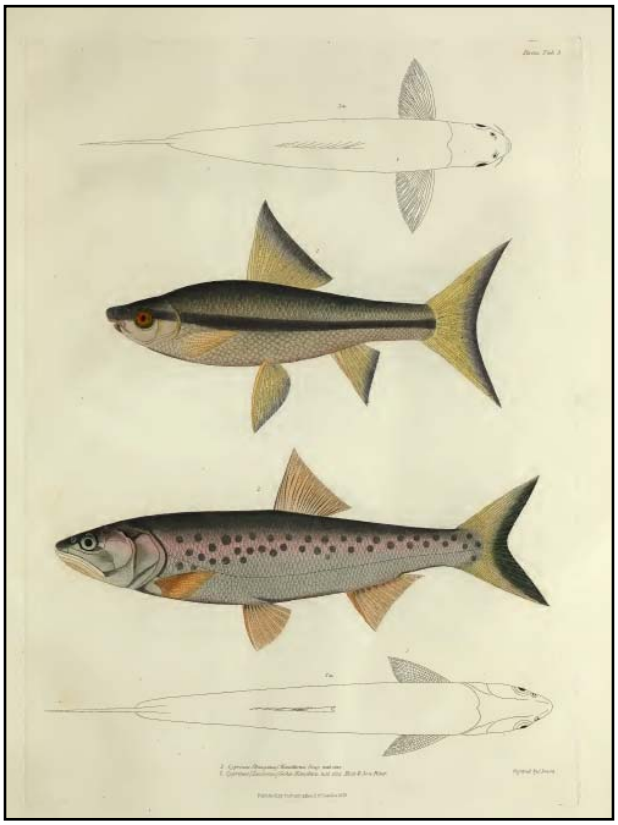

Figure 17: Plate 86 of Hardwicke's *Illustrations of Indian Zoology.*

minerals, some papers on the geography of Ava, several genealogical tables, nine hundred Indian coins, gold and silver, a collection of Indian drugs, his notes on Natural History, a few drawings and about twenty curious Hindu MSS. He then proceeded to Scotland, where he hoped to enjoy the fruits of his toil in quiet. On his arrival, he found his elder brother, Colonel Hamilton, involved in financial difficulties, from which he could only be partially relieved by the sale of such parts of the family estates as had not been entailed. Buchanan, who was himself next heir and Colonel Hamilton having no children, agreed to pay his brother's debts, which amounted altogether to upwards of £15,000. His brother soon after died abroad where he had gone in the hope of recovering his health, and Buchanan, succeeding him in his estates, adopted his mother's family name of Hamilton referring to himself as "Francis Hamilton, formerly Buchanan" or simply "Francis Hamilton." However, he is variously referred to by others as "Buchanan-Hamilton," "Francis Hamilton Buchanan" or "Francis Buchanan Hamilton."

He was now fixed at his residence at Leney and in his retirement still found pleasure in following the studies and scientific pursuits which had engrossed the busier part of his life. His garden occupied much of his attention and he introduced into his grounds many curious plants, shrubs, and flowers. Hamilton contributed largely to the scientific journals of the day, particularly the *Edinburgh Philosophical Journal, the Edinburgh Journal of Science, the transactions of the Linnaean Society of London, the Memoirs of the Hibernian Natural History Society, and the Transactions of the Royal Society of Edinburgh*. Also in the *Transactions of the Royal Asiatic Society* are several papers taken from his statistical survey of the provinces under the Bengal Presidency of Fort William, deposited in the Library of the East India Company. In 1819, he published his History of the Kingdom of Nepal, already mentioned, and in the same year a *Genealogy of the Hindoo Gods*, which he had drawn up some years before with the assistance of an intelligent Brahman. In 1822 appeared his *Account of the Fishes of the Ganges*, with plates. Hamilton died in 1829, in the 67th year of his age.

WHAT'S IN A NAME?
THAT WHICH WE CALL A KILLIFISH...

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, February 17, 2018)

Felipe Alonso is an Argentine biologist , specializing in ichthyology and dedicated to the study of the behavior and evolution of Neotropical (a zoogeographical region comprising Central and South America) fish, and is an Argentine educator and naturalist and one of the founders of the *Killi Club Argentino*. Both are associated with the *Institute of Bio and Geosciences of the National Council of Scientific and Technical Research*, National University of Salta (a city in the northwest part of Argentina).

In a paper appearing in *BIBKCA* in 2018, a publication of the *Killi Club Argentino*, titled "The viviparous killifish and the history of the application of the word killifish (Cyprinodontiformes)," these two authors urge aquarists to apply the common term "killifish" to the livebearing as well as egglaying members of the Cyprinodontiformes (Cyprinodontiformes is an Order currently containing ten families of fishes primarily living in freshwater ecosystems. It includes what aquarists customarily call "killifishes" and "livebearers).

THE TECHNICAL BACKGROUND

Cyprinodontiforms are a diverse group of approximately 900 pantropical and temperate fishes, mostly found in freshwater. Whereas the vast majority of fishes lay eggs (oviparous), this group is unusual in that four groups of cyprinodont fishes give birth to living young (viviparous). Traditionally, it had been classified in five families: the worldwide, oviparous Cyprinodontidae, and four New World viviparous families: the Poeciliidae, Anablepidae, Jenynsiidae, and Goodeidae (see Figure 1). Fishes of the diverse Cyprinodontidae, in turn, have been divided into as many as eight subfamilies. This classification scheme implied that the viviparity would have appeared only once in the evolution of this group of fish, in a single ancestor common to all these families of viviparous fish and that the oviparous fish formed a separate group corresponding to the Cyprinodontidae family.

In 1981 Parenti examined the cyprinodontiform fishes with the following objectives (I have omitted the sixth objective since it is not relevant to this discussion):

(1) determine if the cyprinodontiform fishes as a whole form a monophyletic group (i.e., a group descended from a common evolutionary ancestor or ancestral group);
(2) determine if each of the five families is monophyletic;

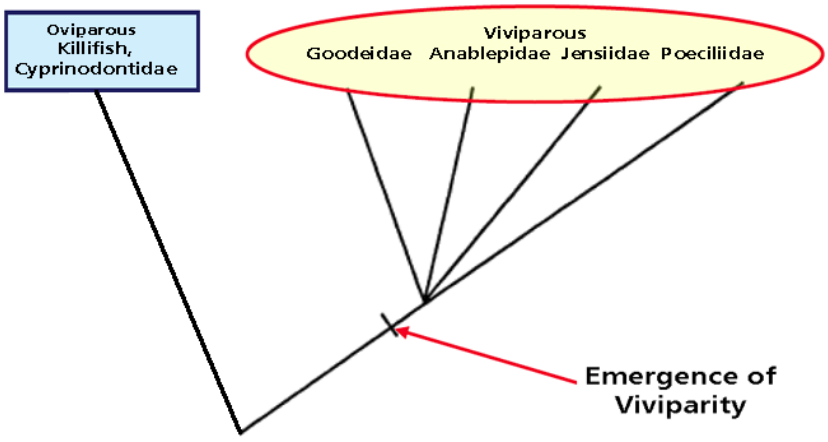

Figure 1: The traditional classification of the Cyprinodonts.

Figure 2: Dr. Lynne Parenti

(3)define the major subgroups of Cyprinodontiforms, concentrating on the genera of the Cyprinodontidae;
(4) determine the interrelationships of the subgroups;
(5) present a comprehensive classification of the Cyprinodontiforms that reflects the interrelationships.

The fishes in Parenti's study comprised the order Cyprinodontiformes Berg and were divided into two suborders, the Aplocheiloidei (which previously comprised, in part, the Cyprinodontidae), and the Cyprinodontoidei (comprising all other cyprinodontiforms as well as the four viviparous families). Parenti obtained the following general results by using the methods of morphological phylogenetic systematics (i.e., the formal name for the field within biology that reconstructs evolutionary history and studies the patterns of relationships among organisms):

(1) the Cyprinodontiforms are considered to be monophyletic by their sharing derived characters of the caudal skeleton, upper jaw, gill arches, position of the first pleural rib, pectoral girdle, and aspects of breeding and development;
(2) the family Cyprinodontidae is nonmonophyletic as it contains some of the most primitive and derived cyprinodontiforms;
(3) each of the four viviparous families is mono-

Cyprinodontiformes

Figure 3:
Classification of Killifish Taxa by Parenti.

phyletic; however, their previous definitions in terms of uniquely derived characters have been altered;
(4) the development of an annual habit, exhibited by members of the aplocheiloid killifishes and possibly some cyprinodontoids, includes derived reproductive traits exhibited to some degree by all killifishes; therefore, the annual habit does not define a monophyletic group of killifishes;
(5) similarly, viviparity is not hypothesized to be a uniquely derived character, but has apparently arisen at least three times within the group.

Parenti's classification of killifish taxa is shown in Figure 3 and her phylogenetic hypothesis is shown in Figure 4. The latter shows that viviparity would have arisen 3 times independently in the order Cyprinodontiformes, and what were previously two distinctly different groups, that of the former family Cyprinodontidae (the oviparous killifishes) and that of the viviparous Cyprinodontiformes were intermixed. What was believed to be a group of species closely related to each other (the oviparous "Cyprinodontids"), actually turned out to include species that were much more related to viviparous species than to any other group of oviparous killifish. For example, oviparous killifish of the subfamily Fluviphylacinae, such as members of the genus *Fluviphylax*, are more related to a Guppy or a Molly (*Poecilia* species), or a swordtail or a platy (*Xiphophorus* species).

For the next ten years Parenti's work stood alone. About this time the collection of molecular (DNA) data became feasible due to newly-invented and much improved laboratory protocols. Suddenly Parenti's phylogeny became a prime ground for comparison with the newly generated molecular data. Two lineages sharing a common ancestor from which no other lineage has sprung is called a "sister group" (see Figure 5 next page for examples). The sister taxon relationship of the Andean *Orestias* and the Mediterranean dwelling genus *Lebias* [*Aphanius*] was quickly tested with molecular data (Parker and Komfield, 1995), and Parenti's hypothesis was supported. The hypothesis that *Empetrichthys* and *Crenichthys* were more closely related to the Goodeidae than to the genus *Cyprinodon* was also tested with molecular data (Meyer and Lydeard, 1993; Grant and Riddle, 1995), and the molecular data also supported these results.

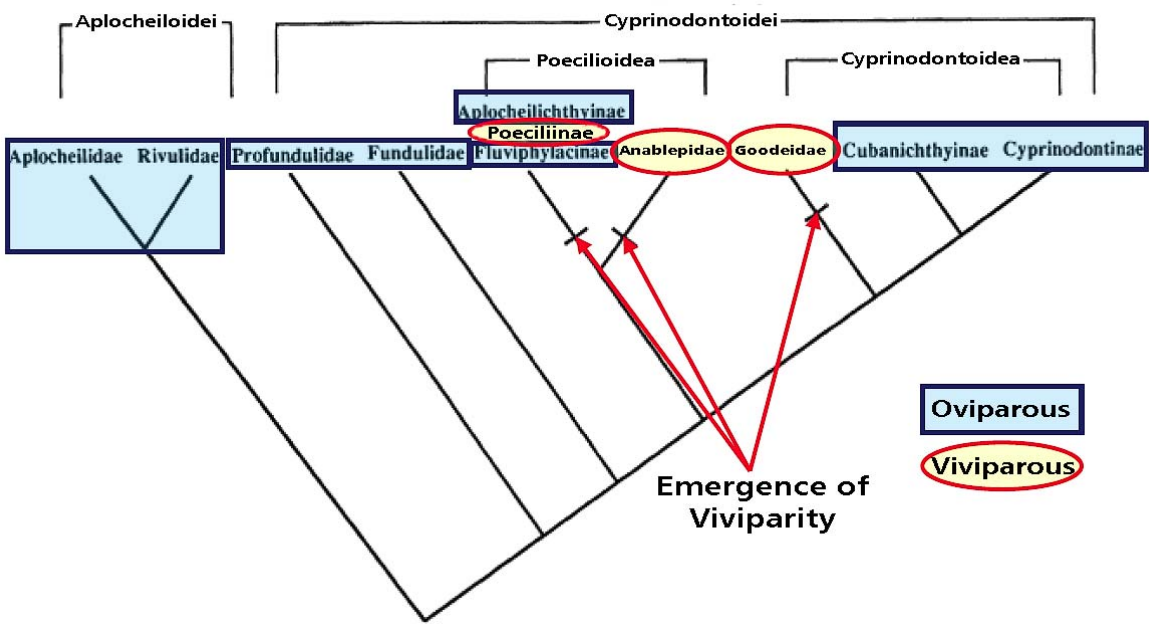

Figure 4: Parenti's phylogenetic hypothesis of the Cyprinodontiformes.

This is not to say that all the relationships that Parenti proposed were supported. In the molecular study by Meyer and Lydeard of numerous members of the order Cyprinodontiformes, several of Parenti's relationships were rejected. This study for example found that the genus *Profundulus* was closely related to the Goodeidae plus *Empetrichthys* and *Crenichthys*, rather than being one of the basal 'primitive' groups within the Cyprinodontiformes. Among other things, this study showed that synonymizing the genera *Jordanella* and *Garmanella* was erroneous and that *Jordanella floridae* was actually not at all related to *Garmanella pulchra*. It did indicate, however, that viviparity probably evolved independently three times in cyprinodontiform fishes: in the subfamilies Goodeinae, Anablepinae and Poeciliinae (*sensu* Parenti 1981). Advanced forms of viviparity, in which the mother provides additional nourishment to the embryos through placenta-like structures (ovoviparity), apparently evolved at least three times from egg-laying ancestors: in the subfamilies Goodeinae, Anablepinae, and more than once in the Poeciliinae. Obviously there is only one true phylogeny that reflect the evolutionary history of the group. We are getting there, but we are not there yet.

Alonzo and Calviño's point from all of this is that since many oviparous killifishes are much more closely related biologically with viviparous species than with other killifish, the definition of killifish as "oviparous Cyprinodontiformes" is considered by some ichthyologists to be an artificial or unnatural group that does not represent a biological entity. **All this is true but it is hardly relevant to aquarium organizations, most of whose members couldn't care less about evolutionary theories.**

ALONZO AND CALVIÑO's ARGUMENTS

The following are their five reasons for making this name change and appended to them are my comments below each.

1) The original definition (i.e., egglaying cyprinodonts) is arbitrary and lacks a pragmatic or logical basis.

As the one responsible for the wide-spread usage of the term in this sense, I can categorically state that this is not true and I expand upon this in the following section.

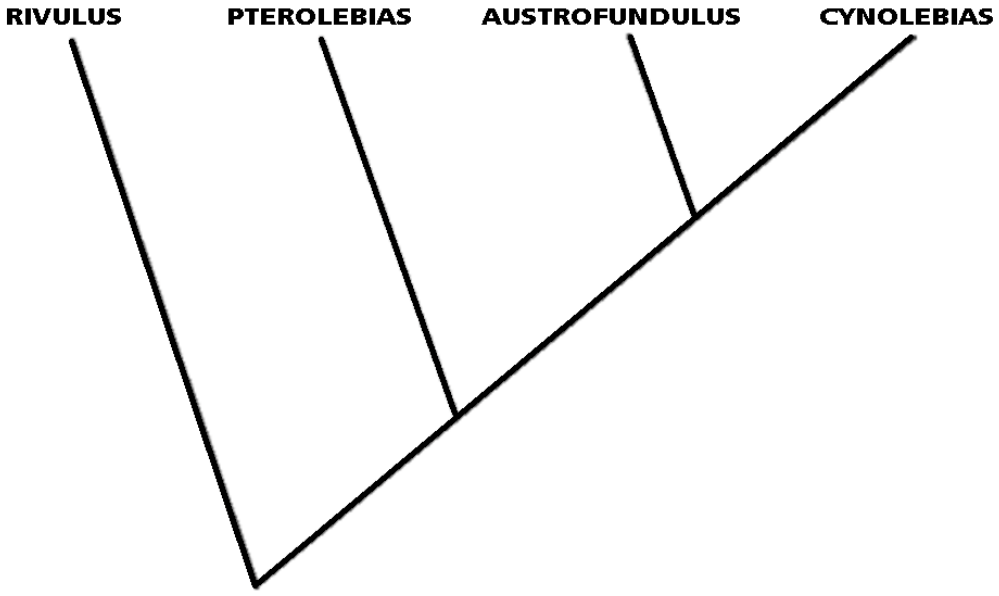

Figure 5: Taking the "austro-cyno" group as a unit, its sister group is *Pterolebias* since *Pterolebias, Austrofundulus* and *Cynolebias* all had a common ancestor. Taking the "ptero-austro-cyno" group as a unit, *Rivulus* is the sister group since all had a common ancestor.

2) When considering viviparous and oviparous Cyprinodontiformes as separate things, it leads to errors and confusions when describing or studying the biology of these organisms.

Noting that killifish is not a scientific term but an aquarium one, I can attest that the American Killifish Association has never had any problem in describing the fishes of interest to them or in studying their biology.

3) In order to carry out serious projects that aim to study and preserve killifishes, it is essential to study ALL the Cyprinodontiformes as a whole and not an arbitrary cut of some yes and no others.

It is not essential at all. The AKA has serious projects that aim to study and preserve killifishes and, analogously, the American Livebearer Association has serious projects that aim to study and preserve livebearers. They do not need to be studied en masse.

4) There are no good reasons not to include the viviparous Cyprinodontiformes in a new definition of Killifish, rather than an attachment to the old definition, a mere opposition to change or simply custom. While we understand that there is a question of traditionalism, we can also see that the definition of the term killifish has been changing and arbitrary throughout its history.

On the contrary, this is not a "mere opposition to change or simply custom." Change for change's sake is dangerous to any organization but especially in hobby organizations like ours, where constant change can trigger confusion, resistance and unnecessary learning curves, all of which can lead to disastrous results for their memberships. Changes should only be made if organizational objectives are not being met (not whether ichthyological objectives are met) or if there is a better way to do it. Alonzo and Calviño seem to think that those like myself who think this is a ludicrous idea do so because we are old fogies refusing to keep up with the times. This is rather presumptuous of them.

5) According to the knowledge that we currently have about the evolution of these fish the need is imperative for a new adjustment to the definition of killifish.

As is clearly shown in their publications, aquarium organizations have little or no interest in the evolution of their fishes. Taxonomic ichthyologists have two main tasks: classification and supplying the latest "correct" scientific name (although some of my friends disagree and would describe their main tasks as reclassification and renaming). In any case aquarists are interested only in the naming task.

THE HISTORY OF COMMON NAMES

Surprising as it may seem, professional ichthyologists do not always relish the use of long, difficult-to-pronounce scientific names. When the great American ichthyologist David Starr Jordan wanted a common name to apply to all members of the family Cyprinodontidae on the North American continent, he decided to use "killifish" as his term. In Jordan and Gilbert's "Synopsis of the fishes of North America" (Jordan, 1882), the term "killifishes" was used as the common name for the

Figure 6: David Starr Jordan (1851-1931).

Cyprinodontidae. At the time, the egglaying and livebearing cyprinodonts were not separated so the family included both groups and this explains why so many livebearers were also called killifishes. What Alonzo and Calviño are suggesting, therefore, is really not new.

In Jordan and Evermann's "The Fishes of North and Middle America Part I" (Jordan, 1896), they placed all of the Cyprinodonts in the family Poeciliidae, since Theodore Gill (the eminent ichthyologist and professor of zoology at George Washington University who was associated with the Smithsonian Institution for over fifty years) argued that although it was generally believed that Agassiz was the first to detach the cyprinodonts from the cyprinids, Agassiz never did define the new family (Gill, 1895). Now it was the turn of the family Poeciliidae to carry the common name of "killifishes."

At the time Gill published his 1895 paper on the taxonomy of the cyprinodonts, Samuel Garman had just published his Memoir, "The Cyprinodonts" (Garman, 1895), and Gill was forced to add an addendum to his paper. Garman split his Cyprinodonts into eight subfamilies, pretty much agreeing with Gills own "Families and Subfamilies of Fishes" (Gill, 1893) except that Gill listed his subfamilies under Poecilliidae instead of Cyprinodontidae. Gill used no common names in his 1893 paper and neither did Garman except he started his paper with: **The Cyprinodonts," "Top minnows," or "Toothed Carps," as they are variously called, form a well-defined group.**

In Jordan's "A Classification of Fishes Including Families and Genera as Far as Known" (Jordan, 1923), the cyprinodonts were now placed in the order Cyprinodontes (*Microprini*). Jordan commented that:

Hitherto the viviparous and Oviparous Cyprinodonts have been placed in a single family, but the differences within the group are ex-

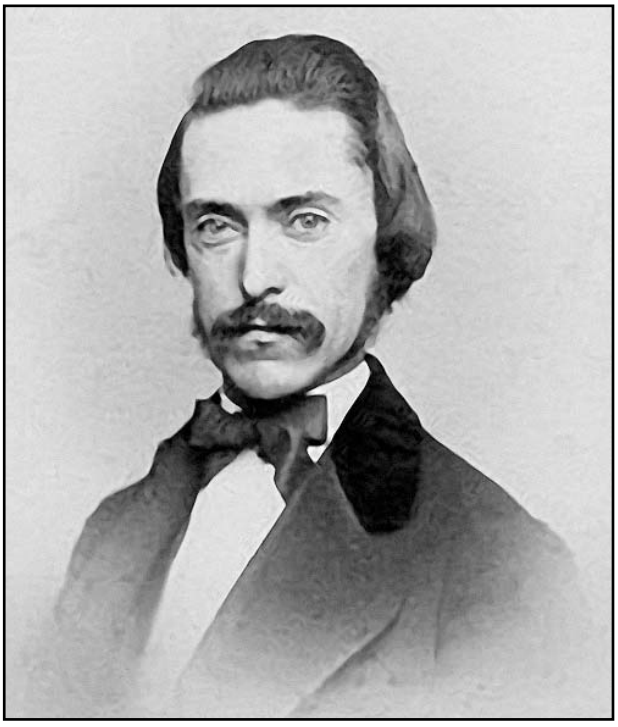

Figure 7: Theodore Nicholas Gill (1837-1914).

tensive and if the species were not all of small size they would certainly be assigned to two or more family groups.

Among the ten families he lists in this order are Cyprinodontidae, with "killifishes" as their common name, and Poecilidae, with "Top Minnows" as their common name.

In an article that appeared in the *Tropical Fish Magazine* in March 1955, the pioneer specialist in the classification of cyprinodonts, Dr. George S. Myers, proposed that aquarists use killifish for the egglaying cyprinodonts and a new term, gambusino, for the livebearers. Gambusino is from the Mosquitofish, *Gambusia affinis*; it is a Cuban term meaning "nothing," as the Mosquitofish is quite small. Gambusino, however, never caught on and was soon forgotten.

Other names had been used by aquarists in the past but they tended either to be awkward like "egglaying toothcarps - or misleading like "mudfish" and "topminnow" or both. However, the most prominent of these was the term "Panchax," used mostly by aquarists. Here we must go back some years to the time when ichthyologists recognized Panchax as a valid generic name, such as *Panchax lineatus, Panchax chaperi* and others. But as times change, so does ichthyological opinion and knowledge, and "Panchax" was adjudged to be a synonym of other names and thus was dropped from the rolls of scientific nomenclature. It is important to remember that even in its heyday, it never did apply to the whole family or even a subfamily, and so it was hardly a fitting term for aquarists to use. I wrote a lot about killifishes in those days and it was anathema to me to have refer, for example, to a group of *Aphyosemion* species under the rubric of another scientific name no longer used.

Thus I started to follow Myers' advice using killifish in my own writings and this was followed by some of my friends who also were interested in the group. The word was a short, easy to pronounce term for any egglaying member of the family Cyprinodontidae and had logical roots and the support of reputable scientists. Thus it was the name we used when Bob Criger and I founded the *American Killifish Association*. It was a great surprise to me when aquarium organizations all over the world decided to use the term as well. However I can well understand it: "Eierlegende Zahnkarpfen," for example, is quite a mouthful! Thus the argument that the original definition of killifish as used by aquarists was arbitrary and lacked a pragmatic or logical basis is clearly not true.

WHAT IS SAUCE FOR THE GOOSE IS SAUCE FOR THE GANDER

As far as Alonzo and Calviño's urging that we add the livebearers to the definition of killifish, common names are arbitrary labels but they are important and have specific meanings to organizations that carry them. Furthermore, Alonzo and Calviño are somewhat hypocritical when suggest-

Figure 8: George Sprague Myers (1905-1985).

ing that we aquarists adjust to this significant name change when zoologists themselves are just as reluctant to change their own names.

The botanists long ago adopted a system of uniform endings for the names of their higher taxa, but zoologists have never been able to agree on one. In 1950 one zoologist suggested the following endings: Superorder, **-ica**; Order, **-ida**; Suborder, **-ina**; Superfamily, **-icae**.

This provoked a flurry of criticism. Carl Hubbs, for example, pointed out (Hubbs, 1952), if there were an order Poeciliida and a family Poeciliidae, we would not know which was meant when someone wrote familiarly about poeciliid fish. Although there was some support there has been little progress since. At the Colloquium on Zoological Nomenclature held in Copenhagen in 1953 it was decided that the Colloquium was of the opinion that there should be no prescribed terminations for the names of taxa belonging to the Order/Class-Group and the Phylum-Group. No regulations for the nomenclature of higher taxa were included in the New Code adopted by the Colloquium on Zoological Nomenclature held in London in 1958 either.

There is no question concerning the advantages of a system of uniform endings. In fact, it would be analogous to the move out of the confusing world of ounces, grains, pennyweights, drams, scruples, carats, pounds, short tons and long tons into the logic and consistency of the metric system. Even the beginning student would know the rank of each taxon at a glance, an impossibility under the present chaotic system. In 1953, for example, the following list (and this was not all of them) of 16 endings were used for the names of orders: **-ura, -ptera, -ida, -ozoa, -aria, -icha, -ina, -ora, -acea, -oela, -dela, -chia, -ata, -iformes, -tia,** and **-pha.**

Although ichthyologists have agreed on the ending **-morpha** for superorders, **-iformes** for orders and **–iodei** for suborders, there is no agreement on the ending for these taxa among zoologists. Currently the *International Commission on Zoological Nomenclature* (*ICZN*) has no rules for taxa higher than the superfamily (a category between family and suborder) for which it reserves the ending **–oidea**.

Changing to a new system admittedly would be somewhat bothersome to the present generation of taxonomists but if they are reluctant to agree to change names why should we aquarists? I suggest that Alonzo and Calviño buy a copy of Smith and Cornwellth's book, "The Complete Dictionary of Bible Names" (available on Amazon for $16 plus shipping), pick one and leave the killifish and livebearer fanciers in peace.

The International Code of Zoological Nomenclature: Principles and Problems

By Albert J. Klee, Ph.D.

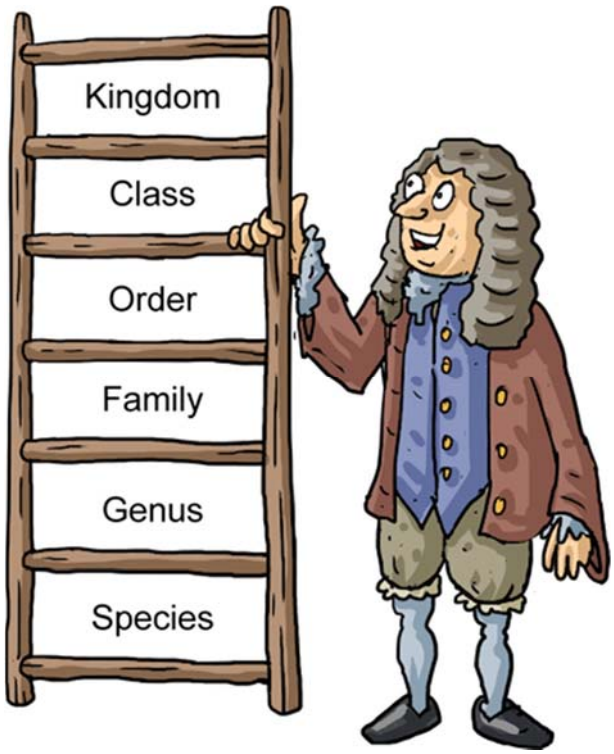
(Aquarium Hobby Historical Society of America, Facebook Files, February 24, 2018)

Taxonomy is how taxa are correctly classified in agreement with a biological system. Nomenclature is how the names of these taxa are defined and correctly spelled. This is a very basic and important difference.

(a) If a scientist finds that a species consists of two reproductively isolated units, this is taxonomy. The scientist is free to classify the two units as two independent species, and it is not necessary to record this anywhere.
(b) Placing a species in another genus, elevating a subspecies to the rank of a species, classifying a genus in a different family, subdividing a genus into various subgenera, placing genera into another family, lumping two species into one single species because they are not reproductively isolated, all this is taxonomy also. These are just proposals for different classifications and no official acts. Such a proposal can be accepted or not.

The founder of botanical and zoological nomenclature, Carl Linnæus (since 1761 Carl von Linné), was primarily a botanist and promoted botanical studies earlier and more intensively than zoological studies. Plants are generally easier to catch and to identify than most animals, so the proportion of early described species in botany was substantially higher than in zoology. The differences between botanical and zoological nomenclature are as follows:

(1) Linnean binominal nomenclature in botany started in 1753, zoology in 1757/1758.
(2) Botanical descriptions must contain a short diagnosis in Latin (since 2012 this can be in English), zoological descriptions have no restrictions to language or form.
(3) Latin errors in specific and generic names are usually corrected or standardized in botany (only one variant accepted for chinensis/sinensis, kamtchatkensis/camtschatensis, etc.). In zoology Latin errors are not corrected (always the original spelling is used).
(4) Botany allows hyphens between words in names (Capsella bursa-pastoris), zoology does not allow such hyphens.
(5) Genus-species tautonymy is allowed in zoology (e.g., *Badis badis*), in botany not.
(6) Family names end **-idae** in zoology, in botany **-aceae**.
(7) Botany has a standardized lists of authors and their abbreviations (with strong recommendations to use these); zoology has nothing (and every taxonomist uses an individual standard).
(8) In botany the author of a new genus-species combination is recorded, in zoology not.
(9) Botanical taxonomy is much more regulated than in zoology.
(10) The term “valid” in botany is used as commonly used in English (valid = correct publication of a name), while in zoology it has the meaning of a name being used as the correct name in an author's current classification.



It may surprise some to learn that no species in zoology has an officially recognized binominal name that must currently be used. The scientific community can accept or reject the results of recent taxonomic studies. However, there are clearly defined rules which determine the names units must receive under a certain taxonomic assemblage. A taxonomist can feel free to regard two taxa as belonging to one species, but the name that must be used for the resulting species is fixed by a frame of nomenclatural rules. Eventually types must be selected, new names must be established, old forgotten names can be suppressed or homonymous names must be replaced - all this is nomenclature. Zoologists are free to classify animals but the International Code of Zoological Nomenclature (ICZN or simply "the CODE) gives no rules for classification; the rules regulate only which names should be used.

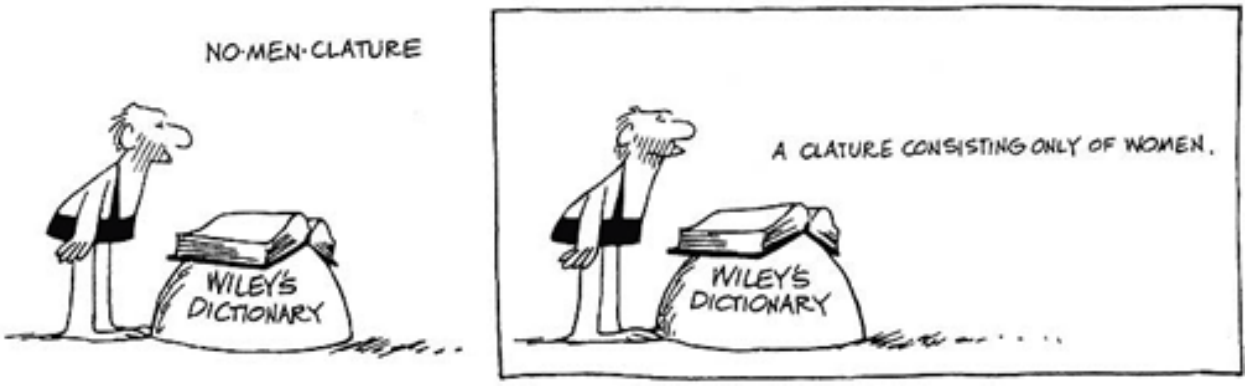
Early drafts of the ICZN existed since the 1840s in several countries, but had not been commonly accepted by all taxonomists until 1895 when international rules were established. Currently effective is the 4th edition of the Code (since 2000). The Code rules only nomenclature, not taxonomy. It is not a legal document and it is not unambiguously considered as a binding law in the sense of a mandatory set of rules and regulations, rather it is based on common acceptance. Zoologists feel themselves invited to apply the Code voluntarily in order to avoid the chaos which would result in the absence of rules. But if they do not consider some of the Code's detailed rules as useful they simply do not apply them. This is no problem if the community accepts the consequences. Names can be used, therefore, that are not acceptable under the Code.

Some rules in the Code are disputed, not all are known, understood, accepted and applied by all taxonomists in all disciplines. Zoology is a very wide field and every single taxonomist is needed to contribute to the knowledge of the community. Contributions of taxonomists who do not accept certain rules are not necessarily rejected for this reason alone.

The nature of the Code is a retrospective law. Every nomenclatural act in the past is exclusively evaluated under the present edition of the Code, and not under a previous edition. A name or nomenclatural act (type selection or whatever) that had been established in 1963 under the then effective edition, is not evaluated under that edition, but under the 4th edition. A name established in France in the 1890s is not evaluated under the rules then commonly accepted in France, but exclusively under the 4th edition.

The Code is not a case law with legal cases establishing precedent to decide subsequent cases with similar issues or facts. The ICZN Commission - an unpaid body of 28 persons not older than 75 years charged to set aside rules of the Code in singular cases - can suppress names or make unavailable names available in Opinions, but every case is singular and other cases cannot be judged using preceding cases as a guideline.

Like most legal works, the Code is extremely difficult to understand by zoologists who are not used to reading legal texts. Like in most other legal works, many regulations allow several interpretations. The Code is used as a guide by zoologists who seek advice how to interpret or spell a name correctly, but it has not been designed as



such. Occasionally it is necessary to know common practice in zoology for understanding provisions in the Code, or in other words, it is necessary to know the backgrounds of why certain articles have been included. As usual in laws, these reasons and backgrounds have never been documented.

A particular feature of the Code is the unnecessary use of internal terms that are not in accordance with their common usage either in dictionaries or in zoology. As I have already mentioned, valid" does not mean that anything is valid as commonly understood. A valid name is the correct zoological name for a taxon, i.e. the oldest potentially valid name of a name bearing type that falls with an author's concept of the taxon. "Potentially valid" means the name must be available, but not otherwise invalid for any other reason, such as being a junior homonym (i.e., a name having the same spelling but different meanings and origins).

"Species-group name" does not refer to a name for a group of species. A species group (superspecies) is a complex of related species that exist allopatrically (i.e., occupy separate habitats and that do not occur together in nature). They are grouped together because of their morphological similarities, and this grouping can often be supported by experimental crosses in which only certain pairs of species will produce hybrids.

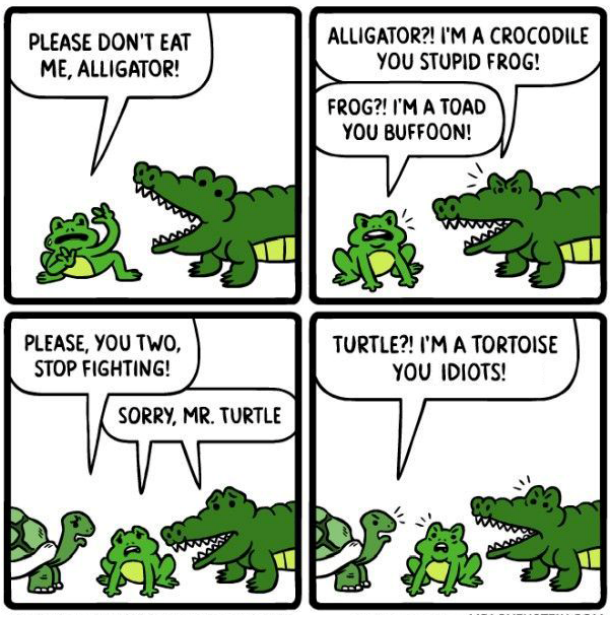
"To conserve" does not mean that something is conserved as is commonly understood. A conserved name is a name otherwise unavailable or invalid that the Commission, by the use of its plenary power, has enabled to be used as a valid name by removal of the known obstacles to such use. Other commonly understood terms also may have vague, undefined or more or less well defined special meanings in the Code, such as "published work," "author" or "word."

The Code leans heavily on Latin and Greek, which were commonly understood languages in scientific communities in the early 1800s, but not anymore today. Problems arise from taxonomists not being linguists, and from the fact that dictionaries do not help in many problems with Latin grammar. Zoologists have repeatedly asked to remove from the Code the need to consult Latin and Greek dictionaries and to abolish gender agreement, but no action has been taken.

Scientific names in zoology are not necessarily Latin names; they may come from any language or can even be fantasy names (Art. 11.3). Many names are based on Latin and Greek, but this is just a tradition. The only requirement is that they must be pronounceable in some language, and it must be possible to treat them as Latin words. Acronyms that cannot be pronounced (the example given in Art. 11.3 is **cbadfg**) are not allowed. However no explanation is given exactly why **cbadfg** is no word in the sense of the Code, and this has led to disputes over whether combinations such as **ansp, anspi or nmnh** or **nmnhi** are admissible as names in the sense of this Article.

The official texts of the Code are written in English and French. Both texts are considered to be equal in force, meaning and authority. If the meaning of the English text is ambiguous, the French text is regarded as decisive. This is an important tool to interpret the Code, and can be very helpful, because linguistically both versions do not cover each other entirely. Examples:

(1) In Art. 30.1.4.2 the English version gives a restriction that is not contained in the French version, probably unintended since it makes no sense



whatsoever. It states that a genus of common gender will be feminine if originally combined with a feminine adjectival specific name in the English version, in the French version with a feminine adjective. (If you have trouble reading this, you are not alone.) The idea behind the passage reflects that the author must have treated the name as feminine, so if the genus was combined with a feminine adjective in a Latin text, the name should be feminine under the French version.

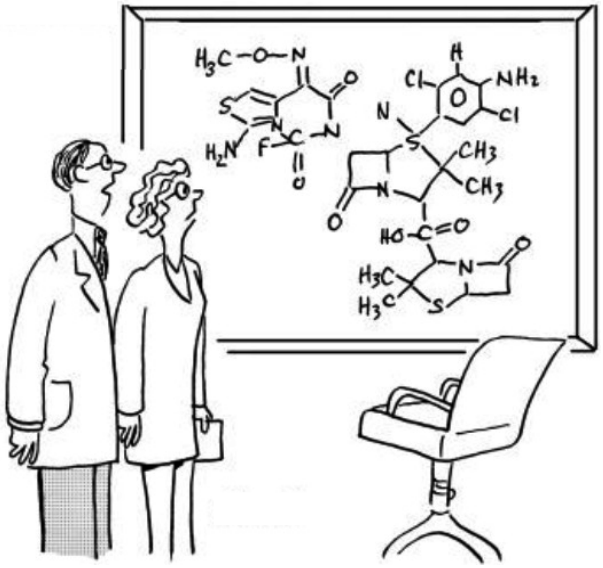
(2) In Art. 32.5.2.6 the French version differs substantially from the English version and looks like a bad translation of a person who did not understand the context. (In the English version numerals must be written in full as Latin words, while in the French version numerical adjectives and adverbs must be translated into Latin.)

(3) In Art. 32.5.1.1 the English and French versions complement each other. The English versions talks of a circulated slip to be inserted in a work, the French version of a slip inserted in a work. The slightly stricter French version makes clear that the slip can have been printed later, but that it must have been inserted by the publisher or printer to the work, after the print and before presenting the work to the public. Sending out a slip later and asking the subscribers or booksellers to insert the slip to the work would not match the French version.

(4) Art. 87 rules that all other officially authorized translations of the Code shall be equal in force, meaning and authority. This certainly indicates a high degree of self-confidence of the Commission, but is not in accordance with experience. Any translation always implies a weak change in the meaning. We can assume that the French Code contains the weakest change because French is probably the second mostly understood language by skilled zoologists. It is obvious that not all 28 Commissioners are able to judge the correctness of a Bengali translation of the 120 pages of the Code.

Like in every legal work, the compilation of the Code is the result of political processes with their proposals and compromises. However, few taxonomists are incorporated in or have influence on the procedure of composing the regulations. In fact, in the past only a minority has ever had access to the small group of persons who have modified the Code (the ICZN Committees, usually consisting of 7 persons). The latest Committees formed have lacked a democratic legitimation. Since 1972 there have neither been regular zoological congress meetings to deal with nomenclatural problems, nor opinion polls, public surveys, queries or public votes offered for zoological taxonomists. The Commission takes its power from a general biological congress (IUBS, International Union of Biological Sciences, Art. 77.2), to which only very few zoologists are invited. In the recent past the members of the official ICZN organs, in particular the Committees, did not literally promote general acceptance by the community. It was also possible that articles were incorporated into the Code by members of the Committee for personal reasons.

For example, in 1993 William Ride established Jackmahoneya (Mammalia, dedicated to Jack Mahoney) and specified its name as masculine. This was literally allowed due to a gap in the 3rd edition of the Code, but contrasted with the commonly accepted basic rules of Latin grammar (such a noun composed of a stem and an ending -a must have feminine gender). In 1999 Ride was chairman of the Committee for the 4th edition and instead of correcting his mistake he managed to insert this as an example in an extended new version of Art. 30.2 for “masculine because its author specified



“Let’s agree to dispense with the rules of nomenclature and call it compound X.”

it" (authors who did the same with names based on Greek words were not allowed to do this).

Some regulations reflect dreams of the future rather than practical life. The List of Available Names in Zoology concept (all family-group, generic and specific names) was inserted in 2000 (Art. 79). More than 10 years later zoologists began to start discussing the purpose of such lists: either to provide a documented record of the previously established names, or to get rid of names that were not used or caused problems as senior homonyms.

Other rules were incorporated without any awareness of a need to consult technical advice. Art. 8.6 was inserted in 2000, based on the assumption that electronic media such as CD-ROMs and DVDs would remain readable for the next 400 years, like printed books.

Some rules unnecessarily contradict the spirit of zoological nomenclature. Art. 3.1 in the version from 2000 defines the names established in Svenska Clerck's work *Svenska Spindlar* to date from 1758 although the indicated and true date was 1757 - contradicting the very basic rule that a name must always carry the true date of publication.

The Committee was rather helpless in face of new technical developments in the 1980s by which textual documents could be published in small quantities by using home printers. It sounds incredible that the present Code (Art. 8.5) still regards two identical prints obtained from a home printer as a fully accepted publication in which a new name can be established.

As a consequence of such shortcomings, the taxonomic community seems to accept only parts of the Code, usually those parts which are commonly agreed to reflect something which may be called the spirit of zoological nomenclature. Clerck's names, therefore, are widely cited with the 1757 date and single sheets issued from home printers are not commonly accepted as published work. This does not mean that the ICZN Code is largely meaningless, but it is necessary to know which parts are accepted, and which parts obviously not.

The force of the ICZN Code was weakened in 2000 by incorporating concepts of "prevailing usage," a largely undefined term intended to promote stable usage of names, that makes nomenclature even more arbitrary and less well defined, and has resulted in many endless disputes on the correct spellings of rarely mentioned names. It is predictable that various disciplines are going to develop different traditions in the interpretation of the meaning of this term. The Rules of Zoological Nomenclature were established in 1905 to overcome the problematic situation that every zoological discipline follows their own rules. Today the trend goes back to a situation before 1905, since many zoologists consider spellings of names as most "stable" if every zoological discipline maintains their own unwritten conventions.

The ICZN Commission has not a very strong position and good reputation either. The main problem concerns communication. Persons who are not elected by the community do not necessarily feel obliged to communicate with the community they represent. Some do it and participate in discussions in international mailing lists, they answer questions, give advice and try to help. But many Commissioners do not even answer their e-mails. This seems to be so much a problem that there are rules to exclude Commissioners after several months from the body if they do not even communicate with the Commission itself (Art. 3.3.3).

Tragedy Strikes at the Linnaean Society Picnic.

One of the major points of criticism is that the Commission is not democratically legitimated, and that its composition is biased towards experienced and well-known persons who know Latin very well, persons who know the Code very well and who speak English fluently.

In contrast, many members of the taxonomic community are young, do not know Latin very well, need a useful and helpful nomenclatural guide and have difficulties in reading the ICZN Code, they communicate in other languages than English, are amateurs with limited financial resources and are not paid for their taxonomic work.

To close this very critical discussion of the ICZN, I should repeat that the basic parts of the Code are commonly accepted by the taxonomic community, and that most Opinions published by the ICZN Commission are almost unanimously accepted. The following presents the spirit of zoological nomenclature as it is intended by the Code:

(1) **Publication**: Everything must be published (except information on type specimens and true dates of publication). No name published before 1758 enters zoological nomenclature (except those of Clerck 1757).
(2) **Binominality**: Names for species consist of two words (Genus species); subspecies have three and all others one word.
(3) **Coordination**: Subspecies are nomenclaturally treated like species, subgenera like genera, subfamilies etc. like families.
(4) **Priority**: If two names refer to the same animal, the oldest name has precedence.
(5) **Stability**: If a very old name was never used, it may be ignored or suppressed.
(6) **Spelling**: Names are spelled in Latin script. The correct spelling of a name must be taken from the original publication. Afterwards a name can usually not be corrected, only the ending of an adjective can change.
(7) **First Reviser**: If two alternative names or spellings were published simultaneously, a First Reviser decides on priority.
(8) **Description**: Any new name must have a description, regardless in which language or script. The content and accuracy of a description is not regulated. Any new name must have been treated as a correct name for a taxon in the author's classification.
(9) **Typification**: The identity of a name is not based on the description but on types. Types are preferably fixed in the original publication.
(10) **Homonymy**: Different animals must not have the same name. An available name that cannot be used can be substituted by a new replacement name.
(11) **Authority**: The author in a name is the person who wrote the description.
(12) **Date**: The year in a name is the true date of publication.
(13) **Accuracy**: For more recent publications, stricter nomenclatural standards apply.
(14) **Legality**: The Code is widely and voluntarily accepted by the community, it is not a binding law. The ICZN Commission can set aside rules in singular cases; these are not regarded as cases of precedence.
(15) **Taxonomy Excluded**: The ICZN Code regulates only nomenclature, not taxonomy. The author who combines a species with another genus is not recorded in the taxonomic name. A species does not have an official taxonomic status, all classifications are only regarded as proposals.

PHYLOGENETIC METHODOLOGIES:
Comment and Critique

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, April 28, 2018)

In my essay, "What's in a Name? That Which We Call a Killifish…" (Klee, 2018), I mentioned that when it came to evolutionary theories most aquarists couldn't care less. This is true in the main but there are exceptions. For example, in the aquarium world there had been a long standing controversy over whether the so-called "Endler's guppy" was a true species or not.

In 2005 Fred N. Poeser (University of Amsterdam) and two of his colleagues published an article based on a morphological study titled "Description of *Poecilia* (*Acanthophacelus*) *wingei* n. sp. from the Paría Peninsula, Venezuela, including notes on *Acanthophacelus* Eigenmann, 1907 and other subgenera of *Poecilia* Bloch and Schneider, 1801" (Poeser, et al., 2005) in which they decided it was a species and named it *Poecilia wingei*, after Dr. Ojvind Winge for his pioneering scientific work on the genetics of the guppy. Shortly afterwards, Susanne Schories (University of Wuerburg, Germany) and two of her colleagues published an article titled "Description of *Poecilia* (*Acanthophacelus) obscura* n. sp., (Teleostei: Poeciliidae), a new guppy species from western Trinidad, with remarks on *P. wingei* and the status of the "Endler's guppy" (Schories, et al., 2005). Schories group, however, disagreed with Poeser's group on the reasons for naming Endler's guppy as a species:

Given the strong variation in male pigmentation the description of *P. wingei* on the basis of coloration was not conclusive. But our molecular data now define the species unequivocally and show that it is a separated taxon from *P. reticulata* and *P. obscura*. Clearly, all fish earlier classified and recognized as Endler's guppies from localities in and around Cumana are *P. wingei*.

They performed a molecular phylogenetic analysis using mitochondrial D-loop and cytochrome *b* sequences. The molecular data were analyzed with maximum likelihood, parsimony and neighbor-joining methods that yielded almost identical phylogenetic results. The topology of the resulting trees was always the same (see Figure 1). The numbers above the branches are bootstrap values - see Section A4).

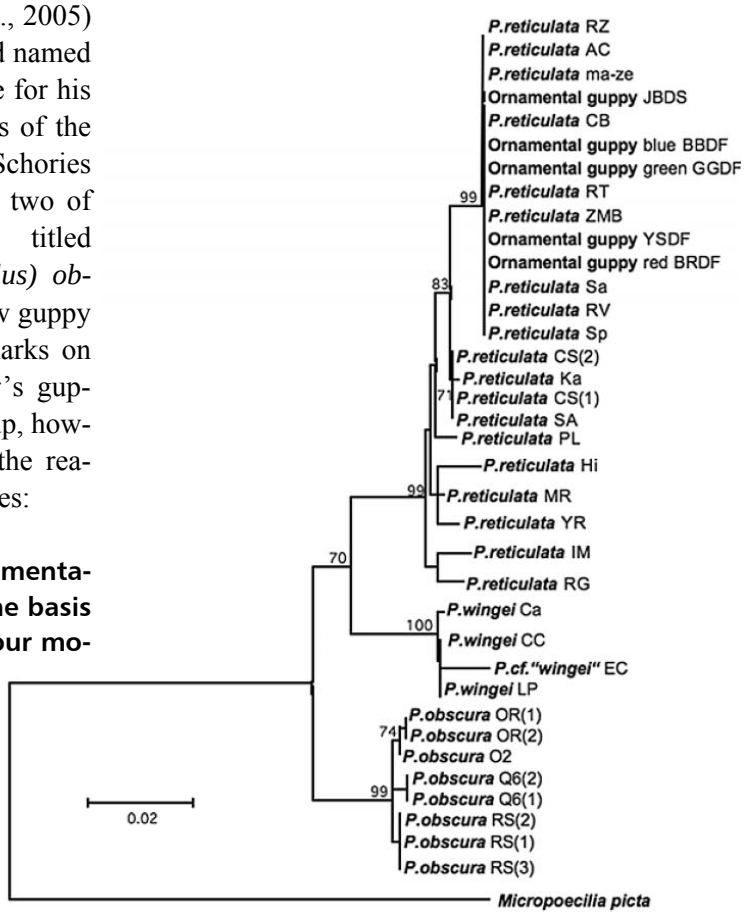


FIGURE 1: PARSIMONY ANALYSIS OF POECILIA.

These two papers caused much turmoil among guppy fanciers and caused me some personal grief as well. On the basis of the Schories paper I brought out a third edition of my book, "The Guppy, 1859-1967" (Klee, 2013), in which I reported the name of Endler's guppy as *Poecilia wingei*. A lot of my friends disagreed with me on this and it caused some ill-feeling that I had "deserted them." These were mostly old-timers used to morphological underpinnings, not molecular ones, but DNA is DNA and it is of course the current basis for our hypotheses about evolution.

A1: SYSTEMATISTS

The task of reconstructing the history of life on earth falls, in part, to **systematists**. Practitioners of systematics study the historical pattern of evolution among groups of living things and this is known as **Phylogeny** (taxonomists merely devise means of grouping or organizing "things" into categories based on a set of rules). Phylogeny is not directly observable; instead, it must be inferred from data that are incomplete at best. Systematists therefore face a set of problems that is similar to those confronted by anyone who makes claims about the past: Is there sufficient evidence? Given the available evidence, what questions can or should be asked and answered? What methods render the most reliable or justifiable conclusions? What are the limits of these methods? In this essay I try to answer some of these questions.

While the shape of these problems is familiar to philosophers and historians, there are particular problems of inference in a field where evidence can be so scarce or difficult to interpret. We can observe fossils, which may give information about common ancestors of living taxa. However, some ancient forms presumably left no descendants, so systematists do not always know what to look for. This situation is compounded by poor or non-existent fossils of soft body parts, as well as by a spotty fossil record.

A2: HOMOPLASY

Before one fires up his or her computer and opens their favorite phylogenetic program, one has to have data because without it, the computer is not going anywhere. There are other kinds of clues to phylogenetic relationships that suggest patterns of ancestry, such as the genetic, morphological and behavioral characters of living taxa. This evidence is sometimes problematic, as it is often difficult to discern whether these characters are similar because of common ancestry or for other reasons. This is called **homoplasy**, the term used when describing a characteristic that two or more different species have in common that was not inherited from their recent ancestor (its counterpart is called **homology**, referring to structures on two or more different species that are similar or the same that came from a common ancestor). In Figure 2, A assumes that the character "Wings" came from a common ancestor. In point of fact, birds are more closely related to *Tyrannosaurus rex* than to pterosaurs. "Wings" in this case is a homoplasy.

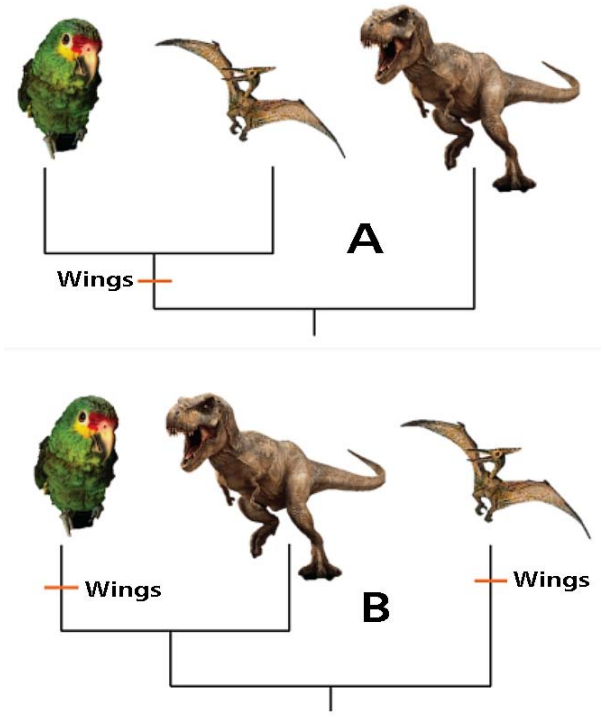

FIGURE 2: A is a Homoplasy.

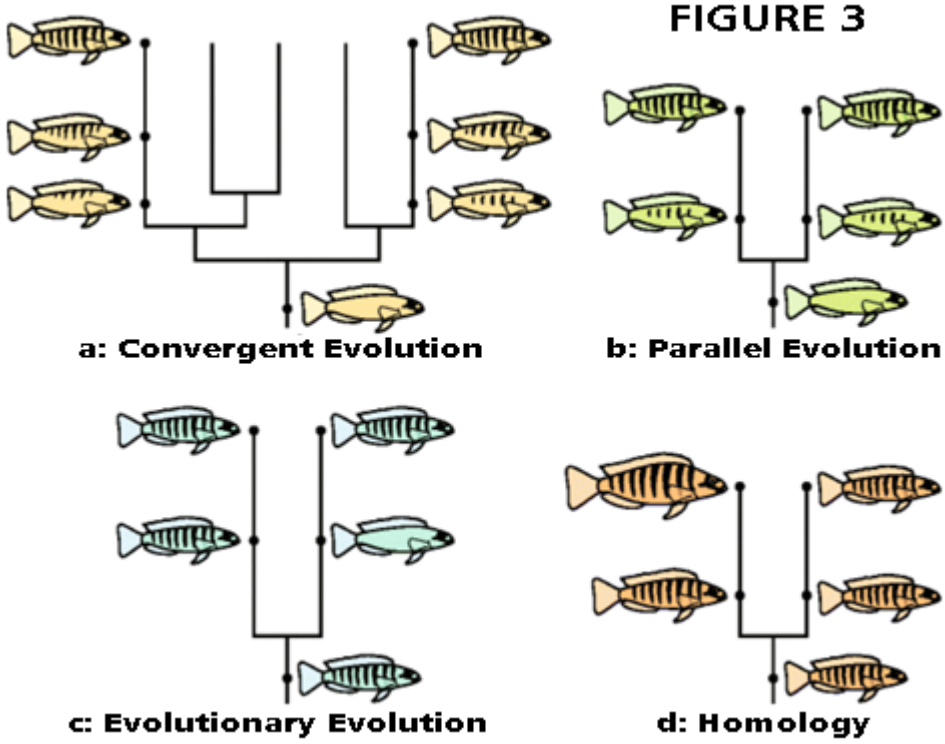
Homoplasy can occur by **convergence, parallelism** or **reversal**. Convergence describes similarities between two species that evolved independently from different features in their common ancestor, often because both lineages face similar environmental challenges and selective pressures. For example, in Figure 3**a**, fish lineages that originally had different body patterns might independently evolve analogous vertical stripes, perhaps because of selection for a particular camouflage pattern.

Parallelism occurs when two groups independently develop similarities from the same structures. This is illustrated in Figure **3b** in which two closely related fish lineages evolve in the same way, resulting in two lineages with a striped body pattern. In a real-life example of parallel evolution in fish, the ancestral stickleback fish was marine-living and heavily armored by sturdy plates. However, several stickleback lineages invaded new, freshwater environments. Many of these now-freshwater lineages independently evolved the same sort of genetic changes that produce a lightly armored body form. Scientists are not sure why the lightly armored trait was favored in so many different lineages, but it may have involved selection for increased body flexibility.

Evolutionary reversal occurs when a lineage evolves toward one of its ancestral traits, effectively losing a more recently evolved trait. If a related lineage has retained the ancestral trait, the two lineages will share a similar feature, not because of inheritance from a common ancestor but because of an evolutionary reversal in one lineage. This is illustrated in Figure 3**c** in which an originally striped fish lineage loses its stripes and then regains them, producing a species similar to a closely related lineage that never lost its stripes in the first place. This occurs when a lineage evolves toward one of its ancestral traits, effectively losing a more recently evolved trait. This is generally thought to involve genetically "reactivating" the ancestral trait. If a related lineage has retained the ancestral trait, the two lineages will share a similar feature, not because of inheritance from a common ancestor but because of an evolutionary reversal in one lineage. Hypothetical examples of the three different categories of homoplasy, as well as homology are shown in Figure 3 (in Figure 3**d**, striping in the descendent fish lineages was inherited from a common ancestor and is homologous).

The bottom line is that the data used cannot be chosen willy-nilly. Bad data in results in a bad

FIGURE 3



evolutionary tree out. Homoplasy is a real problem and characters must be chosen carefully. Unfortunately, there is no infallible way to do this; one basically resorts to the results, experiences and opinions of the researchers themselves and/or of others.

A3: CONSENSUS TREES

I'll mention this subject and the one that follows since they will crop up frequently in this essay. Often a tree building routine will report more than one parsimonious tree. In other words, the data used is compatible with more than one tree. In such circumstances there are two things that one can do. We can choose one of the trees as the one we favor (the criteria by which we do this are varied and usually based on biological or geological arguments) or we can establish the common elements between the trees, i.e., the lowest common denominator. For the second route, consensus trees are constructed.

Let us assume that as a result of an analysis we ended up with three equally parsimonious trees shown in the top row in Figure 4. The simplest way to combine the elements of all three trees into one is to show only those components that appear in all three cladograms. By scanning across the three trees we see that relationships differ between A, B and C, and again between D, E and F. However, the two groups, ABC and DEF, are the same in all trees. Therefore if we combine this information we end up with the tree to the left in the second row. This is known as the Strict Consensus method. The Majority Rule simply takes those solutions that are found in the majority of the trees. Thus the grouping (A,B,C) is found in two out of three trees and the grouping (D (E,F)) is also found in two out of three. Many purists believe that Strict Consensus is the only method that should be considered, all others being tainted by concessions that cannot be justified. Other practitioners think otherwise. These are the sort of arguments that frequent-

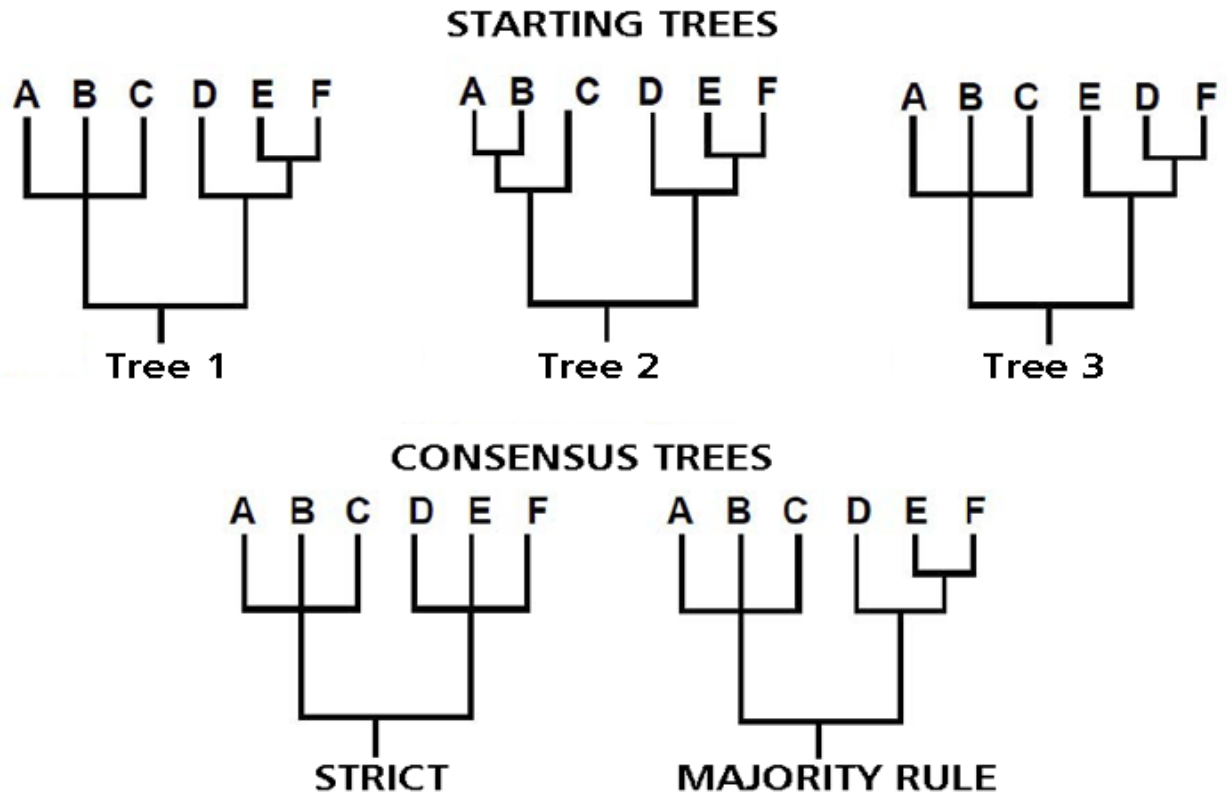


FIGURE 4: CONSENSUS TREES

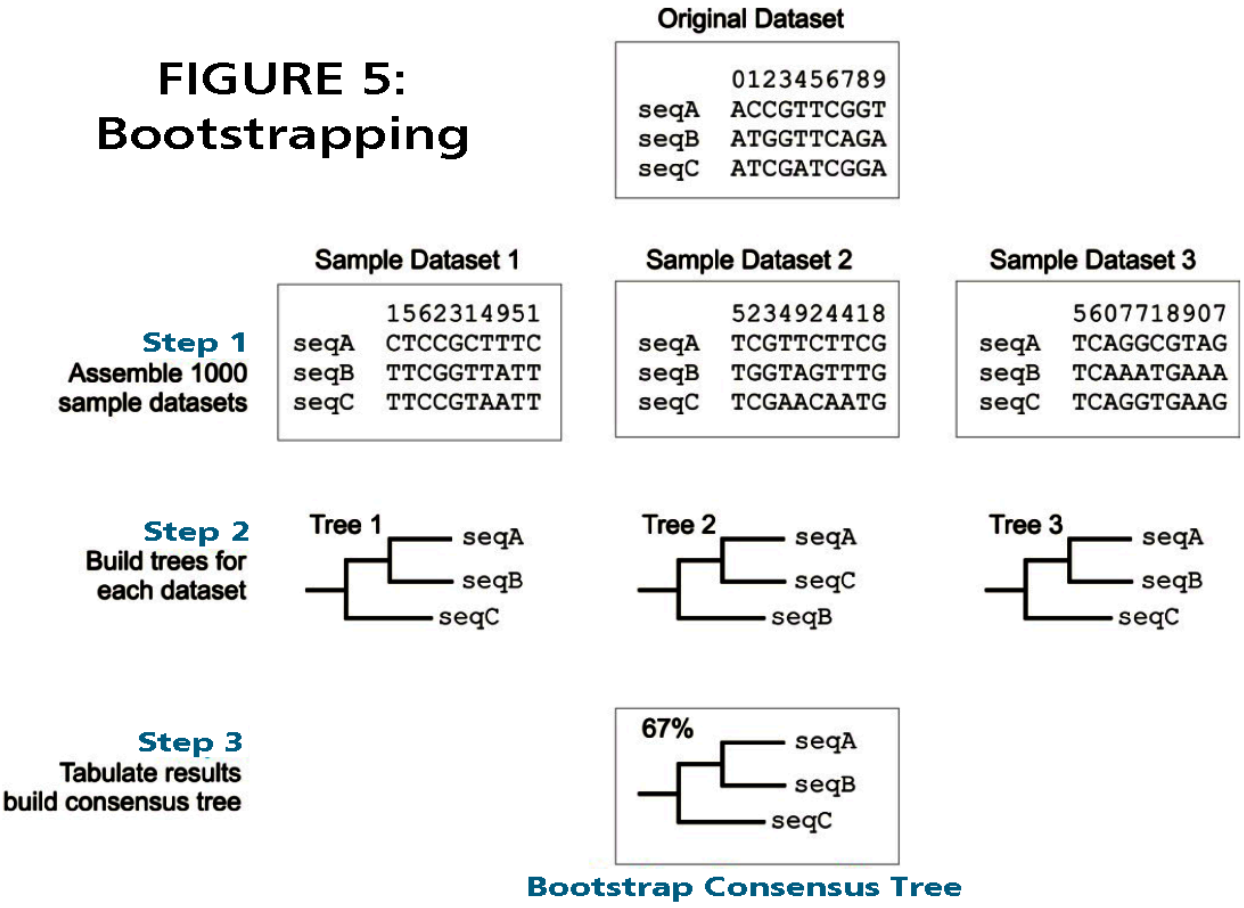
ly crop up in phylogeny when proponents confront each other in print.

A4: BOOTSTRAPPING

In traditional parameter estimation, we attach a confidence interval to indicate the uncertainty involved in the point estimate of the parameter. This has not been possible in molecular phylogenetics, as concepts such as the variance and confidence interval are not meaningful when applied to trees. For distance, parsimony and likelihood methods, the most commonly used procedures to assess the confidence in a tree topology estimate is bootstrap analysis. The expression "bootstrapping" comes from the tales of Baron von Münchhausen who found himself stuck in a deep hole. To get out, he grabbed his boots by its bootstraps and pulled himself upwards until he got out of the hole!

In terms of a phylogenetic tree generated by parsimony or maximum likelihood methods, bootstrapping is accomplished by taking random subsamples of the dataset - each of the subsamples being the same size as the original - which is accomplished by allowing repeat sampling of sites, i.e., random sampling with replacement. Trees are then built from each of these and the frequency with which the various parts of the tree are reproduced in each of these random subsamples is calculated. If group X is found in every subsample tree, then its bootstrap support is 100%; if it is found in only two-thirds of the subsample trees, its bootstrap support is 67%. It is a simple test - non-parametric since no distribution is assumed - but bootstrap analyses of known phylogenies (viral populations evolved in the laboratory) show that it is a generally dependable measure of phylogenetic accuracy, and that values of 70% or higher are likely to indicate reliable groupings.

An example is shown in Figure 5. The bootstrap analysis proceeds in three steps. (1) The dataset



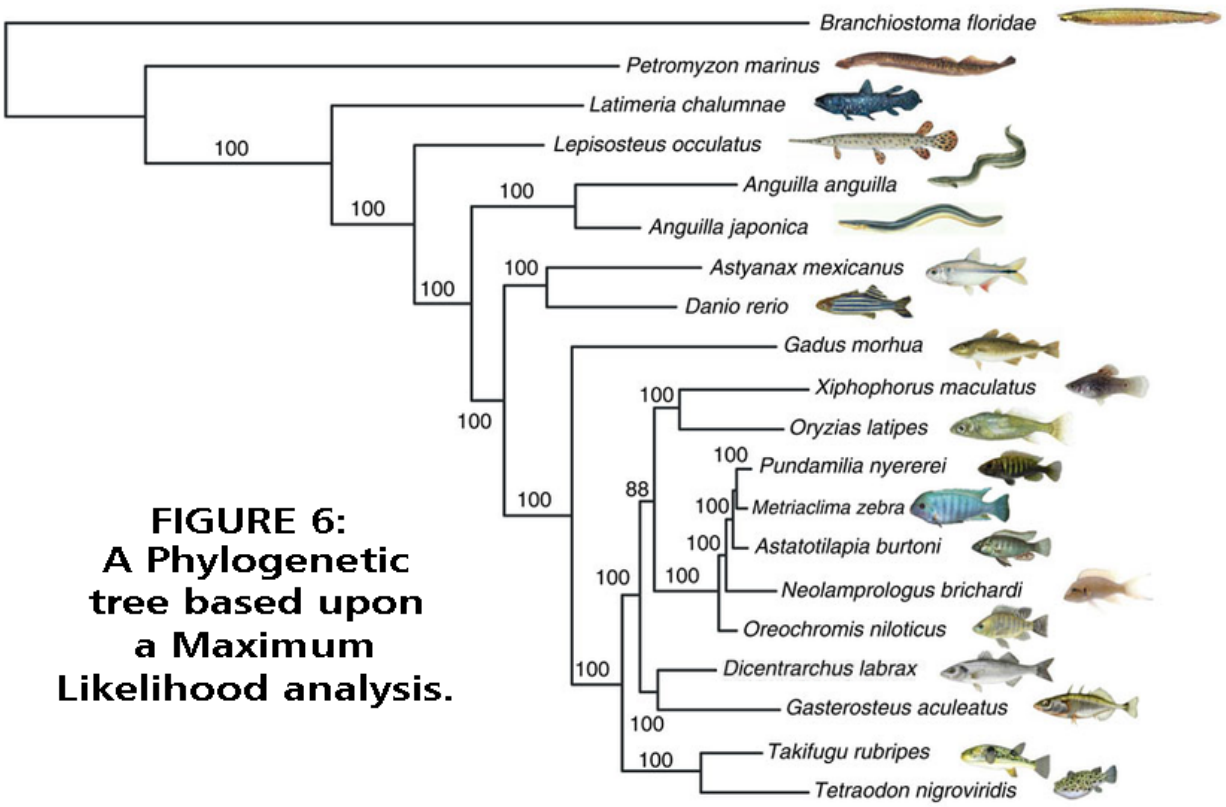


FIGURE 6: A Phylogenetic tree based upon a Maximum Likelihood analysis.

(three taxa and ten molecular characters) is randomly sampled with replacement to create multiple pseudo-datasets of the same size as the original. (2) Individual trees are constructed from each of the pseudo-datasets. (3) Each of the pseudo-dataset trees are scored for which nodes (groupings) appear and how often. In this case, a node uniting seqA plus seqB is found in two of three selected replicate trees. This gives a bootstrap support for this grouping of 2/3 or 67%. As a real example, Figure 6 shows a phylogenetic tree based on a maximum likelihood analysis using molecular data from 20 sequenced fish genomes, showing the relationships that include many common aquarium fish. Bootstrap values are shown above each branch. The lancelet (*Branchiostoma floridae*) was used as the outgroup. Note**:** Figure 1 shows the tree obtained by Schories using molecular data on thirty six variations of *Poecilia.* The bootstrapping values for the *Poecilia wingei* species (i.e., "Endler's guppy) were 100, indicating a very reliable grouping.)

B1: NUMERICAL TAXONOMY (PHENETICS)

So what can biologists meaningfully say about phylogeny? This is one of the central problems in systematics. Broadly, two different issues have been at the center of recent systematics debates: (1) Given the limitations on our knowledge or the degree of its validation, whether any inference of phylogeny may justifiably be drawn; and (2) Given an affirmative answer, what methods ought biologists to use to justifiably infer phylogenies and what are the limits of these inferences? Here I will place these debates in their historical, scientific and conceptual contexts, starting with Numerical Taxonomy or Phenetics.

There is general agreement in the systematics community that meaningful inferences of phylogeny may be drawn. Though the issue of whether phylogeny reconstruction is a legitimate task for biologists is largely settled, the shape of that debate has set the tone for contemporary conceptual debates in systematics. The publication of Linnaeus' *Systema Naturae* in 1735 may mark the

beginning of modern systematics, and the publication of Darwin's *On the Origins of Species* in 1859 obviously had a major impact on biologists. Numerical taxonomy (more commonly referred to today as "phenetics," from the Greek word "phainein," to appear), which started in the 1950s, is the numerical evaluation of the affinity or similarity between taxonomic units and the ordering of these units into taxa on the basis of their affinities. In practice, measurements were made of a large number of characters of a taxon, at least 60 per taxon and often 100 or more. No special importance was attributed to any one of the characters. After the measurements were complete on hundreds of individuals, the data were analyzed statistically with computer programs using cluster analysis or other methods to show purported natural groupings of plants or animals with overall similarities. An example of numerical taxonomy is shown in Figure 7 where three measurements are made on a number of fishes and three groups obtained on the basis of the inter -cluster and intra-cluster distances shown.

Numerical taxonomy arose in response to the then entrenched methods of taxonomy. For advocates of phenetics, a scientific approach to taxonomy amounted to using transparent, explicit methods that produced repeatable outcomes that could be tested by anyone familiar with the methodology and with access to the data set. This stood in contrast to traditional practice in taxonomy, where researchers relied primarily on intuition and appeals to authority. The primary criticism from pheneticists was that taxonomy was being practiced more as an art than as a science. They argued that taxonomists ought to strive for a scientific approach to taxonomy - namely, using methods that were both objective and repeatable. This amounted to a demand for rigor and articulation of method, i.e., a dispute over what could be justified as a scientific explanation or hypothesis.

Pheneticists purge all intuition and subjectivity and strive to be theory-neutral, objective and quantitative, with observation, description and ordering performed as precisely, objectively and repeatably as possible. Hence all evolutionary and phylogenetic interpretations are rejected by them as being too difficult and subjective. They consider that phylogenetic reconstruction is nearly impossible to know with any degree of certainty, and therefore, if classification were to be scientific, this futile quest should be abandoned.

Testability, repeatability and transparency of methodology were tied to a notion of objectivity, in particular to the notion that overall similarity

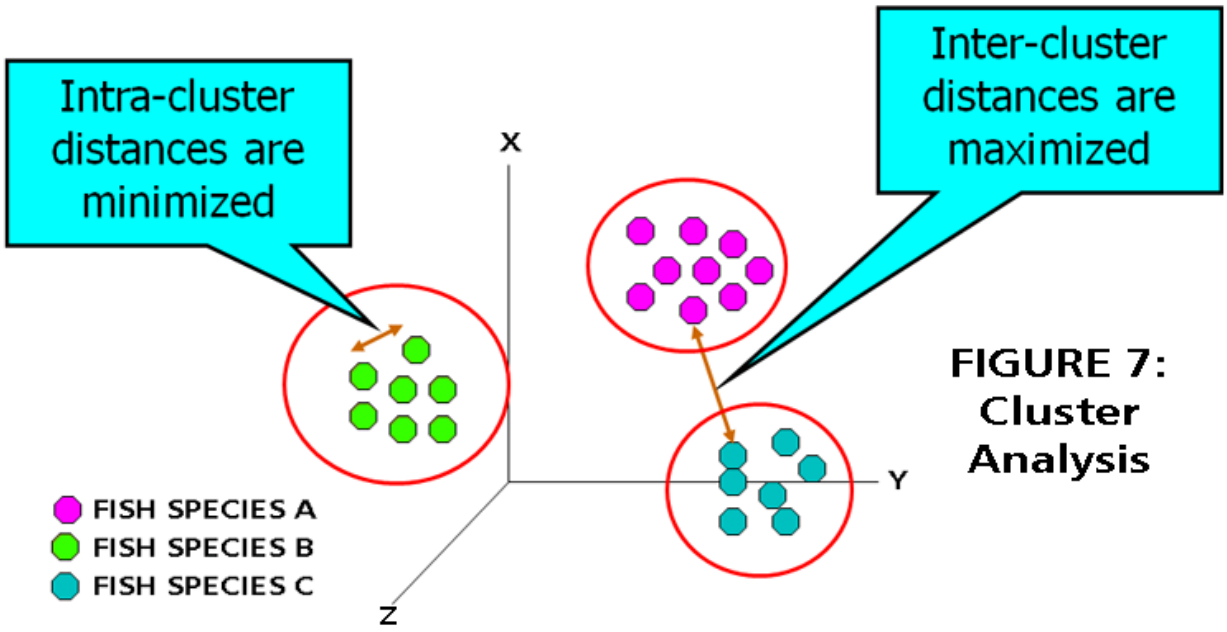

FIGURE 7: Cluster Analysis

between organisms is a function of the similarity of the characters being compared between the organisms. "Objective" was not meant to imply that the affinities between entities were theory free; simply that given some set of parameters and data, a mean similarity could be determined without resort to subjective interference. There is an underlying assumption in numerical taxonomy that selection and identification of characters was a strictly empirical procedure, and that theory should not enter into such selections.

Whether the notions of "objective" advocated by pheneticists in theory are consistent with phenetic methodology in practice and whether its notions are coherent, however, is a matter of some controversy. A phenetic classification represents the morphological similarity for a large numbers of characters. Any consistency in a classification of this sort does not follow from the phenetic system itself since there is no hierarchy of morphological similarity which exists in nature.

A phenetic classification is imposed subjectively based on feature similarity by the taxonomist. This is shown in Figure 8. There are five species with two characters: length of tibia and length of wing vein. We start by grouping each species with its phenetically nearest neighbor. Two clusters of species 1 and 2, and 4 and 5 are created. But to which of these clusters should we join species 3? Using the Nearest Neighbor approach the nearest species is 2, and so we put it with cluster A, forming the tree on the lower left. However, if we use the Average Neighbor approach where we calculate average distance of each cluster as a whole, the answer is the opposite - cluster B has the nearest average neighbor to species 3 and we form the tree on the lower right. Phenetic classification, therefore, even in its modern numerical form, is not objective. It can produce classifications, but classifications that lack a deep philosophical justification.

However, it is insensitive to outliers where accuracy can be affected from noise or irrelevant features and there are no assumptions about data. It is a simple algorithm to explain and interpret, and it has a relatively high accuracy.

In the end, Phenetics was unsuccessful and eventually abandoned in favor of cladistics for a number of reasons, including numerous difficulties encountered owing to homoplasy and a shortage of diagnostic characters. Even so, certain phenetic methods, such as neighbor-joining, have found their way into cladistics as a reasonable approximation of phylogeny when more advanced methods (including parsimony, maximum likelihood and Bayesian inference) are too computationally expensive. Also, with the rise of molecular systematics, distance methods, which are basically phenetic methods, have become popular.

C1: CLADISTS AND PARSIMONY

It is only rather recently that the broad goal of systematics has been to display the evolutionary relations of taxa using phylogenetic trees. The cladistic school arose in the late 1960s/early 1970s and challenged phenetics. Phylogeneticists argued that no such objective classification was possible based on the inductive methods of phe-

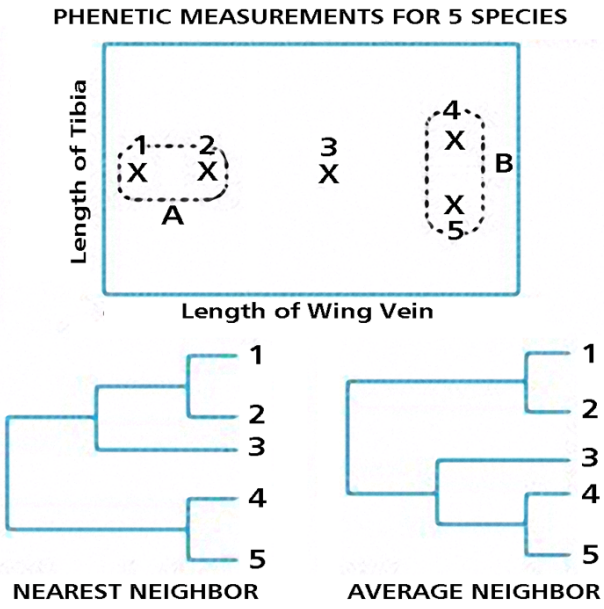

FIGURE 8: Phenetic Classifications.

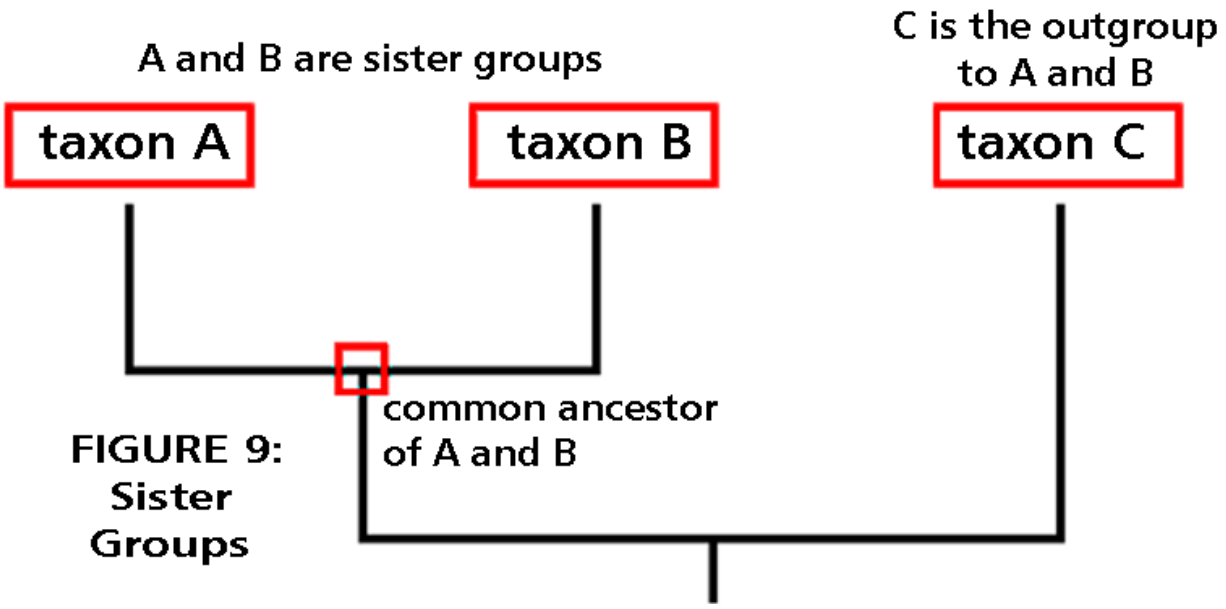

FIGURE 9: Sister Groups

netics, and that inferences of evolutionary relationships of taxa could indeed be justified.

Phylogeneticists followed Willi Hennig in taking the aim of systematics to be the construction of phylogenetic trees that reflected nested sets of sister-taxa, that is, taxa that are descended from a common evolutionary ancestor or ancestral group, especially one not shared with any other group (Figure 9). These sets of sister-taxa were called *clades*, hence the term *cladistic analysis*.

Phylogenetic analyses produce *cladograms* that display phylogenetic relationships but do not necessarily convey any objective similarity between the taxa. This reflects the phylogenetic claim that morphological similarity alone does not necessarily correlate to evolutionary relatedness and that only derived traits are informative in systematic analysis. Not surprisingly, phenetic and phylogenetic analyses of data can produce significantly different results (Figure 10).

Indeed, cladist criticisms of phenetics call into question the entire notion of objective similarity in evolutionary analysis. In its place, cladists argued that in a phylogenetic context, relevant similarity should be understood in terms of a shared, derived history. This argument amounts to the claim that absent some theoretically justifiable

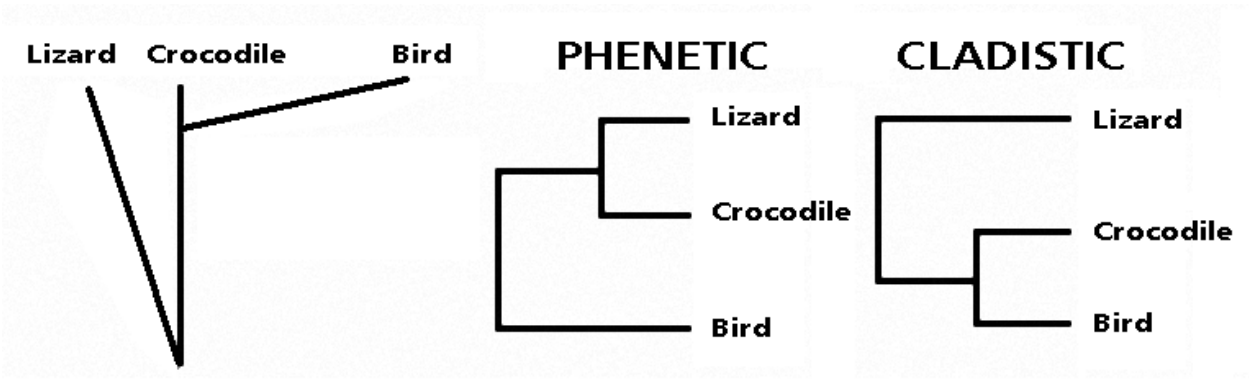

FIGURE 10: Phenetic versus Phylogenetic Analyses.

notion of relevance, similarity is an empty claim. Specifying phylogenetic context as a theoretical basis for relevance, however, provides content to claims of similarity.

Cladists rejected the notion that objective similarity was something that could be discovered using quantitative analysis and instead advocated a systematic analysis justified by an appeal to theoretically driven notions of relevance. Nonetheless, cladists embraced the notions of repeatability and testability as criteria of scientific methodology that must be met to produce satisfactory hypotheses of phylogeny. These criteria concern which techniques are suitable for inferring phylogeny; hence the shift in systematics from debates over *whether* to infer phylogeny to debates concerning *how* to infer phylogeny.

The cladist's method of building phylogenetic trees is based purely on parsimonious principles, i.e., *Pluralitas non est ponenda sine necessitate* (plurality should not be posited without necessity). This rule comes from theologian and philosopher **Wilhelm of Ockham** (~ 1280-1349), and is now called the **Principle of Parsimony** (in the popular literature, **Ockham's razor**). It states that when trying to explain a phenomenon, it is always better to make the least number of assumptions (in other words, when you hear hoof beats, don't start looking for zebras). A rock stays on the ground because of gravity and density, not because an assumed invisible man is pushing it down.

In Figure 11, Hypothesis A requires five evolutionary changes and Hypothesis B requires six. Although both fit the available data, the parsimony principle says that Hypothesis A is better since it does not hypothesize unnecessarily complicated changes. However, do not confuse this with meaning that the simplest possible explanation is the correct one. The simplest possible explanation for whale evolution, for example, is that whales evolved directly from already-marine fish, but their physiology and fossil record make it clear that a more complex scenario happened (i.e., secondary evolution to an aquatic lifestyle). What the principle of parsimony in this case states is that if you had to explain it, it's better to assume a complicated origin of aquatic whales from terrestrial ancestors rather than a simpler origin from fish, *given that there is no evidence supporting a simpler origin*.

In evolutionary biology, the principle of parsimony is very important because of the chaotic nature of evolution. The probability of the same mutations and developmental processes evolving independently is low, consequently it's safer to assume that similarities between organisms are due to common descent (i.e. the mutations occurred once in a common ancestor and have been passed on) rather than due to convergence (i.e. that they occurred multiple times independently).

Many leading cladistic theorists initially justified parsimony techniques by explicitly appealing to philosopher of science Karl Popper's falsifica-

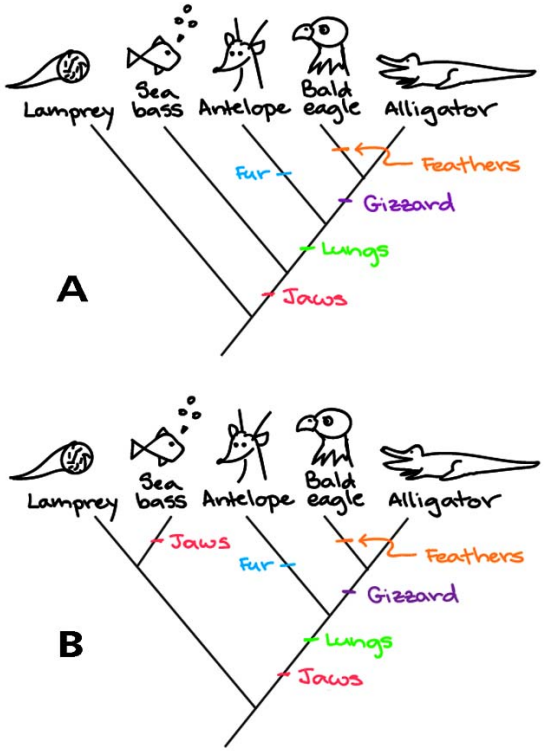

FIGURE 11: The Parsimony Principle.

tionism (Popper, 1959), i.e., experiments producing confirming evidence of a theory are of little to no value; only experiments that test scientific theories by seeking falsifying evidence offer evaluative information conforming to the scientific method. They are falsifiable if it is possible to conceive of an observation or an argument which could negate them. Thus, the term falsifiability is synonymous with testability. For example, the universal generalization that all swans are white is falsifiable since it is logically possible to falsify it by observing a single swan that is not white. Some statements, such as it will be raining here in one million years, are falsifiable in principle, but not in practice.

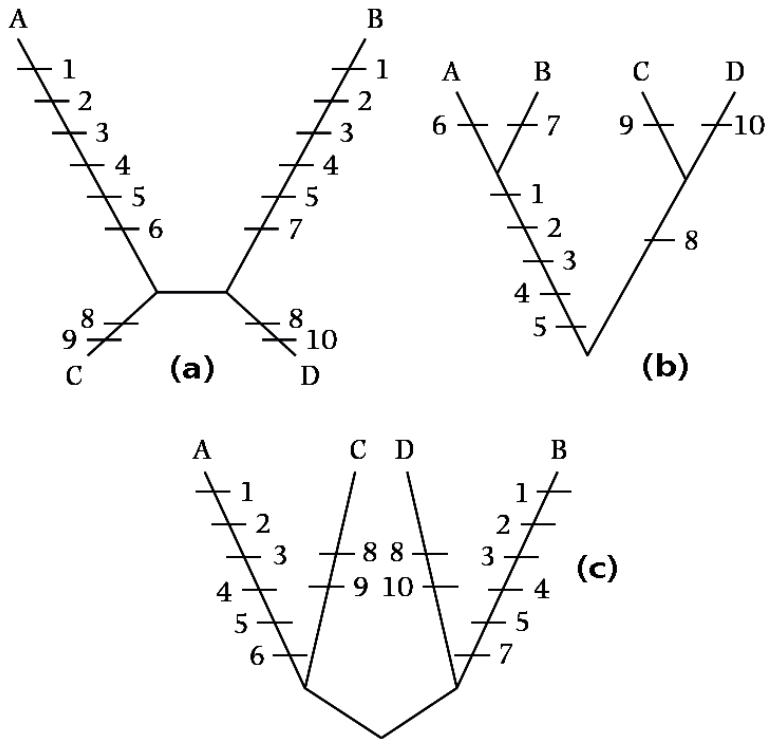

FIGURE 12: The Long Branch Attraction.

Cladists pressed falsificationism into service to solve the problem of phylogenetic inference, while simultaneously satisfying the criteria of scientific methodology inherited from prior debates in systematics. Phenetic methods were decried as confirmationist, while parsimony analysis was framed in a falsificationist framework. The most parsimonious phylogenetic tree was said to be the most corroborated phylogenetic hypothesis. This phylogenetic tree was subject to being falsified if the discovery or addition of new characters revealed a more parsimonious phylogenetic tree.

Most contemporary philosophers of science are critical of the idea that falsificationism is the *only* acceptable method of science. Many question whether it is even a very good thesis about scientific methodology and most have come to reject the thesis that any scientific hypothesis can be falsified in isolation.

C2: LONG BRANCH ATTRACTION

In the late 1970s, phylogeneticist Joseph Felsenstein discovered that lineages of a certain shape were subject to a systematic error in parsimony analysis (Felsenstein, 1978). One example of this problem is called **long-branch attraction (LBA)**. In phylogenetic trees, branches connect nodes to other nodes or taxa. The length of these branches can be used to represent the amount of evolutionary change along a branch. In long-branch attraction, the taxa at the ends of long branches of lineages are mistakenly grouped together by parsimony instead of with the groups with which they actually share a more recent common ancestor.

In Figure 12, (a) represents the actual pattern of evolution (i.e., the actual historical lineage of A, B, C, and D), with the branch lengths indicating amount of evolutionary change; (b) is a parsimony analysis of the data from (a), whereas (c) is a Maximum Likelihood (ML) analysis of the same data. ML picks out the phylogenetic tree that has the highest likelihood conditional on the data. The evolutionary relationships displayed in the parsimony phylogenetic tree in Figure 12 are not

identical with the actual evolutionary relationships. The long-branch error occurs in (b) in hypotheses based on the number of proposed evolutionary events needed to account for all the characters exhibited by the taxa. For example, hypothesis (b) would receive a parsimony score of 10, whereas (c) would receive a parsimony score of 16; (c), however, is the correct solution.

Long-branch attraction is not merely a problem at an operational level, but also presents a challenge to the falsificationist underpinnings of parsimony. As more data (in the form of characters) are discovered or added to analyses, the previously most parsimonious phylogenetic trees are subject to being falsified in favor of more parsimonious phylogenetic trees. These new phylogenetic trees, then, are held up as bold hypotheses and either corroborated or rejected in favor of ever more parsimonious trees that are subject to being tested.

Felsenstein showed that as more characters are added, parsimony techniques become *more subject* to making a long-branch attraction error. This is because as more characters are added, it raises the possibility that there will be a long branch in the tree. In other words, parsimony techniques are more prone to rejecting hypotheses that correctly capture actual phylogenetic relations while corroborating less accurate but more parsimonious phylogenetic hypotheses – seemingly producing a systematic inferential error.

To avoid long-branch attraction, Felsenstein proposed using maximum-likelihood (ML) techniques to formulate phylogenetic trees (Felsenstein, 1981). Simulation studies at the time showed that ML methods were not subject to long-branch attraction. However, the tree space modeled was always one in which the two long branches never occurred as sister taxa, and a number of studies have shown that ML can also become inconsistent and suffer from LBA artifacts when the model assumptions are violated. When Siddall (1998) modeled a tree space where the long branches were sister taxa, parsimony outperformed likelihood methods, which instead, according to Siddall suffered from "long-branch repulsion." The following is a quote taken from the paper, "Performance of maximum parsimony and likelihood phylogenetics when evolution is heterogeneous" (Kolaczkowski and Thornton, 2004):

All inferences in comparative biology depend on accurate estimates of evolutionary relationships. Recent phylogenetic analyses have turned away from maximum parsimony towards the probabilistic techniques of maximum likelihood and Bayesian Markov chain Monte Carlo (BMCMC). These probabilistic techniques represent a parametric approach to statistical phylogenetics, because their criterion for evaluating a topology - the probability of the data, given the tree - is calculated with reference to an explicit evolutionary model from which the data are assumed to be identically distributed. Maximum parsimony can be considered nonparametric, because trees are evaluated on the basis of a general metric - the minimum number of character state changes required to generate the data on a given tree - without assuming a specific distribution.

The shift to parametric methods was spurred, in large part, by studies showing that although both approaches perform well most of the time, maximum parsimony is strongly biased towards recovering an incorrect tree under certain combinations of branch lengths, whereas maximum likelihood is not. All these evaluations simulated sequences by a largely homogeneous evolutionary process in which data are identically distributed. There is ample evidence, however, that real-world gene sequences evolve heterogeneously and are not identically distributed. Here we show that maximum likelihood and BMCMC can become strongly biased and statistically inconsistent when the rates at which sequence sites evolve change non-identically

over time. Maximum parsimony performs substantially better than current parametric methods over a wide range of conditions tested, including moderate heterogeneity and phylogenetic problems not normally considered difficult.

The bottom line is that although in the beginning LBA was only discussed as a potential problem for parsimony, subsequent research has shown that no method is perfect under all conditions. The main objection that has been made against parsimony is that the simplest hypothesis is not necessarily the true one.

C3: AN EXAMPLE OF PARSIMONY ANALYSIS

Figure 13 shows a parsimony analysis of the family Cichlidae based upon molecular data (Farias, et al., 1999). The numbers above the branches are bootstrap values (only values above 50 are shown). Cichlids from Madagascar and India were found to be the most basic groups of the family Cichlidae and sister to African-Neotropical cichlids. Important phylogenetic findings included the placement of the controversial genus *Heterochromis* basic among African cichlids, the South American genus *Retroculus* as the most basic taxon of the Neotropical cichlid assemblage, and the close relationship of the Neotropical genera *Cichla* with *Astronotus* rather than with the crenicichlines. Based on a large number of South American genera, the Neotropical cichlids harbor significantly higher levels of genetic variation than their African counterparts. Relative rate tests suggest that Neotropical cichlids have experienced accelerated rates of molecular evolution. But these high evolutionary rates were significantly higher among geophagine cichlids.

D1: MAXIMUM LIKELIHOOD (ML)

Sir Ronald Aylmer Fisher was a British statistician and geneticist. For his work in statistics, he has been described as "the genius who almost single-handedly created the foundations for modern statistical science" and "the single most important figure in 20th century statistics." His method of maximum likelihood was first proposed in 1922, but his advisors didn't think it was such a useful idea!

In probability theory we consider some underlying process which has some randomness or uncertainty modeled by random variables, and we figure out what happens. In statistics we observe something that has happened, and try to figure out what underlying process would explain those observations. For example, a probabilist starts by knowing the proportion of red and green jelly beans in a jar and finds the probability of drawing a red jelly bean. A statistician infers the proportion of red jelly beans by sampling from the jar.

Since ML requires an underlying model, I have picked as an example the Bernoulli distribution, named after Swiss mathematician Jacob Bernoulli, which is the probability distribution of a random variable which takes the value 1 with probability p and the value 0 with probability 1-p. We want to estimate the probability p of getting a head upon flipping a particular coin. We flip the coin "independently" 10 times (i.e., we sample n = 10 flips), obtaining the following result: HHTHHHTTHH. Assuming n equals the number of observations and k equals the number of heads, the probability of obtaining this sequence - in advance of collecting the data - is a function of the unknown parameter p of the Bernoulli distribution (the vertical line in the equation means "given"):

$$\Pr(\text{data}|\text{parameter}) = \Pr(\text{HHTHHHTTHH}|\ p)$$
$$= p^k(1-p)^{n-k}$$

But the data for our particular sample are *fixed*: We have already collected them. The parameter p also has a fixed value, but this value is unknown, and so we can let it vary in our imagination between 0 and 1, treating the probability of the observed data as a function of p. This function is called the likelihood function, L:

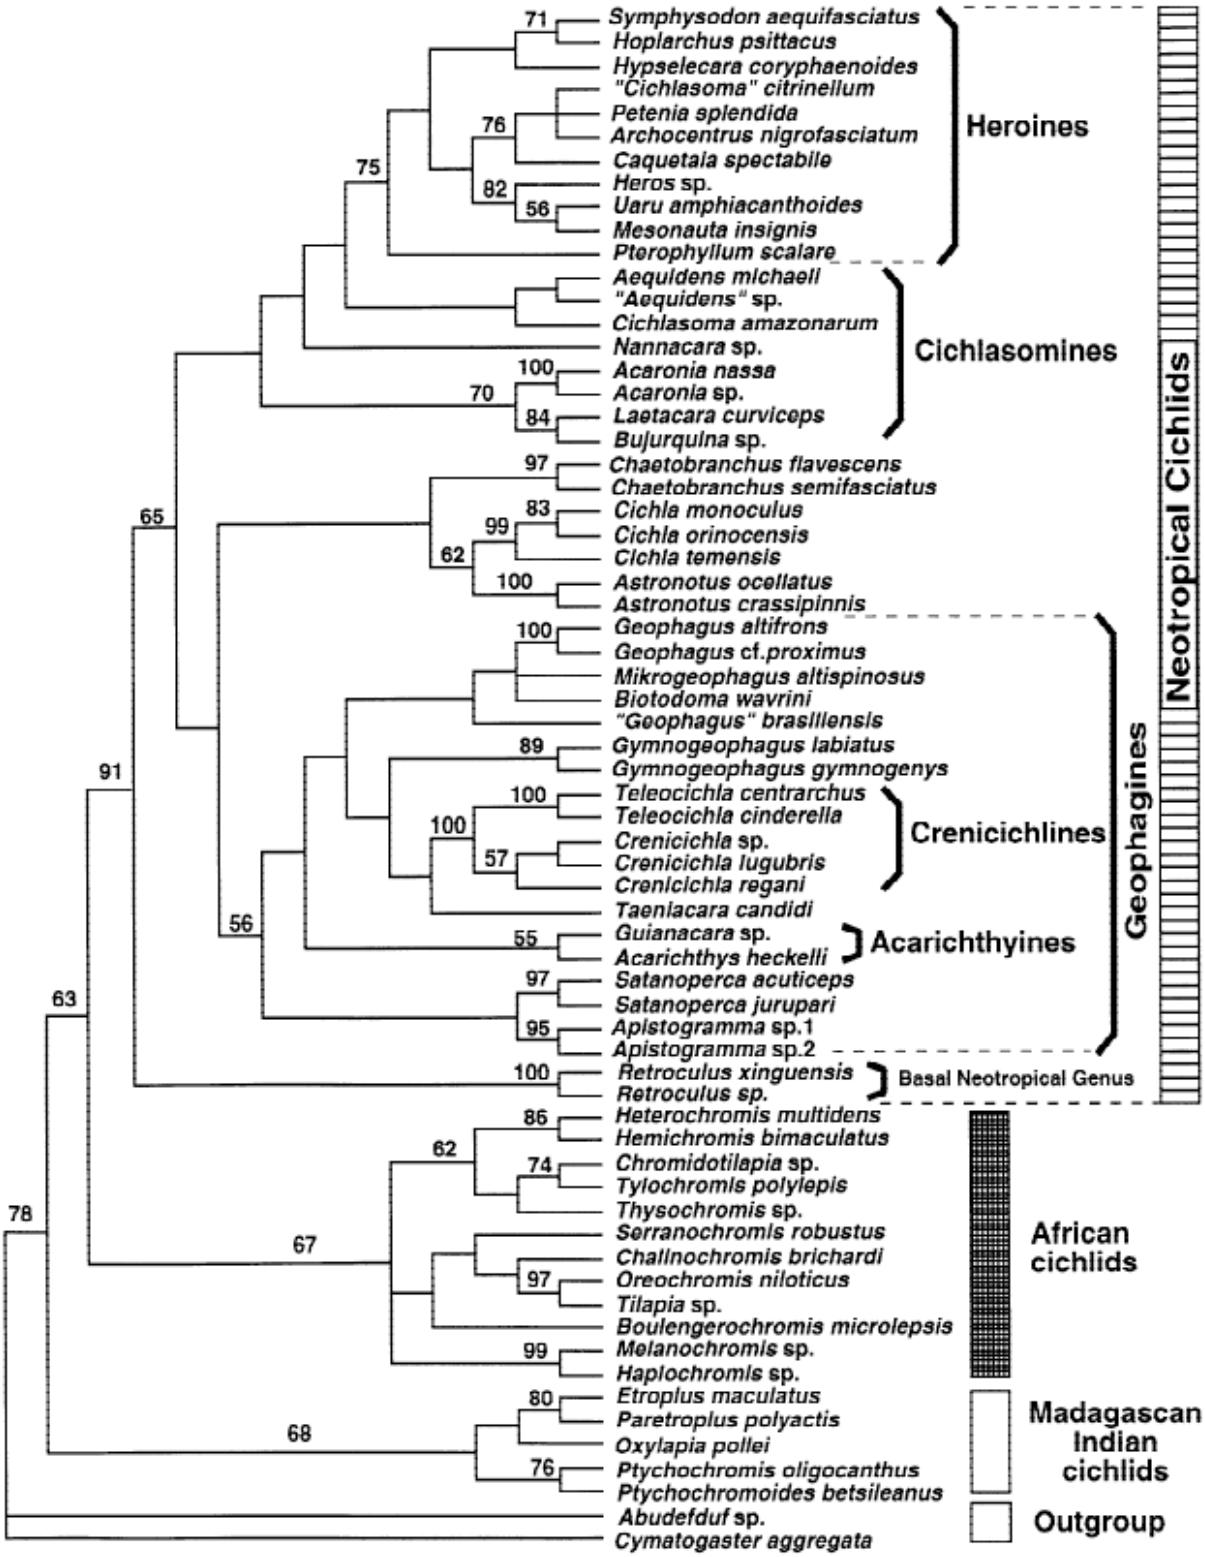

FIGURE 13: A Parsimony Analysis of the Family Cichlidae.

TABLE I

π	$L(\pi \mid \text{data}) = \pi^7(1-\pi)^3$
.0	.0
.1	.0000000729
.2	.00000655
.3	.0000750
.4	.000354
.5	.000977
.6	.00179
.7	.00222
.8	.00168
.9	.000478
1.0	.0

L(parameter|data) = L(p| HHTHHHTTHH)
= $p^k(1-p)^{n-k}$

The probability function and the likelihood function are given by the same equation, but the probability function is a function of the data with the value of the parameter fixed, while the likelihood function is a function of the parameter with the data fixed. Table I lists some representative values of the likelihood for different values of p where n = 10 and k = 7.

The complete likelihood function is graphed in Figure 14. Although each value of L(p |data) is a notional probability, the function L(p |data) is NOT a probability or density function - it does not enclose an area of 1. Note that the probability of obtaining the sample of data that we have in hand, HHTHHHTTHH, is small regardless of the true value of p. Any specific sample result - including the one that is realized - usually will have low probability.

The value of p that is most supported by the data is the one for which the likelihood is largest. This value is the *maximum-likelihood estimate* (MLE), denoted L_{max}. Here, p = 0.7, which is the sample proportion of heads, 7/10. (I won't go into the calculus here but more generally, for n independent flips of the coin, producing a particular sequence that includes k heads and n-k tails, the ML estimator of p, L_{max}, is k/n.)

The method of maximum likelihood is very broadly applicable and is simple to apply. Once a maximum-likelihood estimator is derived, it provides standard errors, statistical tests and other results useful for statistical inference but this is true only for infinite populations. For example, maximum likelihood estimators from small samples are biased. The major disadvantage of the method, however, is that it frequently requires strong assumptions about the structure of the data.

D2: THE PROBLEM WITH MAXIMUM LIKELIHOOD

I am not suggesting that statistical estimation is beyond the pale of serious science, but it is limited to abstractions. Statistical estimation procedures are designed to make generalities about the universe. Whether or not some killifishes are more closely related to some livebearing cyprinodontiforms than to some other killifishes is not an

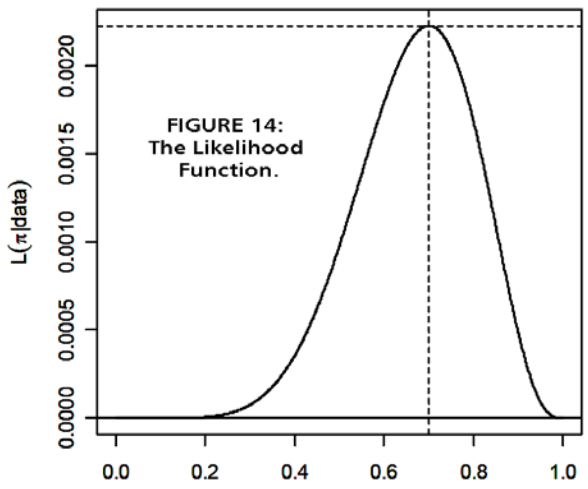

FIGURE 14: The Likelihood Function.

abstract generality. When this logical relation is taken to be a symmetrical one, that is, when *specifics* are inferred from *generalities*, probability theory steps beyond its logical bounds.

Bernoullian probability theory, for example, states that in the case of large numbers, the objective probability p will lie very close to the observed frequency and thus the observed frequency will probably be a good estimate of the objective probability. What likelihoodists confuse in this theoretical framework is that this relies on *repetitive* cases and large numbers (truth being obtained in the infinite). In phylogenetics we are NOT faced with large numbers or repetitive cases. So long as time is taken to be linear, history has occurred but once. Large numbers and their generalities cannot be relevant to finite singular cases.

Consider some event's occurrence (1) or non-occurrence (0) and the series of observations:

0, 1, 0, 0, 1, 1, 0, 0, 0, 0, 1, 1, 1, 1, 0, 0, 0, 0, 0, 0, 0, 0, 1, 1, 1, 1, 1, 1, 1, 1.

We will assume that the relative frequency of occurrence is $f(0) = 0.5 = f(1)$ and in the infinite this holds as well. In the more limited case, however, it does not. Suppose we only observed five of these in a row. There are 26 ways in which we could have done this and these are listed in Table II. From these 26 samples we estimate the likelihood, which in this case is the average of each of the 26 samples. For five flips per sample the only possible averages are 0, 0.2, 0.4, 0.6, 0.8 and 1. The number of each of these averages is shown in the small table below the main table and is converted into probabilities (or likelihoods) by dividing by 26. The maximum of these occurs with the mean of 0.4; thus the L_{max} of p is 0.4, an estimate that is 25% too low.

Even if we observed all possible series of five observations in a row we would come to the conclusion that $f(1) = 0.48$. The reason for this anomaly that in the above series of events, even though under the law of large numbers given the series in its infinite iteration we can be certain that $f(1) = 0.5$, in the finite case there is more structure to the data than a mere stochastic process. Bernoullian laws, for example, cannot distinguish the above series from the following:

0, 0, 1, 0, 1, 0, 0, 1, 0, 1, 1, 1, 0, 1, 0, 1, 0, 0, 1, 0, 1, 1, 0, 1, 0, 0, 1, 0, 1, 0.

The observation that some phenomenon matches the expectations of a random process "in the long run" does not allow us to infer that the process is, in fact, random or that it will have been in any particular case. Consider flipping a coin 10 times. In one series we obtain:

H, H, H, H, H, H, H, H, H, H.

In another series we get:

H, T, H, H, H, T, H, T, H, H.

Assuming the coin is equally weighted, which observation is more probable? The likelihoodist

TABLE II

No.	Sample	Mean
1	0, 1, 0, 0, 1	0.4

0.6	4	0.154
0.8	3	0.120
1.0	4	0.154
Total	26	1.000

would hasten to judge the second to be more probable than obtaining 10 heads in a row. However, if the events are conjoined somehow, this need not be so. That is, if getting "heads" depends on what happened before it (is historically contingent), probability theory falls apart in the face of its requirement for sampling independence.

What, then, if the events are wholly independent? If the coin is equally weighted, the probability of getting a heads on a toss is 0.5, and so is tails. Using the formula = $p^k(1-p)^{n-k} = p^7(1-p)^3$ then

p(H, H, H, H, H, H, H, H, H, H) = 0.001 and
p(H, T, H, H, H, T, H, T, H, H) = 0.001.

They are equally probable. What if we take the likelihoodist's perspective of saying that the probability of heads, as ascertained from the second series, is 0.7? In this case, the first series of throws (p= 0.028) is actually *more* likely than the second (p = 0.002) from which the rule was derived. Again, this is only damning of frequency probability calculus applied to the particularness of the singular series, not of its relevance to abstract generalities like "a throw on average." Regarding phylogenetic inference, arguments for efficiency measured in terms of finding the correct solution at a given frequency might be germane if, in fact, there were frequencies of history. Insofar as there is but one history for a given set of taxa, this statement is not applicable to phylogenetics.

There is a fundamental distinction that can be drawn between the task of statistics and that of phylogenetics. Statistical measures are required for making estimations regarding collections of observational propositions by way of an abstract generality. That is, there is no real thing belonging to both space and time that we can point to called a "mean" or a "variance." These are useful abstractions that exist only in our psychology as scientists. "Mean," "median" and "mode," for example are simply measures of central tendency for a population of individuals. But neither does "central tendency" exist in any physical objective reality. Consider that the mean number of dorsal fin rays in a group of snakehead fishes can be said to be 51.5. Whereas this may be a useful construct for estimating whether or not this group of snakeheads has more rays than some other group, we can simultaneously be certain that there is no snakehead anywhere that has 51.5 dorsal fin rays. We can also reasonably state that even though this group of snakeheads can be said to have "significantly more" dorsal fin rays than some other group, this does not mean that all snakeheads in this group necessarily have more dorsal fin rays than all snakeheads (or a particular snakehead) in the other group.

Genealogical hypotheses that describe how various species are related to each other do not, by themselves, confer probabilities on the observations and so likelihood methods require the adoption of a model. The main objection that has been made against likelihood methods is that in practice they require one to adopt a model of the evolutionary process that one has scant reason to think is true.

The reason likelihood methods require the adoption of a model in the first place is that genealogical hypotheses that describe how various species are related to each other do not, by themselves, confer probabilities on the observations. Pierre Duhem (1914) was a French physicist, historian and philosopher of science who contended that physical theories do not involve observations as a necessary or inevitable part or consequence unless they are supplemented with auxiliary assumptions. Forty-some years later, the American philosopher W.V. Quine (1953) generalized Duhem's thesis, claiming that *all* theories (indeed, all hypotheses), whether or not they are in physics, fail to entail observational predictions. From a likelihood point of view, it isn't essential that the hypothesis we wish to evaluate *deductively involves* observational claims about the characteristics of species. What is required is that they *confer probabilities* on these statements. The

problem is that they do not. In the language of statistics, genealogical hypotheses are composite, not simple.

D3: AN EXAMPLE OF MAXIMUM LIKELIHOOD

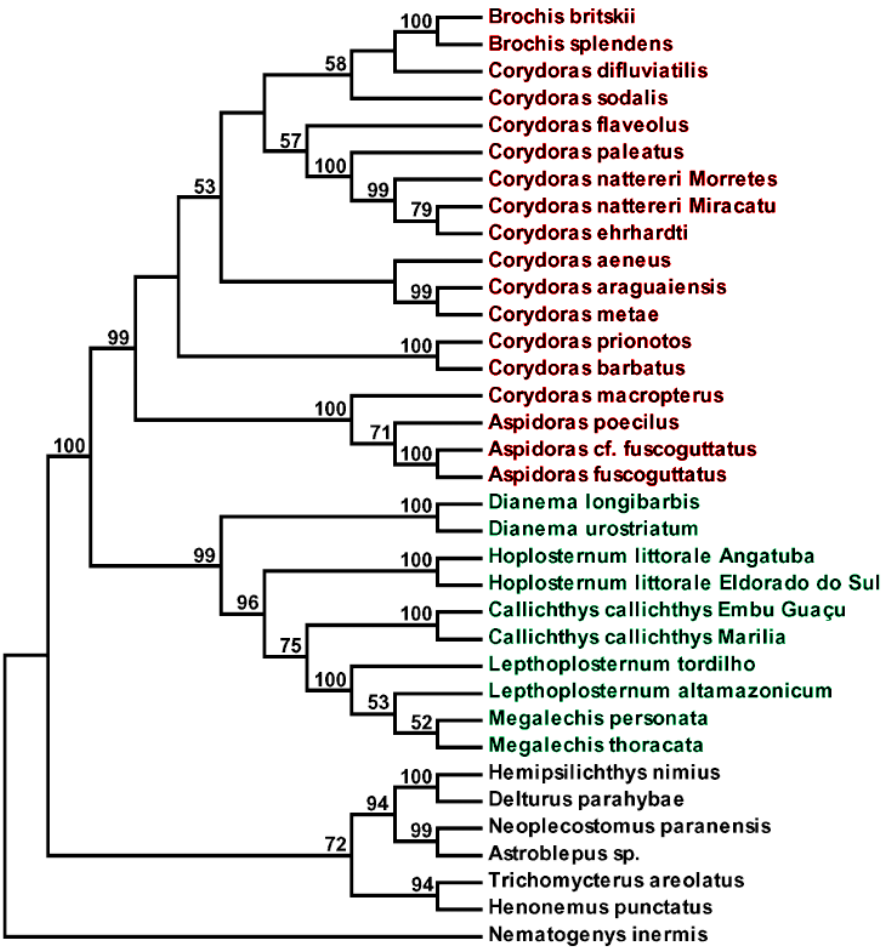
The family Callichthyidae comprises eight genera of fishes widely distributed across the New World. In the present molecular study of this phylogeny of the armored catfish family (Shimabukuro-Dias, et. al, 2004), sequences of five mitochondrial genes were obtained from 28 callichthyid specimens. The sample included 12 species of *Corydoras*, three species of *Aspidoras*, two species of *Brochis, Dianema, Lepthoplosternum*, and *Megalechis*, and two local populations of *Callichthys* and *Hoplosternum*. Sequences of *Nematogenys inermis* (Nematogenyidae), *Trichomycterus areolatus*, and *Henonemus punctatus* (Trichomycteridae), *Astroblepus sp.* (Astroblepidae), and *Neoplecostomus paranensis*, *Delturus parahybae*, and *Hemipsilichthys nimius* (Loricariidae) were included as the outgroup.

Phylogenetic analyses were performed by using the methods of maximum parsimony and maximum likelihood. The results of almost all analyses were very similar (the maximum likelihood results are shown in Figure 15; the numbers above the branches are bootstrap values, but only values above 50 are shown). The results showed that the family Callichthyidae is monophyletic and comprises two natural groups: in red, the subfamilies Corydoradinae (*Aspidoras, Brochis*, and *Corydoras*) and in green, Callichthyinae (*Callichthys*, *Dianema, Hoplosternum, Lepthoplosternum*, and *Megalechis*), as previously demonstrated by morphological studies. The relationships observed within these subfamilies are in several ways, however, different from those previously proposed on the basis of morphological data.

E:1 BAYESIAN PHYLOGENETIC METHODOLOGIES

Bayesian phylogeneticists, as the name implies, use Bayesian phylogenetic techniques to construct phylogenetic trees. Its goal is to distribute posterior probabilities (probabilities that take into account evidence and prior knowledge) over a range of possible phylogenetic trees. Bayesians

FIGURE 15: Maximum Likelihood Analysis of Catfish Data



use what are known as Markov Chain Monte Carlo (MCMC) algorithms to approximate the rational distribution of these posterior probabilities that lead to the selection of which phylogenetic (or consensus) trees are most probable.

The setting for Bayesian statistics is a family of distributions having one or more parameters along with a prior distribution for those parameters. I'll use terminology and notation in the general case where X is a discrete random variable and there is only one discrete parameter θ. In statistics, we don't know what the value of θ is; our job is to make inferences about θ. The way to find out about θ is to perform many trials and see what happens, that is, to select a random sample from the distribution, $\mathbf{X} = (X_1,X_2,...,X_n)$ where each random variable X_i has the given distribution. The actual outcomes that are observed I'll denote as $\mathbf{x} = (x_1, x_2,\ldots, x_n)$. Now, different values of θ lead to different probabilities of the outcome **x**, that is, $P(\mathbf{x} \mid \theta)$ varies with θ. In contemporary statistics this probability is called the likelihood of θ given the outcome **x** and denoted as $L(\theta \mid \mathbf{x})$. The reason the word likelihood is used is the suggestion that the real value of θ is likely to be one with a higher probability $P(\mathbf{x} \mid \theta)$. But this likelihood $L(\theta \mid \mathbf{x})$ is **not** a probability about θ. What Bayesian statistics does is replace this concept of likelihood by a real probability.

Using Bayes' theorem, $P(\theta \mid \mathbf{x}) = P(\mathbf{x} \mid \theta)P(\theta)/P(\mathbf{x})$.

This conditional probability $P(\theta \mid \mathbf{x})$ is called the posterior distribution on θ. It's the probability you have after taking into consideration new information from an observation. Note that the denominator $P(\mathbf{x})$ is a constant, so the equation says that the posterior distribution $P(\theta \mid \mathbf{x})$ is proportional to $P(\mathbf{x} \mid \theta)P(\theta)$. I'll write proportions with the traditional symbol ∝ so that the last statement can be written as

$$P(\theta \mid x) \propto P(x \mid \theta)P(\theta).$$

Using proportions saves a lot of symbols and we don't lose any information since the constant of proportionality $P(\mathbf{x})$ is known.

Note that the random variable X will be either discrete or continuous, but our parameters in the phylogenic case will all be continuous, not discrete. Therefore, I can't use the symbol *P* since that is used for probability mass functions. In the continuous case there are, however, analogous statements using the symbol *f* instead of *P*. In particular, $f(\theta \mid x) \propto f(x \mid \theta)f(\theta)$ where $f(\theta)$ is the prior density function on the parameter θ, $f(\theta \mid x)$ is the posterior density function on θ, and $f(x \mid \theta)$ is a conditional probability or a conditional density depending on whether X is a continuous or a discrete random variable. With this background we are now ready to explore the Bernoulli process, a process I have previously to explain Maximum Likelihood earlier in this essay.

E2: THE BERNOULLI PROCESS

A single trial X for a Bernoulli process, called a Bernoulli trial, ends with one of two outcomes; success where X = 1 and failure where X = 0. Success occurs with probability p while failure occurs with probability q = 1 - p. The term Bernoulli process is just another name for a random sample from a Bernoulli population. Thus, it consists of repeated independent Bernoulli trials $\mathbf{X} = (X_1,X_2,...,X_n)$ with the same parameter p. Let's suppose you have a large number of coins but you have no idea what the probability of heads (p) is. We'll consider here that the outcome "heads" is a success and the outcome "tails" is a failure.

The problem for statistics is determining the value of this parameter p. All we know is that it lies between 0 and 1. We also expect the ratio of the number of successes k to the number trials n to approach p as n approaches 1, but that's a theoretical result that doesn't say much about what p is when n is small. Let's see what the Bayesian approach says here. We start with a prior density function $f(p)$ on p, and take a random sample $\mathbf{x} = (x_1, x_2,\ldots, x_n)$. Then the posterior density function

is proportional to a conditional probability times the prior density function,

$f(p \mid \mathbf{x}) \propto P(\mathbf{x} \mid p) f(p)$.

Suppose, now, that k successes occur among the n trials x. Then referring back to Section D1,

$P(\mathbf{x} \mid p) = p^k(1 - p)^{n-k}$

and therefore, $f(p \mid x) \propto p^k(1 - p)^{n-k} f(p)$.

Thus, we have a formula for determining the posterior density function $f(p \mid \mathbf{x})$ from the prior density function $f(p)$. (In order to know a density function, it's enough to know what it's proportional to, because we also know the integral of a density function is 1.) But what should the prior distribution be? That depends on your state of knowledge. You may already have some knowledge about what p might be. But if you don't, maybe the best thing to do is assume that all values of p are equally probable. Let's do that and see what happens.

Assume now that the prior density function $f(p)$ is uniform on the interval [0, 1]. So $f(p) = 1$ on the interval and 0 off it. Then we can determine the posterior density function.

On the interval [0,1],

$f(p \mid x) \propto p^k(1 - p)^{n-k} f(p) = p^k(1 - p)^{n-k}$.

Well now, that's enough to tell us this is the beta distribution, Beta(k+1, n+1-k), because the probability density function for a beta distribution is

$f(x) = x^{\alpha-1}(1-x)^{\beta-1}/B(\alpha,\beta)$

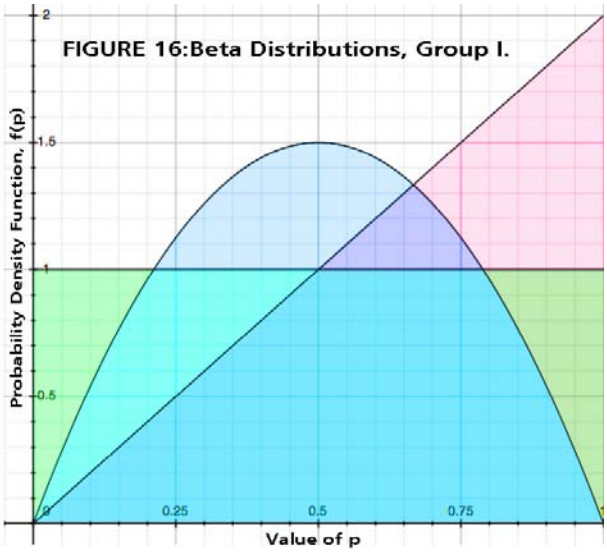
for $0 \leq x \leq 1$, where $B(\alpha,\beta)$ $[=(\alpha-1)!(-\beta)!/(\alpha+\beta-1)!]$ is a normalizing constant to make the integral of the probability distribution sum to one.

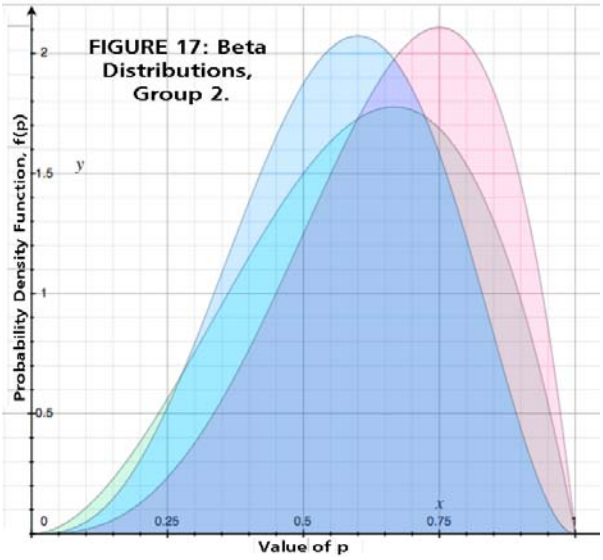
E3: CONJUGATE DISTRBUTIONS

Every time we apply Bayes' Theorem in this example, the Prior and Posterior distributions are Betas and the Likelihood is Bernoulli. Whenever the prior and posterior belong to the same family of distributions, we call the prior and posterior Conjugate Distributions, and the prior is called a Conjugate Prior for the likelihood function. Having a conjugate prior for a likelihood greatly simplifies Bayesian inference as the posterior is obtained simply by updating the parameters of the prior.

Note that the prior distribution $f(p)$ we chose was uniform on [0, 1], and that's actually the beta distribution Beta(1,1). This uniform prior density is shaded green in Figure 16. Now you select a coin, flip it once and put it back. If it was heads, your new distribution on p is Beta(2,1). The density function of this distribution is $f(p) = 2p$ and is shaded pink in Figure 16. The probability is now more dense near 1 and less near 0.

Let's suppose we do it again and get a heads. Now we've got Beta(2,2). So far, one heads and one tails, and the probability is shifted back towards the center. Now $f(p) = 6p(1- p)$ and is shaded blue in Figure 16. Note that the constants α or β increase by one after each pick, α if the pick was red or β if it was green.





Suppose the next three are heads, heads, and tail, in that order. After each one, we can update the distribution. Next will be Beta(3,2), then Beta (4,2), and then Beta(4,3) They appear in Figure 17, the first green, second pink and third blue.

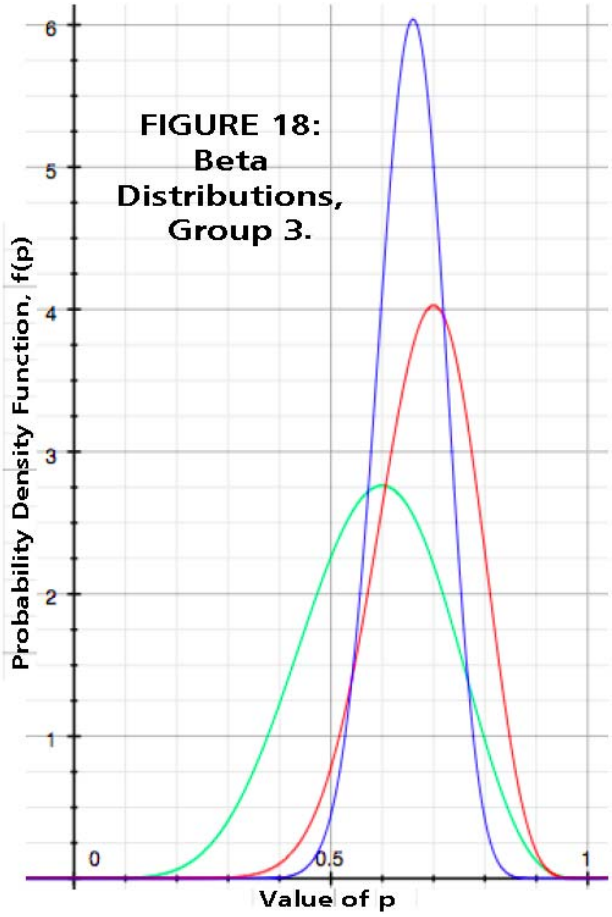
With each new piece of information the curve slowly narrows. We can't say much yet with only 5 flips, 3 heads and 2 tails. A sample of size 5 doesn't say much. Even with so little information, we can still pretty much rule out p being less than 0.05 or greater than 0.99. Let's see what the distribution would look like with more data. Take three more cases. First, when n = 10 and we've drawn heads 6 times. Then when n = 20 and we've gotten 14 heads. And finally when n = 50 and we got 33 heads.

Those have the three distributions Beta(7,5) graphed in green, Beta(15,7) graphed in red, and Beta(34,18) graphed in blue in Figure 18. These are much skinnier distributions, so we'll squeeze the vertical scale a bit. The mean of a Beta distribution is $\alpha/(\alpha + \beta)$ and its variance is $\alpha\beta/[(\alpha + \beta)^2 (\alpha + \beta + 1)]$. Thus for the blue curve its mean is $34/(34+18) = 0.65$, its variance is $34*18/[(34 + 18)^2(34 + 18+ 1)] = 0.00427$ and its standard deviation is 0.065. We can actually graph the complete curve as well, since we have a distribution on p, although the high values of α and β make hand calculations of the value of B(α,β) difficult without consulting factorial tables.

Conjugate priors are possible only for special combinations of the prior and likelihood. As we have just seen, they are theoretically convenient as the integrals are tractable analytically, but they may not be realistic models for every problem at hand.

E4: BAYESIAN METHODOLOGY

Although Bayesian phylogenetic methodologies were first developed in the 1960s, the approach remained relatively obscure until the initial release of the software application, "MrBayes." Since that time, the popularity of Bayesian phylogenetics has increased tremendously, and it now must be considered a primary method of analysis on a par with maximum likelihood, parsimony and distance methods. The popularity of Bayesian



analysis can be attributed to computational efficiencies that allow for explicit model-based analyses of large data sets in real time with simultaneous estimation of nodal support in the form of posterior probability values.

Despite the initial enthusiasm generated by the availability of a fast likelihood-based approach, Bayesian phylogenetic analysis remains somewhat controversial. Much of the controversy is focused on two related issues: (1) the relationship between posterior probability values and nonparametric bootstrap proportions with the nagging suspicion that the posterior probabilities are too liberal, and (2) the influence of prior probabilities, especially so-called flat or uninformative priors. Although there has been a spate of simulation studies published during the past 2 years, most have focused on the relationship between posterior probabilities and bootstrap proportions. The relative impact of priors on posteriors has only recently received the detailed study that is required to determine if current Bayesian implementations are appropriate and, if not, how they might be corrected.

Bayesian phylogenetic analysis requires the designation of prior probabilities for each parameter in the analysis including those for alternative tree topologies, branch lengths and the nucleotide substitution model. In each case, we usually have little a priori information that would allow us to select an appropriate informative prior distribution, thus researchers generally attempt to accommodate their ignorance by applying uninformative priors. Because the posterior probability is proportional to the product of the prior probability and the likelihood, a truly uninformative prior should allow the likelihood function to drive the outcome of the analysis. Unfortunately, the designation of truly uninformative priors is notoriously difficult, and advocates proceed with the hope that the likelihood will overwhelm inappropriately informative priors when they cannot be avoided. The viability of Bayesian phylogenetics may depend on inferences being robust to these unavoidably informative priors.

The computation time required by bootstrapping limits its application so as an alternative, the much faster Bayesian inference of phylogeny, which expresses branch support as posterior probabilities, has been used. However, it has been observed that bootstrap support values, calculated under parsimony or maximum likelihood, tend to be lower than the posterior probabilities obtained by Bayesian inference even when the trees are clearly incorrect. This fact leads to a number of questions such as: Do posterior probabilities lead to overconfidence in the results? Are bootstrap values more robust than posterior probabilities? However, a bootstrap proportion is an index of repeatability, *not* of the accuracy of the results. A Bayesian posterior probability, conversely, is a direct probability statement that the results reached are true, given the data. Although both posterior probabilities and bootstrap supports are of great interest in phylogeny as potential upper and lower bounds of node

reliability, they are surely not interchangeable and cannot be directly compared.

E5: THE PROBLEM OF PRIORS

Bayesian estimation is unique among phylogenetic methods because, along with the usual assumptions about the evolutionary process that generated the observations, it forces the investigator to specify any prior beliefs. The necessity to specify a prior, however, is one of the more controversial pieces of Bayesian analysis. All parameters in the evolutionary model, including phylogeny, branch lengths and substitution model parameters, must be associated with prior probability distributions. But why is it necessary to specify prior beliefs? Doesn't the explicit incorporation of prior beliefs make all Bayesian probabilities subjective?

One can turn the first question around and ask, "Why should background knowledge be ignored?" It is not only sensible to base conclusions on all the available information (total evidence); in some cases, it is even critical. Assume, for instance, that you are asked to bet money on the relative probability, *P*, of turning up heads with a particular coin. You are only allowed to toss the coin twice, and it turns up heads both times. Maximum likelihood estimation based on these observations would give the estimated value $P = 1.0$. Of course, you cannot exclude the possibility that the coin is so heavily biased that it always turns up heads. However, the coin was taken from your wallet and it looks and feels just like a normal coin. If the coin were fair, there would still be a probability of 0.5 of turning up either heads or tails twice in two tosses. Given this information, it seems unlikely that the maximum likelihood estimate is close to the true value. In situations like this, the only sensible approach is to combine the information from your observations with the available background information, in this case suggesting that the true value of *P* is likely to be closer to 0.5 than to 1.0.

As more and more data are added to a Bayesian analysis, the influence of the prior beliefs on the posterior distribution decreases. In a typical Bayesian analysis of phylogeny, the results are likely to be rather insensitive to the prior. Even if it is unlikely to be a problem in most Bayesian analyses of phylogeny, the sensitivity to the chosen priors remains a legitimate concern. It is good practice to describe the priors of a Bayesian analysis carefully, particularly if they are nonstandard. If there is reason to believe that the data are weak, the influence of the priors on the posterior distribution can be examined by rerunning the analysis with different priors. A good way of illustrating the relative contributions of priors and data to the posterior probability distribution is to formulate the support for a particular hypothesis before and after analysis in terms of odds.

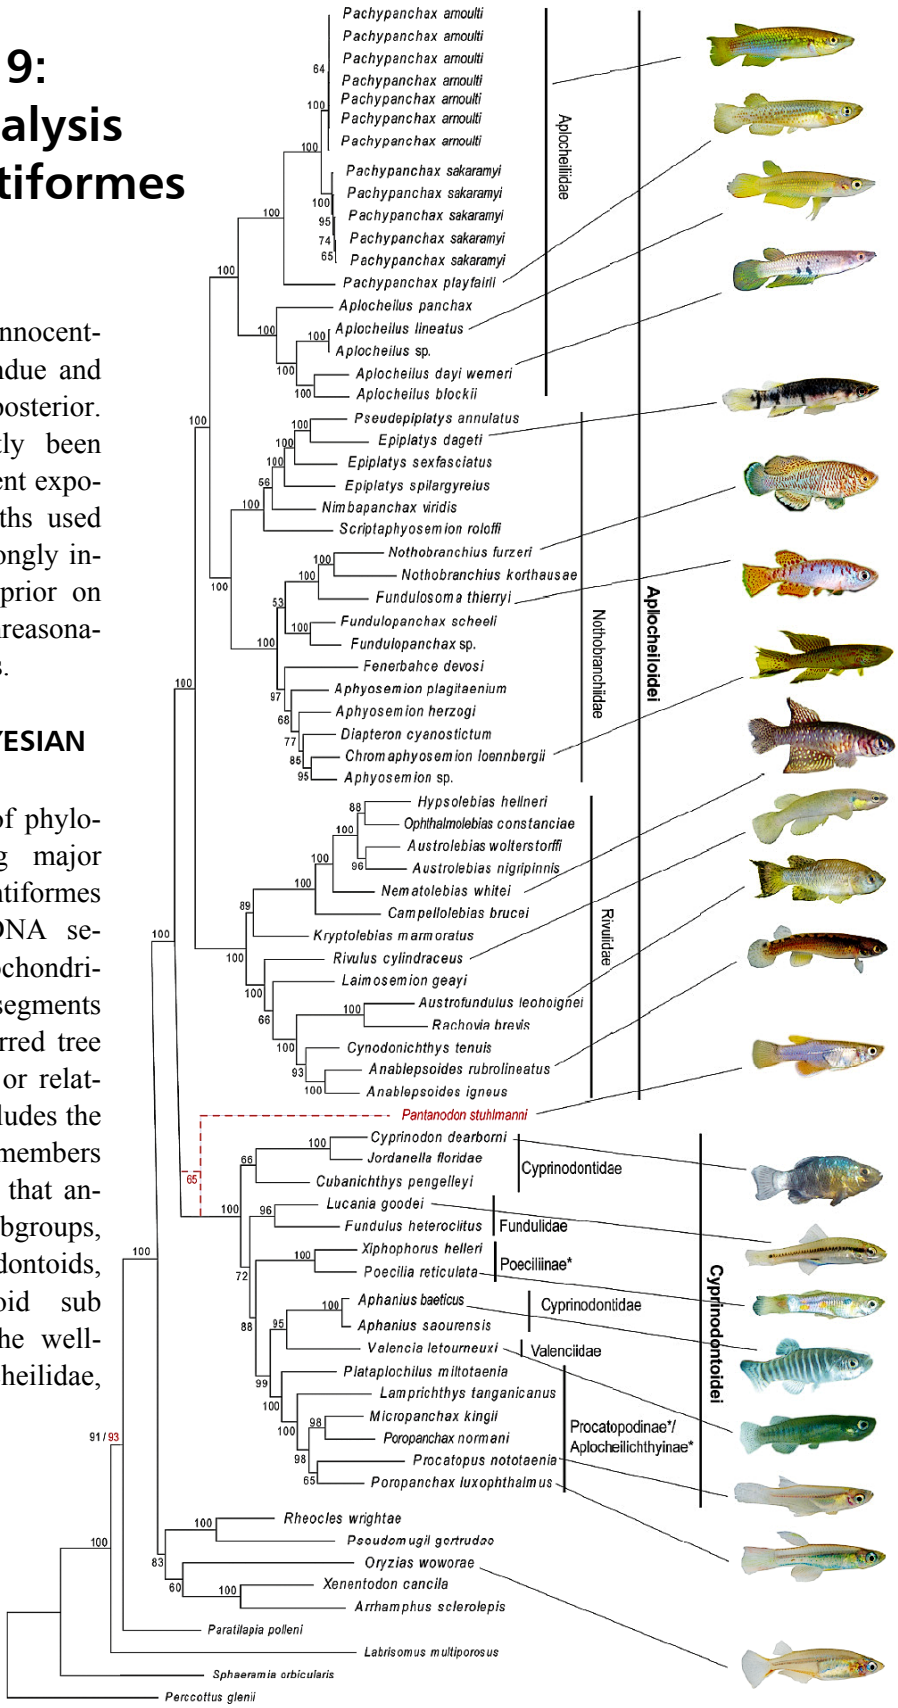
However, such information is rarely available, and specification of the prior is most often a burden on the user. Priors can be created using a number of methods. A prior can be determined from past information, such as previous experiments. A prior can be elicited from the purely subjective assessment of an experienced expert. An uninformative prior can be created to reflect a balance among outcomes when no information is available. Almost all data analyses are conducted using the "default" priors in the computer program. High-dimensional priors are notoriously

FIGURE 19: Bayesian Analysis of Cyprinodontiformes

hard to specify, and an innocent-looking prior can have an undue and unexpected influence on the posterior. For example, it has recently been pointed out that the independent exponential prior on branch lengths used by MrBayes can induce a strongly informative and unreasonable prior on the tree length, producing unreasonably long trees in some datasets.

E6: AN EXAMPLE OF BAYESIAN ANALYSIS

Figure 19 shows the results of phylogenetic relationships among major branches in the Cyprinodontiformes based on a concatenated DNA sequence alignment of two mitochondrial and three nuclear gene segments (Pohl, et al., 2015). The inferred tree supports monophyly (i.e., of or relating to a group of taxa that includes the common ancestor of all the members as well as all descendants of that ancestor) of the major subgroups, aplocheiloids and cyprinodontoids, and of several aplocheiloid sub branches corresponding to the well-established families Aplocheilidae,



Nothobranchiidae and Rivulidae, each of which is restricted to the major continental settings, India-Madagascar, Africa and South America. Contrary to previous molecular studies, this research supported a sister-group relationship of the aplocheilids and nothobranchiids, rather than a nothobranchiid-rivulid branch. Within cyprinodontoids, the phylogeny matched more closely continent-scale distribution than current classifications, suggesting that the definitions of the families Cyprinodontidae, Poeciliidae and Valenciidae are in need of revision. The East African *Pantanodon stuhlmanni* did not show close relationships with any other taxon in their analysis, suggesting that the phylogenetic position and classification of this rogue taxon is in need of further study.

F1: CONCLUSIONS

Using the principle of parsimony as a tool relating to the theory of knowledge (especially with regard to its methods, validity and scope) and the distinction between justified belief and opinion, ensures that we have the most robust empirical result given the data; adopting the most parsimonious summary of the data with respect to outgroup comparisons ensures that the most robust result can be interpreted phylogenetically.

Likewise, fitting data to a model provides explanations, but only if the model is known or assumed to be true. That is, there is no means by which model-based methods can test the veracity of any given model or its assumptions. Researchers generally choose a model for a given set of data based only on an ad hoc preference for simplicity in showing the relations between the concepts and categories in a subject area (this is known as ontological parsimony).

As more data are added to the study, however, frequency methods such as Maximum Likelihood and Bayesian analysis generally move more quickly to the most complex model. The principle of maximum entropy in Bayesian theory provides a rationale for choosing the most complex model, rather than simplest, for explaining a complex system by reasoning that adopting the most complex model among all those that explained a system completely would expose our ignorance of possibilities, while adopting the simplest would give us a false sense of security, leading us to think we had more complete knowledge than we had.

If all three methods produce identical results (and frequently this is the case), there is no way, or even reason, to choose between them. Conflicting results in part of the tree highlight peculiarities in the data set (e.g., long branch attraction, rapid diversification, heterogeneity, etc.). In this situation, the choice of method depends upon the resistance of each method to the particular vagaries of the data. Parsimony analysis is the best *discovery* method we have in phylogenetics because its results are dependent on a minimum of *a priori* assumptions and thus the range of potential discoveries indicated by the data is greater than for any other approach. In a complementary manner, the maximum likelihood and Bayesian approaches are admirably suited as *evaluation* methods, methods allowing us to investigate the processes potentially underlying phylogenetic patterns. The most complete explanation for phylogeny is thus the one that incorporates information from both parsimony and frequency approaches.

However, there are no objective means by which one can choose among these methods. Consequently, it is no surprise that some of the most contentious interactions among phylogeneticists concern the very subjective issue of which methods are "best" or "proper" or "correct." It is common for groups of contending scientists, faced with such a situation, to resort to philosophical arguments in an attempt to claim priority for one viewpoint over another on the basis of some set of first principles. This has certainly been the case with phylogenetics.

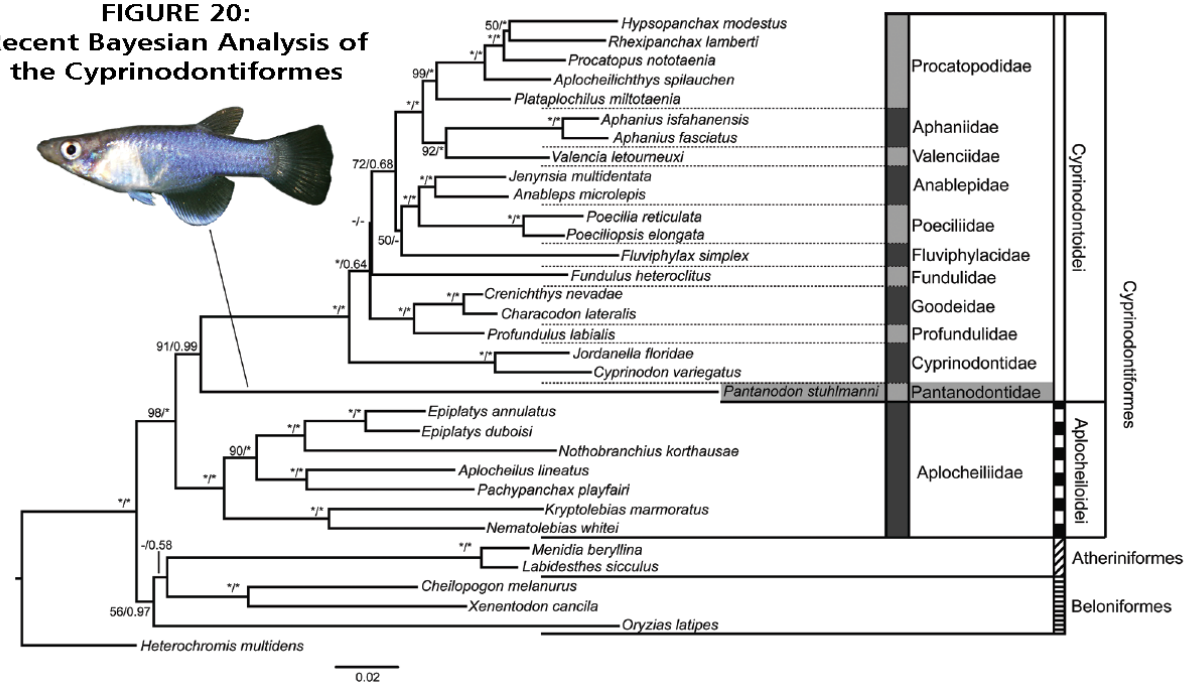
While it is often true that disputes among scientists are the engines of innovation and development, they can also have the opposite effect. There is no

doubt that quantitative phylogenetic analysis has revolutionized evolutionary studies and has had significant impacts in many areas of biology, both basic and applied. Much of the academic infighting associated with the development and deployment of different methods for phylogenetic analysis, however, has obscured the real progress that has been made in reconstructing the phylogenetic history of life. This, in turn, has undermined efforts by systematists to gain proper credit for their role in making possible the explosion of comparative evolutionary biology during the past 30 years and, more recently in dealing with the global biodiversity crisis.

With the rapid advance of phylogenetic techniques that use molecular data, aquarists should be prepared that the classifications they are currently using will be changing fast also. In Section E6 I described a 2015 classification of the Cyprinodontiforms that concluded that a number of families needed revision and that the relationship of the East African *Pantanodon stuhlmanni* within the order essentially was a mystery. *Pantanodon*, containing two African extant species and four European fossil species, for a long time had an uncertain position among the Cyprinodontiformes due to its peculiar morphology. In the last decades, *Pantanodon* has been considered closely related to African lampeyes of the Procatopodinae, which is contained in the Poeciliidae, a teleost fish family with a broad geographical distribution in Africa and the Americas.

In a very recent paper (Braganza, et al., 2018), using both maximum likelihood and Bayesian methods (which essentially produced the same results) the researchers analyzed one mitochondrial and five nuclear loci for 27 cyprinodontiform taxa and 6 outgroups, and obtained a well-supported phylogeny, except for Poeciliidae where the monophyly as previously supported by morphological data was refuted (Figure 20). *Pantanodon stuhlmanni*, the type species of the genus, was identified as the most basal cyprinodontoid lineage, and other African taxa formerly placed in Poeciliidae were found to be more closely related to European non-poeciliid cyprinodontoid genera than to other taxa (numbers on each node are bootstrap percentages of the Maximum Likelihood analysis and posterior probabilities of the Bayesian analysis; asterisks indicate maximum values, 100 or 1.00 respectively, and a dash refers to values under 50 or 0.50 respectively.

FIGURE 20:
Recent Bayesian Analysis of the Cyprinodontiformes



Since this tree topology was not compatible with the present classification of the suborder Cyprinodontoidei, a new classification using available family group names was provided: Pantanodontidae is used for *Pantanodon*; Procatopodidae, for the African lampeye branch; and Fluviphylacidae, for the South American genus *Fluviphylax*. Poeciliidae is now restricted to the American livebearers, hence restoring the classification generally used prior to 1981.

"But to us, probability is the very guide of life." *(Bishop Joseph Butler, 1692-1752)*

The Case That Changed the World of Plants

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, October 27, 2018)

PART I: THE WARDIAN CASE

The simple Wardian case - it was nothing more than a box with a tight seal of a glass cover - was the direct forerunner of the modern terrarium and the inspiration for the glass aquarium. It also found great use in the 19th century in protecting foreign plants imported to Europe from overseas, the great majority of which had previously died from exposure during long sea journeys, frustrating the many scientific and amateur botanists of the time. The Wardian case was the accidental discovery of Dr. Nathaniel Bagshaw Ward (1791–1868) of London. In the summer of 1829 Ward had buried the chrysalis of a sphinx in some moist mold contained in a wide-mouthed glass bottle and covered with a lid. In watching the bottle from day to day he observed that the moisture that, during the heat of the day, arose from the mold, condensed on the surface of the glass, and returned whence it came, thus keeping the earth always in the same degree of humidity. About a week prior to the final change of the insect, a fern seedling and a grass made their appearance on the surface of the mold. some grass had sprouted. The fern was more important than the insect since for years Ward was unsuccessful in his attempt to propagate ferns in his Wellclose Square home in East London. The sooty, dark and polluted conditions were not ideal for growing ferns and the idea of growing them and other plants in closely glazed cases was a solution.

Figure 1:
Dr. Nathaniel Bagshaw Ward (1791-1868).

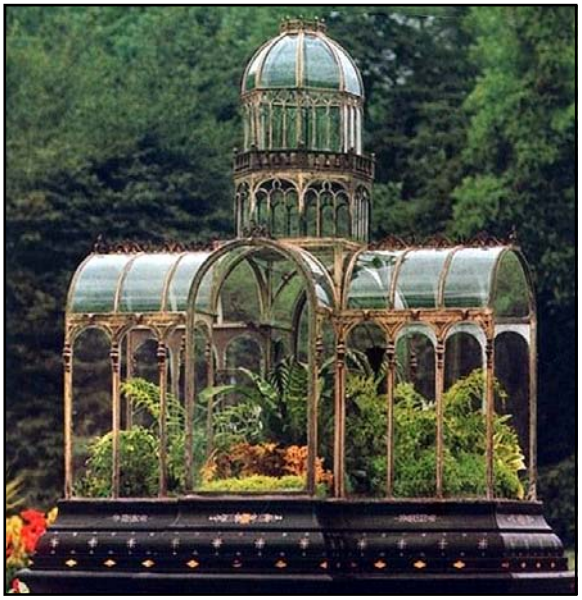

Figure 2: A Wardian case, modeled after the Tintern Abbey.

In 1834 he wrote an article for a gardening magazine titled “On growing ferns and other plants in glass cases, in the midst of the smoke of London and on transplanting plants from one country to another by similar means,” in 1836 the Director of the Kew Gardens wrote an account in a botanical magazine on the subject of Ward’s improved method of transporting living plants, and in 1842 Ward published a book titled *On the Growth of Plants in Closely Glazed Cases*. After experimenting with hundreds of ferns and obtaining success with his cases, he built a small house about eight feet

square outside of one of his staircase-windows facing the north and, proceeding from ferns to those plants with which they were associated, filled it with a mixed vegetation. This was his "The Tintern Abbey House" (The abbey fell into ruins after the "Dissolution of Monasteries" in the 16th century but its remains have been celebrated in poetry and painting from the 18th century onwards) and was followed by The Alpine Case, The Drawing-room Case, Crocuses and Winter Aconites Case, Crocuses with Artificial Light, Case, Case with Spring Flowers, Fairy Roses Case and the Aquarium for Fish and Plants. In his 1842 book, Ward described the last-named as follows:

Aquarium for fish and plants.—I commenced my experiments on fish and plants about ten years ago, in a large earthen vessel, given to me for the purpose by my friend Mr. Alfred White. This vessel contained twenty gallons of water, and in it I placed ten or twelve gold and silver fish, in company with several aquatic plants, viz. *Valisneria spiralis, Pontederia crassipes, Papyrus elegans*, and *Pistia Stratiotes*, which plants, by means of their vital actions, as had long been well known, maintained the purity of the water, and, as in the atmosphere, kept up the balance between the animal and vegetable respirations. Placed in the centre of my fernhouse and nearly surrounded by rock work (rising five or six feet above the margin of the vessel, clothed with *Adiantum* and other lovely ferns, and partially overshadowed with the palmate leaves of *Corypha australis*, the plants and fish continued to flourish for years, prior to their removal to Clapham in 1848. The only enemy I had to contend with was a species of *Vaucheria*, which, from its rapid growth, required to be kept constantly in check. My friend, Mr. Bowerbank, always alive to scientific inquiries, followed up these experiments with equal success, but substituted stickle-backs and minnows for the gold fish. (Mr. Warington, who subsequently experimented upon the same subject, states that he found it necessary to introduce a few snails - *Limeus stagnalis* - to get rid of a slime produced by the decaying leaves of *Valisneria spiralis*.)

It should be noted that it was this jar of Bowerbank's that attracted the attention of the Secretary of the Zoological Society, David Mitchell, and gave him the idea for the public aquarium that was opened in 1853 in the Zoological Gardens in Regent's Park. It also should be noted that the "aquarium" mentioned here by Ward was not the "aquarist's aquarium" but the "gardener's aquarium" dating back to Linnaeus in 1748, which was simply a pond, basin or cistern of water for the growth of water plants. Ward was not the first to consider the addition of fish to the gardener's aquarium. This was first suggested by John Loudon in 1824 in his 1,311 page Encyclopaedia of Gardening in which he showed several exam-

Figure 3: Ward's cases (lower right in this illustration) appeared in the Crystal Palace Great Exhibition of 1851.

ples of the more ornate aquaria and suggested that fish might be added to them (see Klee, 2014).

ALLAN ALEXANDER MACONOCHIE

Professor Allan Alexander Maconochie of Meadowbank and Garvock in Scotland was born in 1806 the eldest son of Alexander Maconochie, 2nd Lord Meadowbank. His grandfather was the 1st Lord Meadowbank, having received the title as a member of The Senators of the College of Justice. The College is a set of legal institutions involved in the administration of justice in Scotland. Senators of the College use the title Lord or Lady, along with a surname or a territorial name. *Meadowbank* is a suburb of Edinburgh and Garvock is about 10 miles northwest of Edinburgh.

Maconochie qualified as an advocate in 1829 and in legal documents he was referred to as A. A. Maconochie.. Advocates in Scotland are comparable to barristers in England and Wales; they work as independent lawyers offering advice about legal cases to clients and conducting defense and prosecution work within courts.

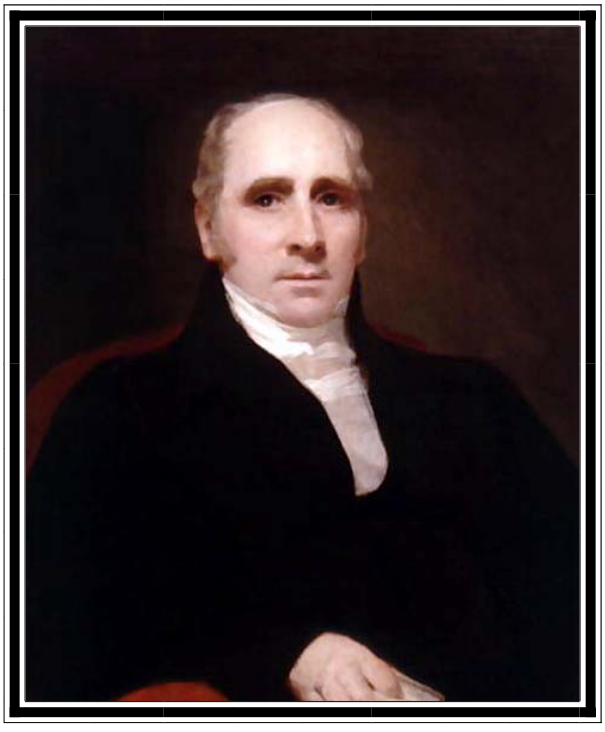

Figure 4: Thomas Charles Hope (1766-1844).

In 1840 he was elected a Fellow of the Royal Society of Edinburgh, his proposer being Thomas Charles Hope. Thomas Charles Hope (1766-1844) was a Scottish physician, chemist and lecturer at the University of Edinburgh. He proved the existence of the element strontium and gave his name to "Hope's Experiment," which shows that water reaches its maximum density at 4 °C (39 °F). Charles Darwin was one of Hope's students, and Darwin viewed his chemistry lectures as highlights in his otherwise largely dull education at the University. For Maconochie to be nominated by Hope to the Royal Society of Edinburgh was quite an honor.

From 1829 until his appointment as professor of Roman and Scots law at Glasgow University in 1842, "He was an enthusiastic professor, who took much interest in his students and endeavoured to assist them in other ways than by lectures," according to a memoir about the school published in 1927. In 1855 he received an honorary doctorate (LLD) from Glasgow University. Succeeding his father to the family estates in 1861, he became Allan Alexander Maconochie-Welwood, 3rd Lord Meadowbank, adopting the name after his grandmother, Elizabeth Welwood of Garvock. Maconochie died on 29 May 1885.

THE AMATEUR BOTANIST

Besides bring an advocate, Maconochie was an accomplished amateur botanist. It was while he was considering the experiments of Nicolas-Théodore de Saussure (1767-1845), a Swiss chemist and student of plant physiology who made seminal advances in phytochemistry and was one of the major pioneers in the study of the respiration of plants, together with Alexander von Humboldt's observations on a plant of *Fucus vitifolius* found growing and preserving its usual color at an immense depth in the ocean where the light must have been less than a hundredth part of that afforded by a common candle viewed from the distance of a quarter of a mile, that the idea struck him that plants, whose habitats afforded

them decomposed light only, might, if supplied with soil and moisture, vegetate in a confined atmosphere and in a light more or less decomposed by the refraction of two surfaces of window glass.

It should be mentioned that simply living in Glasgow was damaging to health. The 1830s witnessed major cholera outbreaks in the city as elsewhere, affecting rich and poor alike. Air quality was bad due to industrial pollution and coal fires, which is why the middle classes migrated up-wind to the West End.

Around 1825 Maconochie experimented with exotic ferns and clubmosses obtained from the Glasgow Botanic Gardens, which he planted out in peat in a goldfish bowl. The success of this first experiment induced him to get a glazed case, or " Miniature Greenhouse," made by a country carpenter. Of the plants that he found to grow most luxuriantly in its confinement, none surpassed *Hoya carnosa* (the porcelainflower or wax plant), the whole tribe of *Cypripediums* (orchids), *Trilliums* (part of the lily order), nearly all Ferns and *Lycopodiums*, several *Euphorbias* (a group of which the poinsettia is a member) and the *Melocacti* (the melon cacti).

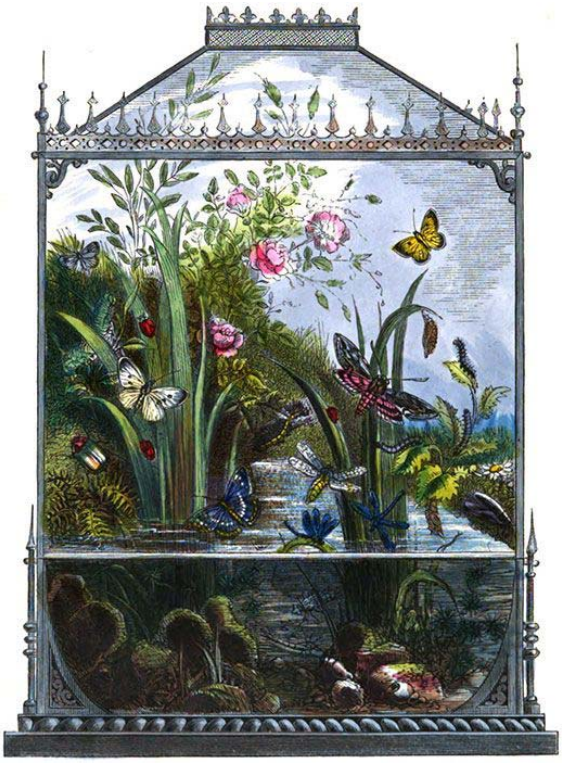

Figure 5: A Wardian case, combination terrarium and aquarium.

Thus, Maconochie was truly the inventor of the so-called "Wardian case." Based upon the botanical research of de Saussure and Humboldt, he designed and had built what Ward accidentally discovered four years later.

To his credit, Ward never patented a design for his case. He held the benevolent view that his cases could be of benefit to many, not just scientists and nurserymen. In 1845. Ward wrote in a letter to the Harvard botanist Asa Gray:

"My closed cases are gradually extending amongst all classes of the community, and have been recommended in an official report to Government by the "Health of Towns Commission" as a means of improving the condition of the labouring poor." It was a technology that he promoted through his many networks both at home and abroad.

WARD'S REACTION TO MACONOCHIE'S PAPER OF 1840

In 1840 Maconochie published a paper in the *Annual Report and Proceedings of the Botanical Society of Edinburgh*, "On the Use of Glass Cases for Rearing Plants Similar to those Recommended by N.B. Ward. Esq." In this paper he described his experiences with the Wardian case he had built in 1825, which was some four years earlier than Ward's discovery in 1829. Ward, normally a positive and encouraging man, was quite affronted by Maconochie's claims to the invention and in 1840 after the publication of Maconochie's article he wrote a letter written to William Jackson Hooker (1785-1865), the Director of Kew Gardens at the time, in which he described the claims as "one of the most barefaced falsehoods ever uttered." This was, of course, both intemperate and without any evidence.

In his paper Maconochie stated that, although it was well known to many of his personal friends

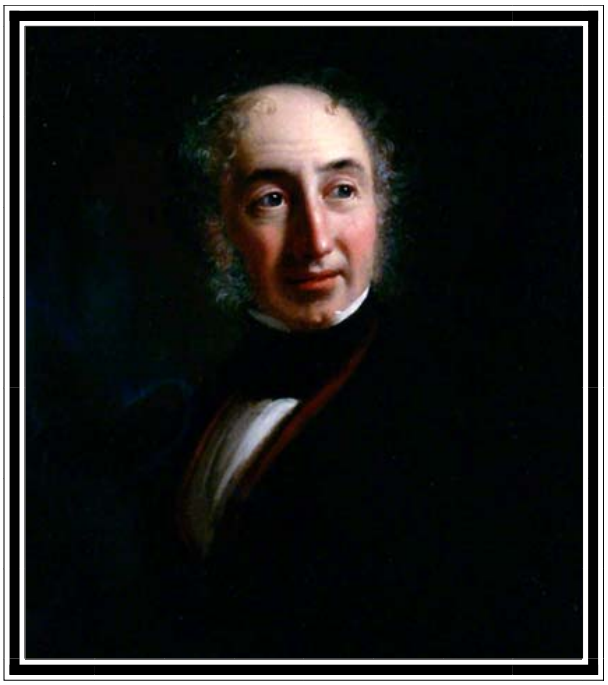

Figure 6: William Jackson Hooker (1785-1865), Director of the Kew Gardens.

and acquaintances that he had had a glass case very similar to those employed by Ward for more than fourteen years, still **"he had no wish to detract from Ward the merit of also having made the discovery, or that of having first made it known to the public."** Under the circumstances, Maconochie was magnanimous in this respect.

Although Ward knew nothing about Maconochie, Hooker certainly did. In 1820 he accepted the Regius professorship of botany in the University of Glasgow, a position he held until 1841, and where he soon became popular as a lecturer. He worked with the Glasgow botanist and lithographer Thomas Hopkirk to establish the Royal Botanic Institution of Glasgow and to lay out and develop the Glasgow Botanic Gardens. Ward's tantrum was not known to outsiders and I suspect that it was Hooker who quieted him down. Hooker was in a position to describe Maconochie's status in Scotland and point out that Macononochie's achievements with his case was well known to many of his personal friends and acquaintances. If Ward made his views public, he would involve himself in a battle royal, much to his detriment. Consequently, nothing ever was made public about Ward's feelings and following this incident Ward's name was forever connected in the naming of the case.

PHOTOGRAPHIC CHEMISTRY

Among his many other interests was chemistry. By May 1839 Maconochie was able to show photogenic drawings, negatives and positives, of contact prints of botanical specimens to his friends Sir Walter Calverley Trevelyan (1797-1879), an English naturalist and also a fellow of the Royal Society of Edinburgh), and his wife, Lady Pauline Trevelyan. Writing to Sir Walter on January 7, 1843, Maconochie advised that he had "made great strides in the Photographic art" the previous summer, always striving to shorten the exposure time to better capture action. Working in the weak Glasgow sunlight of the dead of winter, he eventually managed to reduce the exposure times for his calotype negatives to as little as seventeen seconds.

Figure 7: Sir Walter Calverley Trevelyan (1797-1879), an English naturalist and also a fellow of the Royal Society of Edinburgh).

Maconochie attended the first meeting of the Photographic Society in London in 1853, showing instantaneous photographs taken on glass. No one knew him, but as the *British Journal of Photography* recalled some years later, the images "were at once recognised as wonderful; and it seemed as if the producer of them had dropped from the clouds he so faithfully depicted." The following is from the *British Journal of Photography*, July 15, 1861:

One of the first to show pictures so rapidly taken as to give an image of objects in motion was, I think, Professor Maconachie, then of Glasgow. He showed some pictures at the first meeting of the London Photographic Society. They were at once recognised as wonderful; and it seemed as if the producer of them had dropped from the clouds he so faithfully depicted. When the meeting was over, nobody knew who he was or where he could he found. Somebody said they thought he was a Scotchman—probably hazarding that opinion in consequence of one of the pictures shown being a view at Granton, near Edinburgh. By-and-by the Scotch gentleman took a more definite shape in the Society's Journal, in a letter to the Secretary (Mr. R. Fenton). Mr. Wellwood Maconachie detailed in this letter the preparations he used in taking the pictures which had commanded so much approbation. He recommended a stable normal collodion, iodised in the usual way, to which he added iodide of iron when about to operate. That was the peculiarity in his process. Iodide of iron had been used before in photography, and it was known to give great sensibility. Since then no one who has written on the means of producing pictures rapidly has proposed the addition of any new or before-unused substance in the collodion.

Figure 8: Roger Fenton (1819-1869), a British photographer noted as one of the first war photographers.

Maconochie began a correspondence with Roger Fenton (1819-1869), a British photographer noted as one of the first war photographers, in which he analyzed the properties of collodion and suggested ways to make it more stable. He was particularly excited by the shortened exposures he was able to achieve. Obviously impressed, Fenton published extracts of Maconochie's letters in the *Journal of the Photographic Society*, which led the firm of W. E. & F. Newton to write to the journal in August 1853 about a "Method of Deepening Negatives," which had been communicated to them by the professor **"some time since."** By allowing the correction of problems caused by too short an exposure, Maconochie's method helped make it possible to obtain instantaneous photographs, and it seems unlikely that he ever returned to the slower paper negative. A remarkable man was this 3rd Lord Meadowbank!

PART II: THE EVOLUTION OF THE WARDIAN SHIPPING CASE

There are two types of Wardian cases, each developed to solve different problems. The oldest involved transporting live plants on ships and the newest with protecting household plants from the noxious fumes of the air in polluted cities such as

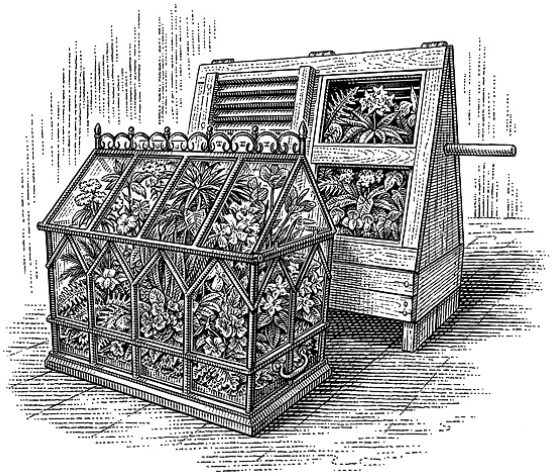

Figure 9: The two types of Wardian cases. Front, Indoor case; Back, Shipping case.

mid-nineteenth century London. Since the Wardian cases used in the Nineteenth century for growing plants indoors are well known to aquarists, I will concentrate on the types used to transport plants on the old sailing ships of the Eighteenth and Nineteenth centuries. The Wardian case is part of a long history of using boxes to move live plants that could be transported as seed. However, at times it was simply better to send seedlings as they could be quickly planted out on a plantation.

THE JOHN ELLIS CASE

John Ellis (circa 1710-1776) was a linen merchant and naturalist who studied coral and also imported seeds and plants. He corresponded with other naturalists and was a member of the royal societies of both London and Uppsala. Ellis worked as an agent in west Florida and Dominica and had the opportunity to collect specimens such as Venus flytrap, which he named *Dionaea muscipula.* He sent a description of Venus flytrap in a letter to "Sir Charles Linnaeus," dated 23 September , with an illustration and a specimen, and began: "My dear Friend, I know that every discovery in nature is a treat to you; but in this you will have a feast." His letter to Linnaeus about this newly found species was also published in Uppsala and Erlangen.

In a book published in 1770, he discussed techniques for transporting plants and "included a catalogue of exotic plants that might be successfully and usefully grown in the American colonies." His use of the term "West-Indies" in his book refers to a region of the North Atlantic Ocean in the Caribbean that included the island countries and surrounding waters of three major archipelagos: the Greater Antilles, the Lesser Antilles and the Lucayan Archipelago (Bahamas). The following is an excerpt (and see Figure 10):

To this I must add a method that promises success for bringing over plants from the West-Indies, and the southern parts of North-America, particularly West-Florida, the voyage from hence being longer than from the West-Indies, and more attention is required to keep the plants in health, than from any other parts of our North-American settlements: but as there is a good deal of difference in the climates of these places, it will be necessary to observe that plants from the West-Indies should be put on board in the latter-end of Spring so as to arrive here in warm weather, otherwise they will be destroyed by the cold of this latitude; and the ever-greens, which are the most curious from West-Florida, must be sent in the winter months while their juices are inactive, so as to arrive here before the heats come on. If the plants sent from these countries were planted in pots or boxes, and kept there a year, they might be brought over with very little hazard; or even if they were first transplanted from the woods into a garden, till they had formed roots, they might be sent with much more safety.

The size of the boxes that will be most convenient for stowing them on board merchantships, where there is very little room to spare, should be three feet long, fifteen inches broad, and from eighteen inches to two feet deep, according to the size of the young trees; but the smallest will be most likely to succeed, provided they are well rooted. There must be a narrow ledge nailed all round the inside of the box, within six inches of the bottom, to fasten laths or packthread to form a kind of latticework by which the plants may be the better

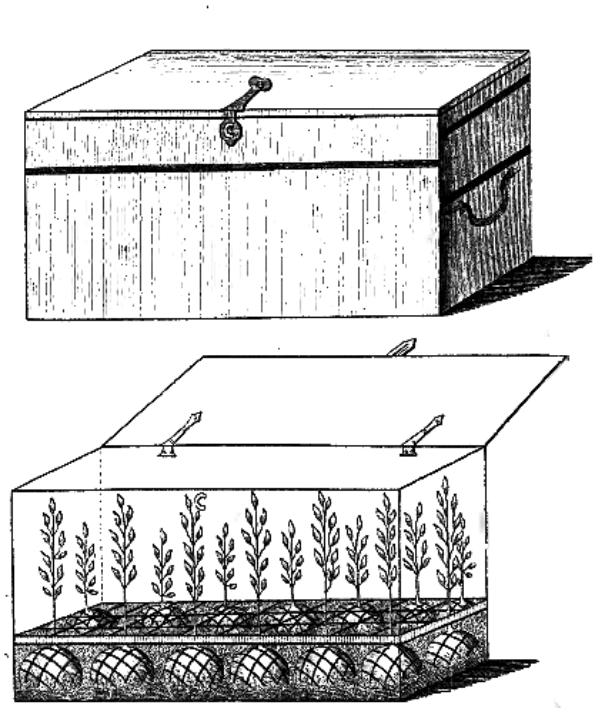

Figure 10: John Ellis' shipping case.

secured in their places. If the plants are packed up just before the ship sails, it will be so much the better.

When they are dug up, care must be taken to preserve as much earth as can be about their roots, and if it should fall off it must be supplied with more earth so as to form a ball about the roots of each plant, which must be surrounded with wet moss, and carefully tied about with packthread to keep the earth about the roots moist: perhaps it may be necessary to enclose the moss with some paper or broad leaves (as the palmetto) that the packthread may bind the moss the closer. Loamy earth will continue moist the longest. There must be three inches deep of wet moss put into the bottom of the box, and the young trees placed in rows upright close to each other, stuffing wet moss in the vacancies between them and on the surface; over this, palmetto leaves, if to be had, should be put to keep in the moisture, and over them the laths are to be fastened cross and cross to the ledges or pack-thread to be laced to and fro, to keep the whole steady and tight.

The lid of the box should be either nailed down close, or may have hinges and a padlock to secure it from being opened, as may be found necessary, with proper directions marked on it to keep the lid uppermost. There must be two handles fixed, one at each end, by which means there will be less danger of disturbing the plants. Near the upper part of the ends of the box, there must be several holes bored to give air: or in making the box there may be a narrow vacancy left between the boards of one-third of an inch wide, near the top, to let out the foul air (this is the method shown by the dark bands on the front and sides in Figure 10**); and perhaps it may be necessary to nail along the upper edge of these openings list, or slips of sail-cloth, to hang over them, to secure the plants from any spray of the sea; and at the same time it will not prevent the air from passing through. Boxes with plants packed in this manner, must be placed where there is free air, that is, out of the way of the foul air of the ship's hold.**

THE JOHN COAKLEY LETTSOM CASE

John Coakley Lettsom (1744-1815) was an English physician and philanthropist. He was born on Little Jost Van Dyke in the British Virgin Islands, into one of the early Quaker settlements in the territory. A Fellow of the Royal Society and the Linnaean Society, and a close friend of Benjamin Franklin, he used his private fortune and considerable medical income to support philanthropic ventures as well as a museum, library, and botanical garden on his estate of Grove Hill in Camberwell. In the diversity of his interests, as physician, philanthropist, botanist, mineralogist and collector, he had few equals.

In 1783, Lettsom published his *Hortus Uptonensis* in which appeared his "Directions for bringing over seeds and plants from distant countries." Although most of Lettsom's directions are identical to Ellis's, Lettsom does add some innovations (Figure 12). Lettsom's plant transportation box is slightly larger than Ellis's and includes hoops over the top of the box so that canvas can be draped over the

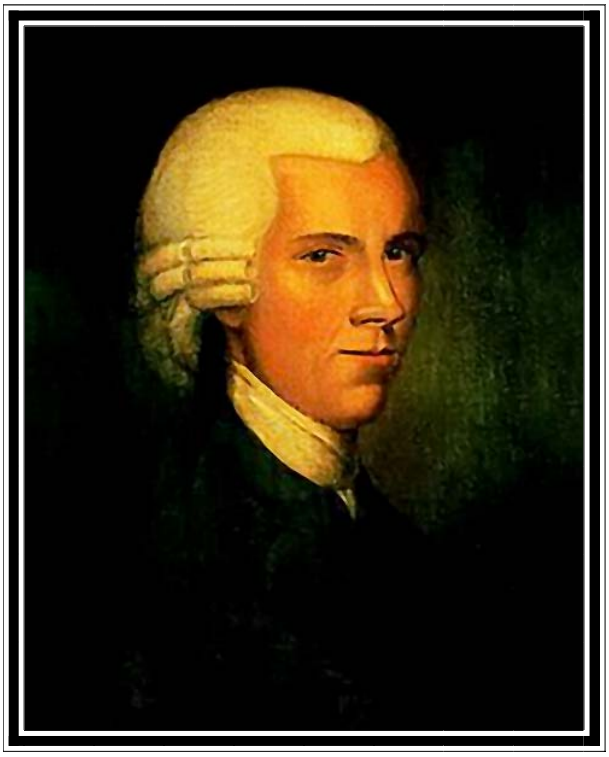

Figure 11:
John Coakley Lettsome (1744–1815).

plants on windy days when there is too much salt spray in the air. Both Lettsom and Ellis encourage trial and error to arrive at the right procedures for planting and growing vegetation aboard ships. Plants often arrived in England dead or in poor condition. During the eighteenth century, Kew gardens had special hothouse areas reserved for nursing sickly plants back to health after long sea voyages.

THE MAURITIUS CASE

John Lindley **(**1799-1865) was an English botanist, gardener and orchidologist. Lindley was appointed assistant secretary to the Royal Horticultural Society (the Horticultural Society of London became the Royal Horticultural Society at a later date) and its new garden at Chiswick in 1822, where he supervised the collection of plants. In 1829 Lindley was appointed to the chair of botany at University College, London, which he retained until 1860. He also lectured on botany from 1831 at the Royal Institution, including delivering the 1833 Royal Institution Christmas Lecture, and from 1836 at the Chelsea Physic Garden, starting the society's flower show in the late 1830s. John Claudius Loudon sought Lindley's collaboration on his Encyclopedia of Plants, which covered nearly fifteen thousand species of flowering plants and ferns. It was a massive undertaking and Lindley was responsible for most of it.

In a 1824 article written by Lindley in the *Transactions of the Horticultural Society of London* titled "Instructions for Packing living Plants in Foreign

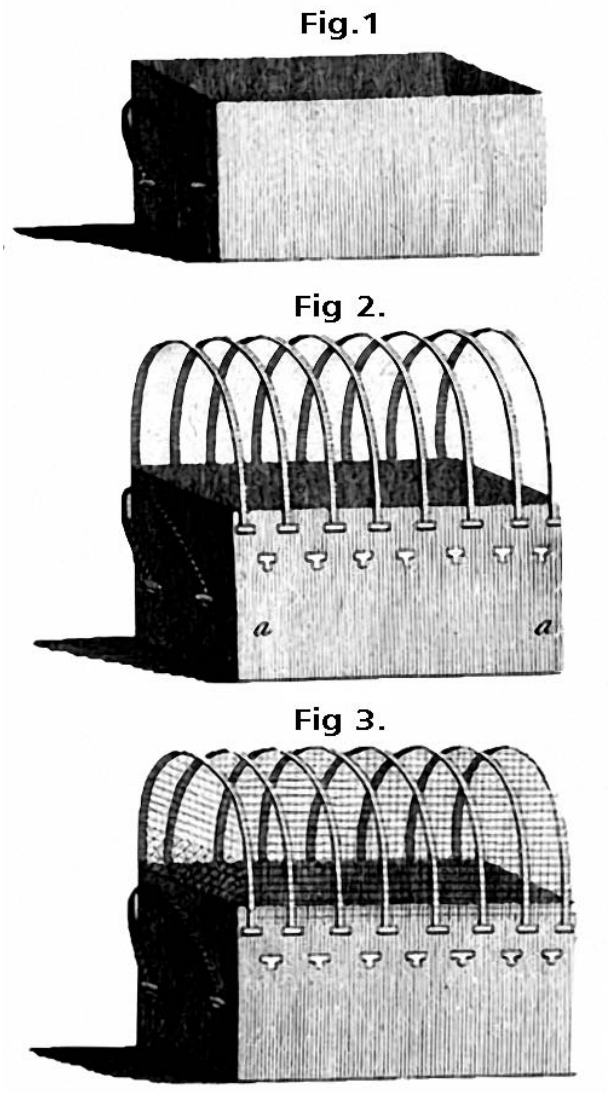

Figure 12: The Lettsom case. Top, The form of the box; Middle, the same with hoops and loops, a a, for securing the canvas; bottom, The same netted.

Countries, especially within the Tropics; and Directions for their Treatment during the Voyage to Europe," Lindley wrote:

Among the cases received by the Society this year from its numerous contributors, were four transmitted by his Excellency Sir Robert Farquhar, from the Mauritius (now an island country located 1,200 miles off the southeast coast of Africa)**. They were a kind of portable green-house, constructed in a very superior manner to any I have seen elsewhere. It is therefore presumed that an accurate plan and description of them, with such slight alterations as have appeared to be requisite, cannot be otherwise than acceptable. The plants they contained arrived in this country in much better condition than any received by the Society in the same year.**

The following is the description of the cases used, the references being to the figures in Figure14:

They were made of stout inch board well fastened together. Their height was three feet, length four feet, breadth one foot eight inches (Fig. 1). Twenty inches from the bottom they sloped off like a penthouse till the top was not more than two inches and a half wide. The sloping part on each side was closed by a shutter (Fig. 1. a. a.) formed of wooden bars two inches wide and two inches asunder, connected by a cross-rail at their ends. To the inside of these, panes of stout coarse glass were fixed by means of narrow slips of tin fastened to the centre of the bars where necessary, and well puttied in. (Fig. 3. a. a.) The shutters were moveable by means of hinges on their lower side, and in fine weather were kept open by hooks (Fig. 2. a. a.) fixed within three or four inches of the top into each side of the end of the boxes, and fitting into a staple in the corresponding edge of the shutter ; they were long enough to sustain the shutter, when open, in a perpendicular position (Fig. 2. b.) The shutters fell down so as to close the boxes completely in rough weather, and were kept together by two hooks fixed in the upper edge of one shutter, and catching into a corresponding staple in the opposite shutter. (Fig. 4.) A piece of tarpawling (Fig. 1. b. b.) was nailed to the top of the boxes, and in rough weather was unrolled and fell down over the sides, so as to protect them from the sea spray. In fine weather, when the shutter was opened, it was rolled up again, and tied together with two pieces of cord so as not to interfere with the shutters opening and closing. The trees were planted in square wooden boxes, just large enough to contain a single plant, and perforated with holes in their sides and bottom. (Fig. 5. a. a.).

I would recommend that square wooden boxes be used for the plants instead of earthenware pots, not only because the former are less liable to be broken, but also because they are lighter. When the period for embarking them arrives, they should be placed in wooden cases, the tops of which must be capable of being opened, and should slope both ways like the roof of a double green-house. These cases

Figure 13: John Lindley (1799-1865).

must be furnished with a tarpawling, fixed along their tops, and sufficiently large, when unrolled, to cover them completely, so as to protect the plants from being damaged by the salt water dashing over them in rough weather.

It cannot be expected that heavy cases should meet with very gentle treatment on shipboard, and it is certain they will be handled in the roughest manner by watermen, carters, and custom-house officers, after they have arrived in port. The materials, therefore, of which they are made, ought be of a very strong description, and the joints of the lower part either secured by iron bands, or well dove-tailed together ; but as the former method is attended with less trouble, and is equally secure, it will probably be the more generally adopted. Instances are not uncommon of fine collections being delivered from the custom-house with the sides of the cases beaten in, and the plants and pots broken in pieces.

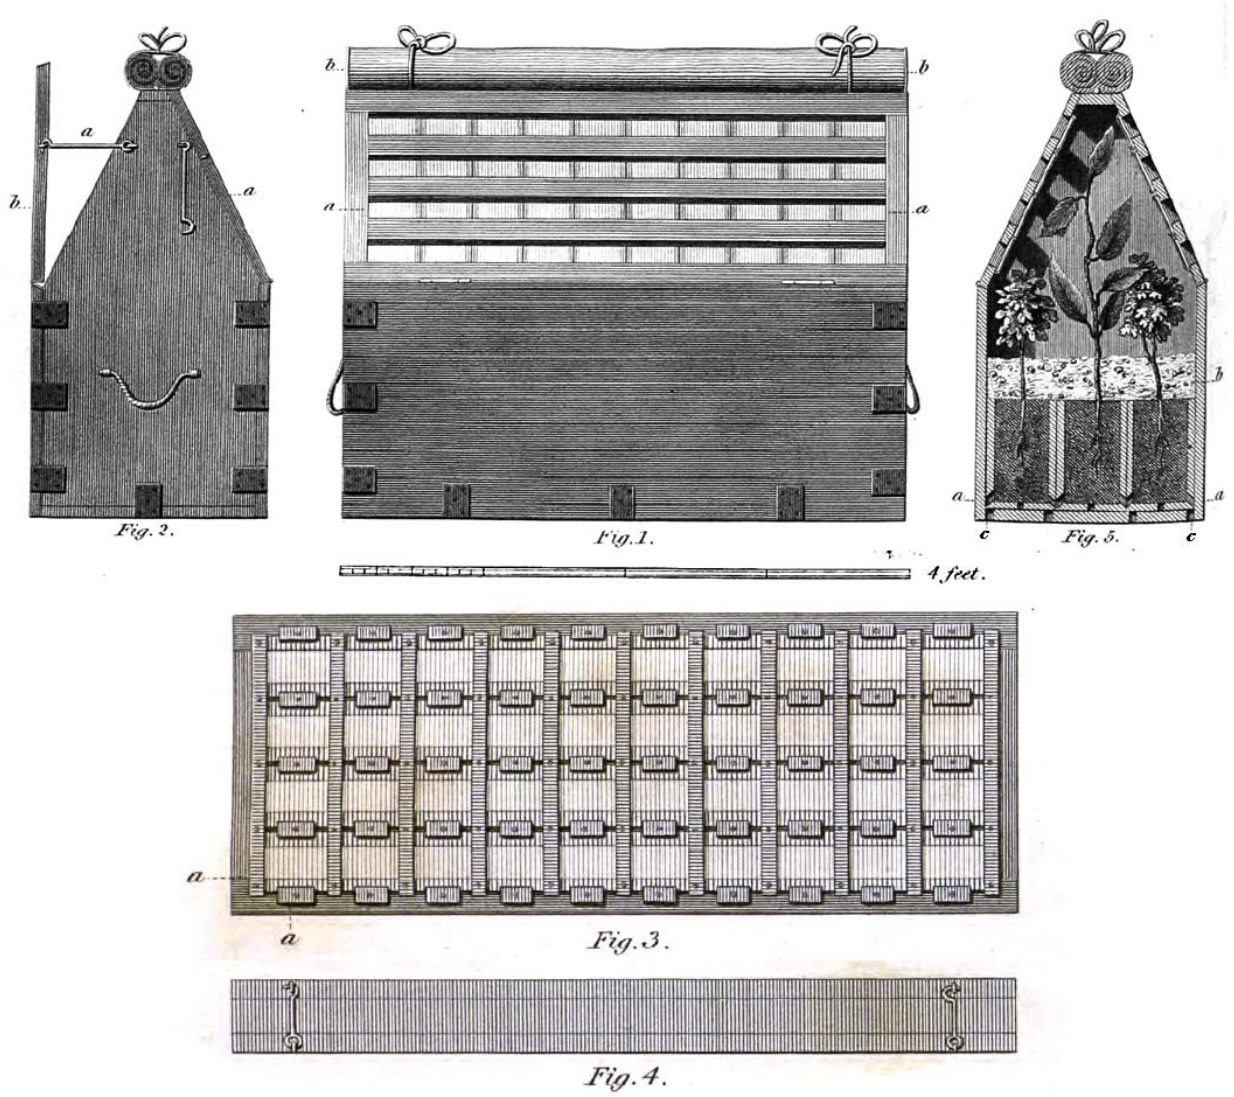

FIGURE 14: Fig. 1. Side view of the Mauritius case, with the shutter (*a a*) closed, and the tarpauling (*b b*) rolled up, and fastened with cords. Fig. 2. End view of the case, with one of the shutters (*b*) opened. Fig. 3. Inside of a shutter, showing how the tins (*a a*) for fixing the glass are placed. Fig. 4. The top, showing in what way the shutters when closed were fastened. Fig. 5. Section of a case. c*. c.* holes for draining, *b.* the moss above the pots.

The person in charge of the cases on board should have directions never to exclude them from air and light in fine weather, unless to protect them from the cold, as the vessel makes the land, and after she is in port, or during high winds, or especially when the seamen are washing the decks; but in foul weather to close the lids down and to unroll the tarpawling over the latter, so as to exclude the sea spray effectually. If, notwithstanding these precautions, saline particles should become encrusted upon the leaves and stems of the plants, it is necessary that the former should be removed as soon and as carefully as possible, with fresh water, and a sponge; otherwise the salt soon kills them. The quantity of water the plants receive must be determined by what can be spared; so that no other direction for its application can be given, than to keep the mould just moist. The requisite supply of water must also depend much upon the way in which the cases are drained. The best manner in which this can be effected is by causing holes about half an inch in diameter to be bored through the bottom of the cases and pots. Much mischief being occasionally done to collections by monkeys and parroquets on board the vessels, it is highly necessary that means should be taken to guard against their attacks.

Collections are not unfrequently injured after they arrive in this country, by the pots being shaken so violently as to be deprived of a large portion of their mould (in this context mould is loose soil, especially when rich in organic matter)**. Nothing can well be more destructive of vegetable life than this, which should be prevented by the pots being made square so as to fit accurately into the bottom of the outer case. There then could be no difficulty in keeping them steady; and if they were fastened down by cross pieces of wood, they would be secured still more completely. In addition, the surface of the mould ought to be covered deeply with coarse moss, or other similar substance (not grass,) which might be secured by packthread passed frequently across the box from its sides, or by slender laths, which would be less likely to become rotten than packthread. By this means evaporation of the watery particles which are necessary to the existence of the plants, proceeds much less rapidly than when the mould is exposed; and the latter has an additional security against being shaken out of the pots.**

THE ANDRÉ THOÜIN CASE

André Thoüin (1746-1824) was a French botanist born in Paris. He studied botany under Bernard de Jussieu, and in 1793 attained the chair of horticulture at the *Muséum National d'Histoire Naturelle* in Paris. He was a good friend of U.S. President Thomas Jefferson, and the godfather of Jean Baptiste Lamarck's son Andre. In the Atlas in his 1827 book, "Cours de Cultur de Naturalisation des Végétaux" (A Cultural Course in the Naturalization of Plants) Thoüin shows a plant case that is quite similar to that depicted by Lindley (Figure 16).

Figure 15: André Thoüin (1746-1824)

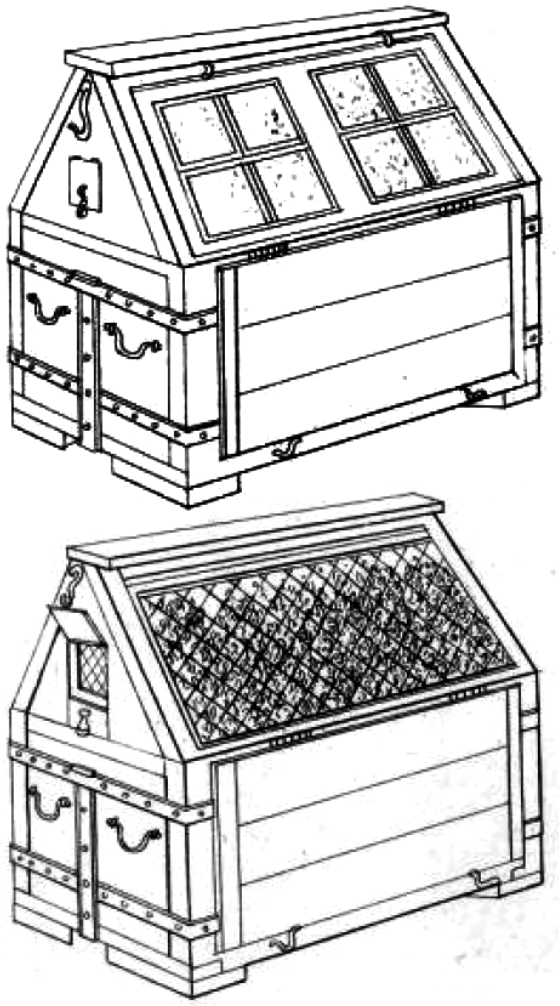

Figure 16: The André Thoüin Case.

A year after Lindley's article, John Loudon published the drawings and specifications for the case in his *Encyclopaedia of Agriculture* (1825). Although it is not known who invented this gable roof design (it may have been the Superintendent of the Botanical Gardens in Mauritius), its popularization was certainly due to both Lindley and Loudon and most likely the inspiration for Ward's cases for shipping plants by boat (and also for Thoüin's case).

NATHANIEL WALLICH'S PRE-WARDIAN CASE ADVICE

Nathaniel Wallich was born in Copenhagen in 1786 and died in London in 1854. From 1817 he took a permanent post as Superintendent of the Calcutta Botanic Garden, and travelled widely in the Indian subcontinent. Wallich published two major works on the plants of the region, however, his greatest contribution to botany was the fostering and assistance he offered to the many plant hunters who stopped in Calcutta on their way to the Himalayas. Wallich had one of the best records for keeping plant material alive for shipping prior to the development of the Wardian Case. A year before Ward started his experiments in sending plants overseas aboard ship, Wallich published a paper in *Transactions of the Horticultural Society of London* titled "Upon the Preparation and Management of Plants during a Voyage from India." The following describes the type of plant cases he recommended:

It has been the custom to make the chests very large, and to crowd into such chests as many plants as they will hold; this practice has had, amongst others, this bad effect, that Captains however well-disposed at first to pay the plants every attention, have soon found the cases troublesome, unwieldy, and unsightly. No case should be more than three feet long, eighteen inches in width, and sixteen in depth below the roof; I have taken these dimensions from a due consideration of the places where plants are generally stowed on board ship, viz. on the poop, or in front of the cuddy. The depth of the roof should be sixteen inches more, so that the shutters, when opened, will be the same depth as the sides of the boxes. The breadth of the upper rail should be five inches, which will admit of a piece of *painted* canvas sufficiently large to cover the whole sides, to be rolled upon it, and fixed to each side.

I would here observe that I would on no account use the common tarred canvas, which is a very imperfect defence against rain and sea spray, and in the next place, that whenever a number of chests are to be placed in a row close to each other, it would be preferable to use one piece of canvas instead of many. Some attention should also be paid to the neatness of the appearance of the cases, as Captains are

very unwilling to allow the deck to be occupied by unsightly objects; they should be well clamped together with iron and painted. On no account should holes be bored in the ends of passing rope handles through; the latter are perfectly useless. The roofs should be glazed either with stout glass or with the Chinese oyster shell; or with plates of thick talc.

Each plant should have a separate square pot made of wood, of such a size that eight should be contained in each case; they should not fit too tightly together, but should be so contrived that any one may be lifted out without disturbing the remainder. This renders it easy to replace deaths if the ships touch at any port on their voyage. The pots should have three or four holes bored in their bottoms : but there should be no holes in the bottom of the chest; for it is at such apertures that rats on shipboard always commence their depredations, and there is no advantage whatever in the holes.

Between the bottom of the pots and the bottom of the case, should be a layer three inches deep of broken glass and pebbles ; the former renders it impossible for vermin to establish themselves in the cases. The cases should be raised two inches from the deck by little feet.

Figure 17: Nathaniel Wallich (1786-1854).

In the treatment on board, too much attention cannot be given to the necessity of exposing the plants to the open air at all times when the weather will admit of it. As a general rule, it may be said that the boxes should be kept shut as long as the sun is above the horizon, and opened during the night, whenever the weather appears steadily fine. In cases where the chests are placed under the awning, the former precaution would be less necessary, and a due consideration of the changeableness of weather at sea, will of course ensure particular attention to the closing the roofs, if bad weather should come on. Whenever a shower falls the plants should be fully exposed to it, taking care at the same time that too much moisture be not admitted.

With regard to watering, it is desirable that the Captain should provide for each plant one pint per diem; because, although in rainy weather no water is required, yet if the weather is very hot, a larger allowance than this may be necessary. The water should be given in such a manner that the leaves and branches may be refreshed, besides the root; part should therefore be sprinkled over them, the rest poured on the earth. Generally, half a pint of water should be sprinkled over the plants before you shut them up in the morning, and the same quantity when the cases are opened in the evening ; a greater quantity will however of course be given in hot dry weather than when the sky is overcast and the air moist. It has happened in the large collection brought home by myself, as well as in another which came subsequently in the same ship, that such has been the vigour with which plants thus treated grew, that it was frequently necessary to have recourse to the knife in order to check their luxuriance.

THE NATHANIEL WARD CASE

In 1836 in a letter from Nathaniel Ward to William Hooker on the subject of his improved method of

transporting living plants in the *Companion to the Botanical Magazine*, Ward had this to say:

I come now to the most important application of the above facts: that of the conveyance of plants upon long voyages. Reflecting upon the causes of the failure attending such conveyance, arising chiefly from deficiency or redundancy of water, from the spray of the sea, or from the want of light in protecting them from the spray, it was, of course, evident that my new method offered a ready means of obviating all these difficulties, and in the beginning of June, 1833, I filled two cases with Ferns, Grasses, &c., and sent them to Sydney under the care of my zealous friend, Captain Mallard, copies of whose letters I have enclosed.

The cases were refilled at Sydney, in the month of February, 1834, the thermometer then being between 90° and 100°. In their passage to England, they encountered very varying temperatures. The thermometer fell to 20° in rounding Cape Horn, and the decks were covered a foot deep with snow. In crossing the line the thermometer rose to 120°, and fell to 40° on their arrival in the British channel, in the beginning of November, eight months after they were enclosed. These plants were not once watered during their voyage, received no protection by day or by night, but were yet taken out at Loddiges' in the most healthy and vigorous condition. The plants chiefly consisted of Ferns, among them *Gleichenia microphylla* never before introduced alive, and the *Hymenophylium Tunbridgense*. Several plants of *Callicoma serrata* had come up from seed during the voyage, and were in a very healthy state. As this experiment was made chiefly with Ferns, I will briefly give you an account of one other experiment, in which plants of a higher order of development were the subject of trial. Ibrahim Pacha being desirous to obtain useful and ornamental plants for his garden near Cairo, and at Damascus, commissioned his agents in this country to send them. I was requested by his agents to select them, and they were sent out in August, 1834, in the Nile Steamer, to Alexandria. They were about two months on their passage, and I have enclosed a copy of the letter from Mr. Traill, his gardener, giving an account of their condition when he received them; and have likewise sent you a list of the plants, which were contained in the Egyptian cases. I have, as yet, received no account of the Syrian plants. Various other trials have been made to other parts of the world, as Calcutta, Para, &c. &c., and with the same success.

I feel well assured that this method of importing plants would likewise be extremely useful in the introduction of many of the lower but most interesting tribes of animals, which have never yet been seen alive in this country.

It appears that it was almost an obsession with Ward that his cases be tightly sealed and, once on board, not to be opened on any account. Ward cites a letter from Captain Mallard where he states that

Figure 18: A Wardian case, circa 1870. The hinges are not original; hence this is not a true Wardian case.

These plants were not once watered during their voyage, received no protection by day or by night. In this article Ward was referring to a letter from Mallard dated January 18, 1834 referring to the return trip from Australia but Ward fails to mention that in Mallard's prior letter dated November 23, 1833 - the outgoing part of the trip - that Mallard stated: **During the very hot weather near the equator, I gave them once a light sprinkling of water, and that is all they have received during the passage.** This means, of course, that the case was opened. As Ward stated in response to a question:

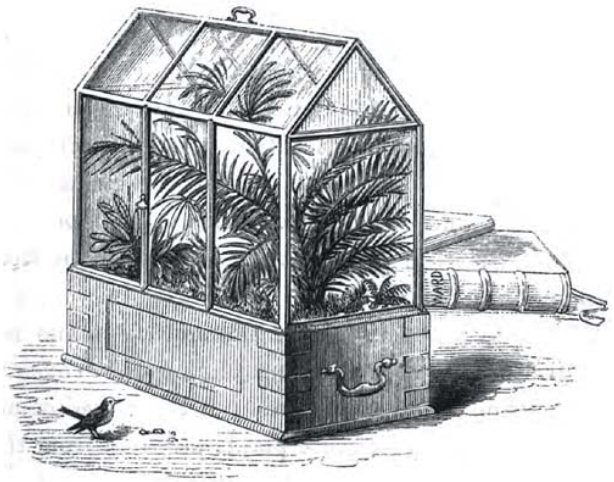
I may remark, that there is one point, upon which misconception exists very generally, even among well informed men. Because my cases are made quite tight, it is imagined, that the plants contained in them receive no change of air. Now, it must be obvious to everyone who reflects for an instant on the subject, that owing to the expansibility of the air by heat, there must, with every change of temperature, be a corresponding change in the volume of air contained within the cases. Without such a variation, the plants would, in all probability, soon perish.

This, however, was a grave error and ultimately led to various modifications of Ward's case, suggesting that Lindley's case, although not a true "Wardian case," was a better one. In any case, Ward's friend George Loddiges (1786–1846; his family managed one of the most notable of the eighteenth and nineteenth century plant nurseries that traded in and introduced exotic plants, trees, shrubs, ferns, palms and orchids into European gardens), who had accompanied him aboard Mallard's ship to witness the first successful transplant from Australia, was more ambitious. He put into circulation over five hundred cases to all parts of the globe. It is the ingenuity and wide usage of Loddiges nurseries that established the Wardian case as the most compelling tool to use for transporting live plants. Nathaniel Wallich was so impressed with the case that he received that he packed that same case and sent it on to the director of the *Jardin des Plantes*, Charles François Brisseau de Mirbel. The director at France's premiere garden was equally impressed and passed on knowledge of the case to the famous Cel family who imported exotics to Paris. Mirbel returned Wallich's case to India, and the Cel's, grateful for the knowledge also sent a newly constructed case of plants to Wallich.

In all his writings, Ward was somewhat vague about the construction details of his cases. He never showed any illustrations of his device except for a drawing in his 1852 edition of his "On the Growth of Plants in Closely-Glazed Cases" with the caption, "On The Conveyance of Plants and Seeds on Ship-Board" (Figure 19). I don't know what Ward had in mind with this illustration as it is clearly one of his cases designed to be used indoors and was made of glass set in a thin metal frame. I doubt that it could have remained intact before the ship even left harbor.

The following is my translation of a portion of a report that Mirbel and four of his associates published in l'Académie des Sciences in 1837 that provided more information in this regard:

Another device, invented for the transportation of plants by Dr. Nath. Ward, of London,



ON THE CONVEYANCE OF PLANTS AND SEEDS ON SHIP-BOARD.

Figure 19: From the 1852 edition of "On the Growth of Plants in Closely-Glazed Cases."

offers still more chances of success than that of Luschnath; but it fills its destination only on the condition that, during the crossing, it will remain exposed to the action of the light and will not experience any serious damage. This apparatus, which we shall call "a traveling greenhouse," consists of an elongated box, surmounted by a glass roof, formed by two frames adjusted so as to make an acute angle. The two small sides of the box, exceeding its base by two or three centimeters, serve as a support for the whole apparatus; and, rising at an acute angle above the opening of the box, close the two sides of the roof. One of the frames is stationary; the other, restrained by a few screws, is placed or removed at will, but the box must be closed for as long as the journey lasts: otherwise the perfect closing of all the parts is difficult. Wooden sleepers, four to five centimeters wide, at a distance of seven to eight centimeters from each other, fit with the lower and upper part of each frame, and serve at once to give it solidity and to support the glasses, which are small, very thick, covered like the tiles of a roof, and puttied in all their joints.

The authors point out that if the frame came off or had to be removed, it would be very difficult to reinstall it. In a moist environment, such as the oceans, wood absorbs moisture and if the box and the frame swelled differently by even a very small amount, the closing of the case would not be easy.

THE WILLIAM BULL CASE

Over the years the Wardian case had many designs and many different constructions. Figure ?? shows a botanist unpacking a Wardian case at the Royal Botanic Gardens, Kew, around 1890. Notice the large hole drilled into the top of the case just below the tip of the triangle that permitted air to enter and leave the case. In other words, the original Wardian cases used by Kew Gardens were now no longer cases as Ward envisaged.

William Bull (1828-1902) was a botanist and owner of a famous exotic nursery, established in 1861 and in existence up to 1917 on Kings Road, Chelsea. In 1887, Bull received the Victoria Medal of Honour for his achievements in importing new varieties and species of plants. Shortly after Ward's death in 1868, he was granted a patent for "An Improved Case for the Conveyance of plants" (December of 1870). In his introduction to his patent, Bull wrote:

It is well known that when plants have to be transported for long distances, and have consequently to remain packed for a considerable length of time, they require to be packed in cases with glass covers so that the requisite amount of may be enabled to reach them. They also require to be more or less moist to withstand a journey of three or four months (more or less) in a closed case, and it is moreover necessary to protect them from the action of sea air and salt water during transit. Heretofore great loss has been sustained in the transmission of valuable plants owing to the direct action of the rays of the sun upon the glass covers of the cases containing the plants, the result of which has been the creation of what

Figure 20: William Bull (1828-1902).

may be termed a " steaming" heat within the case, so that the plants have been literally boiled. Great damage results also from the breaking of the glass on board vessels, which at present frequently happens, thus exposing the plants to the action of the sea air. Various devices have been resorted to for the purpose of obviating these serious evils, such as the nailing across the case strips of wood, bamboo canes, canvass and other plans, but all the means hitherto used, so far as I know, have more or less failed to accomplish the object in view, as they either make the interior of the case too dark, or do not prevent the sun's rays from penetrating directly into the case.

Referring now to Figure 21, the following are the details of the patent:

Now in order to remedy the evils above referred to, and also to protect the plants from injury by the dripping on to them of the condensed vapor from the glass, I cover the glass with a frame or frames formed with louvre pieces *a,* so arranged as to permit the necessary light to enter the ease, but to protect the glass from the direct rays of the sun, and from breakage; and in order to protect the plants from the dripping of condensed vapor, I arrange the glass covers and interior of the ease, as shown in the Drawings, so that the condensed vapor shall pass down the surface of the glass into small channels or chambers *b,* provided within the case to receive it, which chambers *b* are filled with sphagnum moss or charcoal to absorb the moisture.

I furthermore guard the plants against injury from sea water entering the case during the washing of the decks, by constructing the case with projecting parts or legs c in such manner that its bottom shall be raised some distance from the surface of the deck, and thus allow any water to flow underneath without soaking it up. I provide for the escape of foul and overheated air from the interior of the ease by placing at each end thereof, or at one end only, a ventilator of the kind shown at Figs. 3 and 4. A small chamber *d* is formed in the upper part of the end of the ease; this chamber communicates through opening's e with the interior of the case, and through openings *f* with the external atmosphere. The openings *e* and *f*, which I prefer to make about one inch in diameter, are covered by screens *g,* made of the finest wire netting procurable, and outside of this netting by a

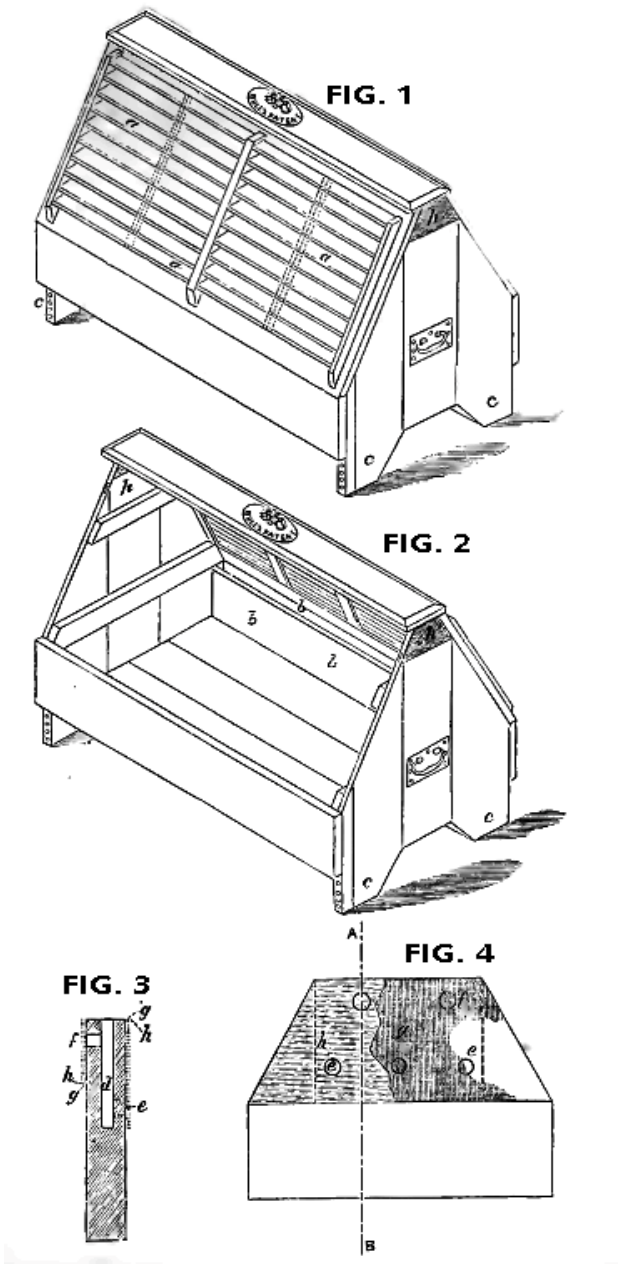


Figure 21:
The drawings from Bull's patent of 1870.

farther covering of finely perforated zine plate *h*, through both of which coverings the air is as it were "wire-drawn" in its passage into and out of the ease. The number of openings *e* and *f* may be varied to suit the requirements of the climate through which plants have to be conveyed, and the length of the voyage or journey, increasing the number of holes *e* and *f* according to the length of the journey, and the nature of the plants, as will be well understood by horticulturists.

This invention is the result of great observation and experience, for as a large importer and exporter of new and rare plants I was induced to turn my attention to devising some practical means for obviating the serious evils already referred to in consequence of having suffered great losses for several years in importing plants, many of which were not only now to this country but to science.

CONCLUSION

Users, whether they were organizations, institutions and nurseries, varied the design according to their needs, the type of plants being sent and the destination. These were not just centralized botanical gardens designing cases, but nurseries and plant collectors making them. Indeed some of the leading innovations came from commercial nurseries. Often it was the needs of the plants and the practicalities of shipping that determined the design of the cases.

The Wardian case is a persuasive and wide reaching example of how a simple technology for moving plants had a major impact on the ecosystems we know and value today. It was a prime mover for botanical enterprises for over a century. But by the 1940s it was largely phased out, with the last journeys carrying ornamental plants occurring in the 1960s. The case was superseded by the use of polyethylene bags and temperature-controlled air transport.

The Wardian case was extensively used by many different groups of people from across the globe to move many different plants; from scientists to gardeners, from ferns to bananas, from Australia to Boston, the case was put to good use. Collectively in the nineteenth and early twentieth century, the use of Wardian cases facilitated a major plant migration across the globe. These plant distribution networks, established with the introduction of the Wardian case, are still in use today.

LA CENERENTOLA: JEANNE VILLEPREUX-POWER

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, February 16, 2019)

Jeanne Villepreux was born during the period of the French Revolution in Juillac on September 25, 1794. The consequences of the Reign of Terror did not reach her because she grew up in a village deep in the countryside. It is located in the Corrèze department in Nouvelle-Aquitaine in southern France (see Figure 1) and at that time, its population was estimated to be about 2,000 (it has lost almost of this since then, its current population being about 1,100). Her father was Pierre Villepreux, also born in Juillac, and her mother was Jeanne Nicot, born in Limoges, about 37 miles north as the crow flies (see Figure 1). In the late 1700s the porcelain industry in Lomages started to develop, favored by the presence of kaolinite which was discovered near Limoges in 1768, and many of the inhabitants became employed in the new industry.

Jeanne (who was called Lili at home, most likely to distinguish her from her mother; she was also for the same reason called Jeannette) was the oldest of two sisters (Marie and Gabrielle) and one brother (Joseph) but after her mother died at the

Figure 1: Map of France showing Juillac.

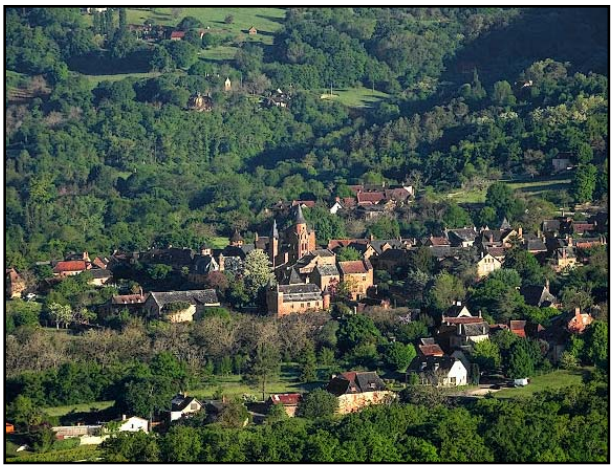

Figure 2: Aerial view of Juillac.

age of 31 in 1805 when Jeanne was only eleven years old, her father remarried two years later - a necessity since there were four children to take care of - and so Jeanne later added three half-brothers and one half-sister to her list of siblings.

Jeanne spent her childhood and adolescence in Juillac. In this small town, then the capital of the canton in the Corrèze department in Limousin, her father held various trades (at that time he worked as a saltpeter miner), while her mother was one of the few Juillac women who could read and write. She taught Jeanne but the other younger children would not be as lucky as their mother

Figure 3: The town of Juillac.

Figure 4: Jeanne Villepreux-Power (1794-1871), photographed in 1861.

died before they were old enough to be taught. The Villepreux were not rich, but they were not poor either since they lived in a house they owned in the Place de l'Eglise as well owning a plot of land.

JEANNE TRAVELS TO PARIS

The death of her mother in 1805 and the second marriage of her father two years later, with the birth of other siblings, marks the adolescence of Jeanne. In 1812, when she was seventeen and a half years old, she left Juillac to go to work in in Paris. She left for the capital, a journal of about 350 miles on foot, accompanied by her cousin who was taking a herd of cows to a slaughter-house in Paris and who also functioned as a guardian for the underage Villepreux. However, along the way her cousin assaulted her and she was forced to take refuge in the police station in Orléans, where she waited for new documents in order to be able to travel to Paris. The workplace she had been promised in Paris had already been taken upon her late arrival, but she nevertheless had the opportunity to work as an assistant to a society seamstress, proving her skills to such an extent that she was entrusted with embroidering the wedding dress in 1816 of Princess Maria Carolina of Bourbon for her marriage to Charles Ferdinand, Duke of Berry and nephew of the French king Louis XVIII.

According to family legend, James Power was impressed by the beauty of the embroidery of the princess's wedding dress and wanted to know the embroiderer. If true, wedding dress with her embroidery would have signaled the first fateful meeting between Jeanne Villepreux and James Power.

INTRODUCTION TO JAMES POWER

At the end of the eighteenth century, Morris Lucas Power and his wife Anne Cuffe, an Irish family of noble origins, had moved from their native Ireland to one of the smallest islands in the Antilles, Dominica, which had been sold by France to

Figure 5: The wedding dress of Princess Maria Carolina that Jeanne did the lace for in 1816.

Great Britain at the end of the Seven Years' War (1756-1763). The reasons that led them to move to Dominca are not known. Perhaps the financial problems and/or the difficult political and economic problems in Ireland at the time was the basis for their decision to move to a safer and less precarious place. Once established in the Antilles, the Powers probably reached that serenity they sought and was here that James Power was born on February 28, 1791.

In Roseau, the Dominican capital where he spent his early youth, James was immersed in the typical mixture of different cultures, languages and populations in the island, then inhabited by Europeans, Amerindians and Creoles. During this time he learned several languages, such as English, French and Spanish.

After the sudden death of his father and the subsequent marriage of his mother in the early nineteenth century, the young James Power decided to leave the Antilles to try and create a future elsewhere by traveling the reverse course to that of his father who, in his time, had left from Ireland to the Antilles. James' first goal probably was England, but this was only a step towards what would become his definitive residence, Sicily, one of the few European areas that was not occupied by Napoleon but for at least a decade was under the English protection.

In particular, in the decade from 1806 to 1815 Sicily was protected by 20,000 British soldiers sent to defend it from a dreaded Napoleonic invasion and to try to win back the kingdom of the Bourbon allies, Naples, occupied by the French. In the period of the Napoleonic wars this Mediterranean island had represented, together with Malta, an essential military base for Great Britain and also an important alternative market for many English merchants penalized by the negative effects of the "Continental Block" with which Napoleon had closed the continental European markets to British trade in 1806. In the "English decade," 1806-1815, along with the Royal Navy and British Army military, there had arrived numerous merchants who, rejected by European ports because of the Continental Bloc, were looking for new markets. In that decade, Sicily and Great Britain, allied in the fight against Napoleon, had developed a substantial interchange based on British exports of industrial products and on Sicilian exports of raw materials and production agricultural (oil, citrus, raw silk, sulfur etc.).

Figure 6: Dominica.

This trade had been initiated and managed by the large merchant community that had settled during the English decade. Before 1806, the English presence was limited to half a dozen merchants residing in Messina and Palermo, while between 1806 and 1815, forty commercial houses were established in Messina and about twenty in Palermo. The number of English merchants was

Figure 7: Location of Messina.

destined to increase in the following decades. After 1815, the new prospects for peace had led new English compatriots to come to Sicily to start new businesses and new expanded networks of exchanges already established during the age of Napoleon. Thus, to the merchants who had arrived in the English decade were added those who had arrived from England in the following years.

From the available sources it is not known if James Power arrived in Messina during the English decade (perhaps in the employ of other English merchants or as the owner of one of his own companies) or immediately after the Restoration by the Congress of Vienna in 1814-1815 that established the political order in Italy that lasted until unification between 1859 and 1870. In any case, here he was soon engaged in a flourishing commercial activity and considered as one of the most important English merchants of the city. His activities, documented for over twenty years starting from 1818, involved not only the commercial sector, but also the financial sector and the entrepreneurial ones. Power was also part of the maritime movement of the Porto di Messina, along with other English merchants resident in Sicily and involved in international trade, through the routes that in the port of Messina connected the different areas of Sicilian and Calabrian production with ports and foreign markets.

In addition to his commercial activities, from the first years of his residence in Messina Power also made financial investments. In 1819 he participated in the establishment of the marine insurance company *Banco di Assicurazioni* as one of its 27 shareholders. The successes of his varied commercial activities permitted him to invest part of his earnings in the subscription of shares as well as in other financial transactions. James Power's investments in the financial sector did not limit themselves to insurance; as shown in a document dated 1823, they also included the purchase of public debt securities of the Kingdom of the Two Sicilies. This was a kingdom in southern Italy from 1816 until 1861, created after the Congress of Vienna of 1814 by uniting the Kingdom of Sicily and the Kingdom of Naples, which had been ruled by Joseph Bonaparte during the reign of Napoleon.

In the mid-1820s (as early as 1825-26), Power was active in the Messina trade under the name "James Power & C." together with a partner (not known).

Figure 8: The old port of Messina, 1786.

English and Sicilian sources included the "James Power & C." among about thirty foreign companies operating in the city (the English ones totaled more than twenty, while the German, French, Belgian and U.S. ones were altogether less than a dozen.

In general, in those years in Messina the commercial activity of James Power, like that of many other foreign merchants, was part of a dynamic circuit based on the export of local products for markets more distant and on the importation of foreign productions that were then redistributed in the neighboring markets. This import trade, in fact, was broken down into that for consumption and circulation by land, and for consumption and circulation by sea for island domains and continental countries.

Even British sources attest to the commercial relations that James Power maintained with foreign markets and specify some details on the goods that were the subject of his trade. From a memorial of May 20, 1825, which concerned problems related to the export of oil from Sicily, it is clear that James Power, like other traders long active in the general trade, was very well integrated into the intense activity of foreign exchange, and especially with England. Within this system he, like so many other English merchants, did not deal only with the business of export of Sicilian products, but also of the import trade of English goods at a time when the trade movement between Britain and the Regno delle Due Sicilie showed a trend of gradual growth until 1840 and a phase of rapid expansion in the following decades (the Kingdom of the Two Sicilies was the largest of the states of Italy before the Italian unification; it was formed as a union of the Kingdom of Sicily and the Kingdom of Naples, which collectively had long been called the "Two Sicilies"). In 1827, for example, among the goods that James Power imported from England, were "18 barrels of manufactured colors" and "a box of hard soap bars" that had been sent from England on the brigantine, *Preceptor del Captain James Leigh*, to be delivered, along with other products of English industries, to the numerous foreign merchants of Messina.

His business did not always have its favorable sides, as can be seen from some controversies that ended in unfavorable rulings of the Court of Commerce of Messina. In 1820, for example, in one dispute over the payment of a bill, Power was ordered to pay it as a part of a debt. There were also problems with customs, rather frequently as a result of the intricacy of the regulations and for the general customs legislation that had changed the old equilibrium, not only between the island and the continent, but with foreign trade in the early period of the Restoration. In 1825, together with other foreign merchants, James was engaged in a judicial dispute for a payment requested by the Director of Duties for the shipment of oil abroad. Also the following year he was engaged, with his colleagues, in another controversy with the customs officials of Messina.

Figure 9: Messina on the waterfront.

Meanwhile, beginning in the late 1820s with the entry into the company of James Robinson Unett, a resident of Liverpool, "Power & C. changed its name and officially became "Power & Unett." Power was active in Messina not only in maritime trade, but he also started a significant new business activity. Starting in the mid-1830s, Power & Unett began to produce sulfuric acid, tartaric acid and cream of tartar

with new technology and asked the Bourbon government to grant them a "Privativa," i.e. an exclusive patent to manufacture those products using steam pipes. With the decree of August 25, 1838, Ferdinando II di Bourbon granted the Privativa for 5 years to the Power & Unett company for the production of tartaric acid and iron sulphate with the innovative use of steam tubes instead of the ancient way of applying direct fire.

The factory had done well and was active at least until the beginning of 1838, so much so that it was reported in his "Economic Memory" (1838) by Alessio Scigliani for the innovations introduced in the production of sulfuric acid:

In the factory of Power and Unett in Messina sulfuric acid was made to perfection, and compared to that of any other country concentrated in high grades with a new method without the aid of glass retorts, damaging the acid from the lead chamber and without the gases causing damage to the lemon trees, olive trees, etc., in which the said local is surrounded,. In the matter of the cream of tartar, that of M. Power, manufacturer of this material in Messina, was highly economical. He made sure that the red scum made at least a quarter to a fifth of the brown tartar cream, while the red tartar did not make more than a third. Furthermore there was a great deal of difference between their prices, since the former is sold from 10 tarì to 14 tarì per 100 kilograms and the red tartar is worth from 3.10 to 3.20 per ounce [30 tarì was equivalent to $2.38 in 1838 currency]. He got it right from the first, especially since it was difficult to transport as well expensive in the matter of fuels. Much economy in fuels was obtained by exploiting the so-called scurcidda [i.e., the internal rind of corks] that the tanners use, the tiny fragments of fossil and vegetable coals, and the residue of the wine lees after having pulled the cream.

CENERENTOLA

Cenerentola is the Italian name for Cinderella and this name certainly applied in the real world to Jeanne Villepreux, a simple girl - but a highly intelligent one - who married a very wealthy man. Jeanne left France to move to Messina, where in 1818 at the age of 24 she married James Power (three years older than she) and where she discovered for the first time the sea, a discovery that would forever mark her life. Equipped with a great spirit of observation, intuition and scientific curiosity, Jeanne had probably practiced these natural talents in her childhood in the countryside of Juillac or in the mountains of Corrèze, but it certainly matured in her almost 25 years of residence along the banks of the Strait of Messina.

The long period spent in Messina can be divided into two phases. In the years between 1818 and 1830 Jeanne was a lady of the city bourgeoisie and, as a wife of a wealthy merchant, could attend local salons and participate in the life of society, but instead preferred to cultivate her growing sci-

Figure 10: James proposes to Jeanne.

entific interests, reading texts of natural history, self-taught studying the various aspects of natural science and getting in touch with the scientific community of Messina. For Jeanne these were the years of her theoretical preparation, which would be followed by a long period of hands-on experience and research in the field of marine biology.

The years between 1830 and 1842 were the years of scientific experiments, systematic observations, inventions and early publications. It is in 1832 that Jeanne invents and builds her "gabbiolina alla Power" ("cages à la Power") and begins to report to the *Accademia Gioenia di Catania* (Gioenia Academy of Catania) the first results of her research on *Argonauta argo*, which would be published in the Acts of the Academy over the succeeding years. This second intense period culminates in 1839 with the publication of her *Itinerario della Sicilia* (Itinerary of Sicily) and, three years later, of her *Guida per la Sicilia* (Guide for Sicily), two books of wide-spread dissemination on the natural resources of the island as well as farewells before her definitive departure from the island of Messina.

JEANNE DISCOVERS THE SEA

In 1818, James and Jeanne Power begin their lives in Messina, residing in Strada Ferdinanda 96 (behind the Palazzata that runs along the port) and, a few years later, in the nearby Strada Austria, where James carried out his commercial activity. As her husband was more and more established in the maritime trade that revolved around the free port, Jeanne discovered the sea that surrounds the city and began, self-taught, to know, observe, analyze and catalog the natural resources of the waters of the Strait.

Jeanne thus came into contact with the leading scientific figures of Messina , such as the ichthyologist Anastasio Cocco and his brother Luigi, who also hosted the Powers in a country house in the Gravitelli district. Moreover, Jeanne was also in contact with experts and collectors of objects of natural history, such as Luigi Benoit, who had a Sicilian ornithological collection and a numerous collection of shells, Giuseppe Grosso Cacopardo, who owned an extensive collection of shells and Mariano Cesareo, who had a large collection of Sicilian seashells. Among her friendships and acquaintances there were also collectors who sold objects of natural history, like Pietro Campanella, who traded in minerals, fossils and living shells, and Mario Olivo, a young man who was paid for collecting objects of natural history, and above all the priest, Father Mario De Francesco, who accompanied her several times in her travels in Sicily and who was a skillful collector of objects of natural history, and particularly of fossil, terrestrial and fluvial shells, the collections of which he sold at very moderate prices.

In the 1830s, Jeanne's contacts were not limited to Messina, but also included scholars and collectors living in other cities of the island. In Catania, the privileged contacts she valued above all were those of the members of the Gioenia Academy of

Figure 11: Messina before the earthquake of 1783.

Figure 12: Carmelo Maravigna (1782-1851)

Natural Sciences (*l'Accademia Gioenia di Catania*, named after the catanese naturalist Giuseppe Gioeni d'Angiò). Among these, in addition to the canonical Giuseppe Alessi, to whom she had close ties of friendship, there was the celebrated Professor Carmelo Maravigna, who taught Philosophical Chemistry, Pharmaceutical and Applied Chemistry at the University of Catania. In his house there was a particularly rich Cabinet (a piece of furniture used for displaying items) with many finds of various branches of the natural sciences. There was also the famous and much renowned in Europe Professor Carlo Gemmellaro, who owned a Sicilian geological collection, and living shells and fossils in addition to a collection of insects collected and sorted by his worthy son, Mario Gemmellaro. In her *Guide for Sicily*, among the experts and collectors of the city of Etna Jeanne also recalled Doctor Mariano Zuccarello Patti for an extensive collection of living shells and crustaceans from the seas of Sicily and a collection of insects, among which included many beetles; the Doctor Andrea Aradas for a rich collection of marine shells of Sicily, fluvial and terrestrial, living and fossil; and the young Giovanni Piazza Ciantar for a collection of Sicilian shells and other objects of natural history. In Siracusa, among her friends Jeanne include Bishop Mario Landolina Nava, known to both citizens and foreigners for his virtues, who owned a collection of organic fossils, including shells and bones of elephants, hippopotamus etc., while Dr. Alessandro Rizza kept a collection of birds, shells and crustaceans.

Among the private collections observable in Palermo Jeanne pointed out, was a special collection of volcanic products, petrifications and shells of the prince of Trabia and an extensive collection of shellfish and nudibranchs, living and fossil, of the Baron Andrea Bivona, son of the illustrious

Figure 13: Carlo Gemmellaro (1787-1866)

Antonio Bivona Berardi; a rich collection of living shells and fossils from Sicily, and in particular from Altavilla by Domenico Testa; and a collection of living shells and fossils from Sicily by Dr. Pietro Calcara. In Termini, she mentioned the Cabinet of the Gargotta Lordswhich was worthy of being observed for its paintings, cameos, medals, works in terra cotta, shells both live and as fossils, minerals, volcanic production and so on, and in Cefalù the rich Cabinet of objects of natural history of Barone Enrico Pirajno di Mandralisca, who "uses it with great success for increasing our progress in this science."

Besides occasionally or systematically sharing many scientific interests with these and other scholars, collectors and expert collectors of objects of natural history in Messina, Jeanne daily shared much of her time with fishermen who, thanks to their activity, provided her raw material for her research. For readers of her *Guide for Sicily*, Jeanne described the method of fishing for marine animals in the Messina Sea and others that she had adopted in previous years and recommended to scholars who visited Sicily for scientific purposes:

Figure 14: Barone Enrico Pirajno di Mandralisca (1809-1864).

To get good specimens of marine animals you have to look for them in autumn and winter, their own seasons. In these times I would take myself on a boat with fishermen, giving them a little money or something to eat, the latter being more appreciated than money.

Whenever the fishermen withdrew the nets or other fishing equipment from the bottom of the sea, Jeanne would spill all the catch into the boat and then choose the specimens to study, putting them in a barrel of sea water open at the top to be able to observe the contents. On returning from these trips, Jeanne often ran into other boats along the coast between the tip of the Lighthouse and the city ("on the shores of Faro or de 'Ganzirri, or of Peace, places close to each other to the other") and, "using urban ways with those barcajuoli, one can see the fruit offered and admire their fragrance and buy something with little money."

With this method, which she recommended for naturalists and lovers of the natural sciences, Jeanne obtained a unique collection of beautiful specimens without having to spend a lot of time and money. Moreover, with this system a haul not only brought up shells and crustaceans, but in the middle it often had sea stars, sea urchins, comb jellies, jellyfish, univalve mollusks, echinoderms, nudibranchs, marine flatworms, cuttlefish, octopus, sea horses and a variety of *Laplysia* and other marine plants that were difficult to procure intact by other means.

She also bought rare fish directly from the fishermen, which she put in a barrel to avoid jeopardizing the scales with the impact of other objects. Among the scales of the larger fish she was able to find small crustaceans like the chiton (marine mollusks) and *Pinnella filosa* (a copepod, parasitic on large pelagic fishes) on the swordfish, the *Mediterranean Echeneis* (a remora that hitches a ride on certain fish) on the gills of *Tetrapturus belon* (Mediterranean spearfish) and the *Palcobdella* (a species of leech) on some venomous

stonefish. Finally, Jeanne learned that the minute and delicate objects, such as hyalea (mollusks), janthina (sea snails) and small nude mollusks, should be carefully placed in "a crystal vase filled with sea water with a cork stopper" to be inserted "inside a little bonnet with a straw so that it will not break."

THE PAPER NAUTILIS

The cephalopod mollusk was known from ancient times as the Nautilus. In an epic quest, Jason and the Argonauts, a band of heroes aboard the Argo, sailed the seas searching for the Golden Fleece that would grant Jason the authority of kingship. In 1758, it was renamed *Argonauta argo by Linnaeus.* The argonaut octopus, of the family Argonautidae, belongs to a group of pale pink-spotted octopuses. These octopuses are known for traversing the open ocean by way of a delicate, curved, creamy white vessel - an external casing often referred to as a "shell" - that gave them their common nickname, the "paper nautilus." These creatures baffled naturalists and philosophers for two millennia, even fooling Aristotle who believed that they used their large pair of webbed dorsal arms as "a sail" to catch the briny breeze and float across the ocean's surface like paper boats. These myths carried weight for centuries, even among naturalists in the 19th century.

Figure15: *Argonauta argo,* also known as a Greater Argonaut.

Figure 16: Aristotle's idea of the Astronaut sailing.

This octopus was a problem because the descriptions were a little funny with the scientists describing it often with old, antique descriptions - sketching it as a sailing octopus. "It uses [the thin webs], when a breeze is blowing, for a sail, and lets down some of its feelers alongside as rudder-oars," Aristotle wrote of the paper nautilus.

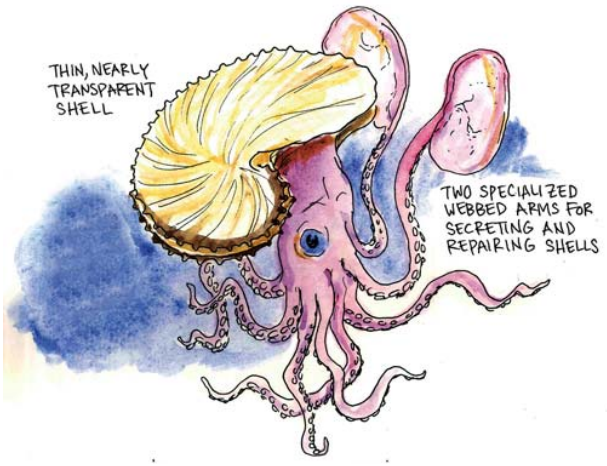

Figure 17: The specialized webbed arms were uses for secreting and repairing shells, not for sailing!

The four known living species of paper nautilus reside in tropical, subtropical, and temperate waters around the world. They feed on small crustaceans, mollusks, and jellyfish, using poison to immobilize their prey. Although they are rarely seen by humans in the wild, their "shells" have been collected in large numbers on beaches across the globe, sticking up from the sand like

Figure 18: Female *Argonauta argo* with its eggs bulging out of its damaged shell.

little cream-colored cornucopias. The abundance of shells washed up on shores after storms have led some to speculate that the argonauts may actually be quite common in the ocean.

But the "shell" of a paper nautilus isn't a shell at all. And confusingly, the paper nautilus is only distantly related to the chambered nautilus, the only living cephalopod with a true external shell. Instead, the female paper nautilus carries a calcite egg case that protects and holds its eggs, because unlike bottom living octopuses, they dwell in the open ocean.

The female argonauts must have a way of brooding eggs in a structure that isn't a cave or a den, and they could be carrying a hefty load of precious cargo. Females can produce up to a million eggs in a lifetime, with individuals in some species found holding over 170,000 eggs at a time. The shell allows her to protect those eggs as they develop until they hatch. In addition to holding eggs, the case also helps the females stay buoyant in the open ocean. The argonaut "gulps" and traps air in the egg case, allowing it to float, not on the surface as folklore depicted, but in the water column at neutral buoyancy. It's more like Alexander the Great's bathysphere than Aristotle's sailing boat.

This thin, nearly translucent egg case plays an essential role in a female argonaut's life cycle. But one big mystery divided scientists for centuries: Where did the shell come from? In the 1800s, most scientists believed that the shell was made by another animal - that argonauts lived in them the same way that a hermit crab will go find a snail shell or a mollusk shell to live in,. Once the octopus grew too large for the shell, it would abandon the shelter and either search, steal or kill the original inhabitant for a larger shell.

JEANNE BECOMES FASCINATED WITH THE ARGONAUT

Argonauta argo, which abounds in the waters of the port of Messina, attracted Jeanne's attention. Living in the ideal place and in favorable conditions ("I had found it so far within reach of being able to make a series of observations on it, that others could never possibly have, due to the lack of those opportunities, and of those means sufficiency I saw myself provided"), Jeanne felt almost obligated to do careful research on those points that concerned the physiological conditions of the cephalopod.

Thus began for a number of years an uninterrupted series of investigations and after repeated and new attempts, combining and renewing the experiments, she finally managed to obtain "results that lead to very useful knowledge, both to elucidate of doubts about the first development of his eggs, both in order to make known many new facts that its customs." Jeanne arrived at these results introducing the method of direct observation, since the lack of actual experiments had up to then resulted in a determined controversy among marine biologists ("Such was the state of things re *Argonauta* when I realized that the lack of experiments was the only cause of such disputes, and that every-

thing had to be made clear with careful scrutiny in such a remarkable subject").

The objective of her research was to demonstrate not only that it was the mollusk that built its shell ("Determined to undertake this task I looked to my eyes the purpose of my observations, that is to assure myself that the blacksmith of the *Argonauta* shell was the cephalopod that inhabited it"), but also to ascertain the structure of the mollusk, examine its relationship with its arms and follow its evolutionary development ("In that case, knowing the structure of this mollusk should be the first of my research; the relationship of the mollusk with its arms was the second, accompanying it on its development of the egg until its entire growth was the third. But how could one make a difficult series of observations to achieve these goals?"

JEANNE'S "CAGES"

For about a decade she closely studied these "suspicious" yet "graceful" creatures. She became intimately acquainted with them, examining, experimenting and describing everything from their feeding behaviors, movements, growth, and development. Unlike her predecessors, she did not turn to dead specimens preserved in jars or shells washed up on the shore. She was determined to find a way to bring live specimens to the laboratory.

If one believes that one will make interesting discoveries on marine animals with aquaria located in rooms, gardens or in cities far from the sea, one is mistaken: one will not make any that are serious. For the anatomical part of their structure it is possible, since a few days are enough: it is not the same for the physiological part. To study the use of each organ, the phenomena that vary according to the circumstances, the places and the times, their fertilizations, constructions, reproductions, their mores and their food among other things, it certainly takes a longer period of time; it is necessary, as it were, to accompany them in all their operations, and for that reason to keep them prisoners, but in their element and in spacious cages or aquaria for small individuals. They would not live enough time in water composed in imitation of sea water, or in the sea water concentrated in aquaria located as I said above for such a series of studies. And what about the food of each species; how does one located far from the sea obtain it? I experienced this when I invented aquaria in 1832, and although I studied marine animals in sea water maintained at the desired degree of heat and I provided food that suited each species, the results were not completely successful; then I resorted to the sea. I invented cages.

According to Professeur Carmelo Maravigna, writing in the *Journal de l'Académie de Cioenia, à Catane* for December 1834 (Margollé, 1864):

Madame Power has three kinds of these devices: the first is made of glass and arranged for the conservation and study of live mollusks in a Cabinet; the second is also in glass but is provided with an external frame, which is a bit higher, that makes it possible to submerge it in the sea and to bring it up for observation; finally there is a third model, suitable for mollusks of the largest size, which can be im-

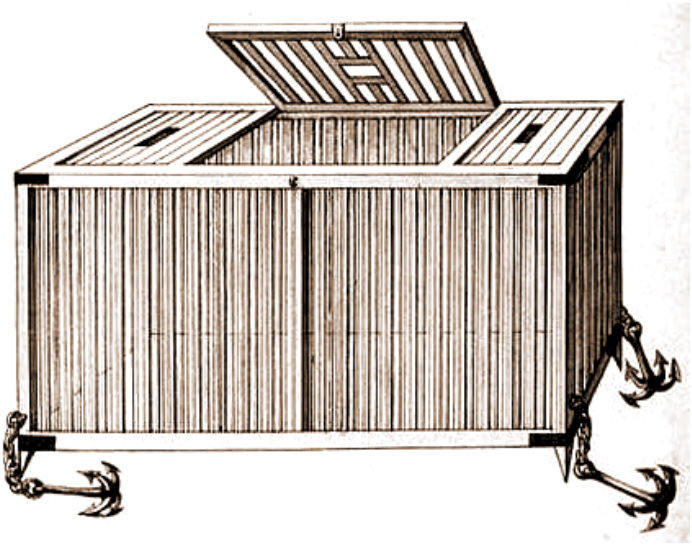

Figure 19: The third type of Jeanne's "cages."

mersed in the shallows of the sea with anchors, the upper part being sufficiently out of the water so that one can study the mollusks therein.

Except for her third type, which she described and pictured in great detail in her 1860 report (see below), we know nothing about the dimensions, shapes or construction of the first type of her cages (a glass one for use in her study of the type that we would call an aquarium today) but we do know that it had an efficient water circulation system that was based on rubber hoses pumping salt water in and out from the nearby sea. We also know very little about the construction of the second except that it involved an aquarium as well. Regarding the third type, in 1856 she described it in detail in her book, (*Observations Physiques Suis le Poulpe de L'argonauta argo, Commencées en 1832 et Terminées en 1843*.):

These cages [see Figure 19] **were 4 meters (13 feet) in length, 2 meters (6.5 feet) in height and 1 meter 40 centimeters (4.5 feet) wide. I left a space between the bars of wood so that the sea water could circulate freely without the mollusk escaping from the cage. An angle iron at each corner held the cage together. A door opened above the cage and two small openings in the door had been formed on the right and on the left. From there I could observe my animals without being seen. At each bottom angle I also had fixed an anchor to keep it firmly in the sea. I introduced into the interior of this cage seaweed, marine plants, small portions of rocks, small pebbles, millipora, venús, tritons and other shellfish mollusks.**

This was the cage she used for her studies on *Argonauta argo*. The name "cage," which she used for all of her containers, immersed or not, was very apt, however, for this one since it was definitely not an aquarium.

The following excerpt written by Richard Owen and titled "Origin of the Aquarium," is from *Cosmos*, Vol. 11, July-December 1857:

Twenty-seven years ago in 1832, Mrs. Power had come to settle on the coast of Sicily and became enthralled with observing the development and behavior of mollusks and other marine animals. It was there that shortly after her arrival she had built two aquariums: one for mollusks without shells, the other for the shell mollusks. At the bottom of these tanks was deposited sand taken from the sea, fragments of rocks to which grasses and marine plants still adhered, and branches of red coral - pink, black, etc. She also populated them with millépores, mollusks, asteri, various species of crustacea, and some small fish; and above all, the main object of her studies, her treasured *Argonauta argus*, whose mysteries she wanted to penetrate. Mrs. Power's home and her aquariums were located on the seashore; she could therefore often renew the water within which her little world lived, and she had not, therefore, had to be preoccupied with the tricky question of their cleaning, the only addition - important, it is true, though secondary - made to modern aquariums.

The *Journal du Cabinet Litteraire* de l'*Academia de Catania* issue of December 1834, *Faro* of May 1836, the *Magazine of Natural History* of February 1838 and the English *Athenaeum* of February 16, 1839, contain if not the description of the basins of Mrs. Power at least the accounts of her observations upon which the famous professors, messieurs Maravigna, Gemellaro, de Giacomo, the illustrious Owen and Charlesworht, made favorable reports. It is therefore certain that it is to our kind and learned countrywoman that the glory of the aquarium was restored. But at the same time she had a happier idea: that of marine cages, called in Italy gabbiolina alla Power - in England, Power Cages - established by her in the lazaretto of Messina on a

very accessible shallow area, with special authorization by the Neapolitan government, and remarkable by its purity in the highest degree and extraordinary transparency of its waters. The cage was circumscribed by bars, spaced enough apart so that the water and the small animals could move around in them without difficulty but narrow enough to restrain the creatures that had been imprisoned there in order to extract their secrets from them.

Rocks were first introduced, with the algae, corals and shells that adhered to them, then argonauts, asteri, sea urchins, fish, etc. Occupying the center portion of the cage, the animals continued their development much better than in the narrow aquariums. Madame Power, their guardian and "mother," twice daily brought them the food appropriate to their needs. A sort of platform or pulpit, raised 50 centimeters [about 20 inches] above the water level, dominated the cage. The cage was covered by a hatch which was raised at will and in which two openings were arranged on the right or on the left, which allowed her to see without being seen. It was there Madame Powers sat for long hours, observing and writing in her journal her observations, noting with great care what she saw forming or performing before her his eyes.

There she saw the argonaut's octopus build or repair her shell; the nodiferous triton, which had been guillotined, to take a new head; it was there that she initiated herself to the entirely unknown habits of *cerithium, coenus, murex, fusus, bulla, pinna, asteria, octopus vulgaris*, and *powerii*, and a large number of other marine animals. Each of our readers will be able to see, in the library of the *Jardin des Plantes*, in the interesting pamphlet entitled *Physical observations on the octopus of argonauta argo*, the descriptions and the drawings of the beautiful cages that we could only sketch.

Let's say a few words about a third portable aquarium designed by Madame Power that served her well in her studies of small mollusks. She took a cylinder of clay and split it along its length so as to transform it into two semi-cylindrical vases open at their extremities. She took a board a little wider and longer than the semi-cylindrical vase and immersed it in the sea long enough for it to be to covered with moss, algae and small shells. It was attached by circular metal strips to the board, its rectangular base open at the bottom and the convex part closed at the top. The middle strip bore a ring, and a rope passed through it served to carry and suspend the little apparatus in the sea or in the cage where small animals were introduced

Figure 20: The Cittadella, the remains of the old fort nearby to where Jeanne lived.

and studied. The openings of the ends of the small cylinder were closed by a framework that was sufficiently open to admit water without allowing the prisoners to escape.

We know from this account that the second type mentioned by Maravigna, "…of glass, for small mollusks, protected by an external cage of bars …," was abandoned by Jeanne and replaced by the fourth one described above by Owen as a "… third portable aquarium..." A glass aquarium would have to be small and would be more difficult to immerse. Jeanne also bemoaned the fact that it was too narrow for her purposes.

In 1836 she wrote in the *Atti dell' Accademia Gioenia di Scienze Naturali*:

For this object I thought of cages which were constructed under my direction; they were 8 palms long, and 4 palms wide with a convenient interval between the bars [she used about 1/3 inch], which allowed the water to enter freely when placed in the sea, whilst the escape of the animal was prevented. I placed the cages in a shallow bottom in the sea near our Cittadella [a fort in Messina] in a spot where I could examine them without disturbance.

With regard to the palm, it was a unit of length dating back to ancient Egypt, originally based on the width of the human palm and then variously standardized; in Sicily at the time it was roughly about 9.5 inches (Palaiseau, 1816). Thus her "8 palms long, and 4 palms wide" was equivalent to 6.3 feet long, and 3.2 feet wide. These dimensions were used in her reports written in Italian and in English. However, in her reports written in French, the dimensions were given in meters equivalent to 13 feet in length, 6.5 feet in height and 4.5 feet wide. This discrepancy suggests that either there were two identical cages differing only in size or else Jeanne made a mistake in the unit conversions. The first is the simplest explanation but a cage 13 feet long does seem overly large for the Argonauts and would be more difficult to handle. However, since she had a minimal (or no) formal education, the second is also plausible, but how then could this happen with James helping her and even translating her Italian papers into English? I leave the explanation to readers of this essay.

USING HER CAGES

In 1832, Jeanne first began to use her cages. In the cages that were immersed into the sea near the Cittadella on the peninsula of S. Raineri that encloses the port of Messina, as well as in those that were kept at home, Jeanne housed and bred the mollusks for her experiments ("There I introduced a quantity of living Argonauts, taking care to prepare them every two or three days for the necessary food with naked and hard shellfish, with the headless conchifera, venus [a bivalve], etc. and what I collected with a rake (oysters)."

In September of 1833, Jeanne conducted multiple experiments before coming up with the idea to

Figure 21: Giuseppe Saverio Poli (1746-1825).

break the shell and observe the octopuses' behavior. She punctured pieces of the shell of an individual and placed fragments from other Argonaut shells into the cage. She watched for three to six hour increments, patience wearing thin, until right before her eyes she saw one Argonaut repair its shell with the special membranes on its front two arms - the ones rumored to be used as sail. It was proof that the paper nautilus did create the egg case itself. She noted how the membranes on the two dorsal arms, which secrete the calcite, moved over the opaque case with gentle craftsmanship. "Nobody before me… has seen how the *Argonauta* appears with its membranes extended on its shell," she wrote. Close studies on the tissue of the thin, membranous webs have shown that they have calcium inclusions that are not found anywhere else on the female Argonauts.

Until the late 18th century, the study of mollusks was based largely on shells. Very little research or published information existed about molluskan anatomy and soft tissues. Giuseppe Saverio Poli (1746-1825), recognized by many as the Father of Malacology, changed this with his monumental publication, "Testacea utriusque Siciliae eorumque historia et anatome" (1791-1827). Returning to Jeanne's comments,

Encouraged by the distinguished Carmelo Maravigna, the most learned Canonico Alessi and other friends, to present to this illustrious Academy [i.e., l'Accademia Gioenia di Catania, named after the catanese naturalist Giuseppe Gioeni d'Angiò] the shell of the Argonauta that I patiently observed to learn the way the animal used to build it, I was made to deduce in a different way to what the famous Poli had done that the Conchiglia belongs to the octopus without any doubt. It will be seen the animal repaired the faults that I made in the Conchiglia, which has two different aspects, the whitest part of the two shells is the most distant of the exhalation and the new formation, and the shell marked N.2 shows the way I worked. It is therefore it pleases me to present this observation of mine to the Academy as a sign of respect in which I hold it. At the present time I am dealing with arranging some objects of Natural History to make a gift to it.

So wrote Jeanne in 1835 to the General Secretary of the Gioenia Academy of Catania, to whom she had already the previous year sent the results of her early research on the *Argonauta argo*, research that was presented ("read") in the session of December 1834 by Prof. Carmelo Maravigna. In November 1835 Maravigna recalled the contacts between Jeanne and the Gioenia Academy:

Of these observations and experiences Madame Power wrote an account of some early research that she asked me to present to Gioenia and in fact it took place in the ordinary session of September 1835. [...] This account was read in the session that month and likewise (I think) included in the Atti Gioenti [Acts of Gioenia] of November 26, 1835, when the members were read this second

Figure 22: ***Argonauta argos*****.**

compendiosa and valuable research [the research tended to prove that the octopus that resides in Argonauta is the true shellfish of the Conchiglia, and also its builder] and Jeanne was "Unanimously proclaimed" a Corresponding Member of the Accademia Gioenia di Catania.

Note that in 1835, women were not members of scientific societies so this was quite an honor for her.

In 1836, in a report that summarized her experiments began many years prior and which was read in the Academy session of November 26, Jeanne presented the picture of the state of zoological knowledge on the *Argonaut Argo* based on her research and, importantly, she explained the method she followed in her experiments and the physiological consequences that derived from them. Jeanne traced the extraordinary experiences that allowed her to shed light, through observation and experimentation, on the mollusk that continued to make naturalists disagree, divided between supporters of her constructive theory versus the parasitic nature hypothesis ("It has been the subject of great controversy for the naturalists to determine with confidence, whether the octopus of the Argonauta was the blacksmith of the shell or if the situation was similar to that of the hermit crab moving in after the true inhabitant was chased away, devoured, or naturally died").

Jeanne's research on *Argonauta argo* continued to be encouraged and supported by her naturalist friends:

The distinguished Prof. Carmelo Maravigna, Prof. Anastasio Cocco, and Prof. Carlo Gemmellaro, encouraged me to push ahead with my research, and having been honored by this illustrious academy of the title of corresponding correspondent, I have been more and more encouraged that my research would be useful. Professor Carmelo Maravigna expressed his admiration to Jeanne: I was amazed by her sagacity and patience, and of the unexpected results of her new observations and discoveries [...] but these virtues bore fruit to other discoveries, and who knows how many others there will be.

In the following months Jeanne expanded her field of research and prepared two more accounts, which she presented to the Gioenia Academy one on the reproduction of the testaceous shells and another on the fossils she found in the area of Capo Milazzo. As Maravigna wrote in 1837:

Madame Power does not content herself with having demonstrated with ingenious experiments and observations that the Mollusk that ordinarily one finds nested in the Argonauta Argo shell is the true blacksmith, not satisfied with the honors received for the reproductions obtained from the limbs cut off from the mollusk of the triton nodiferum, the murex trunculus, and other similar mollusks, in this beautiful labor she offers us a catalog of the fossils she found at Capo di Milazzo. It was a very precious travail because it was our first introduction to some of the fossils belonging to our island.

SO WHERE'S THE MALE?

Even today there is much that we do not know about the Argonaut, and its mating habits are no exception. Argonauts exhibit extreme sexual dimorphism in size and lifespan. Females grow up to 4 inches and make shells up to 12 inches, while males rarely surpass ¾ of an inch. The males only mate once in their short lifetime, whereas the females are capable of having offspring many times over the course of their lives. In addition, the females have been known since ancient times, while the males were only described in the late 1800s. What we do know is that when the male and female hook up, the male leaves something behind, other than sperm, of course. Specifically, it's a specially adapted arm called a hectocotylus, A hectocotylus (plural: hectocotyli) is one of the arms of male cephalopods that is specialized to

store and transfer spermatophores to the female. For fertilization, the arm is inserted into the female's mantle cavity and then becomes detached from the male (see Figure 23).

The hectocotyl arm was first described in Aristotle's biological works. Although Aristotle knew of its use in mating, he was doubtful that a tentacle could deliver sperm. The name hectocotylus was devised by Georges Cuvier (1769-1832), who first found one embedded in the mantle of a female Argonaut. Supposing it to be a parasitic worm, in 1829 Cuvier gave it the binomial name, *Hectocotyle octopodis*. While Villepreux-Power was never able to directly study male Argonauts, she observed hectocotyli during her experiments. She believed that these wriggling appendages were part of the Argonaut reproductive process, but she was rebuffed by the (mostly male) naturalists of her day who, following Cuvier, held that they were parasitic worms.

JEANNE FINALLY RECEIVES SOME POPULAR RECOGNITION

Meanwhile, Jeanne's research on *Argonauta argo* began to be mentioned in Europe by other scholars in their reports. Between 1836 and 1837, some Sicilian periodicals of wider dissemination published her results, such as *Il Faro* (Messina) and the *Passatempo per le Dame* (Palermo).These observations of the "illustrious naturalist" were also published in the twelfth issue of the newspaper *Gioenio di Catania*, where an account was given by Prof. Carmelo Maravigna **"as her achievements, known by a few scholars of the island, and much less among women, deserved a brief mention in this newspaper to make it better known; that in the end, beyond the satisfaction of the spirit, which remains satisfied after the discovery of a truth, no other reward is obtained from us with so many painful trials, than a bit of praise."**

Meanwhile, after the third account of her observations on the octopus of the Argonaut written by "our colleague Madame Power" that was presented at the Gioenia Academy on December 22, 1836 by Prof. Carlo Gemmellaro, the following year Jeanne sent the results of her observations, together with some specimens of mollusks, to the *Zoological Society of London*, but her conclusions did not convince some marine biologists, such as Henri-Marie Ducrotay de Blainville (1777-1850), a French zoologist and anatomist [He was the taxonomic authority of numerous zoological species, extinct and extant, including the eponymous Blainville's beaked whale, *Mesoplodon densirostria* and in 1822 coined the term "paleontology"] who supported the thesis of parasitism of *Argonauta argo* and who was not very convinced either by the experiments made later by the famous French malacologist, Sander Rang (1793-1844) in the port of Algiers, that also confirmed those of Jeanne.

Regarding Rang, Jeanne related it in detail in her book of 1856 and taken again in that of 1860:

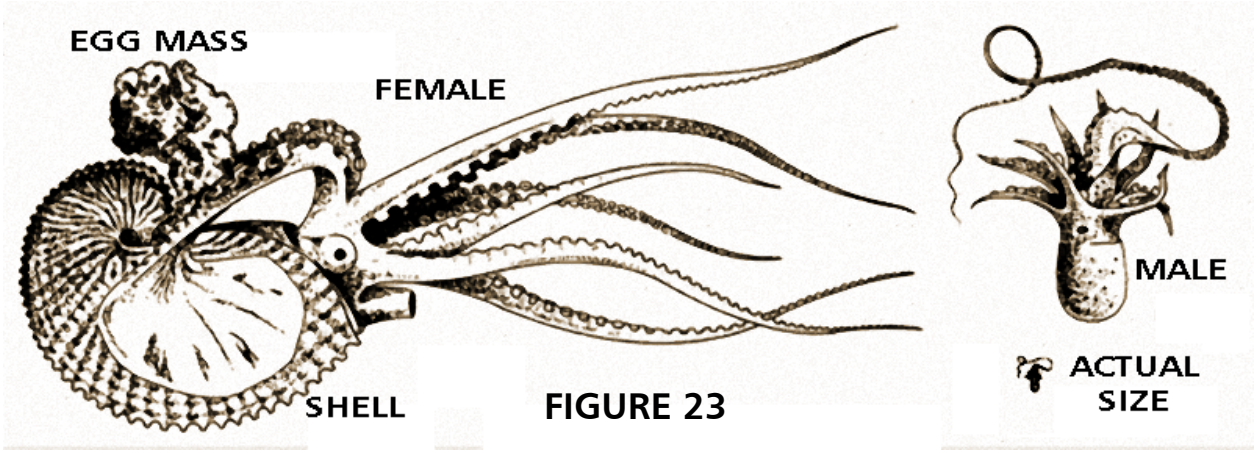

FIGURE 23

Figure 24:
Henri-Marie Ducrotay de Blainville
(1777-1850).

Monsieur le Chevalier Alban de Gasquet, captain of a frigate, having been at Messina at the beginning of 1835, came to see me several times, accompanied by the officers of his frigate. Having informed him of my discoveries concerning the Argonauta, he found them very interesting, and told me that I should send them to the Institute of Paris; that he had a friend, M. Rang, an officer in the Royal Marine Corps, who would be happy to present them on my behalf to the Institute. I gave him a copy in Italian, written in my own hand, accompanied by a letter addressed to M. Rang, leaving Mr. Rang and M. de Gasquet ignorant of the contents of the said memorial. was read in 1834 at the Gioenia Academy of Catania, as can be seen from the newspapers cited below.

Shortly after, I received notice from M. de Gasquet that my memoir and my letter had been personally delivered to M. Rang. Having received no answer from M. Rang, although a long time had elapsed, I wrote him again; he kept a stubborn silence. Finding myself in London in April 1837, I learned that Mr. Rang, abusing the confidence I had in him, and taking advantage of my observations, had written a note on the Argonauta Argo dated 1837, that is to say, three years after my publications in Catania, and two years after my sending him my memoir.

M. Rang claims to have discovered in 1837 the use of the octopus membranes of the Argonauta Argo, a discovery I had already made in 1833 and which had been read in 1834 at the Gioenia Academy of Catania, and on which the professor C. Maravigna had made a report inserted in the Journal of the Literary Cabinet of the Gioenia Academy of Catania, in December 1834. Another report was again made in the same journal by professors Ch. Gemmeliaro and di Giacomo.

It is clear that Mr. Rang did not know the use of the aforesaid membranes, since he does not say that they are used for the manufacture and repair of the shell. He claims that the membrane serves only to maintain the shell so that it does not escape the octopus, while it serves, as I say in my memoir, in the manufacture and repair of the broken shell. The octopus swims with the membranous arms within the shell or on the shell, according to its whim. It swims, the end of the membranes applied on the turns of the shell, and when the sea is calm and a light wind swells them, we see sailing his small boat.

I will not have fun criticizing M. Rang's commentary; I think, moreover, that this would be a perfectly useless task for all the studies of M. Rang do not even have the shadow of probability; and though he had in his hands, as he says himself, the previous observations which I had made, he has not succeeded in giving to the public studies that deserves the slightest merit; however, I will allow myself a few observations on the serious mistakes that exist in his commentary.

Back in 1837 , Jeanne was not shy in commenting upon Rang's work and we see here a different side of her (Power, 1937):

Not only are his observations erroneous, but his drawings are incorrect, and the manner in which they are presented demonstrates perfectly that M. Rang did not study with the thoroughness and perseverance that is necessary to arrive at an exact knowledge of the mores and habits of this animal, but that is what M. Rang wants us to believe. He did not succeed in his observations, and to arrive at such a result, it was not necessary to take a patronizing tone, for although my studies were anterior, they are serious, exact, and animal, as I present it, has the merit of the natural. I reproduce it as I have seen it, as it exists, and as any observer will see it. [...] Finally, M. Rang has greatly expanded on this subject; he talked a lot without saying anything precisely.

The "Battle of the Argonaut" had now begun and would continue between de Blainville in Paris and Owen in London, where Jeanne's theses would eventually prevail over those of parasitism.

RICHARD OWEN

Since Richard Owen was an important figure in Jeanne's scientific life, it is important to introduce him here in some detail.

Sir Richard Owen (1804-1892) was a British anatomist and paleontologist who is remembered for his contributions to the study of fossil animals, especially dinosaurs. He was the first to recognize them as different from today's reptiles; in 1842 he classified them in a group he called Dinosauria. Owen was also noted for his strong opposition to the views of Charles Darwin.

Owen was educated at Lancaster Grammar School and was apprenticed in 1820 to a group of Lancaster surgeons. In 1824 he went to Edinburgh to continue medical training, but in 1825 he transferred to St. Bartholomew's Hospital in London. He was admitted to the Royal College of Surgeons of England, where he was engaged as curator of the Hun-

Figure 25: Paul Charles Léonard Alexandre Rang des Adrets, in publications called Sander Rang, (1793-1844) with his wife, Margueritt.

terian Collections (made by John Hunter, the renowned anatomist) and set up in medical practice. In 1830 he met Georges Cuvier, a celebrated French paleontologist, and the following year visited him in Paris, where he studied specimens in the National Museum of Natural History.

Elected a Fellow of the Royal Society in 1834, in 1836 Owen became Hunterian professor at the Royal College of Surgeons and in 1837 its professor of anatomy and physiology, as well as Fullerian professor of comparative anatomy and physiology at the Royal Institution. Leaving medical practice and devoting himself to research, he was appointed superintendent of the natural history departments of the British Museum in 1856. From then until his retirement in 1884 he was largely occupied with the development of the British Museum (Natural History) in South Kensington, London. On retirement he was created a knight of the Order of the Bath.

Among Owen's earliest publications were the "Descriptive and Illustrated Catalogue of the Physiological Series of Comparative Anatomy Contained in the Museum of the Royal College of Surgeons in London" (1833), which enabled him to acquire a considerable knowledge of comparative anatomy. His Memoir on the Pearly Nautilus (1832) was a classic, and he became a highly respected anatomist.

By 1859, the year of the publication of Charles Darwin's *Origin of Species*, however, Owen's judgment was muddied by his sense that his own preeminence in biology was about to be lost, and he set about to discredit Darwin, who had been a good friend and colleague for 20 years. Owen wrote a very long anonymous review of the book (*The Edinburgh Review*, 1860), on which Darwin commented:

It is extremely malignant, clever, and I fear will be very damaging…It requires much study to appreciate all the bitter spite of many of the remarks against me…He misquotes some passages, altering words within inverted commas…

As Darwin's thesis began to become more accepted in the scientific community, Owen shifted his position somewhat; although he denied Darwinian doctrine, he admitted the accuracy of its basis, claiming to have been the first to have pointed out the truth of the principle on which it was founded.

Unfortunately, Owen developed a reputation for controversy, was accused of stealing other scientists' specimens and undermining people by writing anonymous reviews of their work while supporting them in public. Owen's contemporary and rival Gideon Mantell whose attempts to reconstruct the structure and life of *Iguanodon* began the scientific study of dinosaurs, claimed it was "a pity a man so talented should be so dastardly and envious."

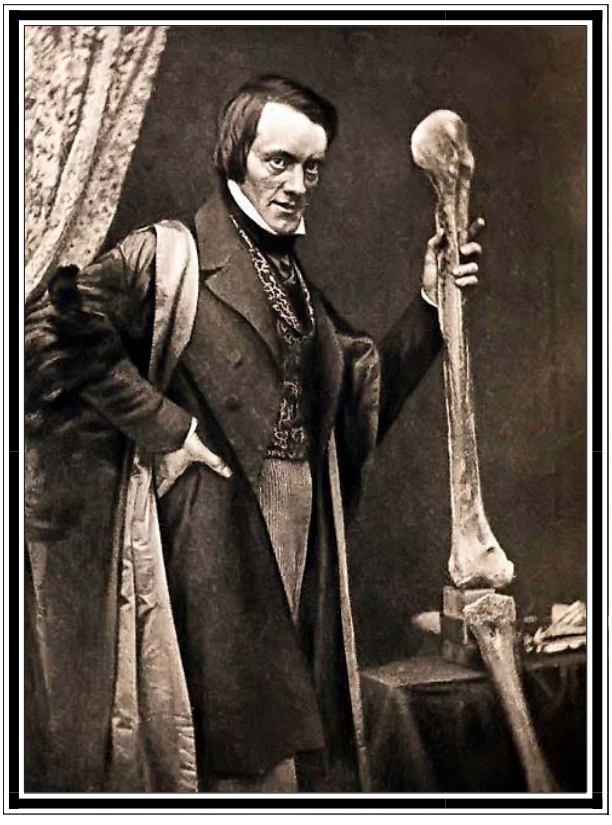

Figure 26: Richard Owen (1804-1892) holding a Moa bone.

MISFORTUNE STRIKES THE POWERS

In 1838, at the time of the publication of the royal decree of Privativa, the "Power & Unett" company was dissolved by mutual agreement between the two partners, the factory already having suspended its activity. On August 31, 1837 Power had communicated to the Court of Commerce the decision, taken jointly with his partner James Robinson Unett, to dissolve the business and to withdraw from Sicily. All the reasons for this decision are not known but on February 22, 1838 Jeannette informed prof. Antonio Di Giacomo, General Secretary of the Gioenia Academy, that she had just returned to Messina with her husband who, on the advice of London doctors, must spend a period of convalescence, after a "serious illness" contracted by her husband, for the healing of which no remedy was found by the London doctors.

In autumn of 1838, the Powers departed from Messina to move to England, leaving behind several objects listed in a notation on September 28, 1837 and kept in 16 closed and nailed cases to be sent to London. At the end of November, James Power asked the Matthey & Oates shipping firm of Messina to send to him in London "all the effects left by Mrs. Power in the hands of Mr. Matthey." At the beginning of the following year, 16 boxes containing books, table cloths, stuff, fossil shells, three pieces of marble, a monetary and an ancient column of agate were loaded on the brig Bramley, but they would never arrive in London. The brig sank at the bottom of the sea of Brittany along with most of the collections that Jeanne had with so much effort extracted from the sea of Sicily. Her Cabinet of natural sciences "by choice and rarity of species" was considered by experts "among the richest and most singular in Europe." The loss was enormous.

Thus, alternating returns to Sicily with departures to England, Jeanne in the spring of 1838 made one of her trips to the island where she wrote her *Itinerario della Sicilia* (Itinerary of Sicily) and then the *Guida per la Sicilia* (Guide for Sicily)." On May 17, having just returned to Messina ("very troubled by the Itinerario della Sicilia book, advised Prof. Di Giacomo that she will leave for England "no later than early August." Meanwhile, between spring and summer, her studies and research resume in Messina ("I'm working, and I'm almost at the end of three other accounts touching upon natural history"). And, being "in urgent need to consult for further travails" the memory on *Argonauta argo* presented by her two years earlier and published in the *Atti Accademia Gioenia*, on July 26 asks the general secretary to send her a copy of the volume containing her accounts of which she has no copy or to return the original manuscripts for a "short time."

A LONDON TRIP

In the early months of 1839 Jeanne was definitely in London and resided in Great Ormond Street. Here on January 26 she received a visit from Richard Owen who could now directly see with his own eyes her collections of fossils, shells and mollusks,

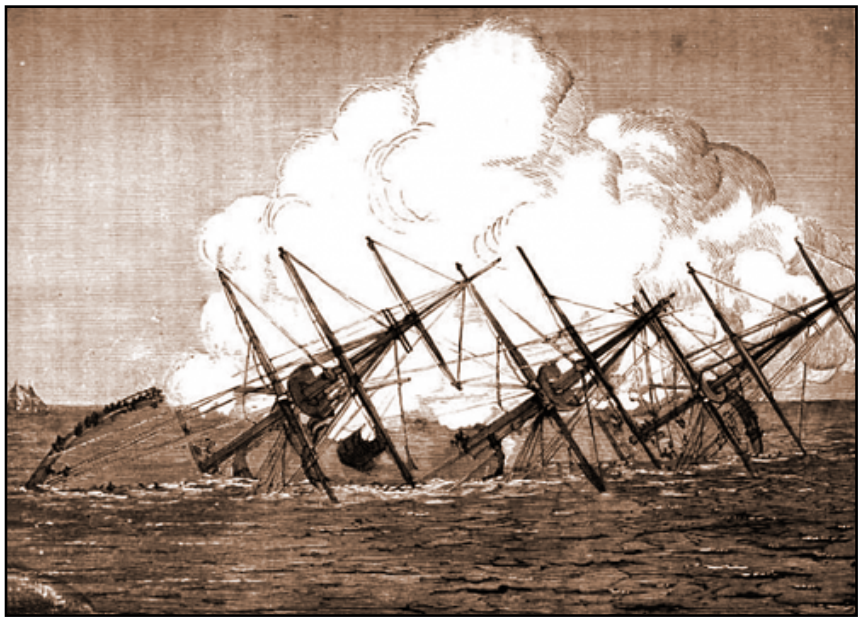

Figure 27: Most of Jeanne's collections sank with the brig Bramley in 1838.

but also and above all the specimens of *Argonauta argo* with the shell specially broken by Jeanne for her experiments, visible in three different stages of reconstruction. Owen's wife describes in her diary in 1839 their meeting with Jeanne:

January 26th. Richard and I to Great Ormond Street, where Madame Power showed us her boxes of fossils shells &c., and some mollusca in bottles and, above all, the argonaut shells with the fractures made by her in her experiments, beautifully filled up and mended: three specimens in different stages of reconstruction, the first filled up with a substance like the lining membrane of a boiled egg. This was done in about ten minutes after the piece was cut by Madame Power; the more perfect restorations had the corrugations formed to match the rest.

On February 2, Owen returned to Jeanne's house, taking away three containers of Argonauts.

February 2nd. Richard to Madame Power's and brought away three bottles full of argonauts. A beautiful collection! One of them has the sail spread back over the shell, the suckers on the points. Madame Power says that if we count the suckers they will be found to correspond with the number of points. This, with other circumstances, makes the question, I think, not whether the poulpe belongs to the shell, but how it has come to pass that, after so many have debated on the subject, Madame P. has been the first to discover these things.

On February 12 1839, during a session of the *Zoological Society of London*, prof. Richard Owen presented Jeanne's observations and research on *Argonauta argo*, of which she also showed some specimens she brought from Sicily. That meeting of the Zoological Society marked the highest recognition of the scientific world towards the theses of Jeanne that Blainville still challenged. And on March 22, 1839, with a letter sent from London to the members of the Gioenia Academy in Catania, she informs them of the success of her London mission. The success was underlined not only by the "unanimous" applause of all persuaded" members of her thesis, "namely that the octopus of *Argonauta* was the true fabricator of the shell and who has the power to redo missing parts," but also from the proposal made by various members to accept Jeanne as a Corresponding Member, to publish a memoir on the reproduction of marine specimens in the *Magazine of Natural History*, as well as the appreciation of "many of prominent scientists in different branches of Natural History who visit her and encourage her to continue her studies on the testacei and molluscs."

In 1839, while Jeanne was abroad, her *Itinerario della Sicilia* was printed in Messina, covering all branches of natural history and several of its historical sites. *The Passatempo per la Dame* deemed that it would not only be a guide to foreign naturalists, saving them both time and money, but also very useful in the education of youth.

Figure 28: Jeanne's Guide to Sicily.

BACK IN MESSINA

At the end of 1839 Jeanne was in Messina and completed a further series of experiments on *Argonauta argo* that January 30, 1840 was described in a letter to Richard Owen ("Experiments and Observations on *Argonauta argo* made during the months of October, November and December, 1839"). In addition to the letter and the specimens of mollusks, she also sent another more detailed account ("Continuation of Observations on the Polypus of *Argonauta* argo, in 1839") with three drawings of *Argonauta argo* in different phases. On 4 April 1840 she also sent to the General Secretary of the *Gioenia Academy of Catania* an account that was the continuation of the previous observations on *Argonauta argo*. To the new account Jeanne could not, however, attach specimens of the mollusk referred to in the text because they had already been sent to Professor Owen on January 30 with the letter concerning the observations so that he could refute in the *Zoological Society of London* the still contrary opinion of Blainville. Although Jeanne's observations had the same effect as when Sander Rang repeated them in Algiers on behalf of Blainville himself, the latter continued to hold the opposite opinion but was well refuted by Owen in the Atheneum with arguments that shocked the Blainville, who was unable to refute them. Meanwhile, in 1840 the material dedicated to *Argonauta argo* in the *Penny Cyclopaedia* was based almost exclusively on passages of Jeanne's texts, which were printed in full. It also contained detailed descriptions of both the invention of her cages, her methods, research and. Also in the spring of 1840, after completing the continuation of her *Argonauta argo* observations, Jeanne had other research in progress, the results of which she intended to send to the Gioenia Academy.

In this same year she proposed to reprint, in a much improved, correct and enhanced edition, her Itinerary for Sicily printed the previous year that contained some "defects" both because of haste and because, in her absence, "people unaware of Natural History [...] added, changed and interpreted her text incorrectly. At that time, while Jeanne was in Messina, her husband was in England and on April 25, 1840, James Power wrote to Richard Owen from London to announce not only the arrival of a letter from his wife for him from Sicily with some specimens *Argonauta argo f*or the *Zoological Society,* but also the publication of an article by Blainville that seems to have finally been convinced of Jeanne's theses.

THE YEARS 1841-1842

Of the following period little is known, but in the first days of 1841 Jeanne was in Messina and in the country house that was home to the Bolognese Domenico Galvani (Jeanne remembered him for his generosity and kindness) where she examined a conch shell found in the outskirts of the city. This period seems, however, to be characterized by personal or perhaps health problems. On January 29, 1841 at one o'clock in the morning in her home and in a hurry, "Lady Donna Giovanna Villepreux-Power, daughter of Don Pietro, wife of Mr. Don Giacomo Power, born in Juilac and domiciled in this City of Messina, in the village of Portalegni in the Gravidelle district, in the presence of the notary Perciabosco and four others witnessed her public testament to leave all her goods to her husband."

In the summer of 1842, the observations Jeanne made at the end of 1839 were printed in Palermo and then sent to Owen and to the Gioenia Acade-

Figure 29: Although did not discover the male *Argonauta argos*, Jeanne did discover the hectocotyl arm and concluded that it was part of the reproductive process and not a parasite.

my. Also in 1842 Jeanne published her *Guide for Sicily* in Naples where, in addition to the more traditional information and statistics useful for foreign travelers, it also offered a Natural History column and catalogs describing subjects of interest in Conchiology, Tetology, Ornithology, Botany, etc. found in Sicily. This Guide, which can be considered her last "gift" to the island where she had produced her extraordinary scientific findings, also marked Jeanne's departure from Sicily. She had arrived in 1818 as a "Cinderella" and now was a scientist known in European scientific circles, as well as Sicily.

THE YEARS 1844-1867

After leaving Sicily and after a stay in London, Jeanne and her husband settled in Paris where James, after recovering from his mysterious illness, became the first representative for France of the *Société du Télégraphe Sous Marin sous la Manche entre la France et l'Angleterre* (Underwater Channel Telegraph Society between France and England); the first submarine cable will come into operation on September 25 1851. Afterwards he was Secretary of the *Compagnie du télégraphe électrique méditerranéen* (Mediterranean Electric Telegraph Company), which in 1856 attempted unsuccessfully to link France and Algeria.

For Jeanne the departure from Messina marked the end of her experiments and her researches: "My untimely departure from Messina forced me to suspend the work that I was fond of." In the 1850s and 1860s and far from the sea, she published in Paris her previous research, which she dedicated to Owen, re-proposing his "Observations physiques sur le poulpe de l'Argonauta Argo," began in 1832 and ending in 1843, and collecting his "Observations et expériences physiques sur la Bulla Lignaria, the Astérias, the Octopus vulgaris et la Pinna nobilis," together with her essays on the marine specimens, Crustacé Poweri, on martens and on turtles in addition to those on *Argonauta argo* and a plan to study marine animals. Even after her departure from Messina, Jeanne wanted to continue to publish her studies, but the loss of her notes in the move from Sicily made this project unattainable: "After publicizing accounts on *Argonauta argo* and other marine animals, I was willing to continue my publications; unfortunately, in the confusion of packaging, when I left Messina my manuscripts went astray but it is only today that I managed to find them and extract the following observations." Thus, as Claude Arnal wrote, "Established in Paris, the naturalist no longer seemed to have had any particular scientific activities, except the publication of her works prior to 1856-60." In later years, however, her scientific interests seem to have changed, but not dormant. Jeanne shifted her scientific observations from the sea to the sky and in 1867 she published her observations on meteorites.

EULOGY

Jeanne Villepreux-Power was a member of many learned societies in Sicily and Europe: two in England, one in Belgium, four in France and eight in Sicily. These integrations were not insignificant as they were not allowed in major institutions like the Academy of Sciences or the Royal Society. They remained rare, as in the case of La Société Polymathique du Morbihan, where only Villepreux-Power and the poetess Elisa Mercoeur (elected correspondent in 1827) appeared in the

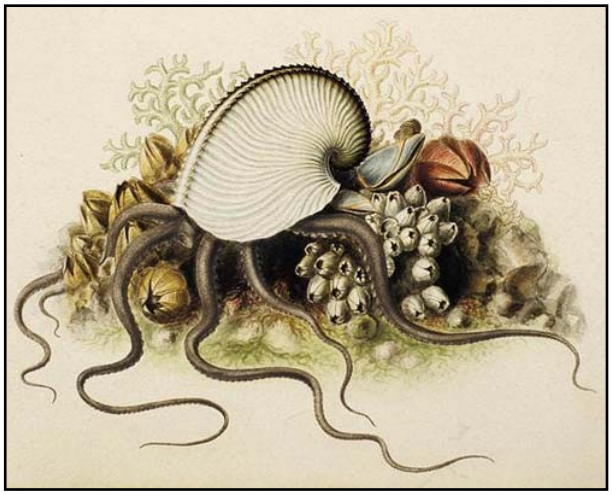

Figure 30: Jeanne was also an excellent illustrator. This is the only surviving example of her work.

list of members. She was accepted at La Société des sciences médicales et naturelles de Bruxelles, composed only of male doctors. Her status as a foreigner certainly facilitated these elections but they were always special and therefore never really legal; she was always a corresponding or honorary member and never a titular one. Jeanne Villepreux-Power was not an influential personality in the scientific institutions of her time, and if she belonged to some leading societies in London and Catania, the rules that relegated women scientists to the periphery of academies, societies and educational institutions were not completely overturned here.

Moreover, such a career was certainly not built without specific difficulties. She sometimes justifies herself in not devoting herself solely to domestic activities. In 1837 she writes:

Having for several years devoting myself to the natural sciences the hours that remained to me free of my domestic affairs (few are indeed the moments of study that people of my status and my sex can enjoy), while I was preparing a few marine objects for my little cabinet, the octopus of the Argonaute fixed my attention more than anything else [...].

1883, Matilda Joslyn Gage, analyzing the inventions made by women, those of Ipazia, Maria Agnesi, and Caroline Herschel, addressed the name of Jeanne Power as

[…One of the most eminent naturalists of the century. It was used by her in making curious scientific discoveries. The value of the aquarium to marine zoölogy is incalculable. Not only can rare species from the Indian, Artic, and Pacific oceans be brought into close comparison, but the subject of embryology can be studied, and the great Darwinian problems of evolution and permanence of type are likely to be solved by its instrumentality.]

Yet, despite the official acknowledgments and prestigious appreciations by some scholars for her research in many other areas of the natural sciences (from oceanography to astronomy, from zoology to botany, etc.), Jeanne Villepreux-Power has been almost forgotten both in the last period of her life and especially after her death. A long veil of silence and oblivion would fall for almost a century and a half upon this "Cinderella" who turned into a "femme savante" in the world of natural sciences that strongly leaned to the male, and who became a pioneer of marine biology and often the first woman to be admitted as a member of academies and other scientific institutions.

In Paris the Powers lived for about 25 years and it was during this period that, while James established himself in new activities, Jeanne disappeared as a scientist, observer attentive to natural phenomena and queen of oceanography: in her place another Jeanne took over, whose main role, if not unique, was now that of wife, a woman en-

Figure 31: *Jeanne Villepreux Power* by Anne-Lan. She and the artist were born in the same Department of Corrèze, France.

gaged in managing the affairs of the house and taking care of daily interests and abandoning her studies and research. Jeanne died at the age of 76, on January 25, 1871 in her native Juillac where she had taken refuge when the Frankish Prussian war had made life difficult in Paris. A year later, on January 9, 1872, James died in Paris in the house of Rue de l'Université 58 where he had spent together with his wife the last years of their long life together. It was an extraordinary couple who had lived in symbiosis since that distant day of 1818 in which their marriage was celebrated.

Thanks to this symbiosis in the 25 years of residence in Messina, Jeanne Villepreux became a true scientist thanks to her personal talents and thanks also to moral support material of her husband. To his wife, James certainly gave support from the human point of view at a time when women were limited and left on the margins of scientific studies. To have alongside her a husband who allowed her to follow her inclinations and passions undoubtedly allowed Jeanne to devote herself without problems to her research. To his wife, who had no personal income of any kind, James guaranteed financial support for her research and for her travels in a period when traveling was exceedingly expensive. Since Jeanne's research required some engineering training, James was the first one she turned to for help. Besides his expertise in commerce and finance, he had designed, had built and operated a sulfuric acid factory where glass containers were in everyday use. Furthermore, he collaborated in the publication of his wife's research by translating some of her scientific papers into English, as Jeanne herself remembered in gratitude.

In 1837, in an article published in the *Passatempo per le Dame* (*Pastime for Women*), in addition to indicating Jeanne as "an example that can serve as a model for all mothers of family," Alessio Scigliani also emphasized the extraordinary talents of her husband James, calling him "a man who was of a very sweet character and of the most amiable manners who should be honored as his embellished fame was united with the great merit of having seconded the genius of his wife for the natural sciences."

As Claude Arnal, the French authority on Jeanne Villepreux-Power wrote recently,

[…it would be unjust to close the eulogy of this exceptional woman without remembering that all this would have been impossible without the companion of his life, this Englishman, he also exceptional, who had the great merit of understanding his genius wife for the natural sciences and to love her enough to bear the consequences. Thanks, James!"

Jeanne Villepreux-Power and the Myth of the Invention of the Aquarium

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, February 16, 2019)

Jeanne Villepreux-Power was on born on Sept. 25, 1794 in the small town of Juillac in Central France. She is best known for her research on the paper nautilus, *Argonauta argo*, a cephalopod that resembles members of the genus *Octopus* in most respects.

Jeanne Villepreux-Power's mother was a dressmaker who knew how to read and write and who taught her daughter. Jeanne moved to Paris at age 17 and served as an assistant to a society dressmaker. In 1816 she crafted a wedding gown for Princess Caroline, the eldest daughter of Francis I of the Two Sicilies, for her marriage to Charles-Ferdinand de Bourbon, the nephew of Louis XVIII of France. This work brought her fame and the attention of the successful merchant, James Power, whom she married in 1818 in Messina, Sicily. The couple remained in Sicily for about 25 years, and during that time Jeanne taught herself natural history and described the flora and fauna of the island.

Between 1832 and 1843 Jeanne closely studied the paper nautilus, *Argonauta argo*. In 1832 she began to use what she called "cages" to aid her observations and experiments on the species. Using these devices she became the first to discover that *Argonauta argo* produces its own shell rather than obtaining the shell from another organism, which was a prominent competing belief at the time. She also made other discoveries involving *Argonauta argo and also other mollusks.*

In 1839 Jeanne published *Observations et expériences physiques sur plusieurs animaux marins et terrestres* ("Physical Observations and Experiments on Several Marine and Terrestrial Animals"), which recorded her work with *Argonauta argo* and other animals. In 1842 she published *Guida per la Sicilia* ("Guide to Sicily"), a comprehensive survey of the island's environment. The following year she and her husband moved from Sicily to new residences in London and Paris. During the transit a major part of her collections, records and other scientific materials was lost after the ship that carried those items sank. Although she continued to write after 1843, she discontinued her research.

Jeanne Villepreux-Power belonged to more than a dozen academies, including the *London Zoological Society* and the *Atti dell'Accademia Gioenia di Scienze Naturali* in Catania (Sicily), something unheard of at that time for a woman. In 1858 the British anatomist and paleontologist Richard Owen referred to Villepreux-Power as the "Mother of Aquariophily" and in 1997 a large crater on the surface of Venus was named for her.

DID JEANNE VILLEPREUX-POWER INVENT THE AQUARIUM?

Jeanne Villepreux-Power was a remarkable woman. In *The Penny Cyclopaedia* of 1840, the following appeared after the description of her research work on *Argonauta argo*:

Now, though there may appear in the account of these experiments evidence of their having been drawn up by one not deeply versed in zoology, there is an air of truth and sincerity about them that makes them to us as valuable at least as any that could have been the result of the inquiries of a more learned observer.

With little or no formal education, she bested Giuseppe Saverio Poli, considered the "Father of Malacology"; she bested Henri de Blainville, an authoritative, well-known figure in the field; and

she bested Baron Cuvier, the famous French ichthyologist. As a result of this, she revolutionized the study of marine biology, a fantastic accomplishment for any one with so little formal education and by a woman in an age where men did not take women seriously.

However, over the years we have read countless times on the internet that Jeanne Villepreux-Power was the inventor of the aquarium. Ironically, she is known more for this myth than for her real and more important accomplishments. That she was the inventor of the aquarium simply is not true.

In 1858 Richard Owen (a British anatomist and paleontologist who is remembered for his contributions to the study of fossil animals, especially dinosaurs) briefly described three cages she employed as attested to by her good friend Prof. Carmelo Maravigna in the *Giornale del Gabinetto Letterario dell'Accademia Gioenia di Catania* of December 1834. Owen had also previously described a fourth one, the second one above having been replaced by it (Owen, 1857).

Jeanne, therefore, had four types of cages: Two were made of glass (the first of which was used at home; the second was used for smaller mollusks and was in a frame so that it could be immersed in water) and the third (Figure 1) was a cage made out of wood designed to be immersed in water. The fourth, invented to replace the second which proved unsuccessful, was a cage made of clay for smaller mollusks and also designed to be immersed in water.

The wooden cage was the one she used for her work on *Argontauta argos* and was the one that made her reputation in the scientific community. It, however, was not an aquarium since by definition aquariums are made to hold water and this one was made to be immersed. If it had been water-tight there would have been the very devil in getting it submerged, it would not have allowed sea water to pass through it (this was important since Jeanne's success was achieved by studying *Argonauta argos* in their natural habitat - the sea - something the previous marine biologists - all men, by the way - had not done) and it would have been heavy and difficult to handle. The volume of this cage was 117 cubic feet, equivalent to almost 878 gallons of water, and if it had held water it would have made it the world's largest aquarium ever existing before modern times!

Nothing is known about the two glass aquariums, neither their shapes nor their dimensions, or whether they were identical, except for Jeanne's comment that the glass aquarium that was in a frame was "too narrow." (The Argonauts preferred to occupy the center of the aquarium; if it was too narrow, there would be insufficient room for them there and they would migrate nearer to the sides where they would be much more difficult to observe and study.)

Now we might conjecture about these glass aquariums but they would only be suppositions, not facts. We might for instance, postulate that they were flat-sided since the whole point to them was to be able to see and observe the mollusks clearly. We might postulate that Jeanne bought or was given them, or had designed and had them

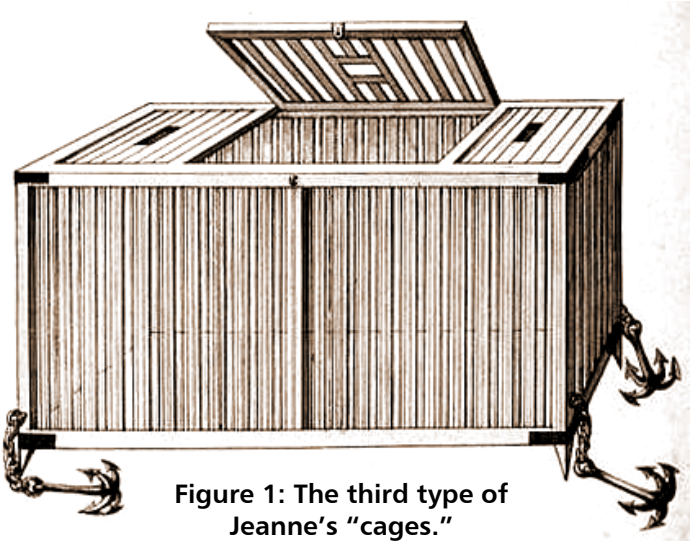

Figure 1: The third type of Jeanne's "cages."

made. If bought or given, then she could not have invented them. If she had designed and had them made then indeed she would had invented the aquarium. However, in Jeanne's days, containers made of glass designed to hold liquids were made by the press and blow method. This involved two molds made of wood and involved five steps:

1. A gob of molten glass was dropped into a blank mold;
2. A plunger then pressed down, forming the blank shape;
3. The blank shape was transferred to the blow mold;
4. The final shape was blown; and
5. The edges were finished off (see Figure 2).

This was a very expensive process for a custom-sized aquarium and some knowledge of the glass thickness required would have been needed if the aquarium was to be large enough to house 10-inch Argonauts. However, recalling Jeanne's remark that the immersible glass aquarium was "too narrow," if this were the case then she could simply have redesigned the aquarium and had another, wider one made. Since this was not done, it suggests that her tanks were purchased and that nothing suitable was available.

One other possibility is that she invented framed glass aquariums, but if they were framed and sealed, Maravigna would certainly have commented on this unique (and it had to be unique since it would be new) construction rather than just describing them as being "glass."

In any event, all this is conjecture and no proof that she invented the glass aquarium. What she did do, however, was to invent the submersible wood cage that was the keystone to her success and fame. So, where did this myth come from?

In one sense it started with Jeanne herself when she noted years later that in many newspapers that there was a great deal of interest in "aquariums and cages." She wrote to Richard Owen in August 21, 1857, reminding him that she had invented several in 1832 and 1834 that she had placed in her house for the studies of *Argonauta* and other marine animals, and also other cages she had placed in the sea, as well as a glass aquarium for smaller individuals. She stated that since it was she who "first had the idea to study marine animals in aquaria or cages," she wanted to keep her rights as inventor and requested Owen's help in this matter. Owen's entry in the Eighth Edition (1858) of the *Encyclopaedia Britannica* exalting her accomplishments and his naming her in the same year as "The Mother of Aquariology" (which he never defined) apparently was sufficient to put her mind to rest as she never raised the issue again.

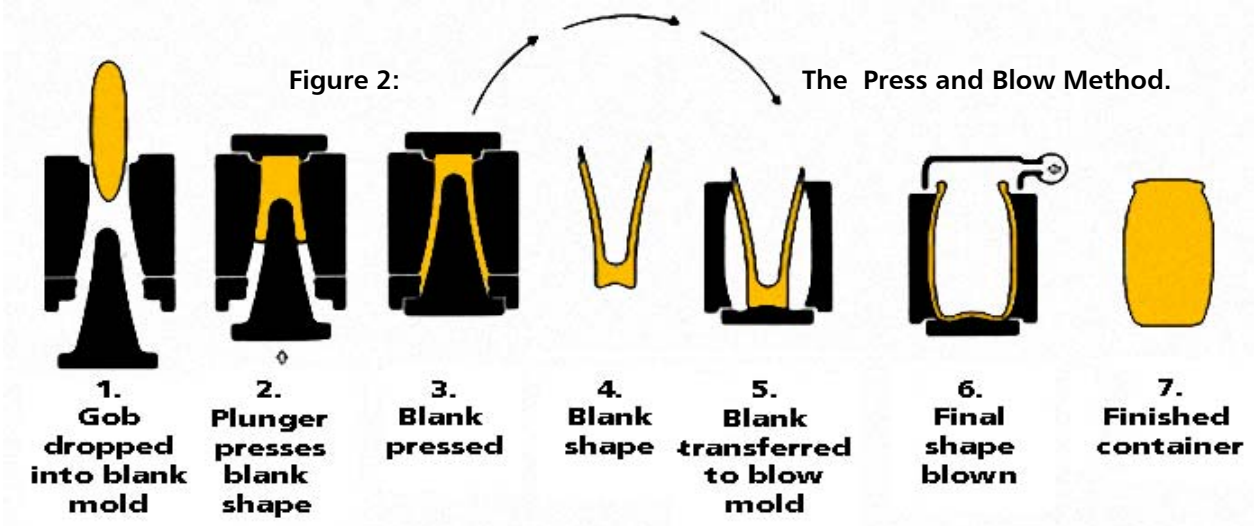

Figure 2: The Press and Blow Method.

However, the fault really lies with Owen who in his *Encyclopaedia* entry mistakenly referred to all three receptacles described by Maravigna as aquaria, rather than including only the first two glass types.

Attributing to Jeanne Villepreux-Power in the myriad of articles appearing on the Internet as the invention of the aquarium has prompted mistaken comparisons with my own essay, "Who Invented the Aquarium?" (Klee, 2012). Jeanne's aquariums were quite different from what she was observing in the newspapers of her day and quite different from those that I was addressing in my essay. The following excerpt is from "Links In The Chain; Or, Popular Chapters On The Curiosities Of Animal Life" (Kearley, 1862) and describes the basis for the definition of aquarium that was the subject of my article:

The chemical principles involved in this ingenious and beautiful contrivance are now too well known to require any lengthened explanation. It is a matter of familiar knowledge, that in the process of respiration, animals consume the oxygen or life-sustaining principle of the atmosphere, and give back in return a quantity of carbonic-acid gas, which is as deleterious to animal life as the oxygen is healthful and invigorating. It thus happens that when animals are confined by themselves in a limited quantity of air, this double process of deterioration speedily renders the fluid absolutely poisonous and destructive of life. But in respect to plants, a precisely opposite state of things obtains. By a process somewhat analogous to the respiration of animals, though not to be confounded with it, the vegetable world is continually appropriating the carbonic acid of the atmosphere, and giving back oxygen. In their relation to the atmosphere, therefore, the two great divisions of the organic world beautifully balance one another - each taking and appropriating to its own use what would he injurious to the other, and each giving hack that which the necessities of the other require.

In respect to the free atmosphere this mutually counteractive influence of the animal and vegetable kingdoms has long been familiar; we owe the Aquarium to the discovery that it equally holds good with respect to the atmospheric air contained in water. The gentleman to whom the world is mainly indebted for this discovery and for its practical application to natural history purposes, is Mr. Warington, of Apothecaries' Hall, who may fairly claim to be the originator of the Aquarium.

The aquariums I was describing in this essay were important to hobbyists since they had long sought out a means to keep fishes without having to continually change their water. Sir John Dalyell's sister, for example, reported that he was most particular in giving his marine animals sea water always out of the sea when it was flowing. He changed the water every morning and often twice a day if he perceived the smallest fragment of dirt amongst it, wiping and washing the glasses very clean. He procured his sea water twice a week and sometimes three times; it was carried in an earthenware jar holding about three or four gallons of water and a person was specially employed for this purpose. Kearley continues, describing what happened after Warington and Gosse had published their findings.

The publication of Mr. Gosse's elegant volume, "The Aquarium," opened up a new source of interest in connection with the subject. It suggested the establishment of the "Parlour Aquarium," by means of which private persons might have in their own houses, and under their constant notice, similar collections of animals to those which attracted such attention in places of public resort. The idea was no sooner suggested than it was eagerly caught up, and forthwith the Aquarium was elevated to the first rank amongst the ornaments of the parlour and the drawing-room. The expense, however, was something considerable at first; and, for a while, it was only in those "desirable residences," as the auctioneers phrase it, the substantial mansions of the people well-to-do

in the world, that you had any chance of meeting with the Aquarium.

But an increase of dealers, and the competition between them, soon made matters different; so that before long the man who had only a few shillings to spare could yet have his collection of pet Anemones, and keep, if he would, a whole aquatic menagerie inside his parlour window. Nor did it matter in the least, apparently, where, or at what distance from the coast he might reside; for like those famous bedsteads one sees announced at the railway stations, the Aquarium, it seems, is expressly adapted to be "sent free by post," and might anywhere he had to order by simply addressing a letter to one of the London dealers. In London itself the passion for the Aquarium raged for a while at fever point. The new invention quickly dispossessed the shop windows of all the old-fashioned globes of gold fish, and created such obstructive crowds upon the footpaths, as to rail for a speedy interference of the police. In West-end squares, in trim suburban villas, in crowded city thoroughfares, in the demure houses of little, unfrequented back streets, and inside the fiat, sillless windows of poverty-stricken Spitalfields and Bethnal Green [both notable slums of London at the time], everywhere you saw the Aquarium in one form or another, and had abundant proof how ardently the cockney of every grade was attached to "the new fancy" which had come into fashion.

Thus the aquariums that Jeanne was seeing in the periodicals she was reading were not her aquariums; she knew nothing about the relationships between plants and animals. Indeed, some periodicals maintained that the cages made by Jeanne could not be called Aquaria, but only receptacles suspended in the waters of the bay. The following is from *The North American Review* for July 1858 and was written by Isabella James, one of our earliest American writers on the aquarium:

As is usually the case with all popular inventions, there are many claimants for the honor of having made the first aquarium. It is easy to see how scientific research into the mysteries of the ocean, replete with life, so little known and still less understood, should lead its votaries in different lands to form similar plans for rendering this microcosm accessible to their own and other eyes.

The cages made by Mrs. Power, a learned French lady residing in Messina in 1832, although she gave to some of them the name of Aquaria were merely receptacles suspended in the waters of the bay to enable her to watch the habits of marine animals. The plan of maintaining the balance of nature by means of plants was unknown to her. To Dr. Johnson, an English naturalist, it appears, should be assigned the first practical application of the well-known theory, that the gaseous exhalations of animal and vegetable life mutually support each other.

Figure 3: Young women around an aquarium, *Le Journal des Demoiselles*, p. 257, August 1864. This was the kind of aquarium Jeanne was viewing in the French periodicals of the time.

The following is from the *Hand-Book to the Marine Aquarium*, June 23, 1873, written by William Alford Lloyd:

In 1840 Madame Power kept marine animals alive in Messina, and when, in 1860, a public aquarium was set up in Paris for the first time, she being then a resident in Paris, it was stated that she had invented aquaria; but this lady, by her own showing, knew nothing of the employment of plants in the manner stated, though she might have used them so, unconsciously, and derived benefit from them.

Although there are some minor errors in both of these accounts, they agreed that Power's cages were not aquariums following the so-called balanced aquarium principles in the sense of Warington, Gosse, Lankester, Bowerbank, Mitchell, Ward and others of the time were not involved. [Note: Although Isabella James credits George Johnston with being first to successfully apply the balanced aquarium principle, in my essay "Who Invented the Aquarium?" (Klee, 2012), I awarded this title to him only for the category of "Marine Aquarium Sans Fishes."]

SO, WHO DID INVENT THE AQUARIUM?

First of all, *I will require that the invention of the aquarium and its development must proceed chronologically without interruption to arrive at how we use this word today* . This lets out the Egyptians and Romans, for example; although they certainly had aquariums, they were not responsible for the word nor did their aquariums have any relationship to the aquariums of today.

In my essay titled "A Few Words on the Origin of the Word Aquarium" (Klee, 2015) I noted that Cato, in 160 BC, was the first author of record to use the word aquarium. Examples from his book, *De Agri Cultura (*"On Agriculture") include the following: **situlum aquarium** ("water bucket"), **urceum aquarium** ("water vessel") and **bonumque aquarium** ("well-watered"). Note, however, that aquarium here meant water and not a container of water.

In Cicero's *Three Books of Offices and Other moral Works*, written in 44 BC, we find the following: Tum Canius inquit, quæ, Pythi, quid est hoc? Hic, ne, tantum piscium, ne tantum cymbarum? Et ille inquit, quid mirum? Quidquid piscium est Syacusis est hoc poco, **hic aquatio**…

"Then Canius says, 'What is this, pray, Pythias – so many fish – so many boats?' And he answers, 'What's the wonder? Whatever fish there are at Syracuse are taken at this place; **here is their watering-place**…'"

"Aquationis" is the genitive (possessive) form of a Latin word that was used by Julius Caesar, Palladius, Columella, Pliny and Cicero with regard to water that had several different meanings but Cicero uses the nominative form "aquatio" here to mean "watering-place; it was not used in the sense of a container to hold fish (or anything else for that matter). Thus at no time did the Romans use aquarium or its cousins in the sense of a container; rather, it was either meant as water or a place (but not a vessel) that held water.

ENTER CARL LINNAEUS

The fame of Carl Linnaeus (1707-1778) - ennobled Carl von Linné in 1757 - rests upon his reform of natural history. Among other things, by introducing binominal nomenclature in his *Systema naturae* (1735), finally adopted in *Species plantarum*

Figure 4: Watering place near Cervara, a municipality in the province of Rome in the Italian region Latium, located about 31 miles east of Rome.

(1753), he created order in a period when there was great confusion in naming animals and plants. His close friendship with Peter Artedi should also be mentioned. Artedi was a Swedish naturalist and is known as the "Father of Ichthyology." Intending to become a clergyman, he went to study theology in 1724 at Uppsala University, but he turned his attention to medicine and natural history, especially ichthyology, a science that he influenced greatly. In 1728 Carl Linnaeus arrived in Uppsala, and a lasting friendship was formed between the two. In 1732 both left Uppsala, Artedi for England and Linnaeus for Lapland; before parting they reciprocally bequeathed to each other their manuscripts and books in the event of death.

Carl showed a deep love of plants and a fascination with their names from a very early age. He disappointed his parents by showing neither aptitude nor desire for the priesthood, but his family was somewhat consoled when Linnaeus entered the University of Lund in 1727 to study medicine. A year later, he transferred to the University of Uppsala, the most prestigious university in Sweden. However, its medical facilities had been neglected and had fallen into disrepair. Most of Linnaeus's time at Uppsala was spent collecting and studying plants, his true love. At the time, training in botany was part of the medical curriculum since every doctor had to prepare and prescribe drugs derived from medicinal plants.

Despite being in hard financial straits, as previously mentioned Linnaeus mounted a botanical and ethnographical expedition to Lapland in 1732. Linnaeus developed an admiration for the Lapps - their way of life and, in particular, their clothing. He found their clothing to be more practical than tight-fitting Swedish clothing. It is reported that Linnaeus was so taken with Lapp clothing that, upon his return, he could be seen in Lapp costume around Uppsala and even courted his wife in this ensemble (Figure 5).

Linnaeus, who was a practicing physician, also wrote *Materia Medica* (1749), a useful reference book for doctors. It was full of aphorisms such as "all excess is harmful" and "eat to keep up your strength, not to stuff your belly." On the rules of diet, Linnaeus often made his students roar with laughter by his descriptions of the follies of fashion, using a joke and a light touch to teach a valuable lesson about the care and preservation of health. So wrote Sven Hedin, one of the many students who were impressed by Professor Linnaeus's ability to lecture.

Olof Rudbeck (1630 - 1702), a professor of medicine at Uppsala University in Sweden (he discovered the lymph system) and for several periods its Rector Magnificus, founded a botanical garden, then situated in the center of Uppsala, close to the

Figure 5: This is a portrait of Linnaeus in Lapp costume when he was about 30 years old.

Fyrisån river). In later years, Carl Linnaeus named an aquatic plant, *Rudbeckia,* after him. The garden was primarily used for teaching botany and pharmacy, and by the end of the century more than 1,800 species were grown there, many of them for the first time in Sweden. It was largely destroyed by a fire in 1702 and since the university could not afford to restore it, it was left unattended for a period of 40 years. Linnaeus became responsible for the garden in 1741 and had it rearranged according to his own ideas, documented in his *Hortus Upsaliensis* of 1748. Under his supervision, it turned into one of the foremost gardens of its time. Although Uppsala University commissioned the famous architect Carl Hårleman to design the garden, Linnaeus was responsible for the planting, including three ponds for plants typical of streams, lakes and marshes.

In his 1742 prologue to his *Hortus Upsaliensis*, Linnaeus defined the following terms under the heading of "Aquaria:" *Aquarium palustre, Aquarium fluviatile* and *Aquarium lacustre*, denoting respectively a marsh pond aquarium, river pond aquarium and lake pond aquarium (Figure 6). Since this is the earliest use of the word "aquarium" by gardeners, it is also the first time the plural of the word was used. Historically then the plural of aquarium should be aquaria, not aquariums.

In front of the lake pond, Linnaeus placed a statue of Venus, bought in 1758 from Piperska trädgården in Stockholm. It caused a scandal in Uppsala, as the Medicean Venus was completely naked. Here is how Linnaeus described the marsh pond aquarium:

Aquarium palustre ad latera truncos horizontales seu parietes habet, aquam a solo separantes, inter illos vero & ipsam humum repletum est spatium humo limosa e paludibus desumta, cui insertae plantae palustres.

The marsh aquarium has horizontal sides of tree trunks or walls that separate the water

AQUARIUM PALUSTRE ad latera truncos horizontales ſeu parietes habet, aquam a ſolo ſeparantes, inter illos vero & ipſam humum repletum eſt ſpatium humo limoſa e paludibus deſumta, cui inſertæ plantæ paluſtres. veluti:

Acorus,	*Iris*,	*Scheuchzeria*,
Aliſma,	*Juncus*,	*Sium*,
Butomus,	*Phellandrium*,	*Schœnus*,
Cyperus,	*Sparganium*,	*Siſymbrium*,
Erigeron,	*Scirpus*,	*Triglochin*, &c.
Eriophora,		

AQUARIUM FLUVIATILE fundo ſuo tenet plantas fluviatiles & lacuſtres; e. g. *Hottonia*, *Hippuris*, *Myriophyllum*, *Potamogetones*, *Sagittaria*, *Utricularia*, &c. margines vero hujus aquarii ſpecies *Caricum* 20 veſtiunt.

AQUARIUM LACUSTRE, ſtellata figura & artificio hortulani inſigne, non alias alit plantas, quam eas, quæ foliis natant: ut, *Nymphæa lutea*, *Nymphæa alba*, *Hydrocharis*.

Figure 9: The river pond aquarium (*Aquarium fluviatile*) in the Linnaeus Garden. It is the same length as the marsh pond aquarium shown above but it was photographed here at one end so its length appears shortened.

Figure 10: The lake pond aquarium (*Aquarium palustre*) in the Linnaeus Garden. The statue caused Linnaeus no end of trouble at the time.

from the surrounding soil; the ground between them is filled with soil from muddy swamps, into which is inserted marsh plants.

Clearly Linnaeus was describing the construction of an artificial container and was not using the word aquarium merely as a synonym for water. Linnaeus, of course, was not concerned with fish but with aquatic plants. From this point on, however, botanists and horticulturists used the term aquarium to mean any receptacle that held water and aquatic plants. One of the most outstanding was that built for the Marquis of Blanford in 1806 (Figure 11). The Marquis' aquarium represented the highest end of the spectrum of the gardener's aquarium, i.e., a pit containing water being its lowest and an intermediate aquarium being a pond. In John Loudon's *Encyclopædia of Gardening*, he

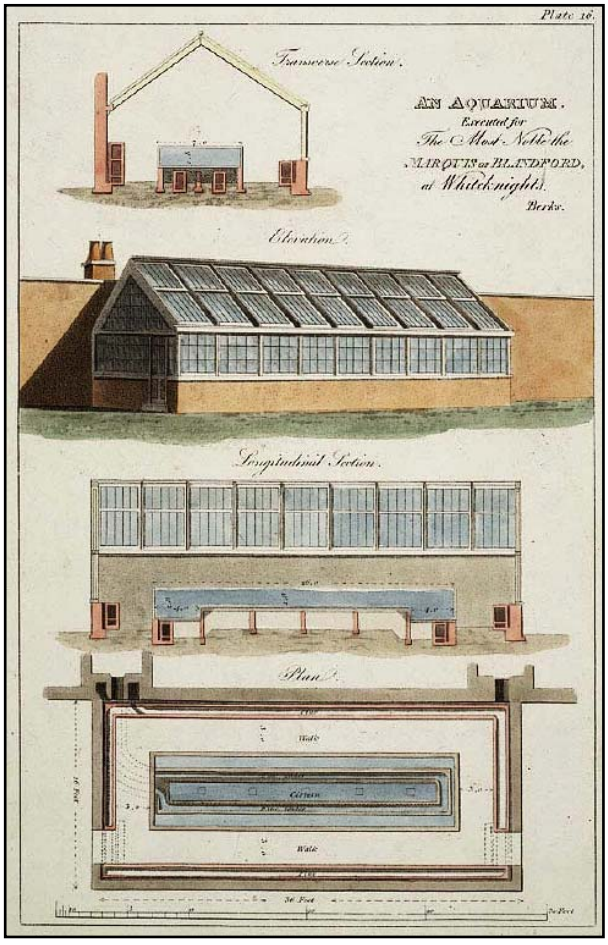

Figure 11: The Aquarium of the Marquis of Blanford, 1806.

showed several examples of the more ornate aquaria and suggested that fish might be added to them (Loudon, 1824):

It is almost needless to add, that exotic aquatic fowls and fishes might be kept in such an aquarium, and either of the sea or fresh water rivers, according as salt water or fresh was used.

Note that this was 13 years before Jeanne's first publication. The definition of aquarium now was expanded to mean any receptacle that held water, aquatic plants and/or aquatic animals. It was the term adopted by Warington and Gosse to replace the awkward term "Aquavivarium," and it also was the term used by the general public. Although Philip Gosse undeniably was responsible for the popularization of the term "Aquarium" in the fish hobby sense, he was not the first one to use it. Warington preceded him. Gosse himself did not claim priority in this matter, the following being his clear and elegant explanation of why he used the term:

A neat, easily pronounced and easily remembered, significant, and expressive term is so advantageous, that it is worth taking some trouble to select the best. For the subject of this volume some have chosen the word Vivarium, and I have myself occasionally used it. The only objection to it is that it lacks distinctness of signification. It literally means any enclosure in which living animals are kept; and the ancients used it to signify a park, a rabbit-warren, and a fishpond; indeed, I am not sure whether our word "warren," is not "Vivarium" Saxonised. Thus it is quite as applicable to the whole Zoological Garden as to any particular house, yard, or tank in it. To avoid this indefiniteness, others have used the term Aqua-vivarium. The objection to this is its awkward length and uncouthness, which render it unsuitable for a popular exhibition or domestic amenity. I have adopted the word Aquarium, as being free from the objections which lie against the other two, while it possesses the neatness of the former, and the definiteness of the latter.

He goes on to say (and herein lies the subject of this essay):

The term had already been in use among the botanists, to designate the tanks in which aquatic plants were reared; and the employment of the same term for our tanks is not forbidden by the character of the service to which they are put, since this is not an alteration, but only an extension. The growth of aquatic plants is still a most important and pleasing feature of our pursuit, and the addition of aquatic animals does not at all detract from the appropriateness of the appellation.

Although the aquarium all but disappeared for a while in the 1860s in Great Britain, the term "aquarium" has survived to this day. Therefore, emulating Richard Owen in coining names, I christen Carl Linnaeus,

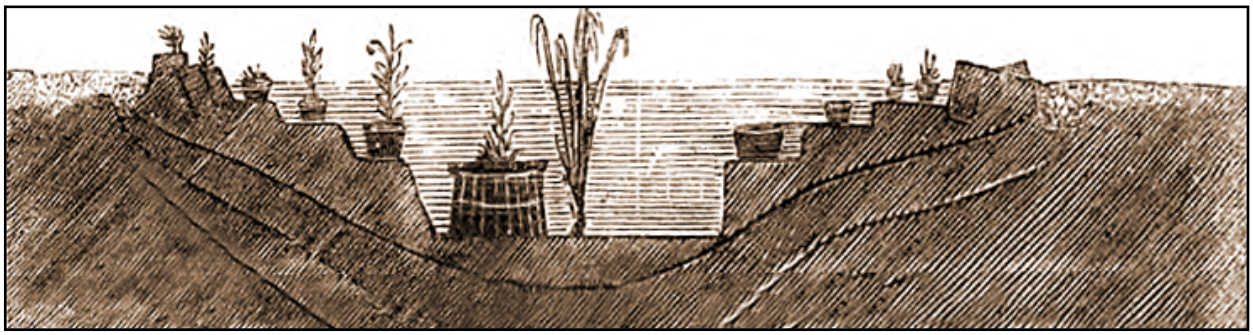

Figure 12: An aquarium from John Loudon's *Encyclopædia of Gardening* (Loudon, 1824).

CARL LINNEATUS
PATER AUTEM AQUARIUM or "FATHER OF THE AQUARIUM."

THE LEISURE HOUR

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, April 13, 2019)

When writing about historical characters, authors often wish that they knew more about the personal side of the characters than just the bare facts expressed in the written sources available. Sometimes these written sources are themselves rife with misinterpretations, exaggerations and even downright lies. I will explore this idea using as examples the two most influential men associated with the invention of the aquarium, Robert Warington and Philip Henry Gosse. First, however, I will start by presenting some brief information about their education and achievements.

A.1 ROBERT WARINGTON

Warington entered an independent private day school for boys in 1818 and in 1822 was articled for five years to John Thomas Cooper, a lecturer in medical schools and a manufacturer of potassium, sodium, iodine, and other then-rare chemical substances. On the opening of the London University in 1828, later *University College, London*, he was chosen by Edward Turner, the Professor of Chemistry, as his assistant. In 1831 he was appointed chemist to the London brewers Truman, Hanbury & Buxton, becoming the first qualified chemist to work for a British brewery. From 1842 until shortly before his death in 1867 he was resident Director to the *Society of Apothecaries*. In 1831 he published his first research, on a native sulfide of bismuth. In 1839 he started a movement to found the *Chemical Society of London*, convening the first meeting in 1841 and serving as its first Secretary for ten years. In 1844 he began a series of investigations into the adulteration of tea, and gave evidence at the parliamentary inquiry in 1855. In 1845 he was one of the founders of the *Royal College of Chemistry*, later part of *Imperial College, London*. In 1846 he took part in the formation of the *Cavendish Society*, of which he was secretary for three years, and from then on had many engagements as a chemical expert in legal cases. In 1851 he revised the *Translation of the Pharmacopœia of the Royal College of Physicians* into English. He was also engaged in the construction of the *British Pharmacopoeia* from 1864, and was joint editor of the second edition in 1867. In 1854 he was appointed chemical referee by four of the London coal gas suppliers, and held this post for seven years. In 1864 he was elected a *Fellow of the Royal Society*, and the *Royal Society's* catalogue lists 47 papers written by him alone. Warington proved the principle of the balanced aquarium, i.e., the use of plants to provide oxygen and to remove harmful carbon dioxide both in fresh water and in salt water. He also was the first to use the word aquarium with regard to a container that was intended to hold fish.

Figure 1: Robert Warington (1807-1867)

A.2 PHILIP HENRY GOSSE

Gosse's formal education as a child was limited to five years of day-school followed by two years of grammar school and because his parents could not afford additional education, he left school at the age of 15. In essence, he was largely self-taught but he taught himself well. Gosse wrote a succession of 31 books and articles on various subjects, including natural history. He also wrote what were (in his own words) "pot-boilers" for religious publications. In 1857, he published his most controversial book, Omphalos, in which he challenged the validity of evolution and presented his case for what today is called creationism. His most significant scientific works, however, were in marine biology and taxonomy, notably Actinologia Britannica: A History of the British Sea-Anemones and Corals (1858-1860) and The Rotifera (with C. T. Hudson) on marine rotifers (1886, 1889).

In recognition of his scientific contributions, Gosse was elected an Associate of the *Linnaean Society* (1850) and a Fellow of *The Royal Society of London* (1856), which, because he had no university position or inherited wealth, gave him a standing he otherwise lacked. The criterion for the latter contained the words "Distinguished for his acquaintance with the science of Zoology, particularly Microscopic Zoology" and the further statement, "The inventor or improver of the Aquarium." It should be noted that he word "aquarium" can be taken in two ways: as the actual vessel that holds the water, also commonly known as the "tank," or as the system that consists of the vessel that holds the water and aquatic plants and/or animals. It is with reference to the first that the term "inventor" is used here. Gosse himself made the claim of inventor in his 1853 book, *A Naturalist's Rambles on the Devonshire Coast*:

But my attention has been directed to the realization of such a desideratum as I have before mentioned, a Marine Aquarium for the Parlour or Conservatory. An apparatus for this purpose has been for some time in the manufacturer's hands; and though there are some minor difficulties attendant on the mechanical part of the execution, they are not such as to throw any material doubt on my confident expectation, that in a short time an elegant vase stocked with algae and sea-anemones, and comprising within itself the elements of its constant self-purification, will be before the world.

However, if we are confined to the Nineteenth Century (which marks the birth of the aquarium hobby), this recognition should go to Warington; he had publication priority by at least a year (see Klee, 2012). If not confined by date, the honor actually should go to Linnaeus (see Klee, 2019).

Although he is often credited with creating and stocking the first public aquarium, i.e., the fish house at the London Zoo which opened in 1858, in actuality Warington designed the freshwater and Gosse the saltwater portion. Although the freshwater portion was a success, the saltwater exhibit was a disaster. His greatest legacy, how-

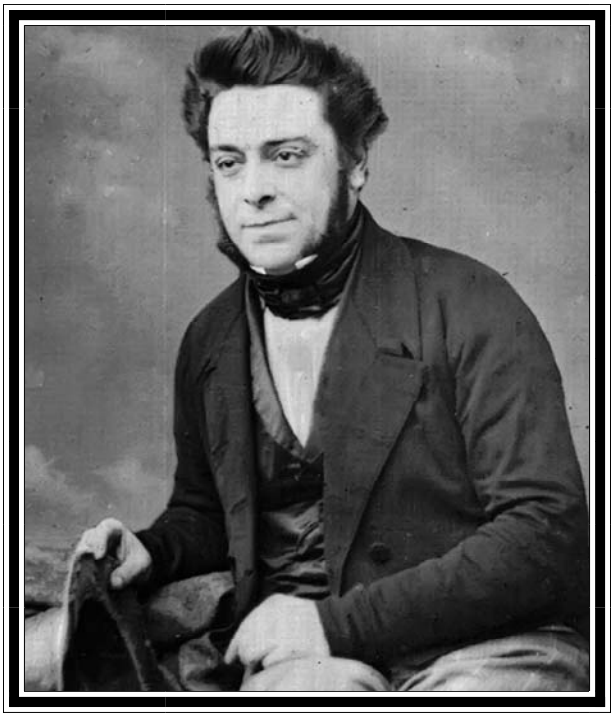

Figure 2: The first known photograph of Philip Henry Gosse, circa 1850.

ever, was as a popular writer of science for the general public.

Gosse was a painstaking, extraordinarily patient and endlessly enthusiastic observer, whose style and character endeared him to his readers. Charles Darwin admired his qualities and would ask him questions and use his observations on such things as whether male Crustaceans ever fight for the females, the pugnacity of the male humming-bird or the impregnation of orchids. But Darwin commented that, whereas in Alfred Wallace's book on the Amazon there are "hardly facts enough, in Gosse's books there is not reasoning enough to my taste." Facts were safe for Philip Henry Gosse. When he tried reasoning, as he would do in his book, *Omphalos*, it would be disastrous.

B.1: THE LIFE OF PHILIP HENRY GOSSE

After his father's death Edmund Gosse published a biography, *The Life of Philip Henry Gosse* (1890). This is the one aquarists should read if they wish to know more about the aquarium aspects of Philip Gosse's life. The reader should be aware, however, that Edmund's knowledge was often spotty, Henry James remarking that Edmund Gosse had "a genius for inaccuracy." For example, when discussing Warington in this book he wrote:

There was no sort of rivalry between these earnest and amiable investigators, but a little later on, when the aquarium had become a fashionable thing, Philip Gosse was accustomed to say that if it was needful to dispute about an invention which was virtually simultaneous, it might be said that Warington had invented the vivarium and he the marine aquarium.

This, of course, was not true as witness their controversy over artificial sea water in 1854 (see below).

B.2 GOSSE'S RELIGIOUS SIDE

Philip Gosse's code was the Bible and the Bible only, without any modern modification whatever, without allowance for any difference between the old world and the new, without any distinction of value in parts or without the smallest concession to the critical spirit upon any point. He had an absolute, uncompromising, unquestioning reliance on the Hebrew and Greek texts as inspired by the mouth of God and uncorrupted by the hand of man. As Gosse admitted, the Bible, however, is full of obscure sayings and needs an interpreter and he did not doubt his own competence to interpret. Admittedly, he had some reason to hold this view since his knowledge of the Bible can hardly have been excelled. Edmund observed that his verbal memory of the Authorized Version included the whole New Testament, all the Psalms, most of the Prophets and all the lyrical portions of the Historical Books. The condition of his memory fluctuated, of course, and was being daily refreshed at various points, but Edmund had

Figure 3: Philip Henry Gosse (1810-1888).

his own repeated assurance that, practically speaking, Philip Gosse knew the Bible by heart.

In a letter to his son, Gosse gives a key to the social isolation of his life. **I am impatient and intolerant of all resistance to what I see to be the will of God, and if that resistance is sustained, I have no choice but to turn away from him who resists.** Edward provides the following example:

His extraordinary severity towards those who occupy the extremes of Christian dogma, towards the Church of Rome and towards the Unitarians, was a result of this idiosyncrasy pushed to its extreme. In 1859, when he was lecturing in Birmingham, before the Midland Institute, he was invited to meet some of the principal personages of the town at dinner, and, in particular, a well-known gentleman, who is now dead. Philip Gosse accepted the invitation with pleasure; but shortly before the party met, the host received a note saying that it had just been mentioned to Mr. Gosse that Mr. — was a Socinian [a system of Christian doctrine named for Fausto Sozzini; it is most famous for its nontrinitarian Christology but contains a number of other unorthodox beliefs as well]**. Had Mr. Gosse been unaware of this, he should have desired to ask no questions, but the information having been volunteered, he had no alternative but with extreme regret and even distress to explain that he could not "sit at meat with one whom I know to deny the Divinity of the blessed Lord." To realize what this sacrifice to conscience involved, it must be recollected that my father was a man of elaborate and punctilious courtesy, and extremely timid. I could multiply examples, but it is needless to do so.**

Philip Gosse made it an invariable practice in advancing life to qualify every public expression of his views on natural phenomena by an attribution of the beautiful or wonderful condition to the wisdom of the Divine Creator. He had done so in his monograph on *The Clasping Organs ancillary to Generation in Certain Groups of the Lepidoptera*, appending to that memoir a paragraph embodying the pious reflections that his conscience dictated him to make.

Rightly or wrongly, these sentiments appeared to the Council of the Linnaean Society to be out of place in a very abstruse description of certain organs, which although are curious are neither beautiful nor calculated to inspire ideas of a particularly elevating nature. In sending to him the proof of his memoir, the Secretary was directed to ask him, in making some other trifling excisions, to be kind enough to put his pen through this little passage also. To the surprise of everyone concerned, he absolutely declined to do this. The Council was then placed in a most embarrassing position. A great deal of money had already been spent, and here was a paragraph that by the rules of the society forbid all contentious matter on the subject of religion, and which yet the author was prepared to

Figure 4: Philip Henry Gosse, age 5, painted by his father, Thomas Gosse, a portrait painter.

Figure 5: Philip Henry Gosse, age 17, also painted by his father, Thomas Gosse.

sacrifice the whole volume rather than agree to the request.

The knot was cleverly untied by Professor E. Ray Lankester, who suggested that it should be represented to Gosse that if in the future an atheist should wish to defend his atheism in the *Transactions* of the Society, the Council could scarcely forbid him to do so if it had yielded to a Christian writer the privilege of defending his faith in Christianity. Gosse saw the force of the argument, and gave way, though with great unwillingness.

B.2 HOW SHARPER THAN A SERPENT'S TOOTH IT IS TO HAVE A THANKLESS CHILD!

After the publication of *The Life of Philip Henry Gosse* it was suggested to Edmund that it contained "the germ of a great book" and so he revised his material and the first edition of *Father and Son* was published anonymously on October 25, 1907 by publisher William Heinemann. This seems to have been a clever marketing ploy to arouse curiosity, and Edmund's name was soon attached to subsequent editions. Edmund was also eager to test the water, to discover just how much he would be attacked for his lack of filial piety. The reviewer in the *Times Literary Supplement* wrote: **The author of this book has no doubt settled it with his conscience how far in the interests of popular edification or amusement it is legitimate to expose the weaknesses and inconsistencies of a good man who is also one's father**. In any event, the anonymous publication indicates some hesitation about owning up to the book, although oddly enough, opposite the title-page of this first impression is a photograph of Philip Henry Gosse holding an open book with Edmund on his knee. In fact, its authorship was something of an open secret in literary circles, and there are indications that

Figure 6: The photograph of Philip Gosse and his son, Edmund that appeared in the "anonymous" Father and Son in 1907.

from the first that Heinemann wanted the facts of Gosse's authorship to leak out.

Father and Son is part biography but even more an autobiography. Edmund Gosse left an epic portrait of his evangelical father as a God-haunted neurotic, declining to celebrate Christmas Day "The very word is Popish," Philip Gosse used to exclaim, "Christ's Mass!" pursing up his lips with the gesture of one who tastes assafoetida by accident. Then he would adduce the antiquity of the so-called feast, adapted from horrible heathen rites, and itself a soiled relic of the abominable Yule-Tide. This objection showed itself in amusing and bewildering ways. He regarded plum-pudding and roast turkey as innocent and acceptable, if the fatal word had not been pronounced in connection with them; but if once they were spoken of as "Christmas turkey," or a "Christmas pudding," they became abominable, "food offered to idols."

After Gosse had moved permanently from London to St Marychurch, Devon, Gosse refused to use the "St" and even gave his address as Torquay, the neighboring borough, so as not to have anything to do with the "so-called Church of England." In 1875 Edmund was to marry Ellen Epps, a young painter who was also the sister-in-law of Laura Alma-Tadema, an artist of high repute. In the summer of 1875 Alma-Tadema wrote to Philip Gosse to urge him and his wife to attend the wedding. However, Gosse could not face the actual Register Office wedding or the reception afterwards at Alma-Tadema's smart Townsend House in Regent's Park, crowded as they would inevitably be with so many who were "alien to Christ." If I said that Gosse's approach to religion was aberrant, it would be a compliment. However, it is easy to criticize deviate behavior.

The reaction of readers to Philip's personality and character, as represented in *Father and Son*, has included phrases such as "scientific crackpot," "bible-soaked romantic," "a stern and repressive father" and a "pulpit-thumping Puritan throwback to the seventeenth century." However, Ann Thwaite has rejected this portrait of Philip Henry Gosse, on the grounds that his own "writings reveal a genuinely sweet character." Ann Thwaite is a prize winning biographer and children's writer. Her book, *Edmund Gosse: A Literary Landscape* won the 1985 Duff Cooper Prize and was described by John Carey as "one of the finest literary biographies of our time." *Glimpses of the Wonderful*, a life of Edmund's father, Philip Henry Gosse, was picked out by D.J. Taylor in the *Independent* as one of the "Ten Best Biographies" ever.

Thwaite has established just how inaccurate Edmund's recollections of his childhood were. Although Edmund went out of his way to declare that the story of *Father and Son* was "scrupulously true," Thwaite cites a dozen occasions on which either Edmund's "memory betray[ed] him - he admitted it was "like a colander" - or he "changed things deliberately to make a better story." Thwaite argues that Edmund could only preserve his self-

Figure 7: Dr. Ann Thwaite, a Fellow of the Royal Society of Literature.

respect, in comparison to his father's superior abilities, by demolishing the latter's character.

However, it was impossible for evangelicals like Philip Gosse to accept that there were other views and, indeed, much of his life was spent convincing himself and others that he was right in his beliefs. Questioning would be akin to Satan talking and must be dismissed, locking Gosse into his narrowness. This single-mindedness, while being a marvelous support for evangelical Christians like Gosse, was oppressive to anyone who did not accept these views, and especially for those who were brought up with them. It is easy to see why Edmund Gosse felt the way he did and emphasize with him, despite having such a benevolent father, and so he eventually gave up talking to his father about their differences.

It is interesting to note that Gosse had the idea that Edmund might like an aquarium in his lodgings - the original one, "a historic relic" which "ought to be an heir loom in my family." He would make his son a present of it, send it up at his own expense, pay for sea-water and collect for him. "What do you say?" So in 1869 Edmund was able to keep most of his father's usual interrogation at bay by filling much of his letters with comments on the activity in the aquarium his father had supplied. He asked lots of questions so his father would have to fill his letters with equally uncontroversial subject matter. Things did not go smoothly in spite of all of Philip Gosse's expert advice. All the details were of "painful interest" to him. Edmund sent lists of the "thriving" and the "precarious. We begin to despair; our little community is dwindling more seriously." His father suggested that he should "aerate the water, pouring it from a jug held at a height. And do not leave this to be done by the ladies; but take *your* share of it, doing it every evening till the whole tank boils and froths."

C.1 GOSSE'S CHARACTER

The letters of Gosse's first wife, Emily Bowes, were full of love. This is an example, written on July 1, 1850 (the baby refers to their son, Edmund):

My love, How lonely you must feel tonight and how much I am sure you must wish me back. I am always thinking of you and dear baby and I long for tomorrow when I shall have a letter from you. Do not forget me for a moment and let me hear your assurance that you love me as I love you. I do not like to go to bed. I shall be so lonely. I miss having you to pray with me and to kiss me. I would write on but I am very tired. Kiss Baby for me and believe in the love of your own wife, Emily Gosse

After Emily's death he met and married his second wife, Eliza Brightwen, a kindly, tolerant Quaker who shared Gosse's intense interest in both natural history and the well-being of his son. Gosse's second marriage was as happy as his first. In 1862 he wrote that Eliza was "a true yoke-fellow, in love, in spirit and in service." Appendix I, written by Eliza and in Edmund's *The Life of Philip Henry Gosse*, also shows more of Philip Gosse's character:

Figure 8: Emily (nee Bowes) Gosse (1806-1857) at age 25, 12 years before she married Philip Henry Gosse.

Figure 9: Eliza Brightwen (1830-1906), Philip Gosse's second wife.

He never opened out to general visitors. He always spoke of himself as a shy man. Some might think him stern and unsocial; he was a recluse, and a thorough student in all his ways, and a true home bird. Often when, in after years, I remonstrated with him on his isolation, and urged him to go out more among his friends, he would say, My darling, "my mind to me a kingdom is," which might seem a trifle selfish, if selfishness could be considered at all a constituent in the heart of my beloved husband. He was of a remarkably even disposition. I never saw him give way to those frailties or minor faults that are so often exhibited in the lives of less exalted, or of uncontrolled characters. His life was given to studies of a grave and more or less religious nature, or else to closely thought-out scientific studies, especially those of natural objects. His mind being habitually occupied with this higher order of thoughts, he seemed to find it impossible to unbend to the lighter topics of everyday conversation. He was wont to excuse himself by saying, "I have no small talk."

Another time Kate (a servant) interrupted Gosse to tell him that the baby had walked all the way from the chair in the hall to the street door. Gosse picked up his rule, rushed into the hall, measured the distance and found it six feet and then, he wrote to Emily,

I induced him to try again and he several times made several steps, but he was excited and could not get on so well. Dear little fellow! It is so funny to see him. How he balances himself first and straddles wide, to get a good broad foundation, then he staggers two or three steps forward and plump! down on his little bottom. He is as good as he can possibly be and sends you, I doubt not, many kisses. At least I do for him … Believe me, as ever, *more than ever*, my darling Emily, Your own affectionate lover, P. H. Gosse.

Gosse's attitude towards animals was also instruc-

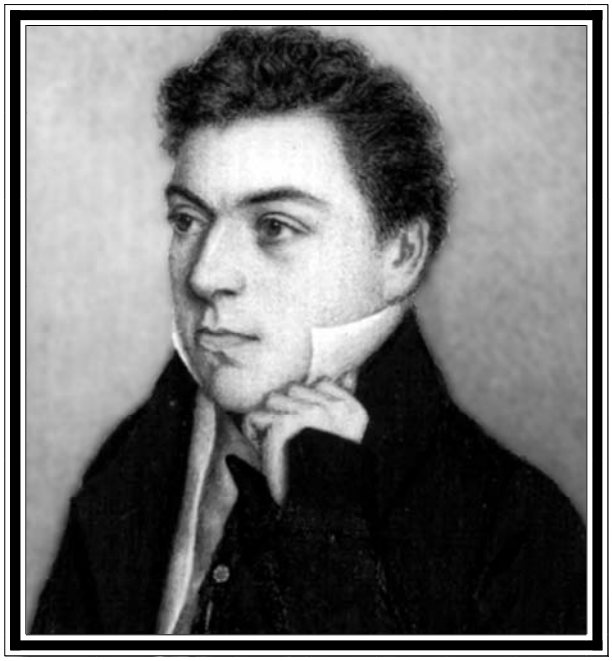

Figure 10: Philip Henry Gosse, age 20, painted by his brother William Gosse.

tive. He had a six year old cat called "Fairy," and he recorded April 18, 1877 as "a day full of sorrow" as she was having great difficulty in birthing her kittens, most of which were stillborn. When it seemed inevitable that she would not recover, he laid the mother cat gently and carefully on a soft bed of dry moss in her kennel. About 6 p.m. he saw, "with an intense sorrow" that his dear little cat was dead. Having restrained his emotion in front of his gardener who had buried the kittens, Gosse went inside the house and wept.

The sorrow which the death, so sudden and unexpected, of this little animal has produced in me is something that I could not have anticipated: it surprises me as I feel it; it is rather that which one feels for the loss of a loved human relative…

When Gosse was dressing, Fairy would remain in the room, very quiet and always watching for the chance of a little play with his watch-chain just before he put it in his pocket. Then she would go down to breakfast with them. Sometimes in the day she would, in her great affection, start licking Gosse as he sat reading. She might start on his fingers or sometimes my nose, eyes and cheeks, or she would make her way to the head of the sofa and, crouching there, would begin an earnest licking of the hair of my head as if I had been her kitten, the evident affection making the operation not unpleasant to me. No wonder he missed her, that source of such unquestioning love.

In 1832, when both he and his brother William were in Newfoundland, they learned that their sister, Elizabeth, was ill in Dorset, that her life was in danger and that she hoped to see her absent brothers once again before she died. Her brothers feared that that was about to happen and they both obtained permission to travel back to England on their own company's ships. Fortunately, after they arrived - a five week journey - she had recovered. Elizabeth Gosse remains a rather shadowy figure, but she was certainly important to her brothers. The year before, she had sent Philip a miniature portrait their father had painted to mark her eighteenth birthday. And on another occasion she sent him two bound volumes of *The Lady's Pocket Magazine*, because it contained an article, "Unwritten Philosophy," she thought would interest him. He kept those volumes all his life. Then there was a time when one of his fellow clerks had taken his sister's Elizabeth's name in vain with some lascivious jest, and Philip had struck him on the mouth with the back of his hand, the only time in all his reminiscences when he recorded his own violence.

C.2 GOSSE'S CHARACTER FLAWS

However, Gosse has some character flaws that Ann Thwaite glosses over so he does not go scot-free here. An example; Gosse wrote the following in a letter soon after his arrival in Alabama in1838:

In the fields of some large estates through which the road led, I saw, for the first time,

Figure 11: Edmund William Gosse, age 13 in 1862.

negro-slaves performing the labours of agriculture. They were ploughing between rows of cotton, which was just appearing above ground. The ploughs appeared to me to be rude and ineffective, the share doing little more than scratching the soil: each was drawn by a single mule.

It was revolting to me to observe women engaged in this laborious occupation, whose clothing - if the sordid rags which fluttered about them deserve the name - was barely sufficient for the claims of decency. Poor wretches! whose lot is harder than that of their brute companions in labour! for they have to perform an equal amount of toil, with the additional hardships of more whipping and less food.

The Emancipation Proclamation, issued January 1, 1863, effectively made the Civil War become a matter of slavery and ethics. This was important because the people of Great Britain had forbidden slavery in their lands and holdings in 1833. In order to avert open rebellion among the working class, Great Britain officially withdrew its support of neutrality that Queen Victoria had issued on May 13, 1861and condemned the Confederate States of America for their continued use and expansion of slavery. Gosse, however, hoped that the South would win its independence, arguing that it would weaken the United States who was in competition with Great Britain for trade and global influence. In effect, Gosse had considered this issue more important than slavery, suggesting that Gosse had more noble beliefs than was the case and was in effect a hypocrite in this instance.

On occasion, Philip Henry Gosse made imprudent decisions as shown by the following four examples.

C.3 THE LONDON ZOO

Gosse's main contribution to the aquarium at the London zoo in 1852-1853 was to provide marine plants and animals, including fish, for which he was to be paid. When he submitted his bill, David Mitchell, the Secretary of the *Zoological Society of London* (who owned the Zoo), presented it to the Society's Council who directed him to try and persuade Gosse to reduce it. Gosse, replied, however, that if he wasn't paid then all collections would stop. Gosse then requested that the matter go to independent arbitration. However, the arbiters soon found that the reason the Council had disputed the payment was that the Council had discovered that Gosse had also collected and sent specimens to the *Surrey Zoological Gardens* (a competitor) during his time in Weymouth collecting but charged the Zoological Society for this time. Understandably, the Council was only willing to remunerate Gosse for the animals he sent to the Zoo. The arbitrators found in favor of the Society, awarding Gosse only £150, which he quietly accepted.

C.4 ARTIFICIAL SEAWATER CONTROVERSY

The second example occurred in 1854. In his desire to be the first to write about artificial seawater, and especially in his desire to beat Warington to it, Gosse visited Warington in on two occasions at Apothecaries Hall, on January 16th and again on January 21st to discuss, among other things, the feasibility of using artificial seawater. However, in discussing the subject in his meetings with Warington, Gosse did not tell Warington about what he knew about the subject during these discussions. One can imagine Warington's surprise when he read Gosse's introduction to his paper the *Annals and Magazine of Natural History* for July1854:

Several scientific friends to whom I mentioned my thoughts, expressed their doubts of the possibility of the manufacture; and one or two went so far as to say that it had been tried, but that it had been found not to answer; that though it looked like sea-water, tasted, smelt, like the right thing, yet it would not support animal life. Still, I could not help saying, with the lawyers, 'If not, why not?' *Experientia docet* [Experience teaches**]. I determined to try the matter for myself.**

There is no doubt that this was included in the introduction to assure readers that he, Gosse, had no assistance from any of the scientific community. One can imagine Warington's surprise when he read Gosse's introduction. Accordingly, he replied in an article submitted on November 1, 1854:

In the *Annals and Magazine of Natural History* for July last, you published a short communication from Mr. Gosse, on the artificial formation of sea water, and having lately had my attention especially directed to this paper by a friend who wished to put the formula given into practice, I was surprised at the difference in the proportions of the ingredients as compared with what I had myself employed in the course of 1853, more particularly from the circumstance, that when Mr. Gosse called upon me in January last, and consulted me on the feasibility of the plan, I told him that there could be no difficulty in the matter, as I had made and had then in use several small quantities artificially produced, and that all that was required was that a good analysis should be taken as the basis for deducing the proportions, and at the same time referred him to the source from which I myself had worked, namely Dr. E. Schweitzer's analysis of the water of the English Channel taken off Brighton.

Gosse's reply submitted on December 20, 1854 was shorter:

If Mr. Warington supposes that I obtained from him one atom of information previously unknown to me, on the subject of making seawater from its constituent salts, he is most thoroughly mistaken. He is no less wrong in saying that I "consulted" him; since I merely mentioned what was on my mind in familiar conversation. With this, however, the public are of course not concerned, and I shall say no more on that head.

Not all believed him. The following appeared in the *Leisure Hour*, January 25, 1855:

It is now some months ago that Mr. Gosse, the gentleman on whom the care of the marine vivarium belonging to the Zoological Society devolves, and to whom the public are indebted for some most interesting works on natural philosophy, published a formula for the generation of sea-water artificially, and having supplied some marine pets with the liquid, found that they thrived in it well. The analysis of seawater chosen by Mr. Gosse was that made by Dr. Schweitzer, the formula of which it appears was suggested to that gentleman by Mr. Warington of Apothecaries Hall."

Thus, Gosse in effect shot himself in the foot and caused what he was worried about come to pass. His actions were decidedly unethical; Gosse and Warington were good friends at the time and good friends do no dissemble like Gosse did in this manner.

C.5 A MEMORIAL OF THE LAST DAYS OF EMILY GOSSE

The third example involved a memorial book dedicated to his first wife, Emily Bowes. Emily Gosse found a lump in her breast that was diagnosed as cancer in April 1856. She began alternative treatment by a quack doctor [Jesse Weldon Fell] on October 10, 1856 and decided to discontinue that treatment on December 17 after the cancer continued to spread, and eventually died from the illness in February 10, 1857. Gosse described the journey in graphic detail, quoting often from Emily's letters and journal, in an 1857 book titled *A Memorial of the Last Days on Earth of Emily Gosse, By Her Husband*. Gosse's extremely graphic account of his wife's death from breast cancer in the memorial he wrote of her is incredibly painful to read and was not well received by his friends and family. The following is an extract taken from Gosse's book:

The whole surface of the left breast, an area of four inches in diameter, was wetted with nitric acid, applied by means of a small bit of sponge tied to the end of a stick. The object of this application was to remove the skin. The smart was very trying, and continued for sev-

eral hours augmenting; the effect being to blister and destroy the whole skin, exactly as if a severe burn had taken place.

On the succeeding day, the doctor proceeded to incise the tumour, in order that it might be penetrated by the peculiar medicament which he used for its separation. With the scalpel he drew, on the surface of the now exposed flesh, a series of parallel scratches, about half an inch apart, reaching from the top to the bottom. When these were made, a plaister of a purple mucilaginous substance was spread over the whole. The next day, on renewing this plaister, the scalpel was passed again along the scratches, deepening them a very little; and a fresh plaister was applied. By the daily repetition of this operation, the scratches were in a few days deepened into long parallel cuts or scores, into which narrow strips of linen rag, covered with the purple mucilage, were pressed, instead of the common plaister. Every day these strips of rag were renewed, and the scores were made deeper and deeper.

The effect of this application was very distressing. In about an hour after its renewal every morning, the breast began to be the seat of an aching, piercing pain, under which my beloved sufferer was fain to wander up and down her narrow room, leaning now and then her head upon the mantel-piece or against the wall, unable from the agony to lie, sit, or stand. For several hours this continued, after which the intensity of the anguish commonly abated. Abatement of suffering, however, was the most she could look for; suffering never ceased from the beginning of the operation, till her spirit was freed from the worn-out body.

With regard to Emily Gosse's treatment, Dr. Thomas Spencer Wells had to say (Well, 1860):

I feel certain that any surgeon who reads this harrowing narrative of useless torture, and compares the history of this painful case with others in which he has removed large cancerous growths in a few seconds, without pain to the patient under the anaesthetic influence of chloroform, and has seen the clean cut wound he has made unite in a few days, will be shocked by the contrast.

The writing of this book was clearly another error in judgment by Philip Gosse.

C.6 OMPHALOS

The fourth example also came about in 1857. Despite authoring an impressive number of books and articles, Philip Henry Gosse is likely best remembered for his strangest, *Omphalos* (the Greek word for navel); his book addressed the question of whether Adam had one. Gosse published *Omphalos* a year before the announcement of Darwin and Wallace's theory of natural selection, and many scientists of the time shared Gosse's belief in the fixity of species. In his 1843 *An Introduction to Zoology*, for example, there is one passage that is worth quoting for its evidence of Gosse's abiding belief in the literal truth of verses 20 and 21 of the first chapter of Genesis. It is his own explanation

Figure 12: Emily Bowes Gosse photographed on her death-bed, aged 51. The photograph was touched up (and also colored) by William Gosse.

of the origin of species, a phrase not yet loaded with its Darwinian freight. Of the word "Species" he wrote that it was

a term used to signify those distinct forms which are believed to have proceeded direct from the creating hand of God ... Thus, the Horse and the Ass, the Tiger and the Leopard, the Goose and the Duck, though closely allied in form, are believed to have descended from no common parentage, however remote, but to have been primary forms of the original creation.

Geologic time, however, was another matter. Mountains of sedimentary rocks loaded with fossils argued strongly that humans were a recent arrival on an ancient planet. How to resolve this troubling evidence with a literal belief in Scripture? Gosse's book was an attempt to rescue Creation itself from the perceived threat of science denuded of Christian authority. Gosse fervently believed that God's word and works were in accord, but if there was any conflict between the two it was because naturalists had been looking at the world in the wrong way.

Gosse attempted to mend the increasing distance between a literal reading of Genesis and the facts of geology in a very peculiar way. If you found the skeleton of an extinct animal, Gosse proposed, you would naturally assume that the bones must have given form to an animal that lived at some distant period. But what if you were mistaken? What if, instead, the bones had been created already in place in the ground and had never been clothed in flesh and blood?

For Gosse fossils were just components of the earth that implied history without actually possessing it. God, in other words, had created the world "already in progress." The first plants and animals were all adults, ready to reproduce after their kind and bearing the marks of age that they would be expected to bear. This rule applied to the first humans, too; Adam and Eve had been created with navels even though they had never actually been connected via an umbilical cord to a mother during gestation. Gosse believed this explanation could reconcile the "lost worlds" of geologists to those who believed that the word came into existence in 4004 (Bishop Ussher's computation). Naturally he rejected any suggestion that life evolved. Gosse rounded off his book with perhaps the most extraordinary suggestion of all, that his theory should not affect geological research.

Gosse thought his explanation perfectly understandable but unfortunately for him, his defense of Genesis was met with scorn from both theologians and naturalists. His fellow Christians disliked the implication that God had deceived (some modern-day creationists, however, still invoke the argument that the Earth just looks really old, aided by fossils placed specifically to test our faith) and scientists thought his argument absurd. The public, on the other hand, took barely any notice at all. Gosse felt that he had developed a brilliant reconciliation between science and scripture, but in the end all he did was publicly embarrass himself. This is another case of poor judgment on the part of Philip Henry Gosse. Fortunately for him, although he was pilloried by theologians and scientists alike, the public took barely any notice at all and the sale of his books afterwards on marine biology were never affected.

C.7 MONEY AND THE HOBBY

Gosse's literary earnings are given in detail (Freeman and Wertheimer, 1980) and we learn that Gosse made over £2,000, roughly $236,000 in 2017 dollars - calculated from the site measuringworth.com and based upon the Consumer price index/Retail price indexes - from the five books he published in the mid-1850s. *The Aquarium* was more than a cultural sensation: it was also a financial success, with earnings of about £818 (roughly $96,700 in 2017 dollars). (However, although Gosse had £14,000 (roughly $1,930,000 in 2017 dollars) of investments on his death, it was mostly derived from an inheritance of his second wife, Eliza Brightwen.) Compared to Gosse, whose liv-

*** For the convenience of postal circulation, Nos. 1 to 20 of these Tracts may be had in the form of small books, very neatly printed on Tinted Paper. They are done up in a packet, price 6*d*. These must be ordered under the title of "GOSSE'S INTERESTING NARRATIVES."

"They were EXACTLY what suited us. I think them far superior to almost any I have seen: short, interesting, and to the point. Some have been circulated in Boulogne; some by our clergyman's lady, who sees so many English here; and others by our friends who meet on Tuesdays to pray for Tract-work in all its branches. Some have also been put into French, and published in various periodicals as articles. Brittany has had several in its Protestant paper, and Dr. Monod's 'Archives' have inserted one or two, abridged."

EXTRACT OF A LETTER FROM FRANCE.

LONDON: MORGAN & CHASE, 38, LUDGATE HILL.

AND MAY BE ORDERED OF ANY BOOKSELLER.

Figure 13: Some of the bible tracts authored by Philip and Emily Gosse.

ing depended a large part upon the books he wrote, Warington was a true aquarium hobbyist and made no money from his research or his writings.

High-quality illustrations, which were quite rare at the time, played an important role in the success of most of Gosse's books. He had inherited his father's artistic talents and is credited with providing the drawings for many of the beautiful lithographic plates that accompany his texts. It was, however, his first wife, Emily, who made the color images for the stunning plates found in *The Aquarium*.

By way of introduction, Emily Bowes was born in 1806 in London. Her parents, William and Hannah Bowes of Boston, Massachusetts, were on both sides of old New England families. She was a talented artist trained by popular landscape painter John Sell Cotman and in 1848 she became the first wife of Philip Henry Gosse. She was a woman of somewhat unusual acquirements, a fair knowledge of Greek and a good Hebrew scholar. Emily, besides publishing two small volumes of devotional verse and a prose work on education was, with her husband, the author of a series of extremely popular religious tracts (see Figure 13). In 1853, also in conjunction with her husband she published, without the name of either author, a volume of sketches in North Devon entitled "Seaside Pleasures." The final chapter, "The Valley of Rocks," is accredited as the prose of Emily who, as well as regularly submitting gospel tracts, was also planning the composition of a series of articles about the Christian care of poor children.

Accurate scientific illustration has often been the purview of women. Yet few Victorian women entered the ranks of scientific illustrators in order to gain recognition for their achievements. Most worked for love or money. Emily Gosse executed all of the underwater landscapes for *The Aquarium* (1854), a stunningly and colorfully illustrated book by her husband, Philip Gosse. This book bears the subtitled "Unveiling of the Wonders of the Deep Sea," a designation that clearly points to the importance of its illustrations. Philip Gosse is here unveiling and revealing nature in this case, the sea through his written text. But Emily Gosse's illustrations are both more dramatic and more accessible to the uninitiated than are Philip Gosse's accompanying words. She is the real unveiler for the public. Nevertheless, although the sale of books like *The Aquarium* was in large part dependent upon the quality of their pictures, she is entirely uncredited on its pages. Instead, her husband's name was inscribed below the images with the legend, "P.H. Gosse, Del." and the lithographer, Hanhart. The "Del." is an abbreviation for delineator, a person who makes a sketch or trace in outline indicating that Gosse supplied the outlines that Emily used to do the artwork on the color images. While it was the general convention at the time for pic-

Figure 14: "Plumrose Anemone," from *The Aquarium*, 1856, 2nd edition. Philip Gosse did the drawing and Emily Gosse did the color artwork.

ture credits in scientific publications to default to the text's author, one does wonder why Gosse failed to mention his wife's contribution at all in his preface, despite finding room to acknowledge the lithograph printers.

Much the same happened with his second wife, Eliza, who was an accomplished landscape painter who filled in landscapes for grouped illustrations of her husband's later works. In *A Year at the Shore* (1864) and *Actinologia Britannica* (1858-1860), for example, Eliza painted the submarine landscapes and Philip painted the creatures that swam, crawled or waved their tentacles in the foreground. One copy of Gosse's *A Year at the Shore*, however, is inscribed like this:

To my beloved wife, Eliza Gosse: whose loving sympathy and fellowship throughout the preparation of this book, it is affectionately presented. P.H. Gosse, January 1865.

D.1 A SLUR ON WARINGTON'S CHARACTER

By way of introduction, William H. Brock is Professor Emeritus of the History of Science and former Director of the Victorian Studies Centre at the University of Leicester. He is a past president of the *British Society for the History of Science* and past chairman of the *Society for the History of Al-*

THE LEISURE HOUR.

A FAMILY JOURNAL OF INSTRUCTION AND RECREATION.

No. 48. THURSDAY, NOVEMBER 25, 1852. Price 1d. Stamped 2d.

THE FUNERAL OF LORD NELSON.

At the present moment, while the recollection of the sublime and imposing pageant attendant upon the recent funeral obsequies of England's great chieftain, by which the nation has so spontaneously testified its gratitude and esteem for his brilliant deeds of arms and sage counsel in the senate, is yet vivid in all minds, it seems natural for us to revert to the burial of Nelson, which

Figure 16: The cover page of Warington's 1852 article on snails and the Stickleback.

chemy and Chemistry. He is considered to be among the most distinguished scholars in the history of chemistry and the history of physics.

In 1991 Brock published a paper titled "The Warington-Gosse aquarium controversy: two unrecorded letters." Oddly enough, the "two unrecorded letters" had nothing to do with the controversy between Warington and Gosse. The controversy recorded by Brock had to do with Gosse's paper referred to above that described his experiments with artificial sea water. Unfortunately, Block missed the whole point of the controversy, attributing it to Warington's pointing out the errors that Gosse made in his formula copied from Edward G. Schweitzer's paper of 1839, rather than focusing on the real controversy caused by Gosse's concealment from Warington of his knowledge of the paper and his own experiments with the Schweitzer analysis during two visits he made to Apothecaries' Hall to ascertain whether Warington was about to publish an article on the subject. Although the facts are clear, Brock concluded that the controversy was Warington's fault because "…he was jealous of Gosse's success in a field in which he had made the major scientific breakthrough," a conclusion for which there is no evidence whatsoever (for further details see my 2012 essay, "Who Invented the Aquarium?" and my 2016 essay, "The Warington-Gosse Controversy revisited"); the fault was clearly Gosse's.

D.2 ROBERT WARINGTON'S CHARACTER

Unlike Philip Henry Gosse, we know very little about Warington's character. What we do know is found in a paper that he intended to present before the Members of the Botany and Zoology Section of the *British Association for the Advancement of Science* at their September 1852 meeting in Belfast, but from sudden and unexpected business engagements he was prevented from attending. His time also was so much occupied as to prevent him copying them in a readable form before the Sections closed. He therefore submitted the final versions to both the *Annals and Magazine of Natural History* and to *Leisure Hour*, the latter being a family journal of instruction and recreation and having quite a different audience from the former. (The *Leisure Hour article* caught my interest and was the inspiration for this essay and hence its title.) The editor of *Leisure Hour* had no problem with this double appearance, commenting that "Independently of the pleasing interest of the facts communicated in the paper, we commend it to the notice of our readers, as pointing out a simple and innocent source of enjoyment to be derived from the observation of the habits of animal life." The title of the paper in the *Annals and Magazine of Natural History* version was "Observations on the Natural History of the Water-Snail and Fish kept in a confined and limited portion of Water."

This paper is of great historical interest, not with regard to its two subjects - water snails and the

stickleback - but rather with providing insights into Warington as the man. My comments on these insights are singled out from parts of the article.
1. The Religious Man. Warington writes:

My object in bringing the accompanying observations before the public is to endeavour to direct, more in detail than I have hitherto been able to do, the attention of naturalists, and those who take a delight and pleasure in the study of God's wonderful and glorious works…

On the matter of God, both Gosse and Warington agree. Both were religious men, Gosse more so. One oddity is that the versions of the paper sent to the *Magazine of Natural History* and to *Leisure Hour* were identical except for the *Magazine of Natural History* where the word :God's" was replaced by "Nature's." Either the editor made the change or Warington did but I suspect the latter, perhaps because he thought that the word God would offend some readers in this more scientific publication.

2. The Modest Man. Warington writes:

And when I state that these observations have been made by one most ignorant on the subject of natural history, and a perfect tyro in this field of research, as the details of this communication will fully demonstrate…

This most beautiful little creature has afforded a subject for much interesting observation for some time past, and I fear that what I have to offer will prove very much a repetition of what has already been published on the subject. As, however, the proceedings and observations of those who dare not rank themselves in the class of naturalists, sometimes from their want of knowledge, cause circumstances to arise which would not otherwise occur, so in the present case my failures through mv own ignorance may develop some new points in the economy of these small fry.

There are several other interesting particulars regarding the habits of the several fish, etc., which I have had the opportunity of experimenting with, and which may form the subject of some future memoranda. I would merely remark in conclusion, that I have, after many difficulties and failures, succeeded in keeping sea-water perfectly clear for upwards of six months, and that I have for the last five weeks had several sea anemones living in it which at present appear extremely healthy, and the water has not been disturbed for the last fourteen days.

Joseph Addison (1672-1719) was an English essayist, poet, playwright and politician. A friend of Jonathan Swift, his name is usually remembered alongside that of his long-standing friend Richard Steele, with whom he founded *The Spectator* magazine in 1711. I like the following quote by him that seems to fit Warington appropriately: **A just and reasonable modesty does not only recommend eloquence, but sets off every great talent which a man can be possessed of.**

2. The Hobbyist Man. Warington writes:

I mention also that they have been made at leisure intervals of very short duration, snatched as an amusement and as opportunities occurred from the weightier matters of professional business…

D.3 WARINGTON RECEIVES HIGH RECOGNITION

In 1857, Warington was invited to present a paper, "On the Aquarium," in the *Notices of the Proceedings at the Meetings of the Members of the Royal Institution of Great Britain*. This year was probably the zenith of the aquarium craze in Britain and the following introduction was made by the Duke of Northumberland, President, in the Chair:

The speaker opened the evening's demonstration, by stating that he had immediately responded to the invitation of the Managers of the Royal Institution to deliver this discourse,

Figure 17: Gosse's quoting from Warington's article on the stickleback indicated that they had reconciled.

on what they had been pleased to call his "own subject," from the feeling that as the originator of the aquarium, he was in duty bound to afford to all those who had taken up this "new pleasure" every assistance, from the results of his own experience that lay in his power in order to render the undertaking more easy and pleasurable; and for this purpose, he proposed to lay before his audience, as far as was practicable, a demonstration of the principles on which it was founded, particularly as very erroneous ideas had been promulgated on the subject, and instructions given in several most engaging publications, which might tend materially to mislead and disappoint those inclined to recreate themselves with this interesting subject.

This is high praise indeed and showed that the scientific community considered Warington to be the authority in the matter of the aquarium, not Gosse.

Warington's paper presented before the *Royal Institution of Great Britain* included aquarium history, principles of the aquarium, water, fresh and marine, vegetation, scavengers, light, heat, food and a few observations on the construction of a microscope for the purpose of employment in connection with the aquarium and the method in which an instrument could be used. It should be noted that when Warington was pressed to give to the world a little manual of instructions for amateurs, he always stated as a reason for non-compliance with the request, that the book market was overcrowded already with the worthless compilations of many scribblers on the subject. He was a really scientific man, and he did not wish to be associated with authors who wrote about things which they had never seen or done.

D.4 RECONCILIATION BETWEEN WARINGTON AND GOSSE

In his 1857 book, *Life in its Lower, Intermediate, and Higher Forms: or, Manifestations of the Divine Wisdom in the Natural History of Animals*, Gosse wrote:

Within a few months of the writing of these pages, a most interesting detail has been published by Mr Warington, of the nest-building instincts and tender care of the commonest of British fishes—the tiny Stickleback, that swarms in every pool.

This was followed by re-writes and excerpts from Warington's 1852 paper in the *Annals and Magazine of Natural History*, "Observations on the Natural History of the Water-Snail and Fish kept in a confined and limited portion of Water." By 1857, therefore, Gosse and Warington had settled their 1854 seawater dispute amiably; Gosse considered Warington be an expert observer of the breeding of this fish and Warington had no objection to Gosse using his material in his book.

E.1 FINAL NOTES

Both Gosse's and one of Warington's sons became even more famous than their fathers. Edmund

Figure 18: Edmund William Gosse (1849-1928), son of Philip Henry Gosse.

Gosse (1849-1928) achieved great renown as a literary critic and biographer. From September 1875, Gosse worked as a translator at the Board of Trade on account of his knowledge of French, German, Italian and, above all, the less well-known Scandinavian languages. He is often credited with bringing Ibsen to the public's attention in Britain. In 1904 Gosse was appointed Librarian of the House of Lords, a position which he held until forced to retire at 65 in September 1914. His presence in Parliament and familiarity with many of the leading figures of the day gave him an extraordinary informal influence. It was during Herbert Henry Asquith's reign as Prime Minister between 1908 -1916 that Gosse was at the height of his influence, being both one of Asquith's most trusted advisors and a member of the *Anglo-French Society*, the *Royal Literary Fund* and the *Royal Society of Literature*. From 1922 Gosse was also President of the *English Association*. Gosse and his wife socialized with Leslie Stephens, the Rider Haggards, Balfour before he became Prime Minister, Lloyd George, and, in later years, Sir Harold Nicolson. Edmund Gosse was knighted in 1925.

The name of Robert Warington Jr. (1838-1907) will ever be associated with one of the most important advances in the agricultural chemistry of the latter half of the nineteenth century, although his classical work on nitrification, which may be regarded as his life-work, bears but a small proportion to the total of that accomplished by him. After studying chemistry in his father's laboratory and attending lectures by Faraday, Brande and Hofmann, Robert Warington Jr. became in 1859 an assistant to Sir John Bennet Lawes at the Rothamsted Experimental Station. Warington was from 1862 to 1867 an assistant to the Professor of Chemistry at the *Royal Agricultural College*. Warington was given by Lawes the post of chemist to his manure and tartaric and citric acid works at Barking and Millwall. His engagement terminated in 1874, but he remained in the Millwall laboratory for two years longer, working on citric and tartaric acids, and ultimately publishing his results in a

Figure 19: Robert Warington, Jr. (1838-1907) , son of Robert Warington.

paper of 70 pages in the *Journal of the Chemical Society* (1875).

He was from 1876 to 1891 an investigator at Rothamsted Experimental Station, where he published many articles on soil nitrification. In 1891 Warington was appointed by the committee for the *Lawes Agricultural Trust* to give six lectures in the United States before the *Association of American Agricultural Colleges and Experimental Stations* at Washington, D.C. from August 12 to 18, 1891. The lectures dealt mainly with the subject of soil nitrification, based upon his own research at Rothamsted. He was appointed in 1894 as an examiner in agriculture for the science and art department of the University of Oxford and was for three years, from 1894 to 1897, the Sibthorpian professor of rural economy at the University of Oxford. He was elected in 1863 a Fellow of the *Chemical Society* and in 1886 a Fellow of the *Royal Society*. Warington's work, placed agricultural science on an altogether different basis from that which it previously occupied, and the institution which gave birth to it has served as the prototype for similar institutions throughout the whole civilized world.

Finally, both of Warington's papers, "Domestic Life of the Water Snail and the Stickleback" in *The Leisure Hour* and "On the Aquarium" in the *Notices of the Proceedings at the Meetings of the Members of the Royal Institution of Great Britain*, are well worth reading in their entirety.

THE EARLY DAYS OF AQUARIUM CONSTRUCTION

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, July 13, 2019)

The word *"Tank"* in this essay is used to signify any angular, flat-sided vessel. A "*Slope-back Tank*" is one in which the back inclines at an angle of about 45 degrees to the base. A "*Rectangular Tank*" has all its *inside* angles as right angles. Vessels of a single piece made by a glass-blower and have their sides variously curved are termed "*Blown Aquariums*." An "*Aquarium*" is any of the above receptacles. I'll further stipulate that any aquarium must have at least one area of glass where the inhabitants can be viewed from the outside. Also, in parenthesis after mention of any British currency is its equivalent in today's dollars).

Over the years, any vessel that would hold water, from a pickle jar to a cistern, was converted into an aquarium. In the first part of the 1500's Guillaume Rondelet's wife had kept a fish alive in a glass of water for three years, although we know nothing about the vessel itself or the fish she kept in it. Samuel Pepys made the following entry in his diary on May 28, 1665: "Thence home and to see my Lady Pen, where my wife and I were shown a fine rarity: of fishes kept in a glass of water, that will live so forever; and finely marked they are, being foreign." The "Lady Pen," it should be noted, was Margaret (nee Van der Schure) Penn (1622-1682), the mother of the Quaker, William Penn of Pennsylvania. As in Madame Rondelet's case we know nothing about the vessel itself but it is highly likely that the fish it contained was a goldfish (see Klee, 2016).

The keeping of fishes as pets did not become a popular pastime until after the goldfish was widely introduced into England during the first half of the eighteenth century. At first they were maintained in ponds on the lands of the well to do. Sir John Hawkins, noted editor of Izaak Walton and Charles Cotton, wrote in 1760: "There has also been lately brought hither from China those beautiful creatures, Gold and Silver Fish. These fish are usually kept in ponds, basins and small reservoirs of water,

to which they are a delightful ornament; and I have known a few of them kept for years in a large glass vessel like a punch-bowl." In the second and third editions of *The Complete Angler* which Hawkins edited, dated 1766 and 1775 respectively, the above footnote was repeated, but in the fourth edition, printed in 1784, he saw fit to alter it, stating that "it is now a very common practice to keep them in a large glass vessel like a punch-bowl." The Reverend Gilbert White corroborates Hawkins in Letter LIV of *The Natural History of Selborne*, based on an entry from his journal dated October 27, 1782: "When I happen to visit a family where gold and silver fishes are kept in a glass bowl, I am always pleased with the occurrence, because it offers me an opportunity of observing the activities and propensities of those beings with whom we can be little acquainted in their natural state."

About the middle of the 1700s much attention was given to a minute fresh-water zoophyte, the *Hydra*, and it became almost as much a fashion to keep it alive in glass jars as it was a hundred years later to keep its larger marine relatives, the sea-anemones. Hydra were described in the Enemies of Fishes section of "Exotic Aquarium Fishes," written by William T. Innes (Innes, 1935). Almost 200 years earlier, in Henry Baker's book, "An Attempt towards a Natural History of the Polype" (Baker 1743), the hydra's mode of maintenance was described and figured (Figure 1). The water was changed regularly but Baker did observe minute plants in his aquaria that came with the hydras he collected. He may, therefore, had unwittingly employed this low form of vegetation as a purifying agent and if so, had therefore kept aquaria unaware he was employing the balanced aquarium principle.

In 1790, Sir John Graham Dalyell began to keep living marine animals for observation in his house in Edinburgh and continued this practice until his death in 1851. His vessels containing them were all made of the very finest, clearest glass, wide at the top and just the same width as at the bottom: they were invariably round and all sizes, some short, some long, some wider, some not so wide. He changed the sea-water two or three times a week and though some of the animals lived for eight or ten years, one particular anemone nicknamed "Granny" survived from the time of its collection in 1828 until 1887, out-living Sir John and several others to whom it was passed on.

In 1834 Jeanne Villepreux-Power had two glass vessels for her marine research on mollusks, the first of which was used at home and the second was in a frame so that it could be immersed in water and used for smaller mollusks. Nothing is

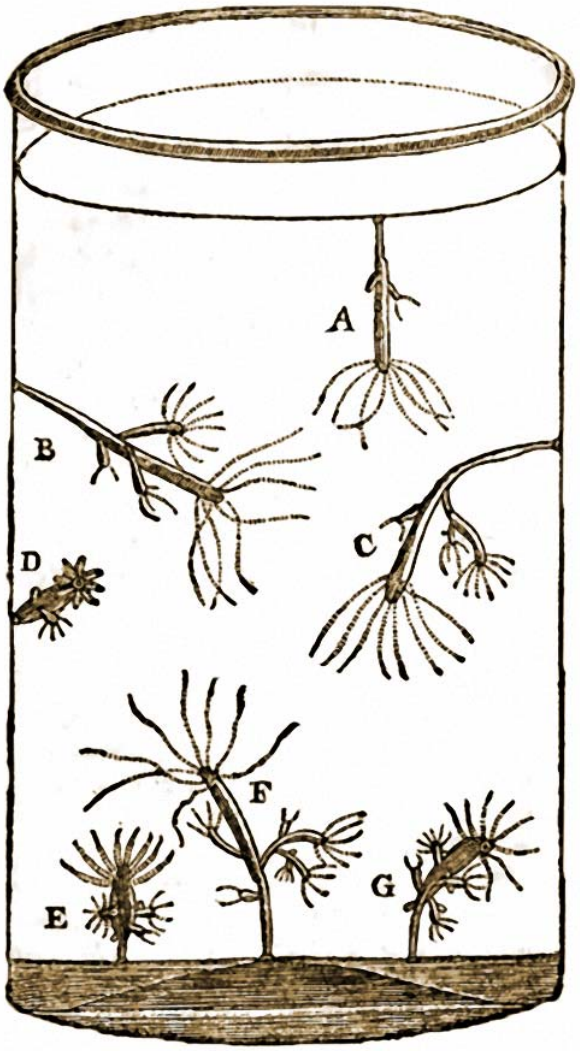

FIGURE 1: The Hydra Aquarium from Henry Baker's book, "An Attempt towards a Natural History of the Polype."

known about these two glass aquariums, neither their shapes nor their dimensions or whether they were identical, except for her comment that the glass aquarium that was in a frame was "too narrow" for the purpose.

Clearly the foregoing historical information does not really shed any light on the history of aquarium construction. However, starting with Robert Warington's paper, "Notice of Observations on the adjustment of the relationship between the Animal and Vegetable Kingdoms," read before the assembled members of the Chemical Society in 1850 (Warington, 1850) and followed by his other papers and articles in gardening and in scientific journals, and with this and the opening of the Aquarium at the London Zoo in 1853 and the publication of Philip Gosse's book "The Aquarium: an unveiling of the wonders of the deep sea" in 1854," the aquarium hobby finally got its start and much more is known now about the construction of aquariums during these times.

BLOWN AQUARIUMS

In the early 1850s, bell-shaped vessels could be obtained at any glass shop in England at prices varying from 1s. ($7) to 15s. ($98). (Those most

FIGURE 2: Hand propagating glasses used by gardeners in the 1800s.

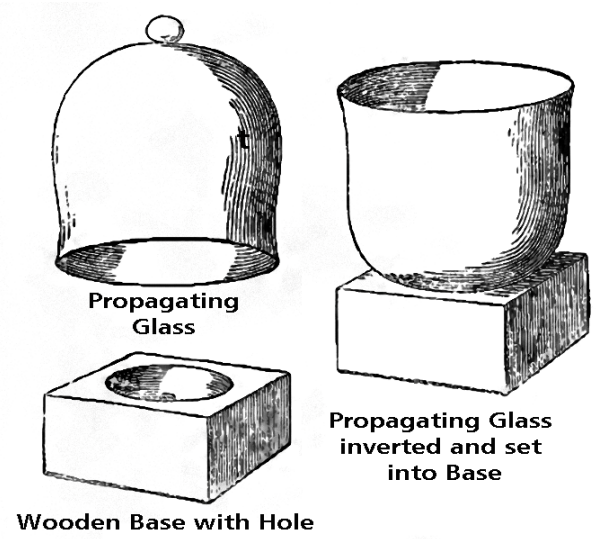

FIGURE 3: Converting a propagating glass into an aquarium.

in use were the common hand-propagating glasses or cloches used by gardeners (Figure 2), which were inverted and supported on a turned wooden stand (Figure 3). Suggested by Thomas Hall (Figure 4), a taxidermist, curiosity dealer and proprietor of an exhibition of stuffed birds and animals, curiosities and natural phenomena, and the owner and exhibitor of the first Kangaroo ever to be brought to Europe, this was the simplest and cheapest vessel ever hit upon for the purpose, and their adoption placed the pleasures of the aquarium within the reach of the poorest student, the village school master, and the inquiring youth. This should come as no surprise since after Warington published his research on the proof of principle of the balanced aquarium in 1850, two years later he was also publishing aquarium material in gardener's magazines.

It is rather curious that while Gosse and others were giving manufacturers perplexing orders for blown aquariums, which cost from fifteen to twenty shillings ($98 to $131) each, a better kind of vessel was to be found in every horticultural glass warehouse, needing only to be turned upside down to bring the difficulty to an end in a moment. This simple trick of creating a cheap and elegant aquarium did more to popularize the

FIGURE 4: Thomas Hall, unknown artist, late 18th century.

aquarium than all the exhibitions and all the books that have been written on the subject, for it enabled thousands to enjoy a delight which had previously been confined to the wealthy few. In time, vessels of this kind of an improved shape, of a quality of glass less liable to fracture than was previously used and of much more elegance were placed on the market (Figure 5).

One shape that was much recommended is that depicted in Figure 6. It is certainly very graceful, but its narrow base was a great drawback, as it neither allowed the introduction of rockwork nor of a variety of bottom plants. Fig. 7 represents a vase which probably surpassed any other for utility since the nearly flat bottom was much desirable. They could be had from twelve to twenty inches in diameter, but a medium size was better as the larger ones were more apt to fracture in frosty weather.

FIGURE 5: An ideal blown glass aquarium.

The greatest objection to all of these circular vessels was that they distorted the objects contained in them.

FIGURE 6: This was a more artistic aquarium, but too narrow at its base for plants or rockwork.

FIGURE 7: This vase probably surpassed any other for utility since the nearly flat bottom was much desirable.

Lastly, a few words about goldfish bowls, the type shaped by a somewhat flattened sphere (Figure 8). They could, of course, be used to hold all sorts of fish but because of their shape, the fish would be distorted both horizontally and vertically, and almost impossible to observe or study with any accuracy. Although this would not have bothered the typical goldfish fancier, it was a deal breaker for the aquarists of the time. The flat-sided goldfish bowl (Figure 9) would have removed most of this distortion but it was not invented until 1916, by George R. West of Pittsburgh, Pennsylvania.

EARLY TANK PROBLEMS

Water weighs 8.34 pounds per gallon so aquariums must be strong. Table I shows the relationship between gallons and weight, and does not include the weight of the tank. Aquarium pea gravel weights about 12.7 pounds per gallon so replacing water with gravel would make the weight even greater. In any event the water in an ideal aquarium should not come into contact with metals that corrode in water, such as iron, zinc or brass and for marine aquaria this is a definite requirement. Goldfish

FIGURE 8: The typical goldfish bowl of the 1800s.

bowls of capacity 1, 2 and 3 gallons were the usual sizes and made completely of glass, so strength and materials of construction were not factors here. Thus the main problems with the tanks of the day included the following:

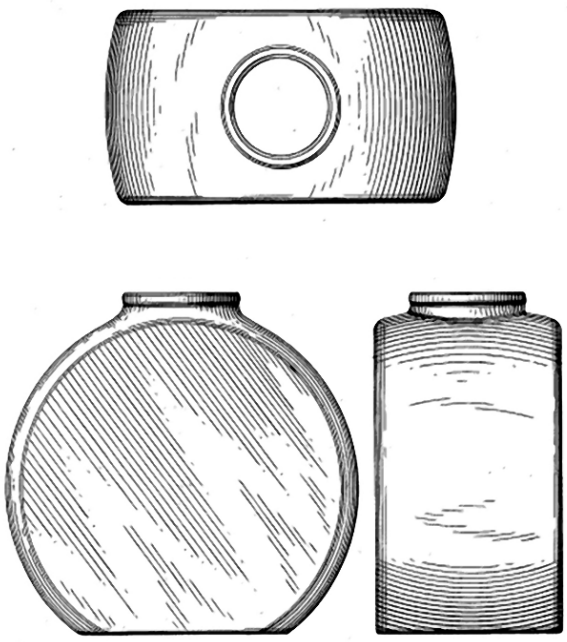

FIGURE 9: The first flat-sided goldfish bowl, patented in 1916.

1. The material of which the frames were made was corrodible or brittle, being of iron, zinc, brass or clay (the last-named will be discussed later in this essay); the glass sides were generally not thick enough and the bottom was commonly either metal or a thin friable slab of roofing slate. All metals will corrode or dissolve in water to some extent. Therefore it is a good policy to keep metal directly out of the aquarium water. This is especially true when the water is soft and acid. The more toxic metals are zinc and brass.

When zinc or brass dissolves in hard water or salt water, the calcium present nullifies, to some extent, the toxicity of the zinc while the magnesium present helps nullify the toxic effect of the copper. Copper is fairly well known as a dangerous metal in the aquarium. It is bad in hard or soft water but especially so in the latter. Very beautiful aquariums were made of copper and brass (a copper alloy) but unless every precaution was taken to insure that the aquarium water would not come in contact with the metals, the fish could be poisoned.

Although not as toxic as copper, zinc in the aquarium is bad enough. For one thing, it dissolves faster than copper, especially in aquariums where the pH is below 7. Here, as in the case of copper, hard water is antagonistic. It is best to keep all aquarium water from contact with this metal. Brass, as mentioned, is an alloy of copper and zinc. The remarks pertaining to the two metals hold as well for brass. In soft water, zinc usually leaches out first, leaving a skeleton of copper which is attacked next. Both metals are dangerous to fish.

As is well known, iron rusts in the aquarium. Iron itself is not particularly toxic, but if enough dissolves (and this happens rarely), the resulting suspension of iron hydroxide or oxide can precipitate on the gills of the fish and cause suffocation. For large homemade tanks, it was a good cheap metal to use for the frames, but in view of its rusting tendencies, the inner surfaces of the frame had to be painted with asphaltum and the top of the frame checked from time to time for rust.

2. Their whole construction was not strong and rigid enough to bear the long continued pressure of the quantity of water. Frequent leakages and occasional ruptures were the consequence and *Punch* in 1857 made sport of the aquarium in this regard (Figure 10).

3. The grooves by which the joints were made were cut on a wrong principle, a very serious error. Thin iron, zinc or brass columns and top-rails were used, upon which the glass was merely abutted as on a shoulder, but not inserted, thus causing continual leakages. Furthermore, the cement usually employed became decomposed and friable in a few months. The glass should be set into deeply sunk grooves cut in the solid slate, firmly wedged in on both sides and secured by slightly elastic cement.

4. Not the smallest attention was paid in the general form and construction, to adapt certain kinds of tanks to certain places. All were made alike, to suit every position, and consequently very serious errors of choice were being constantly made by purchasers.

5. The proportions were usually not such as to secure the largest amount of health to the greatest number of specimens in the smallest space. The law that the value of water for aquarium purposes

FIGURE 10: A Punch cartoon from 1857.

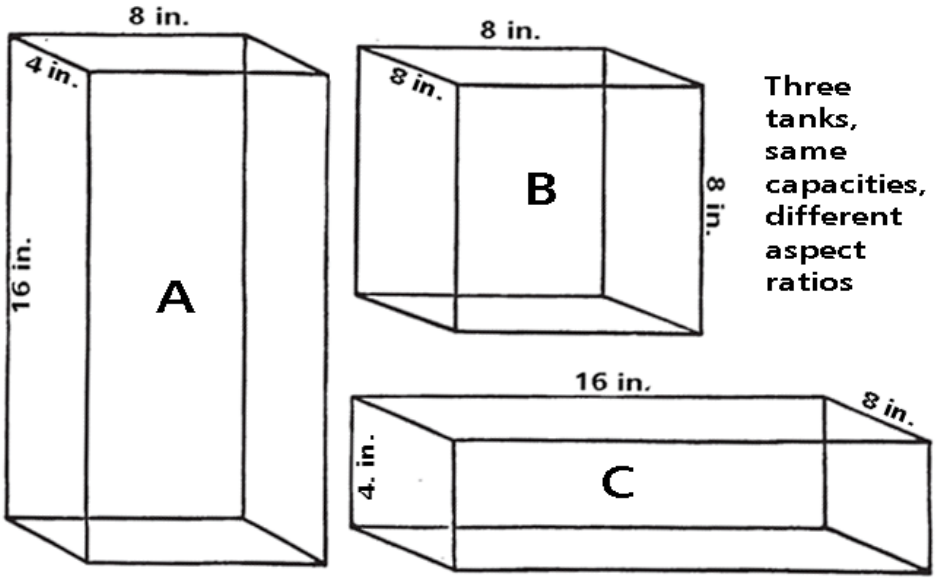

FIGURE 11: Aspect ratio affects water/air surface area even though the tank capacities are the same.

does not, within certain limits, depend so much upon the bulk of it, as upon the advantageous distribution of that bulk over large spaces. Therefore the shape of the tank is a very important matter; and that this is the case is proved by a simple experiment. If a wide-mouthed bottle be filled with water, and an equal quantity of water be poured into a shallow dish or pan about 2 inches deep, and three or four minnows be placed in each vessel, it will be seen that while the fish in the pan remain apparently well, those in the bottle will, after having ascended to the surface of the water, die. The reason that the fish in the one case die and in the other live, is because water is simply a vehicle for holding in solution the oxygen which is necessary to animal life. And the greater the surface of water exposed to the air, the more oxygen will it absorb in proportion to its bulk.

An aquarium of the shape and size of A in Figure 11, which would present to the air a surface of water of 32 square inches, would hardly supply the oxygen necessary for the health of three small fish; while one like B, having a superficial measurement of 64 square inches, would hold comfortably six small fish; but one of the shape and size of C, presenting a surface of 128 square inches, would supply sufficient oxygen for twelve fish. And yet all three aquaria would contain exactly the same quantity of water, viz., 512 cubic inches.

6. No provision was made for the cover as a necessary portion of the tank. Figure 12 shows a tank sold by Lloyd with a plain glass cover for the exclusion of dust, arranged so as to drop into a cavity but made in two or more pieces for the admission of air and ease of removal.

7. Too much glass was used, and too little opaque material. Glass, of course, must be used if it is wished to see the inhabitants as they appear to one another, and not simply as when looked down upon from a higher level. At the same time, glass, unless it is used with caution, has unfortunately the disadvantage of admitting too much light. If the tank is made with all four sides of glass, it must be placed in a comparatively dark situation, and this renders it difficult to see the minute details in the structure of its inmates. On the other

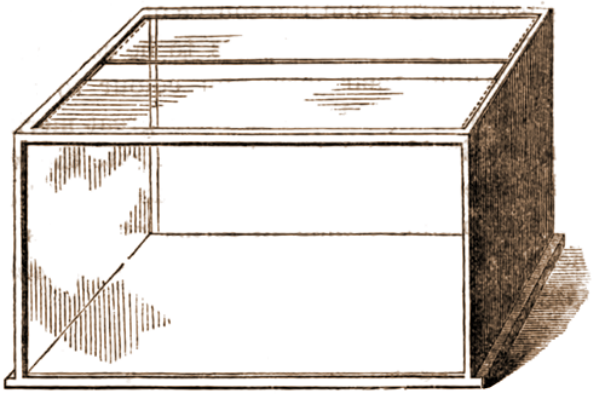

FIGURE 12: An aquarium sold by William Alford Lloyd with a plain glass cover.

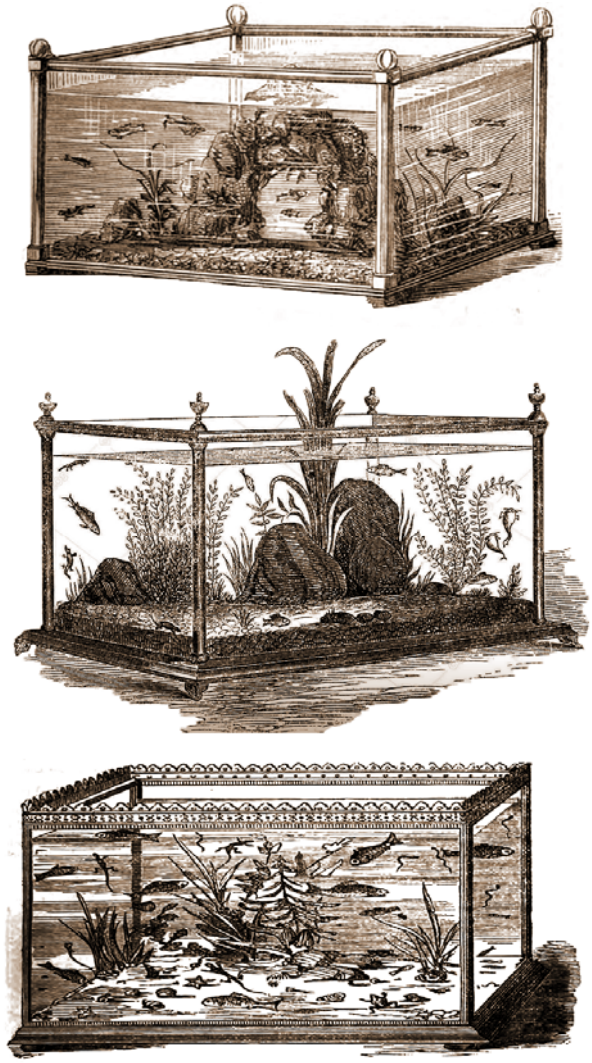

FIGURE 13: Typical ornamentation in the 1800s.

hand, if made partially of opaque material and partially of glass, the light is kept in check, and the tank can be placed in almost any situation such as an ordinary house furnishes.

8. They were not sufficiently ornamental to suit advancing requirements. In the 1850's ornamentation was reasonable simple, as shown in Figure 13. Extreme ornamentation was more common between the Two World Wars (see Figure 14).

THE INVENTOR OF THE FRAMED TANK

The following is from the January issue of *The Garden Companion, and Florists' Guide* (Warington, 1852):

Since the reading of my paper before the Chemical Society, on March 4, 1850, respecting the Miniature Aquarium (*Quarterly Journal of the Chemical Society*, iii 62), I have continued the investigations, introducing other water plants, and also three other varieties of water snail. But the principal alteration has been the construction of a better form of vessel for holding the water, as I found that the globular form of the glass receiver [*see Figure 15*], produced a distortion in the vision of the fish, besides being very inconvenient for observation. I have therefore adopted the form of vessel, of which a sketch is appended [*see top image of Figure 16*], having flat surfaces of plate-glass at the back and front, the bottom and ends being formed of slate, and supplied with a loose plate of glass at the top to keep out dust and soot. To render the whole more ornamental, as it was to stand in a sitting room, some pieces of tufa, or sandstone, were attached to the ends by means of Roman cement so as to form ledges and slopes rising from the water line, on which mosses

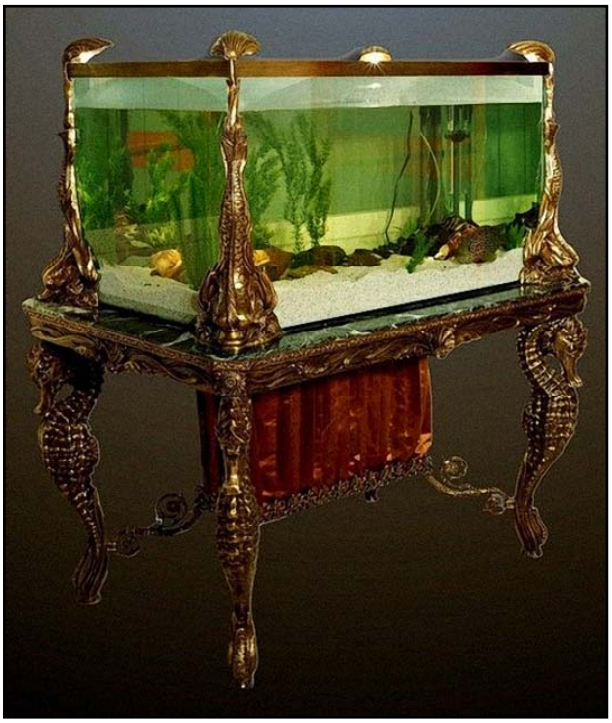

FIGURE 14: Extreme ornamentation was more common between the Two World Wars.

FIGURE 15: Warington's original globular aquarium in which he conducted his first experiments.

and ferns, such as luxuriate in an atmosphere loaded with moisture, could be grown. These materials are set in a stout angular zinc framework, and connected with a mixture of white-lead ground in oil, to which about an equal quantity of red-lead is added. This arrangement I have found to answer all my expectations, as it has been going on most flourishingly since January 1851.

Note: Present day concrete uses a paste of water and Portland cement, a fine powder made mostly of limestone and clay, to hold together small rocks. But it degrades within decades, especially in harsh marine environments. Instead of Portland cement, the Roman concrete used a mix of volcanic ash and lime to bind rock fragments.

This is the first record of the construction of a framed tank. The editors also provided the design shown in the bottom image of Figure 16 with the following comments:

We have already given a view of the parlour aquarium, contrived by Mr. Warington, and which may well bear his name; and have also explained in his own words the principles on which success depends. These principles, it must be obvious, admit of various modes of application so that our former illustration is to be regarded rather as an exemplification of the principle than as a model.

**Figure 16: Top figure - Warington's rectangular aquarium design.
Bottom figure - The Garden Companion's idea of combining this with an upper part that afforded space for a variety of plants.**

The editors also commented as follows:

We now subjoin another design [*see bottom image of Figure 16*] for an aquarium, or Warington case, with the view to indicate, to some extent, the variety which may be attained, by combining this with the Wardian case. It will be obvious that this combination will afford scope for a much greater variety of form than would have been brought out by confining them chiefly to the growth of aquatic plants, and this amount of variety will afford opportunity for the display of a greater amount of ornamentation.

VARIATIONS ON WARINGTON'S AQUARIUM

Thus, Robert Warington is the inventor of the framed tank and of the cover glass as well. His tank was the catalyst for others to devise a plethora of modifications to his design. Figure 17, for example, shows a marine aquarium with the two end sides and the bottom side made of slate and the front and rear sides made of glass. The slates were grooved to receive the glass and the aquarium cement, and two iron bars through the end slates held the aquarium together. I'll discuss this type of construction later in this essay. Figure 18 shows two of the hexagonal and octagonal tanks, framed in iron, that were popular in those days.

In *The Annals and Magazine of Natural History* [Warington, 1854], Warington wrote:

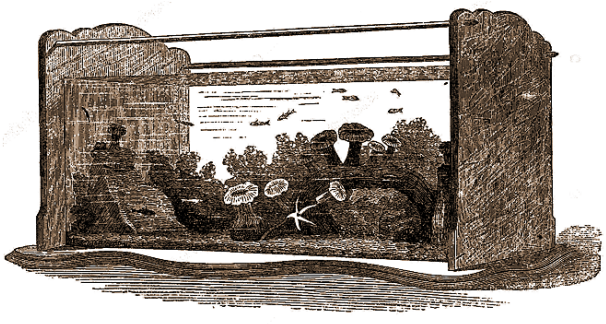

FIGURE 17: A marine aquarium built using two iron rods.

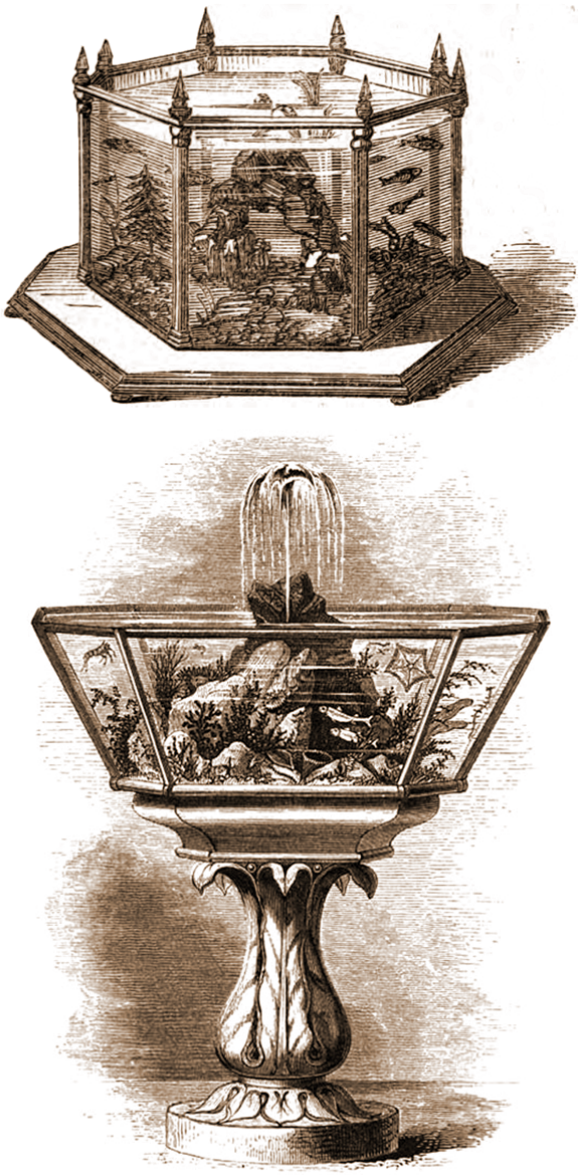

FIGURE 18: Hexagonal and octagonal tanks were expensive but popular aquariums in the 1800s.

The form of aquarium which, after upwards of five years' experience and observation on the natural habits of the various animated tenants, I have now adopted, consists in a four-sided vessel having the back gradually sloping upwards from the bottom at an angle of 45 to 50 degrees, and the consequently extended top sloping slightly downwards and resting on the upper part of the back. The bottom, therefore, becomes necessarily nar-

row. The front for the purposes of observation, and the top for the admission of light, are to be of glass; the back, ends, and bottom being constructed of slate; the whole fixed in a stout framework. The advantages of this arrangement are:

First. That it allows of a most extended view of the whole interior of the aquarium.

Secondly. That it enables the occupants to resort to water of any depth they may desire, or even to ascend the sloping back and emerge from the water.

Thirdly. It admits of a much larger surface of water being exposed to the action of the light; and

Fourthly. The sloping top allows the water which condenses on the glass, from the effect of radiation, to trickle off and return to the aquarium without first resting on the zinc or iron framework.

I need hardly mention that the sloping back is to be covered with light rock-work extending to a short distance above the water line.

This was essentially a triangular-shaped tank (Figure 19) and by "back" Warington meant the sloped bottom side of the tank. Such a tank, of course, could not stand by itself so a supporting framework was supplied for this purpose (bottom image in Figure 19). However, Gosse was a severe critic of the slope-back design:

I have also another tank with a sloping back, made on Mr. Warington's plan. It is of zinc, with the back and two sides of slate, the front and two front-sides alone being of glass. Its form is six-sided, the front resembling a bow window; it is three feet long by one foot ten inches in greatest width, and the same in depth; the peculiarity is that the back slopes inward, so that the bottom is but eight inches wide. I cannot commend this form; its appearance is lumbering and inelegant; the opacity of the back and sides throws the interior into a degree of darkness, (even though placed in a south window), which greatly impedes observation; and I cannot see, by comparison with my others, which are of glass all round, that the advantage anticipated, of admitting the light only from above, is real, or at least of sufficient importance to compensate the uninviting gloominess alluded to. Its depth also is

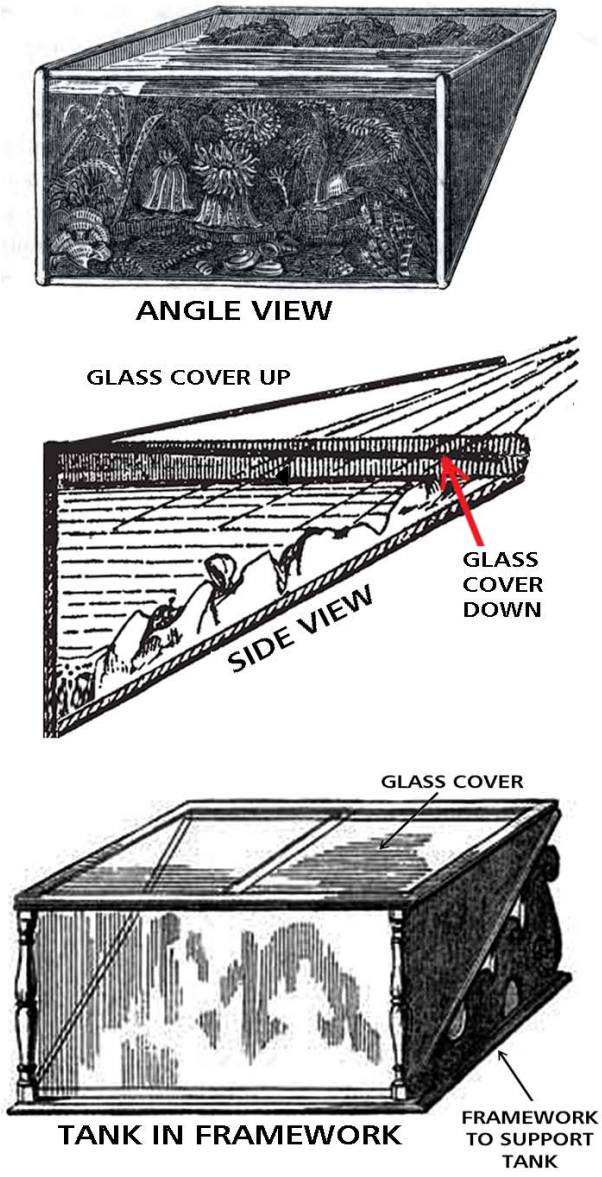

FIGURE 19: Warington's slope-back aquarium.

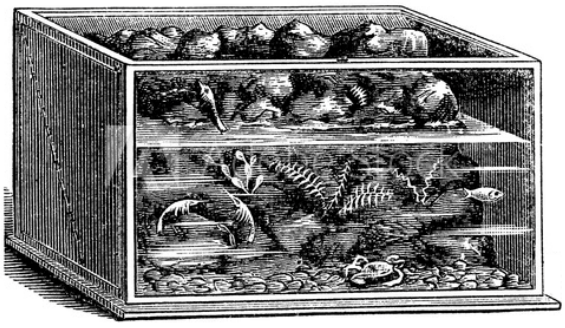
too great; a foot of water is as much as is needful for a parlour Aquarium.

IMPROVEMENTS TO WARINGTON'S DESIGN

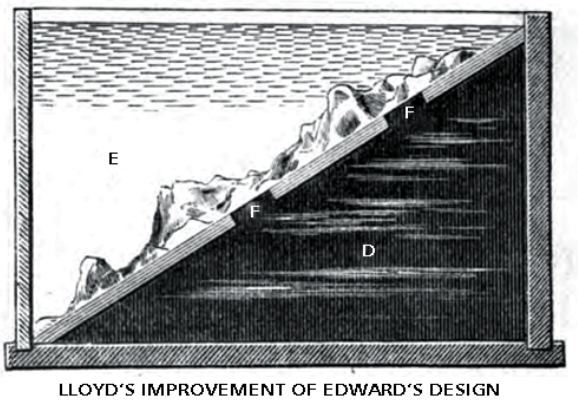
Warington's design was afterwards much improved in 1858 upon by the Welshman, Edward Edwards (1803-1879). Edwards was born in 1803 at Corwen, Merionethshire where he received his education. He started in life as a draper at Bangor, Carnarvonshire, which business he carried on until 1839 when he retired from it. In the following year he established a foundry and ironworks at Menai Bridge, which he carried on for several years with much success. In 1864, being interested in observing the forms of marine life in the waters of the Menai Strait he began to study the habits and characters of the fish in their native element. He was interested in keeping aquatic animals in aquariums in order to study their habits more closely. By imitating the natural conditions under which his fishes flourished, he succeeded in introducing such improvements in the construction of aquaria as enabled him to preserve the fish for an almost an unlimited period without change of water.

His most notable improvement was his dark-water chamber slope-back tank, a modification of Warington's design that incorporated Warington's sloping base within a standard rectangular aquarium provided with a sloping internal divider that converted the triangular space below the slope into a receptacle for water in a state of darkness. This was the result of his close study of the rock pools, with their fissures and chasms, in the rocks on the shores of the Menai Strait. Edwards showed his tank to William Alford Lloyd who suggested that holes be drilled in the divider, small enough so that fish and other animals could not pass through but water could (see Figure 20). Termed the "dark water chamber slope-back tank," it had two advantages: (1) It doubled the amount of water in the tank, diluting contaminants and increasing the oxygen supply, and (2) The dark area decreased algal growth since, without a strong source of light, the algae died. Edwards, in partnership with Lloyd, patented the design on November 24, 1858. The following is a description of the tank in their patent (see Figure 21):

The bottom, sides, and back A of this aquarium or tank are constructed of slate or other suitable material impervious to and not liable to injury from the action of water, and the top and front, B are of glass. C is a partition made of slate or other opaque material so fitted as to divide the tank diagonally, thus forming within it a compartment or chamber D, which is intended to contain water, but is not to be supplied with animals or plants for inspection, and this compartment being sheltered from the light by its situation, by the position of the partition C, and by the material whereof the sides and bottom of the vessel are composed forms a dark chamber, or chamber the contents of which are not exposed to the action of light.



EDWARDS IMPROVEMENT OF WARINGTON'S DESIGN



LLOYD'S IMPROVEMENT OF EDWARD'S DESIGN

FIGURE 20: Edwards and Lloyd's improvements of Warington's design.

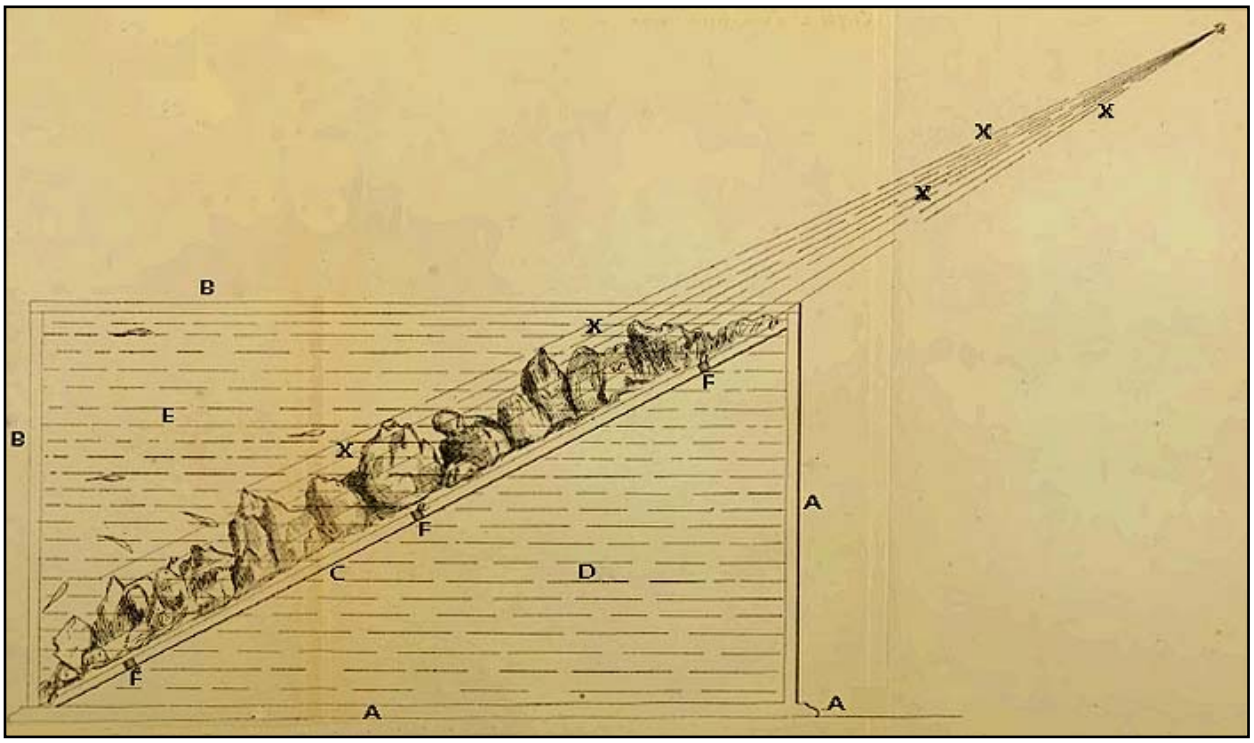


FIGURE 21: the drawing in the Edwards/Lloyd patent.

E is the part of the tank containing the objects exposed to view. The rock work, vegetation, etc., F rest on the surface of the partition C, and the space E is supplied with water and with fish, and other aquatic animals, etc. In some forms of tanks, the portion of the sides enclosing the space E may be of glass, and the other parts or those enclosing D of opaque material. Through the partition C, are a few orifices F, F, F perforating it transversely from surface to surface to afford means of communication between the fluid in the space E, and that in the compartment D. The partition may be fitted in a groove at the bottom of the tank, and rest against the upper part of the back, and it need not quite touch the sides, but may be so placed as to leave a small space between itself and them, through which the fluid in the compartment D may communicate with that in the space E, in this case the orifices through C may be dispensed with. The lines X, X, X etc. illustrate the incidence of the solar rays.

The following is their explanation of what happens in the dark chamber tank:

Now in respect of animals and plants, the construction and arrangement of their receptacles in reference to the effect of light on the fluid contents must be considered as of great importance, and the chief advantage of our arrangement is this, the excessive action of light or actinism on aquaria, &c., tends to develop certain vegetable growths of a nature to render the water turbid, unsightly, and cloudy, and thereby detract from the satisfactory appearance of the collection, and from the clearness necessary for proper inspection thereof; but by forming a compartment in the aquarium, tank, &c., according to our Invention, we obtain a chamber serving as a reservoir of fluid not exposed to the light, and which is therefore retained in a clear and serviceable condition, free from such obnoxious vegetation ; and this fluid being allowed to communicate with that in the space containing the aquatic animals and plants, the excessive and in this respect detri-

mental effects of actinism are neutralized and counteracted. It may also be mentioned that when there is active interchange between the fluid in the space E and that in the compartment D, such minute vegetable growth as may be carried into the latter will speedily perish therein from want of light, and by its destruction will restore the fluid to its original limped condition.

Lastly, the following were the specific claims for the invention:

And having now described the nature of the said Invention, and in what manner the same may be performed, we declare that although we have shewn as one mode of carrying the Invention into effect, an arrangement in which the rock work is placed on a slanting partition, we do not claim as of our Invention the supporting of the rock work of aquaria on a slanting surface, and we lay no claim to any particular external form of aquarium, tank, or such like receptacle; but what we claim as our improvements in aquaria tanks, and similar receptacles for aquatic animals and plants, is, forming therein a compartment or compartments which may be preferably so contrived as to form a dark chamber or chambers, and which is or are to contain no animals nor plants, but to be supplied with fluid caused to communicate with that in the space containing the animals and plants.

The patented dark chamber tank was sold exclusively by Lloyd. Unfortunately, Edwards would be recorded in history as the inventor of this kind of aquarium on a design which had evolved from ideas already explained and published by others, notable Robert Warington and also William Thompson (see Thompson, 1853).

At the time the patent was awarded, Gosse was persuaded by Lloyd to change his mind, at least with regard to the dark-chambered slope-back tank. These improvements on Warington's design staved off for a long time the falling off in the taste for domestic aquaria, and the principle of Edward's and Lloyd's tank was successfully adopted in many of the large public aquariums of the time and in many of the Continental and American zoological schools.

A NOVEL TANK CONSTRUCTION

Gosse, in his "Hand-book to the Marine Aquarium" (Gosse, 1856) described a novel mode of constructing tanks suggested to him by Mr. W. Dodgson, of Wigton, Cumberland. That gentleman kindly furnished him with the following further information on the subject:

I have lately been constructing two Aquariums, and as the way in which they are made may be new and perhaps useful to you, I take the liberty of communicating it. Slate we have no opportunity of procuring in suitable pieces for joining, and our stone is too porous for the purpose. I therefore got the bottom and two ends made in one piece out of the yellow clay used for garden vases, chimney-tops and other coarse pottery, and found it answered exceedingly well and has several advantages. Partly as a means of supporting the ends, but principally to form artificial rockwork and shelter for the animals, the two ends are buttressed inside with very rough pieces of clay, put on so as to leave plenty of holes and fissures; the fire fastens these firmly together and makes them as hard as stone. Grooves are left along the bottom, and up the two ends, for the glass to fit into (Figure 22). The outside is relieved with ornamental work.

Cheapness is a great recommendation; the pot being charged 1d. [$0.55] or 2d. [$1.10] per hundred cubical inches, according to the amount of ornament. I should think your London potters would make something very neat, and the mould once made, they could be supplied very cheaply; and considering their freedom from leakage and their strength, I think they would prove as satisfac-

tory as any kind of cistern. Mine are about three feet long, and thirty inches high and broad, holding thirty gallons each. I bed the glass with white lead, leaving about a quarter inch in depth of the groove unfilled. When the putty is set, I fill it up with shellac dissolved in naphtha and made into a paste with whiting. This sets very quickly, becoming as hard as stone; it is quite insoluble, and prevents the water from coming in contact with the lead, which I think must constantly be giving off small quantities of oxide."

In reply to some inquiries by Gosse, the same gentleman wrote Gosse further as follows:

I have delayed replying to you respecting the price of pottery for Aquariums till I had an opportunity of seeing the party who made mine. The price of one such as you name would be 6s. [$39] or 8s. [$52], but, as it would weigh four hundredweight, the carriage to London would be quite as much. He was rather doubtful whether with his coarse clay he could make one the length you name to hold together; as two or three of mine, which were shorter, separated in the middle when being burnt, from the great weight of the ends preventing the centre contracting regularly. He thinks your best plan would be to get one of the terra-cotta workers to make one, which he thinks he would do more cheaply than it could be sent from here; and their clay being finer, a much neater article could be made. It would be well to be on the spot, and see the rough clay put on the ends, as workmen in general have not much idea of what is required. To prevent the water filtering through the pots, mine were well glazed inside with flint-glaze, free from lead. Probably it would be better to glaze the outside, and leave the inside porous.

More information was published in an 1865 article about aquariums in *The Corner Cupboard:*

The earthenware tanks for aquaria, named by Mr. Gosse, in his "Hand-book" were made by Mr. Robert Lucock, of Broughton-moor [*he was an owner of a brick and tiles works in Broughton-Moor, Cumbria*], and hold about thirty gallons each. The earthenware consists of a bottom and ends, thickly glazed inside, with a groove along the inner edges to receive the glass sides. These, of quarter-inch plate glass, were bedded in red-lead putty, leaving about a quarter of an inch of the groove empty, along the insides, where the putty would have to come in contact with the water, and might have been injurious to the plants or animals. This space was fitted up with cement, made as follows:—Dissolve eight ounces of shellac in one pint of naphtha or spirit of wine. When wanted for use, stir a small quantity of this solution into a smooth thin

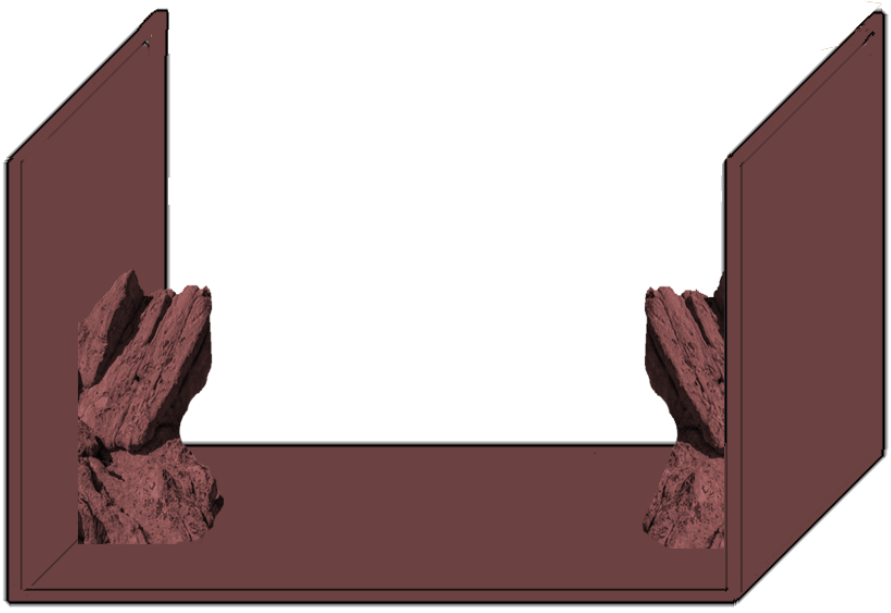

FIGURE 22: The clay aquarium with the artificial rockwork along with the bottom and the sides. The lines denote the grooves for the back and front glass.

paste, with whiting, and apply immediately. If much is mixed up at once it is apt to dry on the outside before it is used. Where there is not a great body of it this cement will set very hard in a few days, and is not injured by water. When the poisonous nature of red-lead is not an objection, it will form a still harder cement than whiting.

Before the tanks were burned in the kiln, rough masses of fire clay were attached to the lower parts of the ends and the bottom, in imitation of rockwork. Owing to the porous nature of the clay at Broughton-moor, and probably in part from the glass not having penetrated the crevices of the rockwork, the water was found, when they were filled; to percolate through the substance of the tanks. They should therefore be made of closer clay, or the rockwork left out and attached artificially afterward. Probably it might be an improvement to glaze the outside and not the inside; the parts exposed to the water would then have more the character of real stone. The earthenware cost about 8s., the glass 18s, for each tank, so that for their size they are cheaper than any other form, and if made of finer clay they would not be liable to leak or get out of order in any way.

Dodgson was not the only one who used clay as a vessel for aquatic creatures. In 1857 Richard Owen (Owen, 1857) described a fourth type (he mistakenly called it a third type) of "cage" that was used by Jeanne Villepreux-Power to study marine life. Her cage, like Dodgson's was made of clay, but fashioned from one half of a clay cylinder cut lengthwise. It was attached by circular metal strips to a board, the openings at the end closed by a framework that was sufficiently open to admit water without allowing its marine animals to escape. It is not known when Villepreux-Power first used this cage but it was sometime after 1834 and before 1857 when Owen described it. Note, however, that this was not an aquarium as it was not designed to hold water.

ROD TANK No. 1

Returning now to the construction tanks held together with rods, it was comparatively easy to make an aquarium to resemble that of Figure 24. It was constructed of glass, wood and slate. The ends and bottom were made of 1 inch well-seasoned pine, dovetailed together, and they were grooved. The grooves ran with the grain, and were 3/8 inches deep, about the same wide, and 3/4 inches from each edge. The ends were held firmly in their places by two bars at the top of the aquarium (G in Figure 23). These bars were 2 inches broad and 1 inch thick and were dovetailed into their places (Figure 24) and had grooves to correspond with those in the bottom and the ends.

The ends were lined with window-glass and the bottom was lined with slate. The sides were formed of plate-glass 1/4 inches thick and were put in their places before the crossbars at the top of the aquarium were fastened, the grooves into which they went having previously been half-filled with the following cement. One pint each of plaster of Paris, litharge, fine white sand, and one-third pint of finely-powdered resin. This (or in this proportion) was kept in a well-stoppered bottle, and when needed, the necessary quantity was made into a putty with boiled oil and driers.

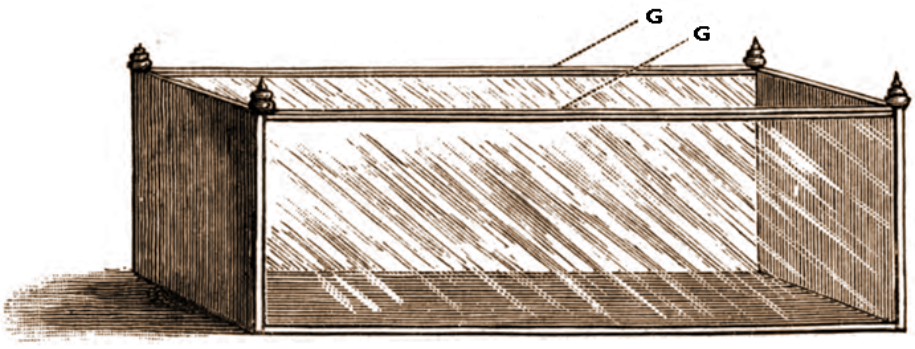

FIGURE 23: The Rod tank No. 1.

This was a very quick-drying cement. It became, if anything, too hard.

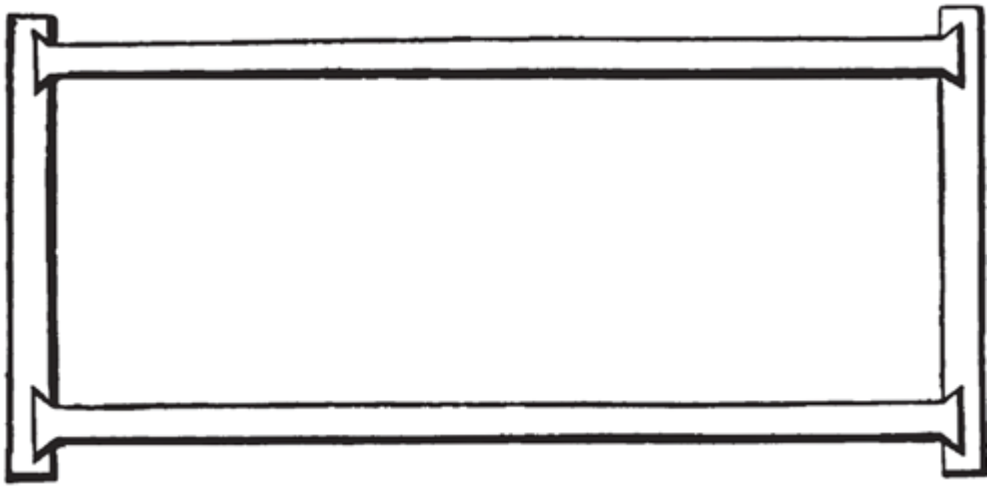

FIGURE 24: The setting of the bars into the top ends of the aquarium.

The bottom was covered with a thin layer of the cement just mentioned, and the slate was pressed firmly and gently into place. In the same way, the glass linings were placed for the ends. The corners were filled with a cement of red and white lead to a depth of 1/4 inch, and when it was somewhat hard, a coating of the cement which was first mentioned was put over it. This cement could be employed throughout but then, for safety, it had to be used a little more liberally than the plaster of Paris cement. The junction of the glass linings with the ends and the dovetailing of the crossbars could be hidden by four strips of wood, 2-12 inches wide and 1/4 inch thick, neatly mitered together and the corners of the framing could be decorated with small turned ornaments as shown in Fig. 23. The woodwork looked pretty good when stained, sized and varnished, or French-polished (this involved applying many thin coats of shellac dissolved in denatured alcohol using a rubbing pad lubricated with one of a variety of oils; it produced a very high gloss surface).

ROD TANK No. 2

Slate, 3/4 inches or 1 inch thick, and plate-glass was required to make a tank like the one shown in Figure 25. The slate could be bought at a slate merchant's at a cost of about 10 penny ($5.50) a foot. The bottom 30 inches long and 16 inches wide and the ends were each 16 inches by 13 inches made an aquarium of good dimensions. At 1 inch from the extremity of each end - that is, across the broad part - a groove 1/2 inch deep and 1-1/8 inches broad was cut. This was supposing that slate 1 inch thick had been chosen but if it was only 3/4 inch thick, then the groove had to be proportionately smaller each way.

The groove could be cut in the following manner: First, the exact place and dimensions of the groove was marked with an awl. Then two straight-edged pieces of wood some inches longer than the breadth of the end were obtained and placed on each side of the line which was to be cut and then nailed to the bench. They had to be just wide enough apart to admit a tenon-saw (see Figure 26).

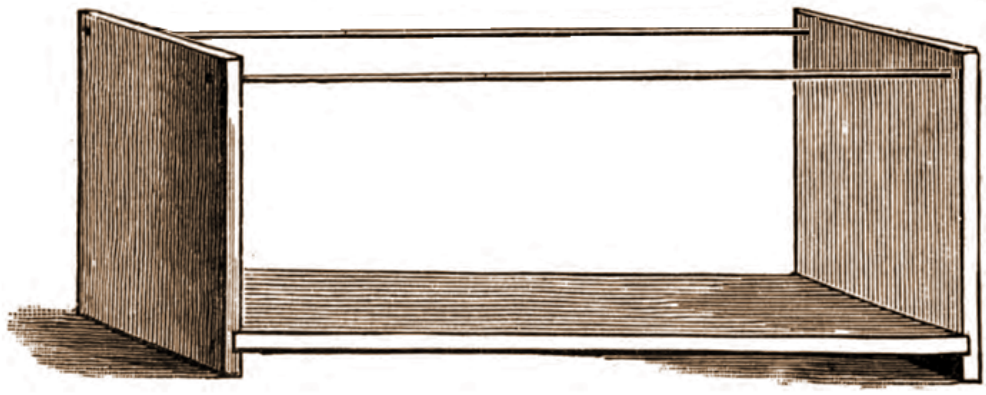

FIGURE 25: The Rod tank No. 2

With the saw, the line was cut to the required depth, 1/2 inch. Without some such preparation as this it would have been difficult to cut the sides of the grooves with the necessary accuracy. When both lines had been sawn in this way, a chisel and mallet were used to cut out the slate that lay between them. But before using the chisel, the precaution had to be taken to put two or three folds of carpet or the like between the slate and the bench to prevent all jarring and the danger of a crack. These grooves were made to receive the ends of the bottom.

There is another way of making the cuts for these grooves. A piece of hoop-iron (i.e., flattened iron in long thin strips used for binding together the staves of casks or tubs - see Figure 27) was obtained, about a foot long, and straightened. Then for a handle, 10 inches of broomstick, more or less, was sawn half through lengthwise, and the hoop-iron was hammered into the groove. The place on the slate where the cut was to be made was marked with an awl and the mark deepened a little by running the point of a three-cornered file a few times carefully up and down. The slight groove thus made was filled with fine white sand, and moistened with water by means of a wet brush. The edge of the tool that had just been made now was run to and fro in this sand and water. By continually doing

FIGURE 26: A tenon-saw.

FIGURE 27: The round bands on these barrels are known as hoop irons.

this, always keeping plenty of sand and water under the edge of the iron, the cut would gradually become deep enough. When the cuts had been made, the portion of slate between them could be chiseled out as before. As a rule, the slate could be split cleanly out by striking the chisel against the edge and not on the top of the slate. This way, there was less danger of breakage. The latter method of making the cuts was the more satisfactory of the two - the former blunted the saw too quickly.

Now along both sides of the bottom and of each end, at a distance of 1/4 inch from the edge, grooves 1/2 inch deep and 3/8 inch broad were cut. These grooves were to receive the plate-glass sides, 1/4 inch thick. After this were bored four holes, 1/4 inch in diameter, right through each end. Two of these were placed 1-1/2 inches from the edge and 1/4 inch below the groove that was to receive the end of the bottom, and the other two 1 inch from the top and just within the grooves cut for the glass (Figure 28).

The holes were for the bolts which ran across from end to end to hold the aquarium together. They were bored with an ordinary brace and a bit used for metal. The bolts preferably were made of brass wire but iron would do. It was a wise pre-

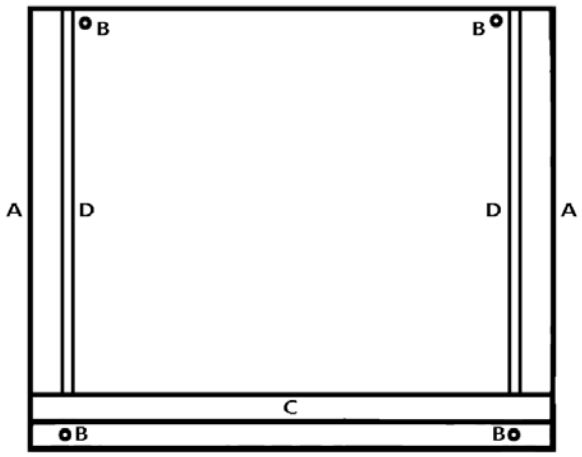

FIGURE 28:
A - End side.
B - Position of the bolt holes.
C - Grooves for the glass.

caution to have the thread for the nut a little longer than necessary, for it could easily be shortened when the bolts were in their places, and the long threading was a great convenience in the screwing-up. Before putting the aquarium together, a little cement was placed in all the grooves. Then the bottom was raised on blocks of wood to such a height that it was level with the grooves cut to receive it in the two ends. When this had been done, the ends, plate-glass, and bolts were put into position and screwed together, turning the nuts of the bolts with only the finger and thumb. Before the nuts were quite screwed home, the glass was pressed gently downward, so that it was forced firmly into its place. Carefully finish by filling up the grooves with cement, and the aquarium will be completed. If iron bolts were used, paint them with Brunswick Black (a quick-drying black varnish used for metal, particularly iron, stoves, fenders and surfaces of indoor equipment. Because of its bitumen content, the coating was highly protective and the finish was attractive and reasonably durable).

A POPULAR TANK FOR HOBBYISTS

An aquarium like Figure 29 was perhaps more suitable for its purpose than any yet described, but was not so ornamental. It could be made either of wood, slate and glass, or of slate and glass only. If made on the former plan, the directions given for the construction of an aquarium like Figure 23 will suffice, with the following exceptions: A wooden side lined with window-glass or roofing-slate, would take the place of a plate-glass side. As the aquarium would be broader than shown in Figure 23, the grooves in the ends for the glass front had to run across the grain and the bottom had to be made the required breadth by clamping and gluing on another piece of wood. The wood work was best dovetailed together, but if this could not conveniently be done, nailing with long French (wire) nails would do. The front had to be framed as well as the top. It made an excellent tank for freshwater fishes.

A useful size for an aquarium of this description was 24 inches long, 20 inches wide and 10 inches deep. If the tank was to be made of slate and plate-glass only, the directions given for making an aquarium like Figure 25 will be enough, except that in the place of a glass side there will be a slate one, and for this the grooves, instead of being 1/2 inch deep and 3/8 inch broad, ought to be 1/2 inch deep and 1-1/8 inches broad. It made an excellent tank for marine specimens.

GOSSES'S AQUARIUM DESIGN

In his book titled "A Naturalist's Rambles on the Devonshire Coast" (Gosse 1853), he wrote the following:

But my attention has been directed to the realization of … a Marine Aquarium for the

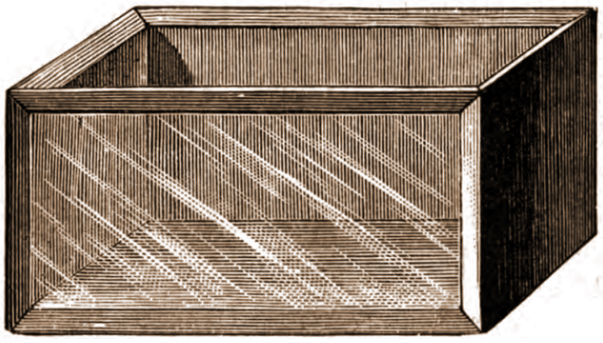

FIGURE 29: A popular tank for hobbyists.

Parlour or Conservatory. An apparatus for this purpose has been for some time in the manufacturer's hands; and though there are some minor difficulties attendant on the mechanical part of the execution, they are not such as to throw any material doubt on my confident expectation, that in a short time an elegant vase stocked with algae and sea-anemones, and comprising within itself the elements of its constant self-purification, will be before the world.

Although the tank in question was not finished at the time of this printing, I suspect that Gosse was trying to establish some sort of priority in tank construction. In any event, as a marine aquarium it evidently did not prove satisfactory and in his book titled "A Handbook to the Marine Aquarium" (Gosse 1853), he wrote the following:

My largest tank (now in use as a fresh water Aquarium,) is a parallel-sided vessel, two feet long, one and a half foot wide, one and a half foot deep; the sides and ends of plate glass, three-sixteenths thick; the bottom, a slab of slate one inch thick; the corners of birch-wood, turned into pillars, each surmounted by a knob, and united by a frame-top or bar going all round. The glass is set in grooves in the slate and wood, and fastened with white-lead putty. I have two others agreeing with this in all respects, except in dimensions, the smallest being (in the clear) fifteen inches long, twelve inches wide, and twelve inches deep. This is a very neat and pretty object for a parlour table, and will hold at least fifty animals appreciable to the senses, provided they be well selected, and a sufficient growth of plants established.

The details on how Gosse's tank was constructed was provided by Reginald A. R. Bennett (Bateman and Bennett, 1890) who commented that if the aquarist was a good hand at carpentering, he could make an aquarium for himself in the following way. A slab of slate was used to form the bottom of the tank, the size of which depended on that of the future aquarium. A good size was l-1/2 inches or 2 inches thick, 30 inches long, and 18 inches or 20 inches wide. In this slab grooves of about 1/4 inch in depth and breadth were formed, running round the sides at about 1 inches distance from the edge. Four pillars were constructed, preferably of birch or mahogany, each 12 inches in length, and two grooves, about ¼ inch in depth and breadth, were made down each pillar at right angles to each other.

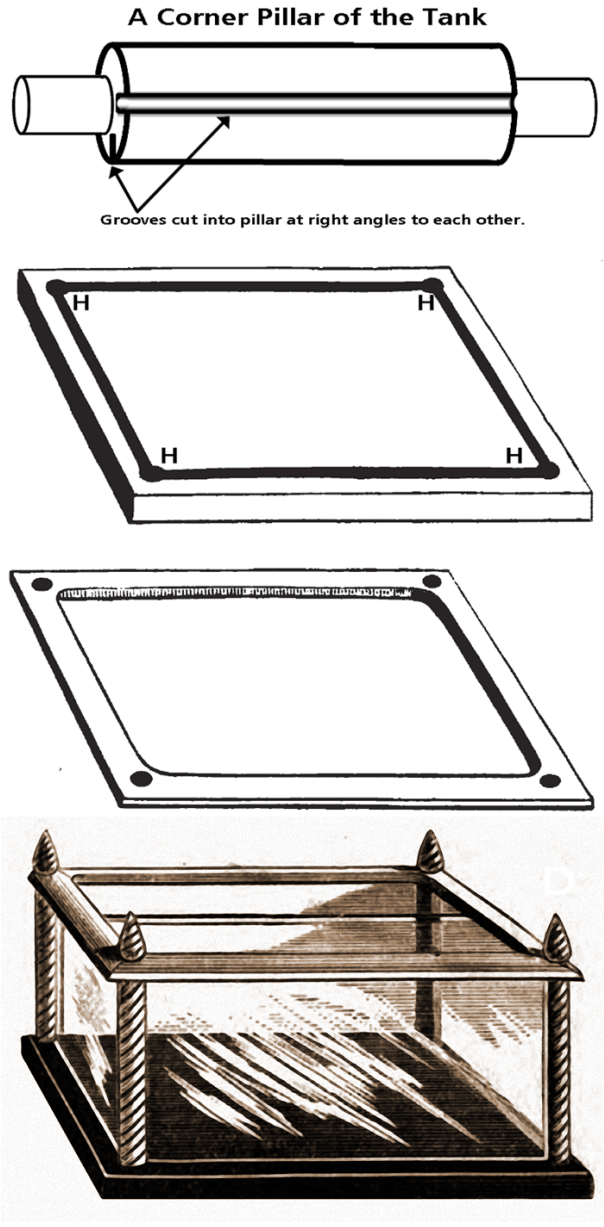

FIGURE 30: Gosse's aquarium design.

These pillars were turned off at the end on a lathe (see image A in Figure 30) so as to exactly fit four holes (each about 1 inch in diameter, and the same in breadth) that was made to receive them at the four corners of the slab of slate where the grooves joined (see H in image B in Figure 30). The pillars were bedded firmly in with a cement to be described in the next paragraph, and allowed some time to set firm in their places. Next, four pieces of what is known as 32oz. sheet-glass of the required dimensions to form the sides of the tank was procured. These were bedded firmly into the grooves in the slate and pillars with the cement, after which a framework was made to exactly fit the tops of the pillars and hold all firmly together (see image C in Figure 30). The last touch was given by inserting ornamental knobs at the top of each of the pillars, and the tank is then completed. Its general appearance is shown in image D in Figure 30.

As to the cement, the following was used in the construction of the tanks at the Zoological Gardens. It resisted the action of salt water and so was used here: 2 gills of litharge, 2 gills of plaster of Paris, 2 gills of fine dry white sand and 2/3 of a gill of powdered resin. It was mixed, sifted and kept in a dry place until required for use. When ready to use it was made into a paste with a small quantity of boiled linseed oil to which a little dryer has been added. The cement had to be used within twelve hours. It would take about a week to dry, and if left for a much longer time, so much the better.

There are several points of importance that Bateman pointed out that had to be carefully observed in the construction of the tank; neglect of them would be a cause of complete failure, or at any rate of considerable discomfort to its owner. A sharp look-out had to be kept on the carpenter to whom the job of making the tank was entrusted to see that he did not use ordinary putty, as this did not withstand the action of the water in the slightest degree. Another point requiring supervision was the insertion of the glass sides, which were sometimes fastened on by abutments, like ordinary window-panes. This was actually done with a tank in Bateman's possession, and the consequence was that it leaked even though every description of cement had been tried to render it watertight. The glass had to be set in grooves and the deeper the grooves the less chance there was of leakage. The red cement used by ironmongers for cementing taps, pipes, etc. at the time was never to be used for an aquarium. It answered well for a short time, but it soon gave off a most peculiar odor that contaminated the water, causing the untimely decease of occupants of the tank if they were not removed immediately when the smell was detected.

If slate could not be easily procured, the bottom of the tank could be made of hard wood, with a piece of glass cemented over it when the tank is put together. The glass would prevent any leakage through the wood that might otherwise take place. The tank could be made broader and longer than described if a larger tank was needed, but a foot of water was considered amply sufficient at the time for a marine aquarium.

As I previously noted, Gosse had designed this tank as a marine aquarium in 1853 but later recommended it only as a freshwater tank. Oddly enough, Bennett described this tank construction in the marine section of the Bateman and Bennett book some 37 years later.

A METAL FRAMED TANK

Although this tank was much more difficult and took much longer to make, it was not beyond the powers of the ordinary amateur mechanic. The materials that were required for its construction were zinc, solder, cement, and plate-glass. The tools necessary were an old tenon-saw, square, hammer, soldering-iron, and a pair of scissors made for cutting sheet metal; but besides these a few blocks had to be prepared. The amateur could either make the blocks himself, or he could get

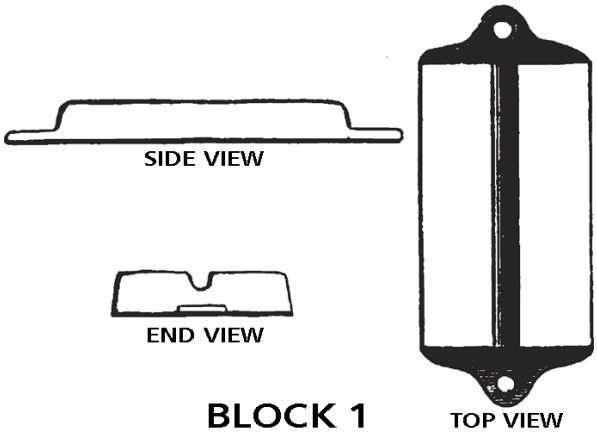

FIGURE 31: Block 1.

them made at a trifling cost. I will describe them in the order in which they were required.

Figure 31 shows an iron block, 6 inches long, having a U-shaped groove down its center. The groove is 3/8 inches wide and 3/8 inches deep. I will call this Block 1.The holes at each end of the block are for the screws that fasten it firmly to the bench. It will not only be useful for the purpose for which it has been made, but at any time it was serviceable as a small anvil for straightening nails and the like.

Figure 32 represents a steel bar a little less than 1/4 inches in diameter, and a little longer than the aquarium is intended to be. Figures 33 (Block 2) and 34 (Block 3) illustrate blocks made of some hard wood. That in Figure 33 ought to be not less than 6 inches long, and the groove in it should be at least l inch deep, and just broad enough to receive a double thickness of zinc. Figure 34 has a groove exactly the same size as that in the iron block of Figure 31. Figure 35 (Block 4) is made of hard wood, faced with two iron plates. The groove in this block must equal that in Block 1 in Figure 31, and the iron plates should be just far enough apart to receive

FIGURE 32: Steel bar with hand hold.

BLOCK 2

FIGURE 33: Block 2.

a double thickness of zinc. Besides these blocks an ordinary miter-block was useful, and all of them were more or less necessary, not only for the preparation of the zinc framework of this particular aquarium, but also for other aquaria of much easier make. The zinc should be moderately stout - that is, about No. 12 gauge.

Having decided upon the dimensions of the tank now about to be made, cut four strips of zinc its exact length, four its exact breadth, and four its exact height. Each piece ought to be 2-1/4 inches wide. Now take a strip of zinc, mark a line down its center, and place it upon Block 1 in Figure 31, the line marked on the zinc being exactly over the middle of the groove and running lengthwise with it. Then take the steel bar in Figure 32 by the handle in the left hand, hold the rod part of it exactly over the line marked on the zinc (and which, of course, was over the center of the groove in the block), and, with the hammer in the right hand, drive the bar and the zinc home into the groove, and about 6 inches of the strip of zinc was bent into the shape of A in Figure 36; bend the rest of the strip in this way, then press, by means of a pair of pincers (B in Figure 36), the zinc tightly round the steel bar. When this has been done evenly and carefully along the whole length of the strip, put the flat part of the zinc into the narrow groove of Block 2 in Figure 33, the bar not having been withdrawn.

BLOCK 3

FIGURE 34: Block 3.

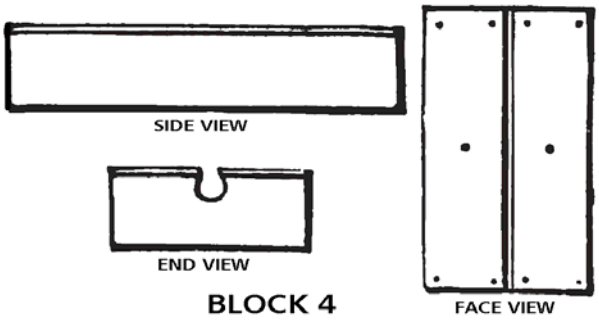

FIGURE 35: Block 4.

FIGURE 36: A - Cross section of the frame; B - Pincers.

This shown in Figure 37 where the flat part of the zinc (A) has been pressed together (B) and inserted into the slot of Block 2 (C).

Take Block 3 in Figure 34, place it over the tubing now formed in the zinc and strike it (the block) with a hammer to rectify any inequality that may have appeared in the molding. Separate the steel bar from the zinc and slide the latter, tubing downwards, into the iron-faced block in Figure 34. Then with a chisel or other like tool open the flat portion of the zinc now facing upwards until it forms as nearly as possible a right angle as in Figure 38. When this has been done, withdraw the molding from the block, and it should now have assumed the shape of Figure 39. If the edges be found to be not quite straight and true, they may easily be made so by hammering them on a side of the miter-block.

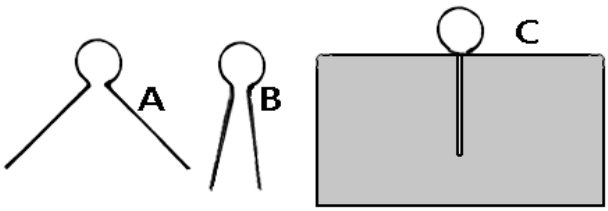

FIGURE 37: Placing the frame into Block 2.

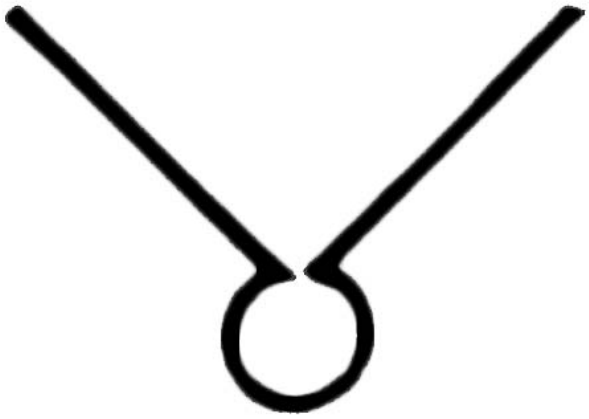

FIGURE 38: The right angle now of the frame.

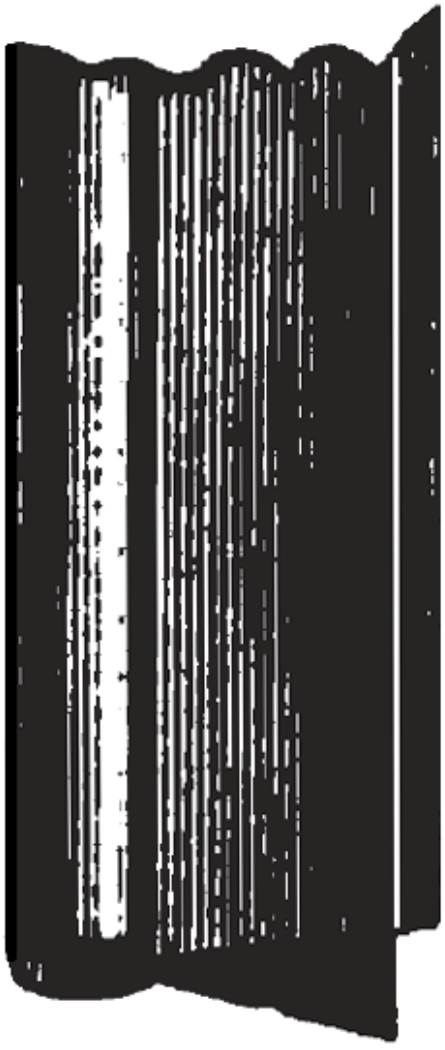

FIGURE 39: The finished frame.

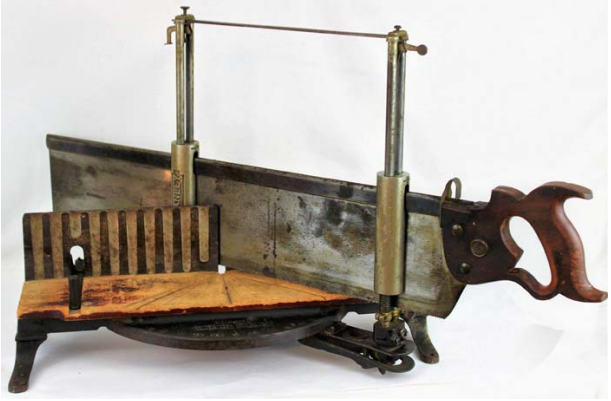

FIGURE 40: Miter-block.

Bend all the other strips in the same way, and then take two of them the length of the proposed aquarium and two of its breadth, and miter them together. The miter cuts can readily be made by means of an old tenon-saw and an ordinary miter-block (Figure 40). Having fixed them in position (Figure 41), solder the corners neatly and firmly together, taking care to have the flat portions of the molding perfectly square - that is one edge quite perpendicular and the other perfectly horizontal (Figure 43). This was for the bottom of the aquarium.

Now take four other pieces of molding, corresponding to the last four, and repeat exactly the same operation, and then the top of the tank was formed. Next join the top and bottom together at the corners by means of the remaining four pieces of molding. Figure 43 will show the way in which these joints are to be made. Care, of course, should be taken that everything is square and true. The framework of the aquarium will now be complete. It is, if properly done, very strong.

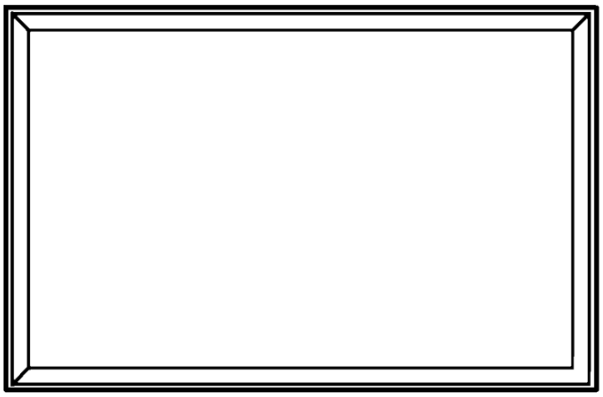

FIGURE 41: The frame ends fixed together and soldered.

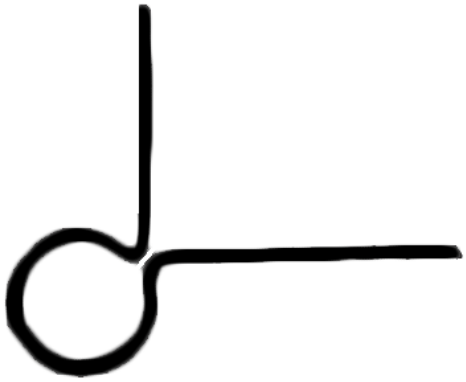

FIGURE 42: Make sure the flat sides are at a right angle to each other.

For a bottom, cut a piece of zinc or slate (the latter being far preferable) the length and breadth of the tank (inside measurements), place it on the ledge that is running round the lower part of the frame inside, and solder or cement it there. The glass for the sides should be 1/4 inches thick, and long enough to go quite across from end to end. But the glass for the ends ought just to touch the glass in the sides, so helping to hold it in its place. Before putting the glass into the frame its bed ought to be painted with gold-size, and then covered with a thinnish coating of cement. Recipes for several kinds of cement are

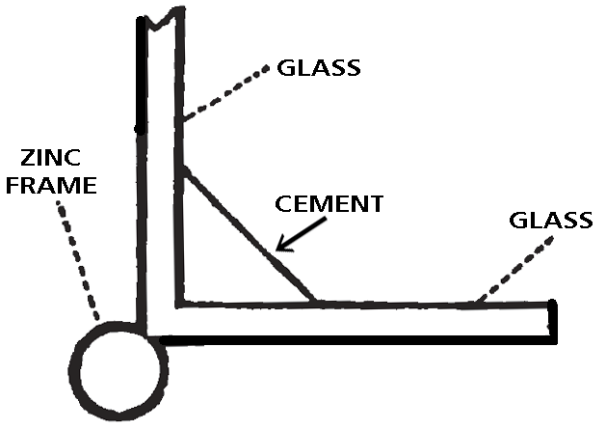

FIGURE 43: Schematic showing how the parts fit together.

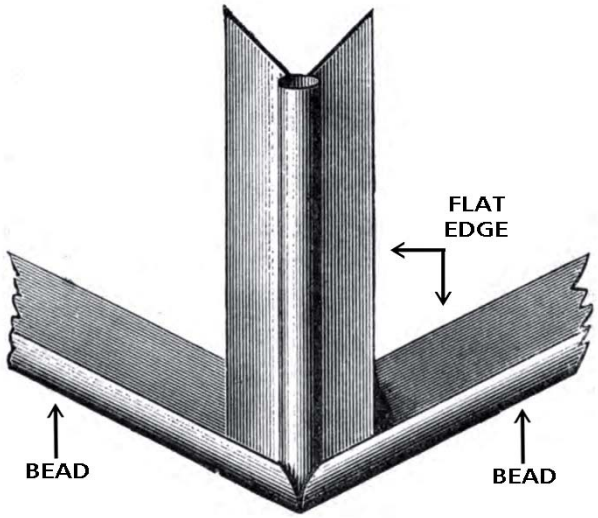

FIGURE 44: Diagram showing how the joints are made.

given at the end of this chapter. But, for an aquarium of this kind, a mixture of red and white lead is recommended. Now put the glass in, and press it gently into its place. Put the sides in first. Paint all the corners with gold-size, and then fill them in with cement to the depth of about 1/4 inches (Figure 45). When the cement has been roughly put into position, the fixing of it may be firmly and neatly completed by gently rubbing it with the finger upon the end of which is some gold size.

The tank should now be left to dry for some days; but during this time a stand and covering for it may be prepared. The stand (Figure 46) can be made of oak, mahogany or pine; this last should be stained and varnished. It ought to be a trifle longer and broader than the aquarium. A groove must be cut in its surface, to receive the beading of the zinc that is at the bottom of the tank. The whole should stand quite firmly. Instead of the heavy-looking covering usually made for such an aquarium as this, a flat piece of glass or of perforated zinc is to be preferred: the former is the better. At the end of a week the cement will have become somewhat hard; and if red and white lead has been used as the cement, it should now receive two coats of a varnish made of the best sealing-wax dissolved in spirits of wine. With this the zinc bottom ought also to be painted two or three times. Japan black may be used instead of the above varnish, but it will not be so satisfactory. If no varnish at all is used, the aquarium must be filled with water for three weeks or a month before it is stocked with plants and fish, the water being frequently changed during the time. The framework of the aquarium was much improved in appearance if carefully painted with Brunswick Black (a quick-drying black varnish used for metal, particularly iron, stoves, fenders and surfaces of indoor equipment. Because of its bitumen content, the coating was highly protective and the finish was attractive and reasonably durable) or enamel of some suitable color; if black is used, it may be "picked out" with gold or yellow.

AQUARIUM CEMENTS

The following eleven cements were used in the 1800s. I have not included minor variations on these formulas. Table II is a list of the definitions of the ingredients used in these formulas.

l. Mix equal parts of flowers of sulphur, pulverized sal ammoniac and iron filings with a good linseed oil varnish, and then add white lead to form a worked mass.

FIGURE 45: A bottom for the aquarium.

2. Whiting, 6 parts; plaster of Paris, 3 parts; white beach sand, 8 parts; litharge, 8 parts; powdered resin, 1 part. Mix thoroughly, and make into a putty with the best coach varnish. Leave the glass in the aquarium a week before disturbing.

3. Linseed oil, 3 oz.; tar, 4 oz.: resin, 1 lb. melt together over a gentle fire. If too much oil is used, the cement will run down the angles of the aquarium: to obviate this it should be tested before using by allowing a small quantity to cool under water- if not found sufficiently firm, allow it to simmer longer or add more tar and resin. The cement should be poured in the corners of the aquarium while warm (not hot). This cement is pliable, and is not poisonous.

4. Take 10 parts, by measure, litharge, 10 parts plaster of Paris, 10 parts dry white sand, 1 part finely powdered resin, and mix them when wanted for use into a pretty stiff putty with boiled linseed oil and driers. This will stick to wood, stone, metal or glass, and hardens under water. It is also good for marine aquaria, as it resists the action of salt water. It is better not to use the tank until three days after it has been cemented.

5. Litharge, fine, white, dry sand, and plaster of Paris, each 1 gill; finely pulverized resin, 1/3 gill. Mix thoroughly and make into a paste with boiled linseed oil to which drier has been added. Beat it well, and let it stand four or five hours before using it. After it has stood for fifteen hours, however, it loses its strength. Glass cemented into its frame with this cement is good for either salt or fresh water. It was used at the Zoological Gardens in London, with great success.

6. Red and white lead, the two being mixed together into a stiff paste. The bed for this cement ought to be painted with gold-size.

7. Gutta percha, in shreds, 4 oz.; black pitch, 8 oz.; shellac, 2 dr. Melt in an iron ladle on a sand bath and stir together. Pour out on a wet slab and roll into sticks. This cement is especially useful for an aquarium made of wood.

8. The best Portland cement.

9. One part pitch and one-fourth part gutta-percha, applied when warm. These should be melted together in an iron ladle over a gas-flame or lamp. This cement is especially useful for an aquarium made of wood.

10. Dissolve eight ounces of shellac in one pint of naphtha or spirit of wine. When wanted for use, stir a small quantity of this solution into a smooth thin paste, with whiting, and apply immediately. If much is mixed up at once it is apt to dry on the outside before it is used. Where there is not a great body of it this cement will set very hard in a few days, and is not injured by water. When the poisonous nature of red-lead is not an objection, it will form a still harder cement than whiting.

11. Gypsum, 2 parts; chalk, 2 parts; litharge, 2 parts; powdered rosin, 1 part. Mix with boiled linseed oil until a mass resembling glazier's putty results.

12. An excellent material for tightening aquaria has been found to be a mixture of litharge and glycerine, which turns as hard as stone within a few hours.

Some of these cements were dangerous. Red and white lead were toxic when breathed, and handling boiled linseed oil and heating pitch and tar -based cements sometimes resulted in severe burns.

EPILOGUE

The modern aquarium was born in Great Britain during the last half of the 1800s but by the end of the century it was in its demise there, to be taken up in the 1900's with a vengeance by aquarists in Germany and the United States. As the Century

FIGURE 46: Gilsonite ore.

moved on, basic aquariums manufactured by firms such as Jacob C. Cassel, the Pioneer Aquarium Company and Excell Tropical Aquarium generally were framed in the typical rectangular pattern and constructed of sheet metal electrically welded (or spot welded, a subset of electrical welding) and finished in green duro.

Gilsonite is a natural, resinous hydrocarbon found in this country in the Uintah Basin in northeastern Utah. It is similar to a hard petroleum asphalt and is often called a natural asphalt or asphaltum. These basic aquariums were generally sealed using a cement made of Gilsonite (1 lb.), a finely mashed resin (1-4 lbs.) and beeswax (1 oz.) the last providing some elasticity to the otherwise brittle compound. They were mixed over a slow fire and applied while hot. Later on, solvents such as linseed oil were added to the asphaltum so that the cement when only moderately warm had the consistency of putty and did not have to be heated for use.

In 1915, John J. Halterbeck was the first to put a one piece aluminum aquarium on market. Others, like Jewel Aquarium, followed with their own designs (Figure 47). Towards the end of the 1920's, an aquarist named M. Raymond Potts of Caldwell, New Jersey, started making tanks under the firm name of the Potts Aquarium Co., Inc. Potts, who was an aquarist, obtained several backers and started producing a new kind of aquarium. Before this time most were made either of sheet metal for the smaller sizes and cast iron for the larger sizes. The former rusted easily and the latter was heavy. Potts, who was treasurer of the firm he founded, came up with a brand new idea - sheet metal that did not rust. Thus the first stainless steel tanks were made available to the American aquarium hobby. This was definitely an American innovation, not popularized in Europe until after World War II. In 1931 the name of the firm was changed to the Metal Frame Aquarium Corporation, although "Potts Aquariums" were still featured. Later the firm was internationally known as Metaframe, Incorporated.

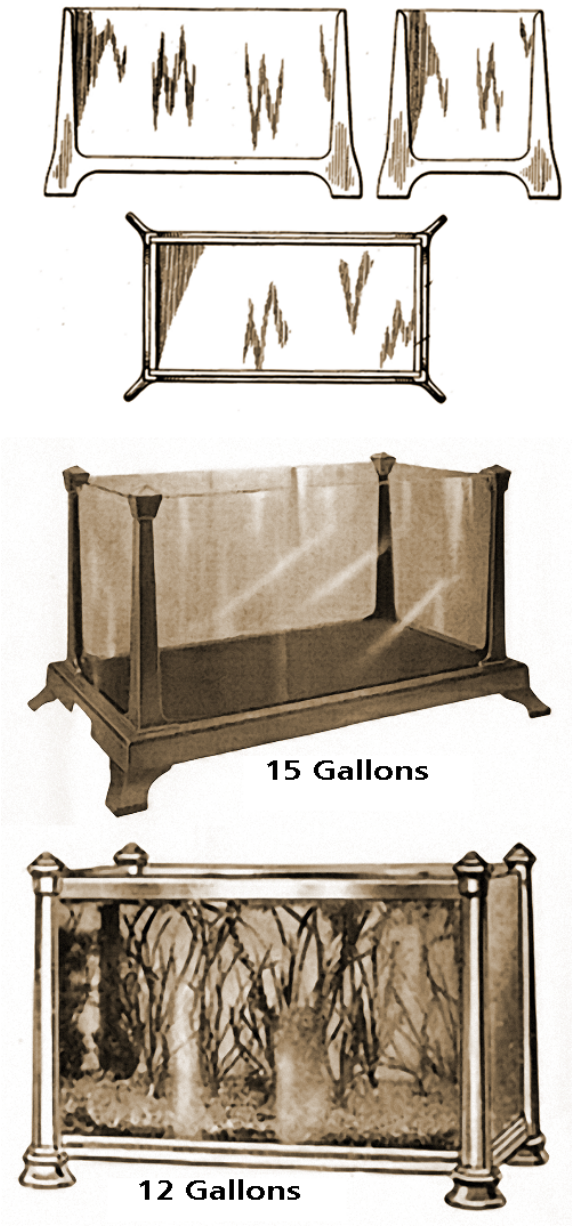

FIGURE 47: Three aluminum aquariums. Top: is Halterbeck's design. Lower two are Jewel Aquarium designs.

FIGURE 48: Two bulb-edged top glass designs.

Because cast iron was very strong, some aquariums were constructed without a top frame. Cut glass is sharp and the top edges had to be smooth and so were rounded off, resulting in a bulb-like edge. Two examples are shown in Figure 48.

Under the Name Jewel Aquarium, the Hans Jensen Manufacturing Company of Chicago created some of the world's finest aquariums circa 1906 to the early 1930s. Their most recognized aquariums featured beautiful iron legs shaped liked seahorses that were hand-hammered then coated with patina bronze (Figure 49). Most of the high-end models Jewel Aquariums sold sat on full black marble slabs. Needless to say, these were exorbitantly heavy. Jewel also made a cheaper line of cast iron tanks in an art deco design. Although these aquariums were cheaper, they were still fitted with a Jewel name tag attached to the lower frame, or had the Jewel name cast into the tank frame on the cast iron tanks (Figure 50). Jewel also made novelty aquaria and one constructed in cast iron in the shape of a house is shown in Figure 51.

The Company thrived during the “Roaring 20s” when tax cuts and loose banking regulations created a glut of easy-money. People spent like drunken sailors, buying up luxury items such as Jewel Aquariums. The company produced aquariums for public consumption from the 1920s but then it all came to a crashing end when the Great Depression hit in 1929. In the 1940s, they shifted to commercial production due to falling public demand for their aquariums and in the 1950s the company stopped operations. Today, original Jewel Aquariums are valuable collector items because of their exquisite workmanship and solid construction. In good condition, they are worth thousands of dollars today.

After World War II another technological development that was to revolutionize the glass aquarium was the invention of rubber-like polymers called polydimethsiloxanes or RTVs, the latter standing for “room temperature vulcanizing,” or simply a rubber which cures at room temperature. Silicone rubber adhesives are made from a complicated process that turns elemental silicon

FIGURE 49: An ornate Jewel aquarium.

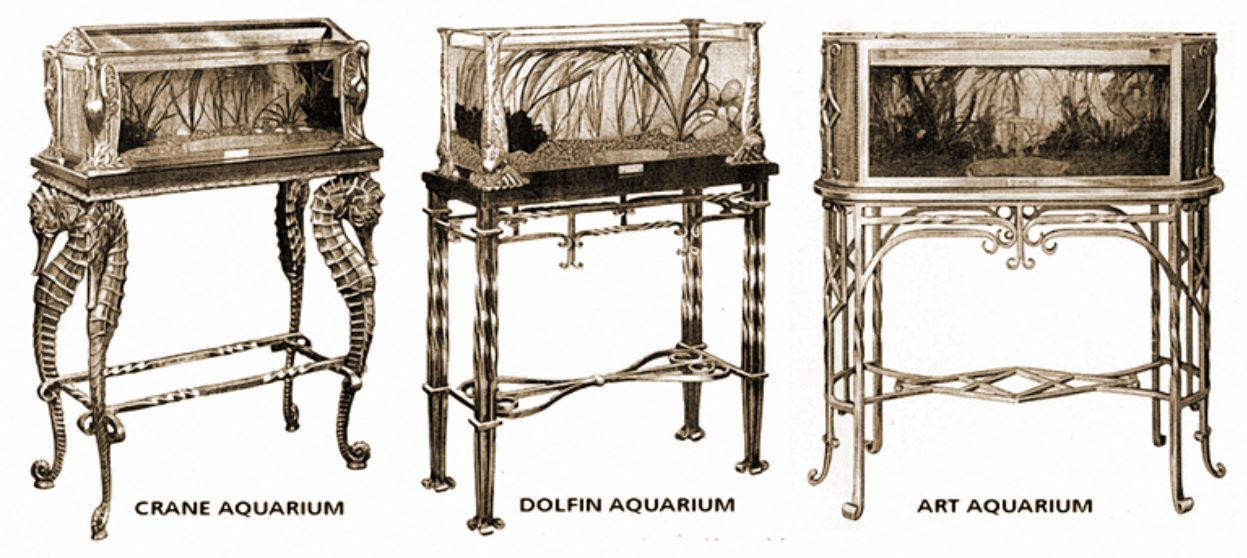

FIGURE 50: Three Jewel Aquarium cast iron tanks and stands.

metal made from sand (silica) into a rubbery polymer. When cured, silicone rubber adhesealants have excellent resistance to moisture that makes them exceptionally suited for bonding glass together to form an all-glass aquarium. In 1963 Dow Corning Trademarked the name, "Silastic," but it was another nine years before the first patent was awarded that involved using this material to bond glass in an aquarium. The patent was filed in 1970 and was awarded to Jerry C. Callan of Dallas, Texas in 1972. Callan described forming his bonds on the outside of the tank rather than the inside because he got his inspiration from a furniture design that constructed corners in a similar manner. In any event, the age of the metal-framed aquarium soon came to a close, to be replaced with plastic top and bottom frames and no vertical supports and all the glass joints sealed with Silastic (Figure 52).

Shortly afterwards, acrylic aquariums became popular. Prior to the invention of UV stabilization, early acrylic aquaria discolored over time with exposure to light but this is no longer the case. Acrylic is generally stronger than glass,

FIGURE 51: A Jewel Aquarium novelty tank in the form of a house.

FIGURE 52: An aquarium with all glass edges sealed with Dow Corning's Silastic.

weighs less and provides a certain amount of temperature insulation but it is more expensive. Acrylic-soluble cements are used to directly fuse acrylic together. The material allows for the formation of unusual shapes, such as the one shown in Figure 53. They are more expensive than glass and are easier to scratch but unlike glass, it is possible to polish out scratches in acrylic.

ROBERT OLIVER CRIGER (1925-2011)

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, July 26, 2019)

Robert O. Criger was born on November 29, 1925 in Trenton, New Jersey to Clo and Euna Criger. His father and mother (nee Euna Hollomon) were born in Jackson, Missouri. At the time Bob was born he had a sister, Elizabeth, some five years his senior. Shortly after his birth his folks moved back to Missouri with the two children where a year later a second sister, Barbara, was born. The 1930, census listed his father's occupation as "Salesman, Sanitizer (i.e., disinfectants, especially in the food industry)."

After finishing one year of college he enlisted on February 2, 1944 at Ft Leavenworth Kansas in the Air Corps with the rank of Private, Reserves. The terms of enlistment were for "The Duration of the War or Other Emergency, Plus Six Months, Subject To The Discretion Of The President Or Otherwise According To Law."

On November 20, 1947 Bob married Sylvia Lee, another Missourian, in Kansas City, Missouri. They had two sons, David and Barry, and one daughter, Cathy. Silvia died in 1985 in Visalia (about 43 miles from Fresno), California at the age of 62. She was born in Missouri and was two years older than Bob.

Bob was a photographer in his early married life but became editor of an 8-page black and white employee newspaper at the Sheffield Steel Corporation in Kansas City, a company that had been purchased in 1930 by the Armco Steel Corporation. The newspaper had evolved into a 32 page four-color magazine. Armco named him Manager of Employee Communications in 1964. Bob also served as area director of the International Council of Industrial Editors - a world-wide group of 5000 industrial editors. He was also was selected by the Council to represent the American Iron and Steel industry on a tour of Russia and Czechoslovakia.

Since I have written extensively on Bob Criger's involvement in the formation and early years of the American Killifish Association I won't repeat them here (see Klee, 2011 and Klee, 2013). Bob's last official activity in the American Killifish Association was in 1963 when he was the Associate Editor of *Killie Notes*. However, Bob was still an AKA member in 1964. It is not known why but we do know that he left Kansas City to go to California in 1966 where he and his family resided in Visalia. In any case, the aquarium hobby did not hear from him between or after this time.

I had always been unhappy that Bob was not better-known to AKA members in the generations that followed. To this end I wrote an article in 2004 about his contributions in the *Journal of the American Killifish Association* (Klee, 2004). A few years later - in 2006 - I tracked him down to where he was currently living in Fresno California and we reconnected after 43 years! At that time Dr. Harry Specht, a very good friend of mine, was writing a series about the Fellows of the AKA and I suggested to him that he interview Bob as he was one of the Association's early Fellows. I supplied Harry with Bob's telephone number and Harry did his interview with Bob that appeared in the *Journal of the American Killifish Association* in its Sep/Nov/Dec/ 2006 edition.

This year I checked again and after some research found that Bob had passed away in Fresno on March 6, 2011. I was very sad to hear of this; he was a good friend and an important part of the formation of the *American Killifish Association*. God bless him in that Great Aquarium in the sky where he no doubt is once again breeding the killifishes he loved.

ADDENDUM

I wish to correct two historical errors about the formation of the *American killifish Association*

that have appeared in the aquarium literature. In Harry Specht's article on Bob Criger's involvement with the formation of the AKA (Specht, 2006b), he writes:

"The first member of the American Killifish Association was Robert Criger. In the previous 'AKA Fellows Profile' we described Al Klee as "Father of the AKA" but that was not, strictly, correct. In fact, it was Bob Criger who, in 1961, took the initiative to contact Al and voice his idea of forming an organization devoted strictly to killifish."

This, however, is incorrect, and the following explains how it happened. In June of 1961 my telephone rang: "Hello! I'm Bob Criger. I'm interested in killifishes and wonder if we couldn't get together tonight for dinner?" Bob, who was visiting his home offices of the Armco Steel Corporation in Middletown, Ohio, some 20 miles from where I lived, projected such bright enthusiasm over the phone that I accepted the invitation and drove out to meet him. It turned out that his telephone call to me was triggered by a series of articles on the genus *Aphyosemion* that I had authored for the old *Aquarium Journal* (Klee, 1960). In any event, Bob had read the series with interest and, knowing that I lived in the area, took a chance, located my telephone number and called me out of the proverbial "clear, blue sky."

Bob was prepared with a list of killy topics for discussion that could have formed the basis for a good -sized book. These were tackled with enthusiasm, for in those days, finding persons who were devoted to killies wasn't that easy. The conversation continued after dinner. We bemoaned the scarcity, not only of information about killies, but of the scarcity of the fishes themselves. Temperamentally, we hit it off beautifully. Bob and I were about the same age and were both interested in editing and knowledgeable about printing technologies.

We were about to call it a night when sometime after midnight, Bob thought out aloud: "Wouldn't it be great if we had some sort of club devoted solely to killies?" At first I was reluctant, but as Bob was particularly interested in developing a professionally produced publication strictly for killies and as he had had considerable publishing experience and access to processes and printers, his suggestion became persuasive. Then, too, the challenge of developing a really successful national aquarium organization was appealing and ultimately irresistible to me. By our fifth highball then, we mutually agreed to attempt the formation of a national killifish association. On this note we parted, Bob returning to Kansas City, his home at that time.

In short, the original intent of his visit to me had nothing to do with the formation of a national killifish association. Furthermore, any reference to either myself or Bob Criger as "The Father of the AKA" is ridiculous. We were, however, its cofounders and we each had our assignments to bring it to fruition and they differed considerably. Bob handled the jobs of publicizing the new organization, correspondence, membership and designing and printing the first issue of Killie Notes. My involvement was in planning, the writing of the By-Laws and the formation of the Charter Committee, of which I was Chairman. In short I built the structure of the organization and determined how it would operate in order to avoid the mistakes of the plethora of unsuccessful prior attempts to organize a successful national aquarium organization.

On a minor point, in Harry Specht's article on my involvement with the formation of the AKA (Specht, 2006a), he writes: "Next they invited five prominent aquarists… to assist in forming the organization." Actually, Bob had nothing to do with the formation of the Charter Committee except that perforce we were both members. Actually, I formed the Charter Committee primarily as a test to see if the Board of Trustees portion of the By-Laws worked as I had written them. As a bonus, the other five committee members provided very helpful recommendations for the operation of the new organization.

5,000 YEAR-OLD IMAGES OF AQUARIUM FISH GENERA BY PREHISTORIC MAN IN NAL, PAKISTAN

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, September 21, 2019)

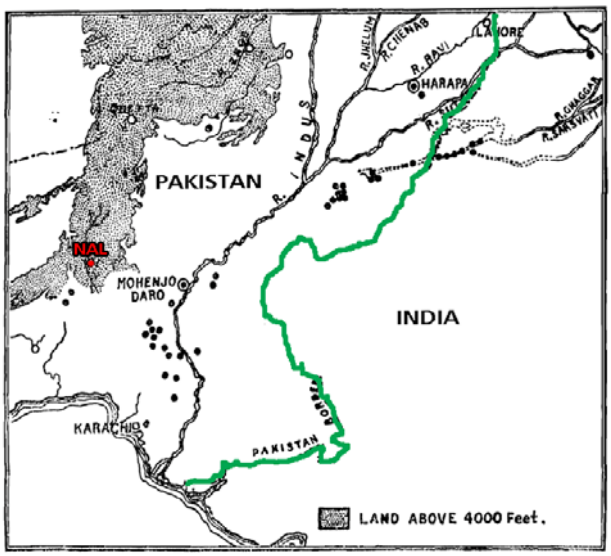

Figure 1: Indus Valley, location of Nal.

The knowledge of the occurrence of fish in India dates back to the third millennium BC. Nal (Figure 1) was located in Baluchistan, India, but after the partition of India in 1947 it is now in Balochistan, Pakistan's largest province. The mound known as Sohr Damb (Figure 2) - the type site of Nal - was founded on a gravel accumulation near a small river. It is about 1,000 feet in length, 600 feet across in its widest part, 43 feet high and is located about 4 to 5 miles to the east of Nal. It had been sporadically excavated in 1903, 1908 and 1923-24 by treasure-hunters, and its beautiful pottery had drawn the attention of archaeologists as early as 1904. But it was in 1924 that it was systematically excavated by the archaeologist Harold Hargreaves of the *Archaeological Survey of India*.

After one season of excavation by Hargreaves in 1924, which made the polychrome Nal pottery widely known, no further work took place until the Joint German-Pakistani Archaeological Mission to Kalat resumed excavations in 2001. So far, 4 seasons of excavations have been undertaken and the Hargreaves excavation has been radiocarbon dated from 3100-2700 BC. Since the Egyptian Eighteenth Dynasty spanned the period

Figure 2: The excavation at Sohr Damb.

Figure 3: Nal vase with an omphalos base.

from 1549/1550 to 1292 BC, this is 1400 years older than the tilapia tiles found in Egyptian fish ponds.

The typical cemetery pottery comprised the following types: (i) bowls with a vertical, inverted, in-turned or everted featureless rim, a vertical or oblique body with a sharp carination (i.e., a shape defined by the joining of a rounded base to the sides of an inward sloping vessel (see the two vases marked A in Figure 4); between the body and the base; (ii) small jars with an out-turned featureless rim and a sharply carinated or concave neck, the profile being squat (with or without carination) or bulbous; (iii) tall vases with similar rim characteristics. A notable feature was the predilection for stable bases in the form of a ring-base, footed base, flat base and even omphalos-base (i.e., a raised, ornamental round base; see Figure 3). The specialized types included (i) bowls with a ring-base, the rim and body deeply pinched at four places to form an Indian lamp (see the vase marked B in Figure 4); (ii) cylindrical bowls with short vertical featureless rim, broad and high shoulder, vertical body and a carinated omphalos-base; and (iii) double cylindrical bowls. Some of these jars and bowls are shown in Figure 5.

The pottery was invariably wheel-made and was of fine texture. The color ranged from greenish grey to buff and pinkish but is also rarely dark brownish or almost black. A large proportion of the pottery had distinctive paintings, the patterns consisting mostly of geometrical designs - vertical or oblique hatching, crisscross, zigzag, dia-

Figure 4: Various Nal pottery designs and three artifacts.

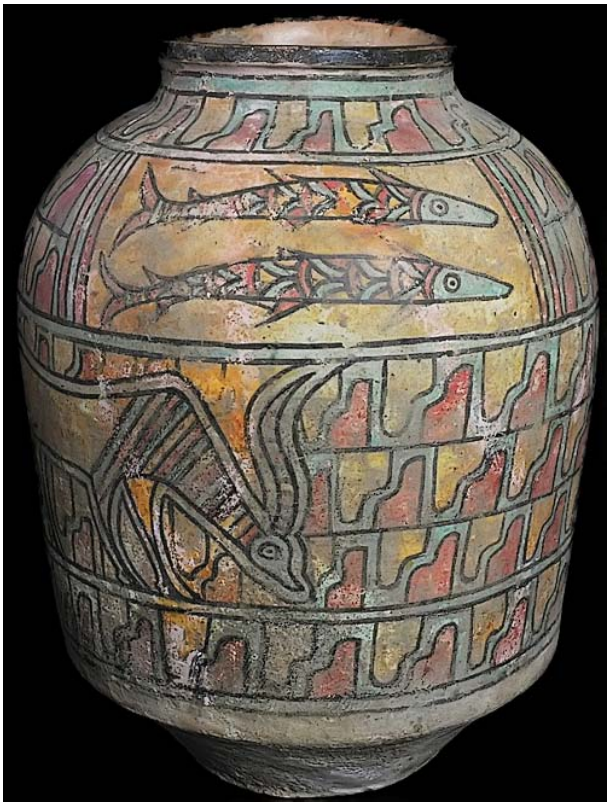

Figure 5: Nal vase showing a fish above and an Ibex below.

mond, single or multiple loops, roundel, omega and multiple "steps." The animals represented were humped bulls, scorpions, birds, fish and ibex. The tumbler shown in Figure 5 contains a drawing of a fish above and an ibex below. Leaf designs were rare but included the *Pipal* (Figure 6). A distinctive feature of the painting was that it was polychrome, the colors used being red, blue, green and yellow. The large variety of colors, applied on a white, red, blackish, greenish grey, buff or pale brown slip, marks out the Nal pottery as unique among the cultures of the Ancient East. Both the pottery forms and painted designs indicated sophistication and maturity.

Figure 6: Nal vase with a painting of the *Pipal*.

At the beginning of 1956 Sunder Lal Hora (Figure 7), a well-known ichthyologist and Director of the *Zoological Survey of India*, Calcutta, noticed a vase in the Prehistoric Gallery of the Indian Museum that had fish paintings on it. The paintings were accurate enough for determining the species as *Tor putirora* Hamilton, the Golden Himalayan Mahseer celebrated amongst anglers. The impressive advancement of art during the Nal Culture made him look for other Nal vases with fish decorations. Six others among those excavated by Hargreaves at Nal were found in the collec-

Figure 7: Sunder Lal Hora (1896-1955).

tion of the Indian Museum with paintings of different fishes that could be immediately identified generically.

FIGURE 8: VASES NOS. 115 and 140 of HARGREAVES' LIST

These are *Garra*-like fish paintings, *Garra* being an aquarium genus. The scales on the body and both the vertical and paired fins are conventionally represented in the painting. With the exception of the dorsal fin, which is shown forward in position, the positions of the pectoral, pelvic, caudal and anal fins are accurately indicated. The caudal fin is deeply forked. The body is sub-cylindrical, with the upper surface gently arched and the lower flat and horizontal. The snout is rounded and fleshy. The general facies of the fish painted on this vase shows that it is adapted to live in rocky streams, where it can cling to stones and boulders with its flattened ventral surface. It strongly resembles fishes of the genus *Garra* Hamilton, which are characterized by the possession of a suctorial disc behind the mouth for adhering to rocks in swift currents. The genus *Garra* is known from the Baluchistan hills, and both Zugmayer (1914) and Jenkins (1909) have identified the species as *Garra lamta* Hamilton. In Hora's revision of the genus (Hora, 1921), he recorded *Garra rossicus* (Nikolsky) and *Garra* sp. from these hills.

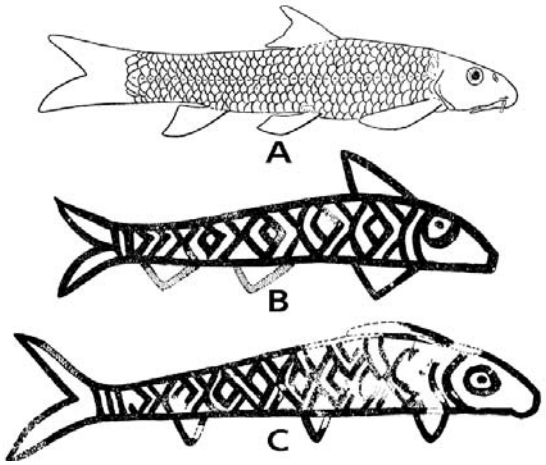

Figure 8:
A. Lateral view of *Garra nagaensis*.
B. Tracing of the painting on vase 115.
C. Tracing of the painting on vase 140.

Garra does not grow to a large size, but occurs in abundance and forms large shoals during the spawning period where they climb up vertical rocks and below waterfalls. They contain much oil and are greatly relished by hill people. It is not improbable, therefore, that the people of the Nal culture also considered *Garra* a food fish of great value and painted it on funerary vases. It may be of interest to add here that when Rama was at the Pampa Lake in South India, he was advised to eat *Cakratunta* (=*Garra*) as a great delicacy.

FIGURES 9 and 10: VASES NOS. 184 and 195 of HARGREAVES' LIST

The paintings in Figures 11 and 12 are comparatively the most accurate representations of fishes, with scales and fins properly drawn. The fish in Vase 184 seems to represent *Crossochilus latius* (Hamilton). C*rossochilus* is an aquarium genus, usually referred to as algae-eaters. The species lives in hill streams all along the Himalayas and is an important food fish. The fish in Vase 195 seems to represent *Labeo dyocheilus* (McClelland) and is of larger size than *Crossochilus*. Both live in hill streams all along the Himalayas and are important food fishes. They are included in Zugmayer's list

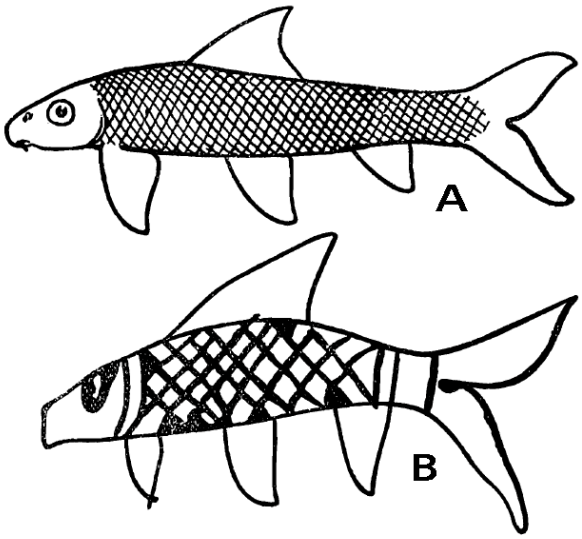

Figure 9:
A. Lateral view of *Crossocheilus latius*.
B. Tracing of the painting on vase 115.
C. Tracing of the painting on vase 140

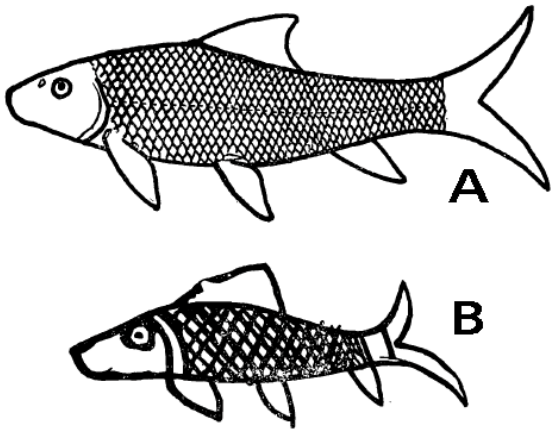

Figure 10:
A. Lateral view of *Labeodyocheilus*.
B. Tracing of the painting on vase 195.

of freshwater fishes from Baluchistan as C*irrhina latia* (Hamilton) and *Labeo dyocheilus* (McClelland). *Labeo dyocheilus* may be regarded as the *Rohita* of the Himalayan torrential streams. The place of *Rohita* in Sanskrit literature is well known (Hora, 1953).

FIGURE 11: VASE NOS. 193 and 196 of HARGREAVES' LIST

The general facies of all the drawings in Figure 11 are the same, but there are variations in the form of the snout as shown in B, C and D. The scales on the body are depicted in the same conventional way as in the case of *Garra.* The position of the dorsal fin is somewhat more accurate, but the painter has omitted to show the pelvic fins. These paintings can be readily identified as those of the Golden Himalayan Mahseer, *Tor putitora* Hamilton. Due to its size, *Tor* is not an aquarium genus. Zugmayer (1914) recorded this species from the Baluchistan hills as *Barbus (Tor) tor* (Hamilton). In Figure 12B the variations in the form of the snout are more marked but the pelvic fins are correctly shown. Variations in the form of the snout ate not due to any fancy of the painter, but are correct representations of what happens in nature. The lips are simple in some specimens, but in others they may be slightly or greatly hypertrophied, as shown in Figure 12. It is remarkable that such differences were observed by the painters of the Nal pottery. The Mahseer, besides being highly prized as a sporting fish, is also esteemed as food. In the Hindu *Dharma-sastras* it is considered superior even to *Rohita* and *Pathina,* as the Brahmins fed on Mahseer remain satisfied forever (Hora, 1953). Even hermits are advised to build their huts at those places in the jungle where Mahseer are available. The value of Mahseer as a food fish seems to have been fully realized by the people of the Nal Culture.

FIGURES, 13, 14 and 15: VASE NO. 256 of HARGREAVES' LIST

For the study of the fish fauna of Nal, the fish in this vase are important, as three pairs of different species of fish are painted on it, with sufficient detail for generic recognition. This it seems desirable to describe each pair of paintings separately. All three are aquarium genera. It also should be noted that the fish are pictured upside down, but it is their positions on the vase.

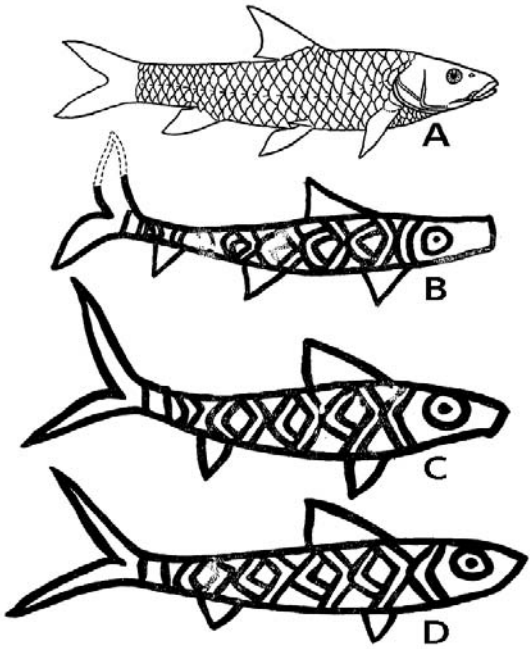

Figure 11:
A. Lateral view of *Tor putitora*.
B. Tracing of the painting on vase 193.
C. Tracing of the paintings on vase 196.
D. Tracing of the paintings on vase 196.

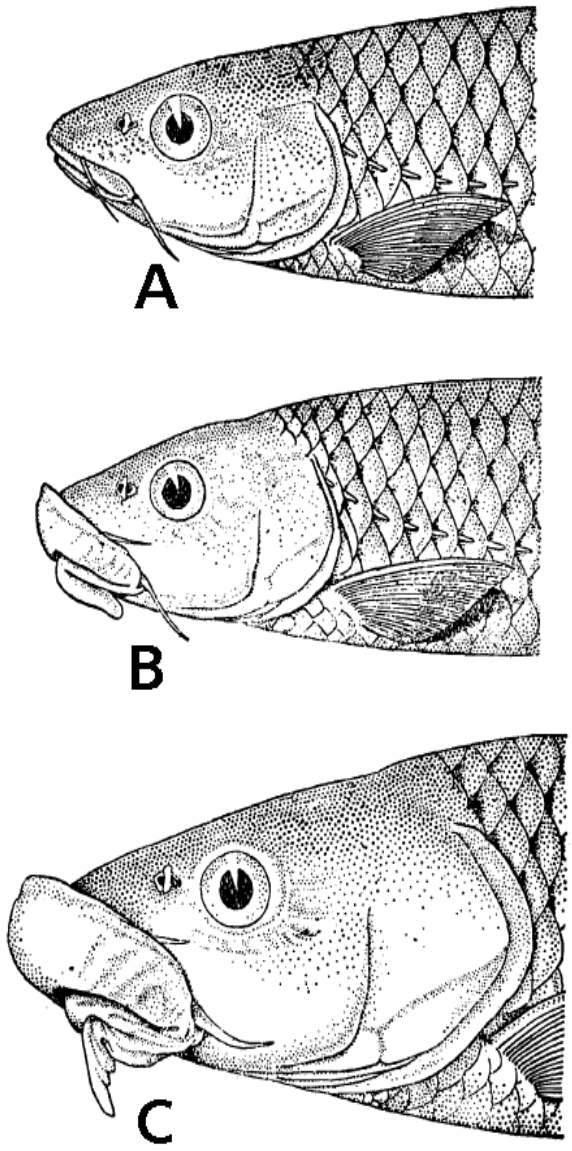

Figure 12. Head and anterior part of the Golden Himalayan Mahseer to show the variations in the shape of the head due to hypertrophy of the lips.

Figure 13: *Nemachilus* van Hasselt.

The painting seems to be that of a banded loach of the genus *Nemachilus.* Zugmayer found three species of this genus in the Baluchistan hills and in regard to coloration the painting seems to represent *N. baluchiorum* Zugmayer rather than the other two species. Such loaches are abundantly found among pebbles and shingle at the bottom of fast-running rocky streams. They do not grow to a large size but they are much prized and are regarded as a delicacy.

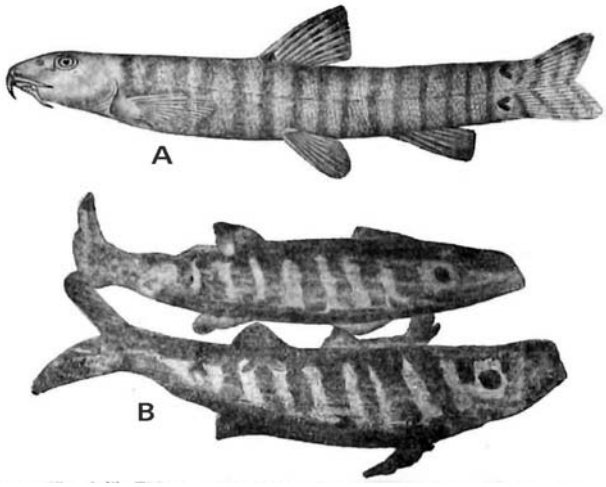

Figure 13:
A. Lateral view of *Nemacheilus baluchiorum*.
B. Tracings of the paintings of a pair of *Nemacheilus*-type fishes on vase 256.

Figure 14: *Botia* Bleeker.

Botia is also a loach-like genus but is usually deeper of body and of a larger size. It prefers to live in the pools of hill streams where the current is slow and debris accumulates at the bottom. Zugmayer recorded *Botia geto* (Hamilton) from Baluchistan but *B. geto* is now considered (Hora,

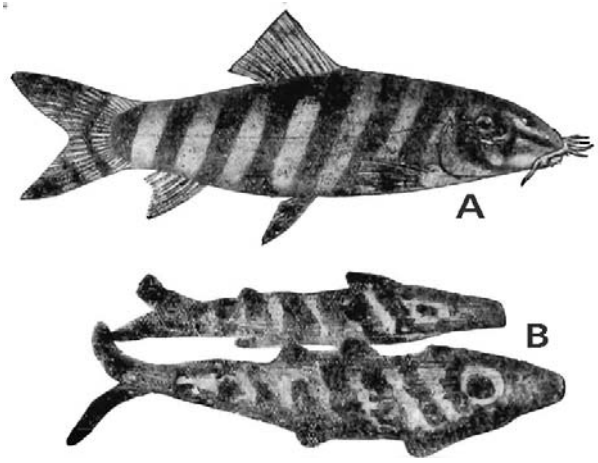

Figure 14:
A. Lateral view of *Botia dario*.
B. Tracings of the paintings of a pair of Botia-type fishes on vase 256.

1932) to be a young form of *Botia dario* (Hamilton). The commonest species in the northwest of India and in the Kashmir Valley is *Botia birdi* Chaudhuri, in which the coloration varies considerably. The color bands on the body run anterio-posteriorly from the dorsal surface, but the Nal painter has shown them running in the reverse direction. With this exception, the likeness between *Botia dario* and the painting is very striking.

Figure 15: *Glyptothorax* Blyth.

This painting represents a pair of catfishes in which the body is not covered with scales. Zugmayer recorded three catfishes from Baluchistan, *Wallago attu* (Bloch and Schneider), *Mystus gulio* (Hamilton) and *Rita rita* (Hamilton). These three species are inhabitants of ponds and rivers and are not found in hill streams in association with the type of fishes referred to above. In the depressed head and body, and the flattened ventral surface, the painting is similar to fishes of the genus, *Glyptothorax* Blyth, which is widely distributed from the upper Euphrates and Tigris river basins in the west to India, Burma, Thailand, Central and Southern China, Indo-China, Malay Peninsula, Sumatra, Java and Borneo. Though the range of the genus is discontinuous at present, it is certain that it once had a continuous distribution. Therefore, it may have occurred in the Baluchistan hills during the period of the Nal Culture.

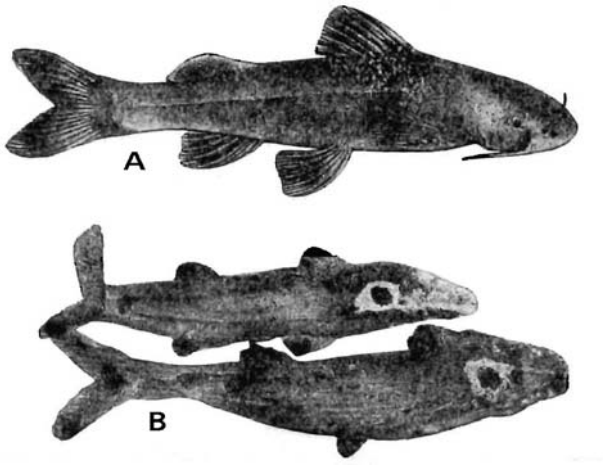

Figure 15:
A. Lateral view of *Glyptothorax pectinopterus*.
B. Tracings of the paintings of a pair of *Glyptothorax-type* fishes on vase 256.

FISH OF PREHISTORIC NAL AND THEIR ZOOGEOGRAPHICAL SIGNIFICANCE

From the fish decorations on Na1 pottery, it is not possible in all cases to be certain of their specific identity but there can be little doubt about their generic identifications. The following genera represented in the paintings, with the exception of *Tor*, are aquarium genera:

1. *Garra* Hamilton
2. *Labeo* Cuvier
3. *Crossochilus* van Hasselt
4. *Tor* Hamilton
5. *Nemachilus*. van Hasselt
6. *Botia* Bleeker
7. *Glyptothorax* Blyth

The association of these genera at Nal shows the presence of fast· running clear streams in its vicinity. Fishes of these seven genera can be collected from any Himalayan perennial stream, as all of them have migrated westwards from their probable origin in the hills of southern China. *Garra, Labeo, Tor* and *Nemachilus* have extended their range as far as Africa though they are not found at present in the barren areas of the Middle East.

Glyptothorax has extended its range as far as the upper ·reaches of the Euphrates and the Tigris, though it is absent from the intervening areas. Its occurrence at Nal about 5,000 years ago would indicate heavier rainfall and far more voluminous perennial streams. The Nal paintings of *Glyptothorax* serve to fill a part of the eastern portion of the gap in the range of its distribution. Another important inference that can be drawn is that the present discontinuity of distribution of some of the Indian hill-stream genera may have come about in the early centuries of the second millennium BC. It can also be presumed that the westward migration of genera, such as *Botia* and

Crossochilus, was interrupted about the same time.

PROBABLE METHOD OF FISHING AT NAL

No fishing implements have been excavated from Nal. Moreover, the usual methods of fishing by nets are not applicable to the torrential streams found at Nal (see Figure 16 for a topological map of the Nal area). The methods of fishing by hill tribes are (i) by damming small channels and allowing them to run dry, then when stranded the fish are caught by hand; and (ii) by poisoning the pools with certain plant juices which stupefy the fish and cause them to float to the surface. Both are now regarded as illegal methods, though still practiced everywhere in the hills. The fish decorations on Nal pottery show that fish were relished as an article of diet and that the fishes used as food came from torrential streams. But how these fishes were procured in sufficient quantities can only be guessed at, though the long survival of traditional fishing methods suggests that the techniques now practiced in the hills are probably derived from these known during the Na1 culture.

A HISTORY OF FISHPONDS

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, January 4, 2020)

Fishponds (or vivaria in old books) are important in the history of the aquarium hobby since they are the forerunner of the aquarium as we know it. In point of fact, fishponds are, in the Linnean sense, aquariums (Klee, 2014). Fishponds can be of two categories, Storage and Cultural. The former are nothing more than temporary holdings of fish designed to be eaten and are often referred to in older references as "stews." The latter can be, for example, of a religious, ornamental, sports or farming (*i.e.*, "aquaculture or pisciculture) nature. Storage fishponds started in the Neolithic Age, the final division of the Stone Age, about 12,000 years ago when the first developments of farming appeared in the Near East and later in other parts of the world. The division lasted until the transitional period from about 6,500 years ago (4500 BC), marked by the development of metallurgy and leading up to the Bronze and Iron Ages. From the Neolithic Age, and in most countries, fishponds have been an important feature in the rural landscape. Wherever we turn, no matter in what clime or country, there we will find them cultivated with great care and perseverance.

A. MESOPOTAMIA

Mesopotamia is a historical region of Western Asia situated within the Tigris-Euphrates river system in the northern part of the Fertile Crescent, in modern days roughly corresponding to most of Iraq, Kuwait, the eastern parts of Syria, Southeastern Turkey and regions along the Turkish-Syrian and Iran-Iraq borders (Figure 1). It is necessary to distinguish between the three main peoples of this area and roughly apportion the periods of the four thousand odd years of history during which each was predominant.

The Sumerians occupied before - perhaps long before - the close of the fourth millennium the land on the lower plain of the Tigris and Euphrates, and on the sea coast as it then was. They possessed an advanced civilization with an organized government, many large cities and considerable agricultural and industrial development. The Sumerians made extensive use of music, especially in their religious ceremonies; they were the founders of liturgical music, which unfortunately it is impossible to reconstruct, as the notes themselves have not survived.

From what place their emigration, to what family, Mongol or other, they belong is not clear. It is settled that they were not Semites like the Babylonians and Assyrians as the language was not well adapted to express peculiarly Semitic sounds. Their language, preserved in liturgies down even to the time of the Persian conquest, and their writing, adopted by the Babylonians and Assyrians which runs, unlike the Hebrew from left to right, disprove Sumerian descent from Shem, one of the sons of Noah in the Hebrew Bible as well as in Islamic literature.

It is impossible at present to fix a definite period for their immigration. The dates assigned vary from 7000 to 4000 BC. The statement, however, that "the Semites and Sumerians were all in a no-

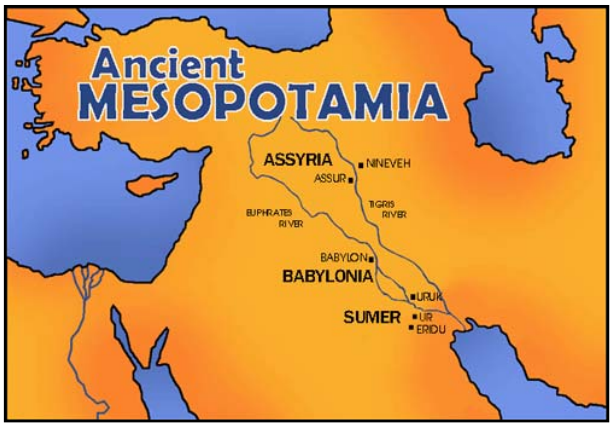

FIGURE 1: Mesopotamia. The Babylonians conquered Sumer and then the Assyrians conquered Babylonia.

madic condition when the early Sumerian settlers in Lower Babylonia betook themselves to agriculture, built great cities and established a stable government" seems hardly exaggerated, even though it postulates a very ancient era.

The Semitic Babylonians started possibly from South Arabia by way of the Syrian coast, and reached the lower part of the Tigris and Euphrates about 3800 BC. It was not, however, until some thousand years afterwards, that they effected a conquest of the Sumerians. Like other defeated peoples, such as the Canaanites with the Jews and the Irish with the English, they grafted their policy on that of their victors and perpetuated many of their racial characteristics and customs as well as their religion. The Semitic invaders seem to have been completely converted. In fact, the Babylonian religion has scarcely anything characteristically Semitic in it.

The Assyrians proper, an offshoot from Babylonia, are found before 2300 BC pushing their way north along the Tigris, on whose western bank they founded their first city and earliest capital - Asur. Wars between them and Babylonia mark the history of centuries. Their definite suzerainty over that country was only established by King Tiglath-Pileser III, *circa* 730 BC and thus, according to many scholars, were the founders of the Assyrian empire.

FIGURE 2: A painting depicting an Assyrian King's Palace.

Vivaria or fishponds, known only late in Palestine, were early and generally constructed in Mesopotamia. As adjuncts of Sumerian temples, they can be traced as far back as 2500 BC. No decent-sized township eventually lacked or could afford to lack, these *piscinæ* with their ever-ready supply of fresh fish. How real was the importance attached to fish and how recognized its value as a food can be discerned from early Sumerian documents. The excavations of Telloh, an ancient Sumerian city, furnish an elaborate description of the new temple built in honor of the god Ningirsu. With this god went also other deities, such as his musician, his singer, his cultivator of lands and his guardian of fishponds.

The Assyrians of Western Asia, including both the Sumerians and Babylonians, were keenly addicted to the eating of fish, which was not, as in Israel or Egypt, half-banned by a prophet or whole-barred to priesthood by custom or a system of belief in which humans are said to have kinship or a mystical relationship with a spirit-being, such as an animal or plant. They attached very real importance to the maintenance of an ample supply of fish.

In their apparent preoccupation with water and hydraulic engineering well before 2000 BC**,** these ancients were known to keep large resources of fish in lakes created by the construction of dams on the Tigris and Euphrates rivers to improve the irrigation of their crops. They built sacred *vivariae piscinae* for their temples, but also *piscinae* or simple fishponds, to provide food and to make a commercial profit. Virtually every Assyrian township had its own fishponds. Records of 422 BC described fishponds belonging to rich merchants and civic prefects that operated under contract for one -half talent of silver and a daily supply of fish for their tables. Each pond had a keeper who taxed the

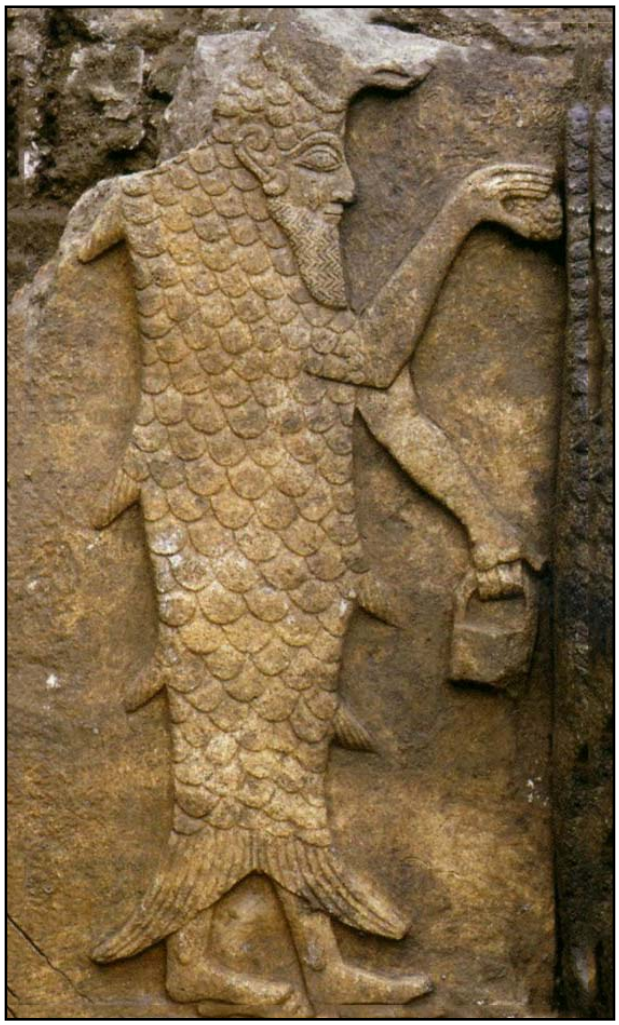

FIGURE 3: Oannes, the Babylonian Fish-God.

public to fish in the commercial pool. Further evidence indicated that small ponds became quite numerous among the Assyrian commoners, but not all were protected by the earliest known regulations regarding fishing rights and ownership. It was noted, for example, that fishponds built by "poor men" were often poached, and that there was no legal redress.

The *Inspectors of Fisheries* were established via the drastic reforms and the thorough cleansing of the bureaucracy initiated by Urukagina, the ruler of the city-state Lagash in Mesopotamia. This sprang from his desire to improve the condition of his poorer subjects, who for years had suffered from the oppression of the rich or the venality of public functionaries who illegally sold fish from these ponds. How general and how numerous fishponds had early become shows in the complaint that "if a poor man built himself a fishpond, his fish was taken; he received neither payment nor redress."

The neighboring Israelites, in spite of their propensity for fish and links with Egyptians and Assyrians, both hostile and friendly, never constructed *vivariae* or fishponds. There is no record of *vivariae* or *vivariae piscinae* in all their prolific writings until almost the beginning of Christianity, when they were probably influenced by the practices of the Mediterranean civilizations.

A1. FISH-GODS

Oannes, in Mesopotamian mythology, is an amphibious being who taught mankind wisdom. Oannes, as described by the Babylonian priest and author Berosus, had the form of a fish but with the head of a man under his fish's head and under his fish's tail the feet of a man (see Figure 3). Dagon or Dagan is an ancient Mesopotamian deity. He is mentioned occasionally in early Sumerian texts but becomes prominent only in later Assyro-Babylonian inscriptions as a powerful and warlike protector and appears to have been worshipped as a fertility god in Assyria and is pictured as a merman in Assyrian art (see Figure 4).

FIGURE 4: Dagon, the Assyrian Fish-God.

The Hebrew Bible mentions him as the national god of the Philistines with temples at Ashdod, Israel and elsewhere in Gaza. Authorities disagree whether Dagon derives his name from the Hebrew *Dāg* signifying fish, or *dāgān*, sheaf or agriculture. The ancient Phoenician writer Sanchouniathon early held, as do most modern writers, the latter view.

Aquarium hobby historians like to picture Mesopotamian fish-gods but in actuality they are neither gods nor did they have anything to do with fish. There is no trace in Mesopotamia of ichthyolatry, *i.e.*, certain fish being accounted sacred or forbidden as food. The nearest approach to abstention occurs in the warning that on the 9th day of Iyyar, a month in the Hebrew calendar, to partake of fish was almost certain to bring on an attack of sickness, just as in Syria ichthyophagy was held to entail ulcers and wasting diseases. Despite the Dagon or Oannes traditions, I doubt that there can be found in the crowded pantheon of Babylon or Assyria there can be found a fish-god proper, or god of fishing, *i.e.* a deity similar to those of Greece and Rome with a temple and established priesthood to whom fishermen made prayer and offerings either for boons received or favors to come.

A cylinder seal is a small round cylinder, typically about one inch (2 to 3 cm) in length, engraved with written characters or figurative scenes or both, used in ancient times to roll an impression onto a two-dimensional surface, generally wet clay (Figure 5). If the word fish-god is limited strictly to those images, half-man, half-fish, which are to be found on cylinder seals or sculptured or depicted in the outer halls or walls of some deity's temple, there is certainly considerable proof of their existence. But if the word connotes the attributes of a special temple, priesthood and sacrifices, such as we find in connection with the Philistinian Dagon at Ashdod in Israel, there is no proof whatever. The fact is that in early Sumer, the fish-god or man-fish was a symbol of Ea, the god of water, probably derived from Aquarius.

There were to be seen in the temple of Belus, according to Berossus, a Hellenistic Babylonian writer, priest and astronomer (Mosshammer, 1979), sculptured representations of men with two wings, or two faces, with the legs and horns of goats or the hoofs of horses; also bulls with the heads of men, and horses with the heads of dogs. Thus the mystic fish-form of Dagon or Oannes is of the same nature and in the same category as the man with the legs and horns of goats, or with the hoofs

FIGURE 5: A cylinder seal. When this seal (foreground) is rotated over a wet-clay surface (background), its surface shows a school of fish.

of horses: but these mythic goat or horse forms were not elevated into goat-gods or horse-gods.

The idea of the deification of the fish-forms, whether that of a man issuing from a fish or of a man whose upper half was human but lower piscine, may, perhaps, have sprung from the undoubted worship by the Philistines at Ashdod and elsewhere of the god called Dagon, and partly to the original description of him in the Authorized Version (A.V.) of the Bible but is now corrected in the Revised Version (R.V.). Dagon, it will be remembered (I Samuel v. 4), after being confronted with the ark of the Lord in the morning, was found fallen: "the head of Dagon and both the palms of his hands lay cut upon the threshold, only the fishy part (A.V.) or stump (R.V.) of Dagon was left unto him." From this passage Milton undoubtedly drew his conception of "Dagon his name; sea-monster, upward man and downward fish" (Milton, 1674).

It is possible that the theory of his having from his navel down the form of a fish, and from his navel up the form of a man - a theory which is unknown to the *Targum*, an ancient Aramaic paraphrase or interpretation of the Hebrew Bible; Josephus, a first-century Romano-Jewish historian; or the *Talmud*, and perhaps is as late as the twelfth century AD merely transfers by the help of etymology the description given by the Assyrian satirist and rhetorician, Lucian, of the goddess Derceto, worshipped on the same coast-line by the Syrians, who were more partial to fish deities than the Assyrians.

B. EGYPTIAN FISHPONDS.

Although the ancient Egyptians enjoyed a plethora of fish in the fruitful Nile, yet they were not contented with the abundance it afforded but constructed within their grounds spacious ponds for fish where they fed them for the table. It is very questionable, however, whether the ancient Egyptians understood or practiced pisciculture. However, they did export dried and/or salted fish to other countries.

Egyptians relied upon the periodical inundation of the Nile to furnish them with stock for their ponds. Herodotus comments (Macaulay, 1890) that the quantity of fry in the Nile on these occasions was something enormous, as it is indeed at the present day and they undoubtedly were caught in great abundance when the river overflowed its banks. His explanation of the cause of their apparently sudden production is questionable and unnecessary, however, as the ponds were always filled by artificial or natural conduits. Also, the same species of young fry which are found there appear at the present time in the river where they aren't of any particular kind but the young of the various fish inhabiting the Nile. The Egyptians evinced a great interest in fatting their pond fish for their table, and brought their ponds to a perfection not short of that attained by the Romans.

They usually constructed their fishponds in the form of a square, an oblong or a canal. Unlike the Roman and Grecian ponds, one cannot form any detailed ideas with respect to the *modus operandi* of their construction or dimensions inasmuch as they have left no literature on the subject to posterity. However, there is no lack of illustrations, sculptures, paintings, *etc.* of their ponds, and from

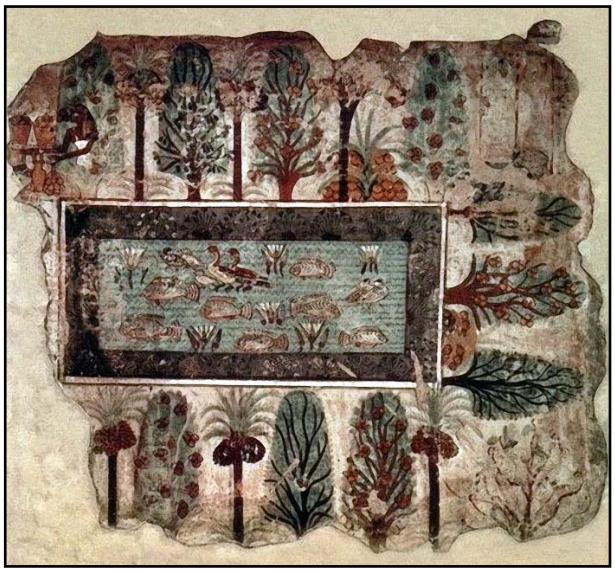

FIGURE 6: A rectangular fishpond with *Tilapia* from the tomb of Nebamun, Thebes, 18th Dynasty.

FIGURE 7: Left: A funerary model of an Egyptian garden, 11th Dynasty, *circa* 2009-1998 BC.

these we can gather very conclusive inferences. Some of those relics among the Egyptian collection in the British Museum represent every pond containing numbers of fish, waterfowl and lotus flowers. On the margin of the ponds fruit trees were invariably planted.

As to the species of fish most prized for the table, and preferred as being more wholesome as well as superior in flavor to others may be mentioned (Wilkerson, 1874) the búlti or booltee (the Nile Perch, *Lates niloticus*), the gisher (*Oreochromis niloticus*), the benni (*Labeobarbus bynni*), the shall (*Synodontis shalli*), the shilbeh (S*chilbe mystus*), the byad (*Bagrus bayad*), the garmoot (*Clarias gariepinus*), and a few others (a differing opinion was "The fish of the Nile are very numerous, but there is not one worth eating; they are all soft and wooly and have a strong flavor of mud," Anon, 1888). However, it was unlawful to touch those that were sacred, such as the oxyrinchus, phagrus, and lepidotus. The inhabitants of the city of Oxyrinchus objected even to eat any fish caught by a hook, lest it should have been defiled by the blood of one they held so sacred.

Oxyrinchus was a mormyrus remarkable among the fish of the Nile for its pointed nose, as the word oxyrinchus implies. The sanctity of the phagrus, which has been identified as one of the Mugilidae (*i.e.*, mullets), like that of the oxyrinchus was probably owing to its unwholesome qualities; the most effectual method of forbidding its use being to assign it a place among the sacred animals of the country. Linnaeus believed the lepdotus to be the carp, Sicard assumed it was the benni and Sir John Gardiner Wilkinson supposed it to have been the kelb el bahr or the dog-fish of the Nile. Sicard was right. The lepidotus is the benni (*Labeobarbus bynni*).

However, the same reverence was not given to the sacred fishes in some parts of Egypt as was observed in others. The people of Cynopolis, according to Plutarch, were in the habit of eating the oxyrinchus, which, he adds, "was the origin of a civil war between the two cities, till both sides, after doing each other great mischief, were severely punished by the Romans." Of all fish the

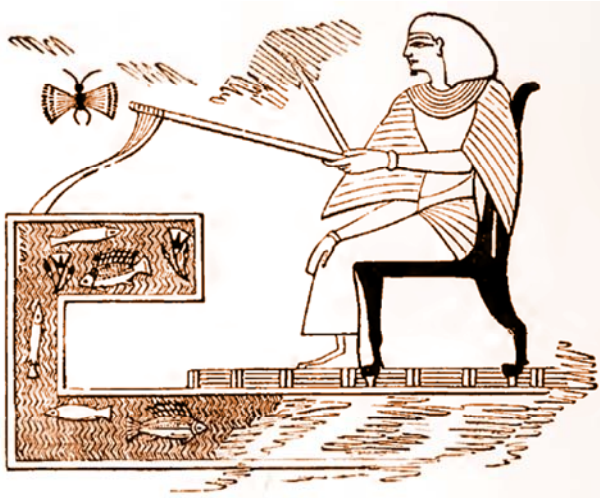

FIGURE 8: The oldest representation (but one) of fishing, circa 1400 BC.

búlti was evidently preferred, and not, indeed, without reason, being still considered inferior to none produced in the Nile.

There can be no doubt that the ancient Egyptians devoted considerable care and attention to their fishponds and fisheries. This we may conclude as beyond dispute for three very tangible reasons. Firstly, the queens of Egypt received all of the revenues accruing from fisheries to the State as their particular special right. Hence we may conclude that they lost no opportunity of sustaining that branch of industry with all their royal influence.

Secondly, we learn from Herodotus that the revenue derived therefrom was very large. During the six months that the water from the Nile flows into the artificial pond or lake Moeris, the take of fish from it realized something under twenty minae (about $1270) per day; and during the other six months, while the water was receding, it yielded a talent of silver ($3830) per day, which was duly paid into the royal treasury for the exclusive benefit of the queen. Thus we find that the aggregate revenue her majesty received from this artificial fishpond was equivalent to $847,000 per annum.

Thirdly, ichthyophagy formed an important feature in their religion, as at a particular period of the year, on the 9th day of the first month (Thoth) every person was obliged, by a sacred ordinance to eat a fried fish before the door of his house, with the exception of the priests who were content to burn one in honor of the occasion. If further evidence were required to establish this case, we need only appeal to the Bible, to find that the Israelites lamented the loss of the fish which they "eat in Egypt freely" (Exod. xi. 5). In summary, every Egyptian of note had fishponds in his gardens for his amusement, profit and convenience of a plentiful supply of water, without which the villa, like those of the Roman nobles, would be incomplete.

C. THE ROMANS

The Romans spared no expense in the development of their fishponds. This fact we know from a variety of authorities, any one of which would be sufficient to place the matter beyond dispute. Great profits accrued from such fishponds, more than amply repaying the investments so profusely lavished upon them. But this abuse, if we can strictly call it such, was not observable in the primitive days of the Roman fishponds. It rose and fell as the extravagance of the age flowed or receded. There can be no doubt that the Romans first conceived their ideas as to the creation of fishponds from purely economic attributes, which subsequently became completely reversed, particularly among what we may term the aristocracy of the age.

Lucinius Murena was perhaps the principal propagator of this branch of rural economy. He was soon after succeeded by Sergius Orata, whose ponds at his house in Baianum, a region on the gulf of Naples were to ichthyophagists the wonder of the world. But this man did not reserve his ponds for his exclusive palate or requirements. Indeed, Pliny (the Elder) assures us that he dealt in their production and derived great revenues from them. The same authority tells us that he was the first person who introduced the Lucrine fishes into Rome (Lucrine was a lake in southern Italy,), and that he was the first to construct ponds for saltwater fish.

The next most conspicuous ponds were those of Lucullus, concerning which so much has been

FIGURE 9: The fishpond at Hadrian's Villa at Tivoli, Italy.

written. Their produce seems almost fabulous, and the sums the fish sold out of them realized read incredulous. Yet, there can be no doubt that when Cato was guardian to Lucullus, he disposed of the fish in those ponds for 400,000 sestertii, or $62000; and at the death of Lucullus they were sold for 3,000,000 sestertii, or $465,000. Plutarch tells us that Cato, who flourished about 150 years before Christ, commenced his distinguished career as the raciest radical of the period. He opposed every unnecessary expense and as Censor would not tolerate expensive fishponds or expensive fish. He railed against the extravagance of that age when a fish cost more than an ox.

The remedies he instituted to prevent the excesses of the time, ,however, proved unsuccessful and fish, instead of becoming cheaper, became more expensive. At last he saw the ineffectiveness of his policy and like most radicals, after he had acquired some riches became a violent conservative. As his thirst for wealth increased and finding his efforts in agriculture rather amusing than profitable, he turned his thoughts to safer bets and employed his money in purchasing and constructing fishponds from which he derived a great revenue. “Such a one,” he used to say, “as Jupiter himself could not disappoint him of.” Here we have an instance of a Roman vivarium properly stocked, being esteemed beyond the power of the gods to mar, and calculated to yield a greater profit than any other branch of rural economy.

C1. THE PONDS OF PHILIPPUS

The ponds of Philippus, at Cassinum, appear to rank next to those already enumerated. Hortensius vied with Lucullus and Philippus in the extent of his, which were constructed at immense cost, with some of them so formed that the tide flowed into them. Under the promontory of Bauli, travelers were shown the *Piscina mirabilis*, a subterraneous edifice vaulted and divided by four rows or arcades, which is supposed by some ancient writers to have been a fishpond of Hortensius. Concerning his ponds at Tusculum and Laurentum we have no particulars but he appears, as Varro tells us, to have been very chary of those at Bauli and when he gave parties at his villa there he usually sent to Puteoli (where he probably had ponds to store fish) to obtain fish for supper. This showed his reluctance to diminish the supply in his favorite ponds. He had a large number of fishermen in his service and devoted so much attention to the feeding of his fish that he had always ready a large stock of small fish to feed the great ones. It was with the utmost difficulty he could be prevailed on to part with any of them and Varro declared that a friend could more easily get his chariot mules out of his stable than a mullet from his ponds. He was more anxious about the welfare of his fish than the health of his slaves and less solicitous that a sick servant might take what was unfit for him than that his fish might not drink water that was unwholesome.

C2. CRASSUS AND CAESAR

Marcus Crassus was another distinguished Roman who evinced great pleasure in the cultivation of his fishponds. Although his moral character was unimpeachable during the greater part of his career, yet when he was somewhat advanced in years he was suspected of criminal intercourse with one of the vestal virgins named Licinia. It seems that the vestal had a beautiful country house, appended to which were some famous fishponds that Crassus coveted, and from paying his court to the lady with great assiduity fell under the suspicion mentioned, and the upshot was the case being brought before a court of the period. But the judge, as Plutarch tells us, knowing

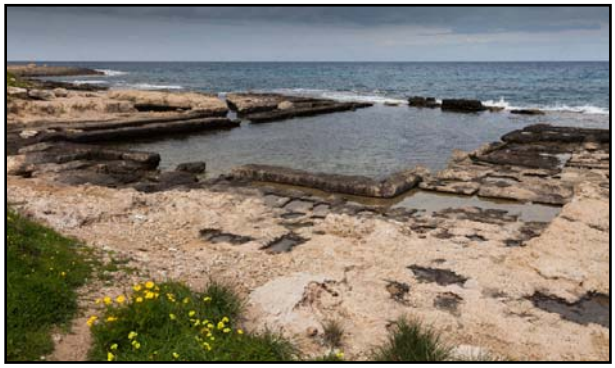

FIGURE 10: The Saltwater fishpond in the ruins of the Roman Lambousa, North Cyprus.

what was at the bottom of it all, acquitted him of corrupting the vestal; the same authority adding that he never let her rest until she had sold him her house and ponds.

Pliny tells us that the emperor Caesar had many country houses where he kept fishes in ponds that would ordinarily come to hand and take food. Nor was this an unusual thing, for fish were commonly so gentle and tractable in small stews and fishponds that it was not looked upon with any undue surprise. Some notable instances have been recorded where fish have evinced this kind of domestication, *viz*., at Floras, a castle in Sicily not far from Syracuse and at the lake of Jupiter Labradius where the eels would take food from the hand, and were sometimes adorned with earrings. The same was observable at the temple of Veterum Delubrum, and in Mesopotamia. Perhaps those at the fountain of Apollo in Lycia were the most remarkable of all, as they answered to the sound of a whistle with the sagacity of a dog. Again, those in the lake of Venus, near Hierapolis, a city in Syria, used to obey the voice of the wardens and sextons who had the guardianship of that temple. The fish there were so tame that they allowed themselves to be fondled and would wag their tails like dogs in a fawning and flattering manner. They would gape with their mouths wide open and suffer their admirers to thrust their hands or fingers into their gullets.
Augustus Caesar, says Pliny, reserved one pond exclusively for the breeding of lampreys and Seneca assures us that he had in his ponds at his pleasure-house Pausilupum in Campania, near Naples, fish sixty years old. The preciseness with which he records the fact leaves little doubt of its authenticity. Pliny cites it to show the age fish will attain in ponds.

C3. THE FISHPONDS OF CAIUS HIRTIUS

The fishponds of Caius Hirtius were no less famous than any of the foregoing. During the triumph of Caesar when the dictator gave feasts that were never equaled, Hirtius furnished him with six hundred lampreys, which he estimated to be beyond any amount of money and specified that they should be replaced by fish of the same description, number and weight. Pliny assures us that his country house was of very meagre pretensions, yet the fishponds about it and their contents sold for four millions of sesterces or $620,000. Those of Fulvius Hirpinus, in Tarquinii and others in the same neighborhood were also famous and associated with some distinctive mark that frequently attracted sightseers from Rome to visit them. Pliny, in his Epistle to Apollinaris, describes his villa, which was situated near a town called Tifernum Tiberinum in Tuscany. In the account of this villa there is a great difference between it and his seat at Laurentinum, the former being his constant residence in the summer season where he had a fishpond of large dimensions in the midst of which was a fountain always playing, "delighting," says he, "both the ear and the eye; for the water, falling from on high, is received in the bosom of the pond, which becomes white with foam."

C4. THE "MOST LEARNED OF THE ROMANS"

Marcus Terentius Varro, whose vast and varied erudition in almost every department of literature earned for himself the title of the "most learned of the Romans," was born in 116 BC. Not only was he the most learned of Roman scholars, but was likewise the most voluminous of Roman authors. He read so much, says St. Augustine, that one must feel astonished that he found time to write

FIGURE 11: A fishpond in Ventotene, one of the Pontine Islands in the Tyrrenian Sea.

anything; he wrote so much that we can scarcely believe that any one could find time to read all that he composed. Like Pliny, and all the conspicuous men of the time, whether scholars, poets, nobles, statesmen, or warriors, he too had his fishponds, and moreover, has left us some valuable information concerning them. His famous *De Re Rustica* was not written till he was eighty years old. This is unquestionably the most important of all the treatises upon ancient agriculture, being far superior to the more elaborate production of Columella, with which it can alone be compared.

I'll reproduce Varro's observations on the Omithon (a building for the keeping of birds), as the affinity between fish and waterfowl is too close to admit of separation for wherever there has been a fishpond, there have also been waterfowl.

I have a canal under the town of Oassinum, which runs clear and deep by my villa, 57 feet broad, with stone banks; and there is a passage by bridges from one villa to the other: the length is 950 feet from an island made by the river Vinius to the musaeum [*i.e.,* museum] , where flows another river to the upper part of the canal where the musaeum stands; about the banks of which is an open walk 10 feet broad. From this walk towards the fields, the place of site of the omithon is enclosed on each side on the right and left by high walls, between which the omithon extends, its breadth 48 feet, in the shape of a writing-table with a head; the square part is in length 72 feet, and the round part, which is the capital, is 27 feet. As a margin, without the omithon, is a parterre, in the middle of which are alcoves; and thence are entrances into the area. In the entrance is a porticus on the right and left, with dwarf-trees placed between the stone pillars of the first row from the top of the wall to the architrave; a hempen net serves for a covering to the porticus, and from the architrave to the pedestal it is filled with all sorts of birds, which are fed through the net, and the water flows through in a small stream.

Adjoining to the inner part of the pedestal, on each side of the upper part of the square area, are two oblong fish-ponds opposite to the porticus; between the two ponds is the only path leading to the Tholus, which is a round colonnade, as in the temple of Catullus, except that they are pillars and not walls… Below the pedestal of the pillars is a stove a foot and a half high from the Falere [*i.e.*, a platform]; the Falere is two feet high from the pond and five feet broad, that the guests may walk upon the culcita [*i.e.,* cushions] round by the small pillars; and the bottom within the Falere is a pond with a margin to walk upon, and a small island in the middle: round the Falere and the pond are hollowed pens for waterfowl. Ducks come into this pond and swim, which is connected by a little stream with the fish-ponds in the garden above-mentioned, in which the fishes swim to and fro.

Here I close this brief sketch of a few of the most important fishponds of the Roman nobles as handed down to us in the writings of many of their greatest scholars. It would be impossible to catalogue the numerous and famous ponds that were constructed in the vicinity of Rome from the time of Numa to Augustus. There is no doubt they continued to increase both in extent and perfection until the fall of Rome, as we know the

FIGURE 12: A Roman saltwater fishpond, Alicante, Spain.

ponds and the luxury of Apicius and Vedius Pallio even surpassed those of Lucullus and Hortensius.

C5. ROMAN FISH CULTURE

Fish culture facilities and practices among the ancient Romans have been reviewed in the Ph.D. thesis of James A. Higginbotham (1991). He thoroughly catalogues the fishpond structures of late Republican and early Imperial times now visible and archaeologically attested to in Italy. This is followed by essays on pond construction and operation, and on the fishes Romans then reared. What here follows will summarize the most important sources and Higginbotham's findings, and add only a short discussion of the later Roman period, which Higginbotham does not treat.

The most important information on Roman fish culture is in the Roman writers on agronomy, the management and operation of rural estates. Fishponds *(piscinae)* are not mentioned in the oldest text (Cato, circa 175-150 BC), but do receive at least cursory treatment thereafter. Note that each successive writer was aware of and often used the works of his predecessors.

Most of what modern readers (e.g. Balon, 1995a,b) think they know of Roman fish culture comes directly or indirectly from Varro's *De Re Rustica* (37 BC) and Columella's *De Re Rustica* (about 50 AD). The two authors wrote while artificial fishponds were at the height of Roman elite fashion between the early years of the first century BC and the end of the first century AD. Columella used Varro's material, and Columella's younger contemporary, the Elder Pliny, cribbed from both.

Writing from the viewpoint of the agricultural manager, Varro treated fishponds as social curiosities, emphasizing with many literary allusions their role in luxury display and consumption, especially at the estates of wealthy Romans around the Bay of Naples. Once, he says (Varro, 1935), Romans kept small freshwater pools near their villas and stocked them with *squali* or *mugili* ("chubs" and grey mullet, both euryhaline marine varieties), but were now sneered at in favor of saltwater ponds and fishes, notably *murenae***.** He continues with several lurid tales of extravagance in rearing what were likely eels of several sorts, but chiefly *Anguilla anguilla* (Higginbotham 1991).

Varro returns in a second passage to the two types of fishponds, fresh and salt water. Commoners, says he, have the former, where natural sources furnish the water for "our own domestic fish" *(piscibus nostris villaticis)***.** The elite, however, maintain very costly artificial saltwater ponds and fishes, especially mullets and *murenae***,** as much for recreational viewing as for consumption. All he describes are tidal and marine.

About two generations after Varro, Columella took a more serious view of fishponds on a Roman estate farm (Columella, 1941-1968). Fish culture was once, says this expert, a fad using saltwater fish in fresh water and stocking eggs and young brought from the sea. In his own time there was less extravagance and fish culture offered a good profit to a landowner with marine access. He details the fishes appropriate to various coastal habitats. The most recommended ponds are open to tidal flow, with the water kept as cold and well-circulated as possible. The

FIGURE 13: Fishpond of the ancient palace complex on the Palatine hill, Rome.

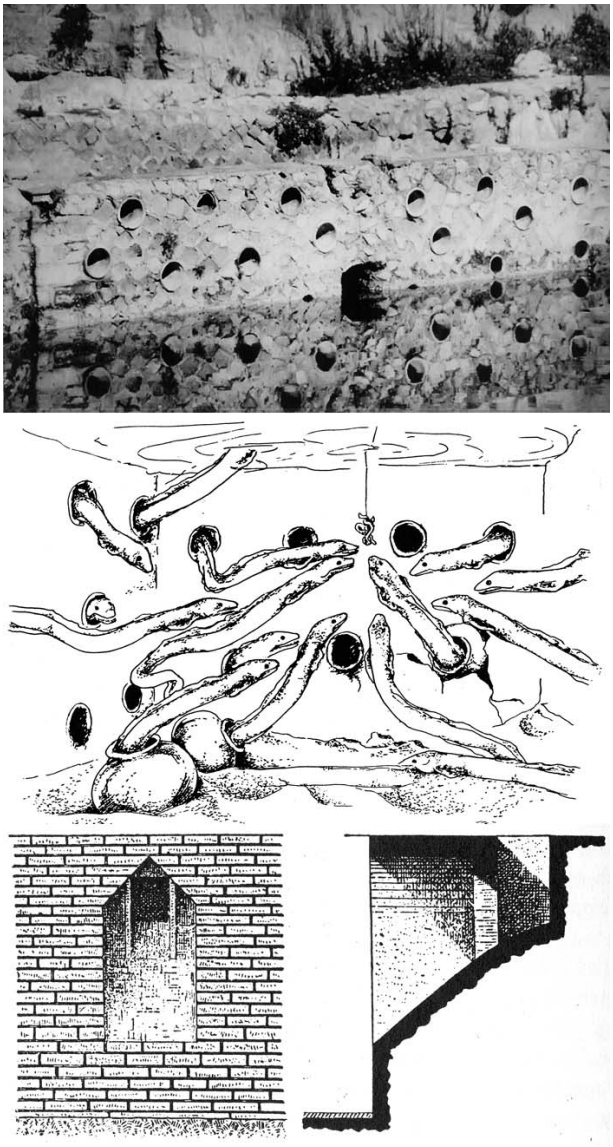

FIGURE 14: Top: Ceramic vessels inlaid in the wall of the Grotto of Tiberius. Middle: Eels in a fishpond with such recesses. Bottom: A different type of recess called a "spectrum." Both types provided protection for fish from predatory tank-mates and the sun.

stock should be chosen in accord with the habitat - again all varieties mentioned are marine - and given small fish or other items to eat. Stock not kept fat would get a poor price on the fish market.

Writing about 70 AD, Pliny (1942-1984) contributed nothing really new to the record of Roman fish culture. He used mainly Varro, but also Columella, to describe a luxury activity using coastal saltwater facilities to rear shellfish, *murenae* and snails for elite consumption and the sheer pleasure of watching the fish. In summarizing this period of intense Roman interest in artificial fishponds, Higginbotham (1991) emphasizes the overwhelming importance of coastal brackish-water ponds for rearing inshore marine species. Sea-trushes were a small spotted fish, not a foot long, of a russet color, with a figure like a tench, living among stones and rocks by which means it was impossible to take them, except in calm weather. They were eaten generally in the autumn, and were esteemed a delicacy among the Romans.

When he was sojourning at his Laurentinum villa during a succession of stormy weather, Flaccus sent to Pliny a present from his ponds of some sea -trushes. It would appear from this incident that Pliny had no ponds at Laurentinum, as he writes a complimentary epistle to Flaccus acknowledging the "delicate" present, for "which during this tempestuous weather," says he, "I can find no equivalent, either from the markets or from the sea. A barren letter, bearing no proportion to the favor I have received, is all the return you will find. I cannot even imitate the policy of Diomedes in exchange. But such is your good nature, that in this point you will more easily grant me a pardon, from the frank confession that I scarce deserve it."

At the peak of fishpond construction they served as elaborate symbols of aristocratic wealth and "demonstrated a control over nature." Fashionable interest waned as first century emperors moved against such ostentation, but smaller, often inland, ponds may have gained favor as a less extravagant way to control nature, please the eye and perhaps supply some food. Fishponds in the Roman suburbs and at villa sites inland of the Bay of Naples, were built of concrete and used to house eel and bass (*lupus),* still euryhaline fishes. Facilities like these have also been recovered from Roman villas in Roman Britain (Zeepvat 1988).

C6. THE LATER EMPIRE

Roman writers of the later Empire had less apparent interest in fishponds. In Oppian's *Halieutica* (Oppian, 1928) the only fish preserve (Greek *bibarion***)** is a marine area kept for imperial use. The next important agronomist, Palladius (1975), who wrote his *Opus agriculturae* about 380, having advised building a cistern of stone and cement, pointed out that the owner could stock "eels and river fish" *(anguillas sane pisces que fluviales)* so that their swimming would make the water surface ripple as if it were moving. His chapter called *De piscinis* (On fishponds) advises choosing a site near the farmstead which is easy to feed from a spring or surface runoff and useful for livestock and waterfowl. It mentions no fish, and neither does any of Palladius' other passing references to *piscinae* as sources of water for irrigation, livestock or household purposes. The word seems disconnected from its original root.

The unravelling thread of Roman agricultural expertise was pulled together about 600AD into a compilation called *Geoponika* (1895), perhaps attributable to a writer named Cassianus Bassus, but now surviving only in an edition made about 950AD under the auspices of the learned Byzantine Emperor Constantine VIII Porphyrogenitus. Book 20 contains 40 chapters on fishes and fishing, which are almost entirely marine, but it begins with one on fishponds. These occur in inland situations, where they are filled with fish from nearby rivers or lakes, or along the coast where sea fish are used. The stock should come from habitats like that in the pond, and can be fed herbage, small aquatic creatures or bits of fig, cheese or bread.

Perhaps it is fitting that a final echo of those classic Roman coastal rock-cut fishponds come in the writings of Cassiodorus, not the letters written in his middle years for the Gothic kings but in the *Institudones***,** a guide for reading and study done in his old age at the Vivarium monastery established on his hereditary estate at Squillace in the Brutti, the ball of the Italian foot. The place even took its name from the fishponds (*vivaria***),** which Cassiodorus described as follows (Cassiodorus, *Institutiones*, 1143):

The site of the monastery of Vivarium conduces to making provision for travelers and the poor, since you have irrigated gardens and the nearby river Pellena full of fish - its waves threaten no danger, but neither is it despicable for its size. It flows into your precincts, channeled artificially where it is wanted, adequate to water your gardens and turn your mills. It is there when you want it and flows on when no longer needed; it exists to serve you, never too roisterous and bothersome nor yet again ever deficient. The sea lies all about you as well, accessible for fishing with fishponds to keep the caught fish alive. We have constructed them as pleasant receptacles, with the

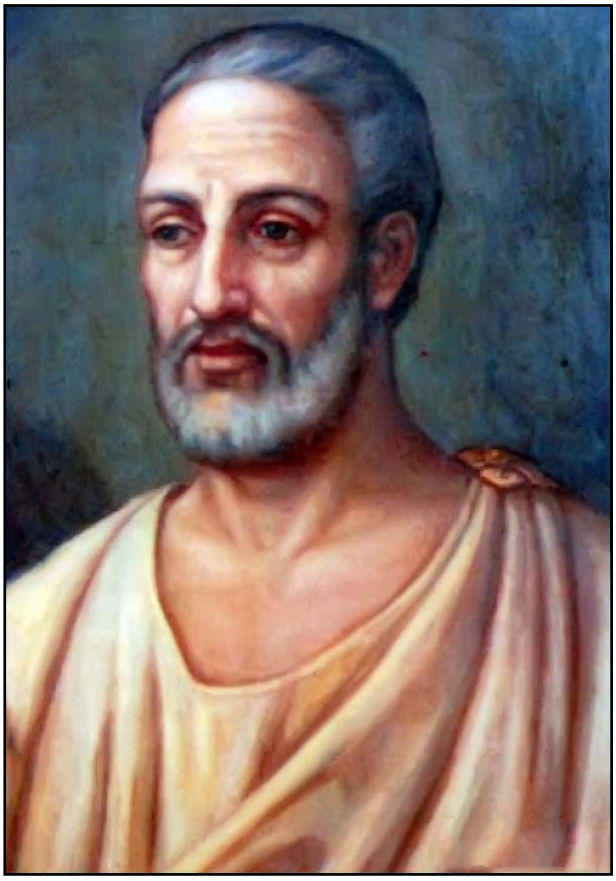

FIGURE 15: Flavius Cassiodorus (c. 485-c. 585).

Lord's help, where a multitude of fish swim close by the cloister, in circumstances so like mountain caves that the fish never sense themselves constrained in any way, since they are free to seek their food and hide away in dark recesses Thus it is that your monastery is sought by outsiders, rather than that you could justly long for other places.

At the site of the one-time Vivarium on the shore at the mouth of the Alessi River south of modern Squillace in southern Italy are still three natural basins in the rock with narrow channels to the sea that could easily have been blocked to create Cassiodorus' holding tanks. But the Vivarium monastery disappeared very shortly after Cassiodorus's death in the 580s (aged over 90!) and book I of the *Institudones* circulated little among medieval historians (O'Donnell, 1979).

D. CHINESE FISH PONDS

In the 1960s, an excavation of Chinese tombs from the Eastern Han Dynasty, in what's now Shanxi Province, unearthed a clay model of a rice paddy that held tiny clay fish. The miniatures, which were created between the years 25 and 220, depict the ancient practice of rice-fish farming, in which farmers stocked their flooded rice fields with carp. It is a symbiotic relationship. When grown together, the rice plants require fewer pesticides and the carp eat weeds and insect pests while also providing natural fertilizer.

References to this kind of aquaculture date back to the oldest surviving collection of Chinese poetry, the *Shijing* or *Book of Odes*, which was written around the 11th century BC. It notes that Chinese farmers reared carp in ponds during the period 1142 to 1135 BC. But the origins of this practice are murky, because fish bones are less easily fossilized than those of other, larger livestock.

The rice-fish farming system is described not only as one of production style, but also as one of the culture. Tombs of the mid-Eastern Han Dynasty (25-220 AD) were excavated in 1964 in Hanzhong county, Shanxi Province1. Two clay models were unearthed: a model of a pond and a model of a rice field. The pond model contained 15 tiny pieces, 6 of common carp, 1 soft-shell turtle, 3 frogs and 5 water chestnuts). These depict the ancient practice of rice fish farming in which farmers stocked their flooded rice fields with carp. It is a symbiotic relationship. When grown together, the rice plants require fewer pesticides; the carp eat weeds and insect pests, while also providing natural fertilizer.

A stone carving of a pond and rice field model was discovered in the brick tomb of the Eastern Han Dynasty in 1977 in Emei County, Sichuan Province. Half the stone was carved into a pond with frogs, fish and ducks. The other half was

FIGURE 16: According to Chinese mythology, carp can be transformations of dragons or can sometimes change into dragons.

carved into a rice field with an inlet and outlet, two farmers toiling on one side, and two heaps of manure on the other. Four mid-Han Dynasty tombs with 200 relics were excavated in 1978 in Mian County, Shanxi Province. One of the intact relics was a rice field model containing 18 pottery miniatures of aquatic plants and animals. There were sculptured frogs, eels, spiral shells, crucian carp, grass carp, common carp and turtles in this model. Another of a winter rice field showed farmland with a reservoir that also contained these fish. These relics not only proved that rice-fish farming system was one of farmer's production practices 1700 years ago. It also proved that the early rice-fish farming system is a very diverse system.

The more detail written record of rice fish farming is from Recipes for Four Seasons which was written by Cao Cao in the Sanguo Dynasty (200-265 AD):

A small fish with yellow scales and a red tail, grown in the ricefields of Pi County northeast of Chendu, Sichuan Province can be used for making sauce.

After that, in Tang Dynasty, in Ming Dynasty, and in Qing Dynasty, there were also numerous written records about rice-fish farming system or culture. For example, Liu Xun (about 889-904 AD), wrote in Wonders in Southern China:

In Xin, Long, and other prefectures, land on the hillside is wasted but the flat areas near the houses are hoed into fields. When spring rains come, water collects in the fields around the houses. Grass carp fingerlings are then released into the flooded fields. One or two years later, when the fish are grown, the grass roots in the plots are all eaten. This method not only fertilizes the fields, but produces fish as well. Then, rice can be planted without weeds. This is the best way to farm.

It indicated that before 1000 years ago, China's farmers had adopted the rotational rice fish farming technology. Another record was found in chronicle of Shunde County, Guangdong Province in Ming Dynasty (1573 AD). It states that:

The periphery of a land was trenched as a plot, called the field base…. In the plot, a pond was dug to rear fish. During the dry season, rice seedlings were transplanted to the plot. The area might be several hectares. It indicated that rice-fish farming technology was further advanced 400 years ago.

References to this kind of aquaculture date back to the oldest surviving collection of Chinese poetry, the *Shijing* or *Book of Odes*, which was written around the 11th century BC. It notes that Chinese farmers reared carp in ponds during the period 1142 to 1135 BC. But the origins of this practice are murky, because fish bones are less easily fossilized than those of other, larger livestock.

D1. A NEW DISCOVERY - 8000 YEARS OLD!

Now, a new study led by Tsuneo Nakajima of the Lake Biwa Museum in Japan and published in *Nature Ecology & Evolution*, suggests the prac-

FIGURE 17: This *wucai* fish vase, intricately decorated with small golden carp, lotus blossoms and undulating grass, dates from the Jiajing reign (1522-1566) of China's Ming Dynasty.

tice of rice fish aquaculture actually began thousands of years earlier than previously believed - around 6200 BC. The researchers had a hunch that these aquaculture systems originated a long time ago, because rice paddies have been around since 5000 BC, four millennia earlier than the first evidence of carp aquaculture. Some researchers guessed that the rice-and-fish system might have developed around that time.

One site showed particular promise for an investigation into the origins of rice fish aquaculture: Jiahu, a settlement occupied from around 7000 to 5700 BC in the Yellow River Basin of Henan Province, in central China. By Neolithic standards, Jiahu was positively cosmopolitan. If you wanted to spend time at a cutting-edge cultural center in Neolithic China, Jiahu was the place to be. It's one of the first places where people learned to make wine from fermented honey and rice, and bone and tortoise-shell artifacts show that the people of Jiahu carved a set of symbols that may be one of the earliest known predecessors of writing. Archaeologists have unearthed many other signs of a complex society there, such as flute fragments carved from the wing bones of red-crowned cranes, some of the earliest examples of playable musical instruments, according to The Metropolitan Museum of Art. In other words, if any Neolithic Chinese culture were to have domesticated fish, it would probably be Jiahu.

To search for Jiahu's ancient fish remains, the researchers excavated the site's trash heaps using a mesh sieve, to filter them from the soil. Mark Hudson, an archaeologist at the Max Planck Institute for the Science of Human History who co-authored the study noted that "Bones from carp and other things that have been eaten are usually jumbled together in rubbish pits. The researchers compared what they found at Jiahu to remains from other contemporary sites in China and Japan, as well as modern-day carp from a farm in Japan's Matsukawa Village.

On land, most species of livestock are physically distinct from their wild counterparts. The skeletons of domesticated sheep, for example, tend to be proportionally smaller and older than those of their wild sheep. This skeletal skewing makes it easy for archaeologists to discern when humans began to rear a given species. But fish bones are much smaller and more fragile than sheep bones, making them far less likely to be preserved. In fish, such skeletal changes are much less well-known, if indeed they exist. Instead, the researchers had to work with the best-preserved part of the carp: their pharyngeal teeth, which are harder and thus more likely to survive than bone.

At Jiahu, the researchers found a surprising abundance of teeth from the common carp. Despite the fish's name, common carp aren't quite as easy to find as crucian carp, which stay closer to shores

FIGURE 18: Henan Province China (light yellow), the location of the Jiahu settlement.

FIGURE 19: Pharyngeal carp teeth.

and riverbanks throughout the entire year, making them an easier catch. Yet 75 percent of the 588 carp teeth that were recovered came from the common carp.

It's relatively easy to extrapolate a fish's body length from the size of its teeth and I refer readers to a short article (Chavez, *et al.*, 2012) that explains the use of a simple regression analysis used to make the connection (see Figure 20). When the researchers calculated the probable body lengths of the Jiahu bones, they found an unnatural pattern, which suggested the carp had been farmed. According to prior research of carp bones at other Paleolithic sites in China and Japan, the body lengths thrown out by hunter-gatherers generally formed a bell curve that peaked at 11.8 inches, the average size of a mature adult carp - the kind you'd want to catch and eat. Bones found in the oldest layers at the Jiahu site produced similar body length patterns.

But starting around 6200 BC at Jiahu, the archaeologists found *two* bell curves, one representing the adult fish and another representing smaller, younger fish (Figure 21). The researchers believe the simultaneous abundance of these two body lengths suggest these fish were not caught wild as adults, but harvested from a pond, meaning that immature fish were caught alongside full-grown ones. This distribution pattern of two common body lengths, adult and juvenile, appeared in excavations of more recent sites with a known history of aquaculture.

The researchers' findings help to answer a larger question at the heart of early aquaculture: whether domesticated carp were moved from Europe to Asia, vice-versa or neither, writes Jennifer Harland, an archaeologist at the University of the Highlands and Islands, in a comment in *Nature Ecology and Evolution* (Harland, 2019). During the Roman Empire, carp were eaten but likely not domesticated in ponds until the 12th century, ac-

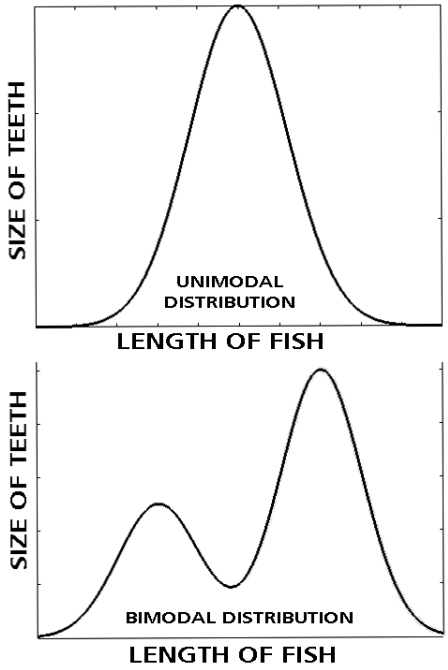

FIGURE 21: The upper image indicates that the sample contained only adult fish; the lower image indicates that both adults and juveniles were present.

cording to medieval historian Richard Hoffman in a 1995 study published in *Guelph Ichthyology Reviews*. Harland believes that the new findings at Neolithic Jiahu suggest the common carp was domesticated twice, once in Asia and once in Europe.

Though the researchers found ample carp teeth at Jiahu, they have not yet found traces of rice paddies. They hope to continue searching for traces of these fields to pinpoint when the rice-fish farming first emerged, as they believe this system - like the domestication of the carp - may be more ancient than previously thought. Today, rice fish farms are found all across China. In the Ailao Mountains in Yunnan Province, for example, a spectacular mosaic of rice terraces cascade down the slopes and support a variety of carp, including crucian (*Carassius carassius*), silver (*Hypophthalmichthys molitrix*), and, of course, the common carp (*Cyprinus carpio*).

D2. LATER RECORDS

The date 500 BC is considered of very great significance in the annals of the history of aquaculture. Many authors round the year as 500 BC although most agree that the exact year is 475 BC and some even use 473 BC as the period when Fan Lai (also spelled Li or Lee by some authors) wrote his book, "The Classic of Fish Culture." This book comprised the earliest monograph of fish culture. Although the narrative also dealt on fantasies and metaphysical aspects, it is the first to record and describe the structure of ponds, the method of propagation of the common carp and the growth of fry. Excerpts of an English translation and Chinese facsimile of this book are appended

The period 500 BC to 500 AD can be considered the Golden Age of common carp culture which has continued to develop in China as well as in

FIGURE 22: Top: The Jiahu team preparing to drain a rice field. Bottom: Junzo Uchiyama preparing to measure the length of common carp removed from the paddy field.

FIGURE 23: Fan Lei, who produced the first written record of aquaculture practices, *i.e.*, a book called *The Classic of Fish Culture,* published about 475 BC.

neighboring countries where the Chinese people migrated or have some form of foreign relations. Not only is actual progress attained in the techniques of culture but also scattered records of the culture systems were made during this period. At about this time in the Indian sub-continent, specifically during the period 321 to 300 BC, the use of reservoirs to hold fish was first described.

The reign of the Tang Dynasty (618-906 AD) is particularly significant in the history of world aquaculture. The Tang emperor in China had the family name of Li which happened to be the common name of the widely-cultivated common carp. Because of this coincidence, an imperial decree was issued prohibiting the culture as well as other activities connected with this fish. This decree, however, instead of putting a constraint to the development of aquaculture turned to be a blessing in disguise. The Chinese people who were then at the time very much engrossed in fish culture as a source of food and livelihood, looked for other species of fish for pond culture. This resulted in the discovery of the silver carp, the big-head carp, the grass carp and the mud carp, all very suitable pond culture species. It was also found that when raised in polyculture in the same pond, these species complement each other by eating different types of food and staying in different environmental strata within the pond. This led not only in the discovery of new species for culture but also in maximizing the productivity of freshwater pond culture,

The initiative to collect fry of cultivable species seasonally along the rivers was started during the Tang Dynasty as a result of the prohibition decree on the common carp, Systematic fry collection and dispersal in natural waters was highly developed during following period under the Sung Dynasty (906-1279 AD), At about this time in India, the published work Manasollasa presented a compilation describing the fattening of fish in reservoirs. In China, in 1243, Chow Mit published his *Kwei Sin Chek Shik* which described fry transport in bamboo baskets.

It was during the Ming period, 1368-1644 BC that works describing the complete aquaculture process were detailed. Methods for culturing fry to adult, the structure of ponds, rearing density, polyculture, stocking/catching rotation, application of food and fertilizer and disease control were dealt with in aquaculture works during this period. In the year 1400 brackish water aquaculture was recorded as having been started in Indonesia. This was suggested in the penal laws of the

FIGURE 24: A "Fish Pond" lobed bowl of the Ming Dynasty was auctioned for $29,000,000 at Sotheby's, setting the second highest record for Ming porcelain.

country (Kutara Menawa) which provided for the prohibition of stealing fish from ponds. In China, in 1639, the Complete Book of Agriculture which included pond fish culture was released. During the Ching Dynasty (1644-1912), further detailed description of fish culture methods were emphasized. This included fry production, season of occurrence of fry, differentiation and separation of fry and transport.

E. ON IDENTIFYING THE CARP AS CYPRINUS

No ancient Greek or Roman text refers to a *carp*. A fish which ancient Greeks called *kyprianos* and subsequent classical Latin authors *cyprinus* is reasonably well documented in the writings of Aristotle (384-322 BC) and others who knew his work. This fish was never then discussed in the context of artificial fishponds or fish culture. In fact, classical writers in Greek and Latin treat it as frequenting both fresh and salt waters, and allude to Asia Minor and the Balkans. None gives this fish a comprehensive description, but rather a passing mention.

In passages of the *History of Animals* Aristotle described *kyprianos* as a river fish with four gills on each side, a fleshy palate, and eggs the size of a grain of millet. It spawns five or six times a year, scattering its eggs in the shallows, but guarding the slowly-developing egg masses if it finds them again. Individuals without reproductive organs become very fat. With less harm than the catfish suffers, *kyprianos* can be paralyzed by a clap of thunder (Aristotle, 1965).

Writing a *Natural History* in Latin some four centuries after Aristotle, the Elder Pliny (23-79AD) noted only that, like the catfish in a river, "in the sea the *cyprinus*" ("in mare ... cyprino") is made drowsy by lightning (Pliny, 1942-1984), a fact he had, of course, copied from the ancient Greek writer. Another hundred years after Pliny, an author from southern Asia Minor, Oppian, dedicated his *Halieutica* ("On Fishing") to the Caesar Commodus, son of the reigning Emperor Marcus Aurelius. Writing in Greek, Oppian once refers to *kyprianos* as a fish of the gently sloping seashore and elsewhere repeats Aristotle on its breeding several times a year (Oppian, 1928). A younger contemporary, Aelian, also speaks obscurely of what he calls the "black *kyprianos*," caught in winter through the ice in the Danube (Aelian, 1958-1959). In perhaps the last ancient reference, a learned Gallo-Roman administrator, Polemius Silvius, included the word *ciprinus* among marine fishes in a list of 147 names of aquatic creatures he put into his *Laterculus*, a compendium of geographical and other knowledge done in 449 (Polemius, 1892).

It is important to note that ancient writers and texts nowhere equate the classical *cyprinus* with a creature called. This seems to happen very much later. Cassiodorus, whose sixth- century reference to *carpa* (Cassiodorus 1973) is acknowledged the oldest extant verbal record in any language, certainly did not gloss this barbaric word with *cyprinus*, despite his famous cultivation of classical literary knowledge. Nor was this done by any of the major scholastic encyclopedists, Vincent of Beauvais, Thomas of Cantimpre, and Albert the Great (Albertus Magnus), whose works were all compiled, revised, and known to each other between 1244 and 1260. In treating *"carpera"* (Vincent, 1624), *"carpo vel carp era"* (Thomas, 1973), and "*carperen*" (Albert, 1916-1920) not one mentions *cyprinus* or any ancient Greco-Roman authority.

It looks rather like the ancient term was put on

FIGURE 25: The Common Carp, *Cyprinus carpio*, a large minnow weighing up to 50 pounds or more.

the familiar common carp only by sixteenth-century humanist-trained authors, always eager to link up their world with that of the classics. For the time being at least, the earliest equation on record is that by Jan Dubravius. Writing in the late 1530s, this learned cleric found in no more than the passages from Aristotle, Oppian and Pliny remarked above, just enough similarity between his carp and Aristotle's description to resolve his doubts. And because the sound of 'carpo' is barbarous, it seems proper on that account to be rejected and in its place 'cyprinus' substituted, which is used widely by the Greeks and the Latins. Plainly the "barbarity" of a non-classical term much bothered Dubravius and he was only too happy to find a more acceptable one. Carp is then ***cyprinus*** in all the path-breaking ichthyologies published in Latin by Pierre Belon, Guillaume Rondelet and Conrad Gessner during the 1550s.

Nowhere in the Roman written or archeological records are there broad dirt-bottomed freshwater ponds with control facilities for complete emptying and filling such as those known in Western Europe from at least the twelfth century and used since at least the thirteenth century to rear common carp. But also nowhere in the Roman written record is there unambiguous reference to the fish now called *Cyprinus carpio* which during imperial Roman times was eaten near the western limit of its natural range at what is now Iza on the middle Danube (Balon, 1995a,b) and near its eastern limit in the Balkans at what is now Novae just above the Danube's mouth (Szymczyk, 1987).

However, Balon (1995 a,b) reports carp remains dating to the second through fourth century AD from the site of a Roman frontier fort on the Danube near what is now Iza, Slovakia. Also, *Carpho* is given as a synonym for Latin *carabus* in a list of fishes in a dual-language lexicon, the *Summarium Heinrici***,** compiled at Worms and the nearby monastery of Lorsch in Rhineland (Hildebrandt 1974-1982). Following publication of the text, Wagner (1975) showed how it must date to about 1100, and not significantly earlier. The revised dating was subsequently acknowledged in Hildebrandt's second volume and by Tischler (1994) and Crossgrove (1994). A mid-fifteenth-century Italian cookbook by a native of Lombardy then working in Rome, Maestro Martino's *Libro de arte coquinaria* provides a recipe for *carpani***,** and thus what so far seems to be the oldest Italian reference to the fish (Faccioli 1966).

F. WESTERN EUROPE FISHPONDS

To serve human demand for fresh fish, medieval Europeans established new freshwater habitats, modified the mix of fish species and created new ecosystems, both domestic and wild. These activities both exploited and multiplied what have been identified as unintended environmental consequences of medieval economic growth.

Artificial constructions for long-term retention and eventual rearing of live fish are plainly a response to inadequacy, whether conceived in nutritional or cultural terms, of natural supply. Fishponds can equilibrate seasonal irregularities, supplement insufficient wild catches, or even entirely

FIGURE 26: This artificial fishpond at Horbach, in Franconia west of Nurnberg, Germany was possessed by lay landowners before Heilsbronn abbey obtained it in the late 1200s. The abbey then managed it in concert with at least five more fishponds it owned there along the spring-fed valley of the River Zenn.

replace wild varieties with preferred domesticates. In some circles the ponds and freshly-reared fish could also make a social statement. The intensity and sophistication of medieval fish culture varied along a spectrum jointly determined by growing technical expertise, priorities, and resources available for investment. Simple storage tanks for seasonally surplus catches were likely always to be found. Heavily capitalized and elaborately managed fish-rearing enterprises were relatively late phenomena.

Even on monastic estates, where rules against eating meat meant proportionally greater fish consumption, hard evidence for fish culture is simply not present in the early Middle Ages. On ascetic grounds the Rule of St. Benedict, since the early ninth century the dominant constitution for monastic life, prohibited eating the flesh of quadrupeds but did allow fish. Monastic dietary regimes generally both reflected and reacted against local consumption practices. No meat did call for more eggs, cheese, and fish than in lay diets. Fish was thought superior food, however, and not eaten daily by the monks. By the eleventh century fish appeared on the table at well-run Benedictine communities two or three days a week and on special holidays, including during the 40-day Lenten fast when monks ate no eggs or cheese. Austere new orders, the Cistercians and Carthusians, avoided even fish during their early decades, and but slowly capitulated to occasional "pittances", special endowments of a fish meal.

All needs of monks and nuns for fish could often and long be satisfied from local wild resources. Of the six freshwater taxa named in Cluny's late eleventh-century customal (a written account of the customs of a manor or other local community), five (pike, trout, lamprey, eel, and sturgeon) could be expected from the extensive river fisheries in the Saone and its tributaries which that house owned two generations later. The rich records of Cluny at its height of wealth and prestige up to the mid-twelfth century refer to the capture and temporary storage of fish but give no sign of their rearing in fishponds. The same may be said of Cistercians well into the twelfth century.

To build a fishpond - and not just a holding tank - is to create a new aquatic habitat. Active construction of ponds for this purpose got under way in the eleventh century and increased rapidly in the twelfth and thirteenth. People built fishponds in regions where human populations and economies were also growing. Disputes over Picard fishponds thus enter the written record around 1100, and major projects in hydraulic engineering there date between the 1170s and 1250s, coincident with such investments in Burgundy and Berry.

It is important to recognize that, despite the ecclesiastical bias of a high medieval record written largely by and for churchmen, both lay and clerical landowners built, owned and operated fishponds in the twelfth and thirteenth-century west. About 1160, while the count of Sancerre was flooding lands near Bourges to make himself a fishpond, Emperor Frederick Barbarossa was ordering construction of another large one at Kaiserslautern. In 1216 Simon de Joinville, Seneschal of Champagne and lord of estates on the upper Meuse River, made sure he exempted his fishponds when he allowed the monks of Clair-

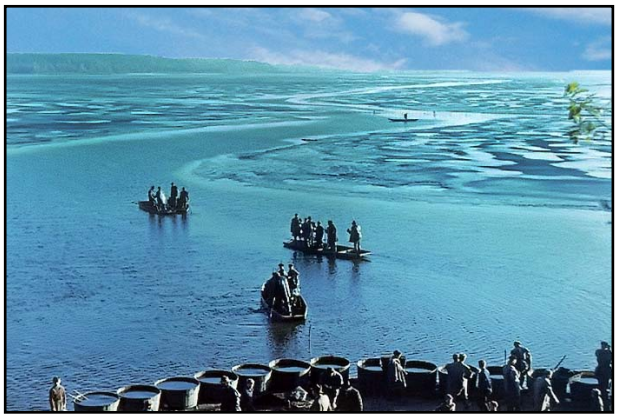

FIGURE 27: A large Bohemian fishpond in the Czech Republic of late medieval origin is drained and ready for harvest by traditional methods still being used in the late twentieth century.

FIGURE 28: The Bream, *Abramus brama*.

vaux to fish in his river. This should in no way be a surprise. Medieval religious and lay elites were everywhere interrelated and interdependent. Church institutions were more durable and kept more records, and by the thirteenth century the Cistercians (latecomers who often received valley-bottom sites) were becoming unusually systematic in their management of water, but recent scholarship is no longer convinced they were any more innovative than their lay neighbors and kin.

Active building of fishponds spread later to east central Europe. The Cistercian house founded in 1133 at Waldsassen in the German-Czech frontier zone of the Egerland did not make its first pond until about 1220. A few ponds may be recorded from eleventh or twelfth century Bohemia, but the first datable construction there was in 1263 and rapid increase came a century after that, when 87 new building projects are recorded between 1347 and 1418. Large and complex hydraulic works were especially undertaken by Czech lords between 1450 and 1550, resulting by the latter year in an estimated 26,000 artificial ponds covering thousands of hectares and some of them fed by rivers which had been diverted as much as 35 kilometers. Pond building in southern Poland lagged a generation or so behind that in Bohemia.

Whether fed by surface runoff, a spring, stream, or diverted river water, fishponds are still, not moving, waters. Medieval Europeans managed their purpose-built fishponds and other appropriate artificial or enhanced ponds (former river channels, millponds, moats) for production of fish varieties well- adapted to lentic habitats with high nutrient levels and warmed water. Probably in the twelfth century and certainly by the thirteenth careful management included close control over the in- and outflow of water and a regular (3-5 year) cycle from stocking with breeders or small fish to drainage of the pond for harvest, followed by a dry season and cultivation of the bottom to raise fertility when the pond was refilled. The elaborate hydraulic system built at thirteenth-century Vauclair put the fishpond where it received nutrient-laden outflow from abbey latrines. A like arrangement fertilized five of Maulbronn's eight nearby ponds. Coordinated management of several ponds serving different functions or at different phases of the production cycle was essential for year-to-year operation of the enterprise. The entire technical system is visible in sources from the western continent and England by about 1200 and seems later further to the east.

Anadromous or cold-water fishes had no place in the pond environment. In the the thirteenth-century they yielded bream, tench, roach, dace, and pike. Most of the fish species recorded in medieval ponds were these western European natives with preferences for still and weedy waters. They now received much increased habitat and even purposeful human help as a consequence of medieval economic development.

Common carp were not native to western and central Europe. Arrival of this exotic species necessarily meant interaction with the ecosystems now receiving it. "Successful establishment of an

FIGURE 29: The Tench, *Tinca tinca*.

exotic species must necessarily precipitate changes in the physical and biological characteristics of the aquatic ecosystem receiving the introduction.... That no effects should result from such perturbations strains one's confidence in ecological principles" (Taylor et al. 1984, pp. 323 and 352).

In common carp, medieval fish culturists introduced a new species remarkably well-suited to colonize the very type of freshwater habitats which economic development was multiplying in the west. Carp are omnivores, feeding principally on bottom- or plant-dwelling small animals. They prefer warm, turbid, slow and still waters with much vegetation for food and where they will broadcast their own eggs in early summer. Carp tolerate low oxygen levels in water and if kept cool and damp can survive some days out of the water. They grow faster than do bream, the native western European cyprinid most like carp in habits and habitat requirements. Medieval western ecosystems offered little competition.

In northern Europe, however, it was difficult to winter and reproduce carp and it was therefore replaced with the crucian carp, *Carassius carassius*, Figure 30, which was bred in ponds and used as food. Other cyprinids (especially bream, *Abramis brama* and pike, *Esox lucius*) were kept as well, but they seldom reproduced in the ponds. These taxa were therefore merely intended for storage ponds. However, the crucian carp was well-suited to the northern climate; it grew quickly if properly tended, and it produced a good yield. By contrast, the common carp was hard-pressed to survive the harsh northern winter. Northern Europe's climate does not allow carp to reproduce either. The crucian carp, however, can be maintained under anoxic conditions for months. It is therefore a very useful species as a pond fish under the conditions northern Europe offers. Both clerical and lay landowners constructed and owned fishponds.

The domestication of the carp, *Cyprinus carpio*, occurred in southeast Europe in the Danube basin during medieval times. Various domesticated varieties have also been available for a long time, especially the leather carp and mirror carp. The tench (*Tinca tinca*) has been kept for food production since late medieval times and it also had a reputation of being good for other cyprinids in the ponds, keeping them healthy.

Ornamental fishponds containing cyprinids have also been kept in ponds for ornamental purposes although only the goldfish has been discussed at length by historians. Crucian carp seems to have been common in ornamental ponds in the seventeenth century. However, with increasing contact with park culture on the continent, various golden varieties of cyprinids were primarily kept for ornamental purposes in garden culture. Other cultural varieties of indigenous cyprinids have also been kept for ornamental purposes. In addition to the crucian carp, four species of cyprinids dominated in the park culture in older times: carp and its varieties, goldfish, and its varieties, and the golden variety of tench known as golden tench, and the golden variety of ide or orfe, *Leuciscus idus*.

The carp is a stunning pond fish, but due to its sensitivity to cold water has been rarely kept in northern Europe. The domesticated mirror carp

FIGURE 30: The Crucian Carp, *Carassius carassius*. It can handle many different environments. Although a warm water fish, it can survive in lakes by lying and pressing against the mud at the bottom of a lake that is not frozen.

FIGURE 31: The fishpond at Skabersjö castle, Scania, Sweden

has been kept in larger garden ponds. Color varieties were developed in Japan in the early nineteenth century. In 1914, color-breed carps were put on show at an exhibition in Tokyo, which was the beginning of interest in the so-called Koi carp in Japan and a real craze for these beautiful fishes developed. Soon exports of Koi carp began and eventually spread worldwide. The name Koi carp is actually a tautology (Koi meaning 'carp' in Japanese). In Japanese they are referred to as nishikigoi, literally meaning 'brocaded carp'.

F1. GOLDFISH

The goldfish that reached Western Europe with their beauty and color attracted the attention of royal courts and academies and no native species could remotely compare with the golden newcomer from China. It was bred for the first time in the Netherlands in 1728 (Tyrbjerg 2006). Few details about its introductions are known though, and therefore some details about its early presence in Sweden may be of interest, based mainly on research by Svanberg (2007).

In Sweden, the goldfish has been known since the 1740s. With the help of Swedish ambassador Nils Palmstierna, the Swedish Academy of Sciences received a preserved goldfish, which was and described by Carl Linnaeus in the proceedings from the academy in 1740. Interestingly enough, Linnaeus also published some information about its care. It was still a fish kept in bowls, not in ponds, in Scandinavia, and it was recommended that it be given fresh water two-three times a week. It should be fed with biscuit, egg yolks, dried lean pork and small snails. It is however unclear if Linnaeus had any personal experience of live goldfish (which he actually might have had from his years in the Netherlands). However, the information he gives about the care of goldfish bears witness that he had received information from someone who knew. One of the depicted gold fish was obviously a fantail.

Linnaeus never ceased to be fascinated by the beauty of the goldfish. In 1744, the merchant Carl Gyllenborg donated "Chinese goldfish" to Linnaeus, but they were preserved in ethanol. Linnaeus was eager to get hold of live fish. In November 1745, he wrote instructions for his pupil Christopher Tärnström that he should bring back goldfish for the queen from his tour to East India. However, Ternström unfortunately drowned in south-east Asia and was never able to complete the task. Linnaeus's enthusiasm for the

FIGURE 32: Nils Palmstierna (1696-1766). A Swedish politician, he was responsible for bringing the goldfish to that country in the 1740s.

goldfish was undiminished. He received further preserved goldfish for his zoological collections from the royal court and King Adolph Fredric and his queen probably kept goldfish in the ponds at the royal palace of Drottningholm.

In 1759, an opportunity arose for Linnaeus to receive a goldfish. One of his pupils, the physician Pehr Bjerchén, was staying in London and kept up a lively correspondence with Linnaeus. He asked Bjerchén to find goldfish for him. Linnaeus became very enthusiastic when he received a letter telling him that Bjerchén had traced down a breeder in his colleague Richard Guy. He had a pond at his country estate with 50 to 60 goldfish. Guy of course was very careful about his rare fish, but Bjerchén persuade him to donate a couple to the world-famous professor in Uppsala. Bjerchén brought them back by ship to Gothenburg. Linnaeus wrote impatiently in September 1759, "Do please send the goldfish already tomorrow with a vessel to Uppsala; they do not freeze that easily; so I will be able to once again see them, something I have dreamed of all my days but never hoped. Let the skipper ask what price he wants, only I get them alive". He finished the letter, "God give I had them alive in my orangery."

Apparently, thrifty Linnaeus was prepared to pay quite a sum to get his coveted goldfish. Bjerchén sent the goldfish together with detailed information about how to take care of them. It is a very interesting sheet of instructions with information about keeping the bowl clean, the importance of fresh water and how to feed the goldfish. In October 1759, one fish was already dead, but the other specimen survived at least the winter and was alive the next year. Dr Guy in England promised to provide Linnaeus with further specimens. More goldfish were offered by Job Baster, a Dutchmen who was breeding them in open-air ponds. It is, however, unclear if Linnaeus received any more live goldfish (Svanberg 2007).

In the late eighteenth century, the goldfish was widely kept in southwestern Europe. In 1780, Louis Edme Billardon de Sauvigny published a famous book about the Chinese goldfish with excellent illustrations. In his book on companion animals, Johannes Matthäus Bechtein (1795: 222–226) gives a rather detailed description of keeping goldfish. The golden tench is mentioned by Marcus Bloch (1777) and seems to have originated in central parts of Europe, probably Bohemia and Silistria. It spread early to other parts of Europe and was kept as an ornamental fish for garden ponds (Shaw and Stephens 1804: 217–218). Another domesticated fish is the golden ide or orfe, which probably came from Germany and seems to have been common in continental fishponds already in the seventeenth century. Leonard Baldner named it "Goldgelbe Rottel" in his manuscript, "Recht natürliche Beschreibung und Abmahlung der Wasservögel, Fische, vierfüssige Thieren, Insecten, und Gewürmb, so bey Strassburg in den Wässern seynt, die ich selber geschossen und die Fisch gefangen from 1666" (Lauterborn 1901).

G. ENGLISH FISHPONDS

FIGURE 33: Pehr Bjerchén, one of Linnaeus' pupils, who shipped live specimens of goldfish to Linnaeus in Uppsala in 1759.

The balance of evidence indicates that fishponds were introduced into Britain after the Norman Conquest (1066) as a secular aristocratic initiative rather than a monastic innovation. Some of the earliest ponds on monastic holdings were actually donated by lay benefactors, and there is no indication that English monasteries adopted a policy of extensive pond construction before the later twelfth century. Investigations of monastic accounts and excavations of dumps for kitchen wastes have now demonstrated beyond question that marine species were extensively marketed, even deep into the English midlands, and contributed far more to the regular monastic diet than freshwater fish. Despite the efforts that went into their construction, the output from monastic ponds can rarely have been sufficient to meet even basic subsistence needs, let alone producing regular surpluses for commercial sale. Other explanations must, therefore, be sought.

Fish in the monastic diet of The Rule of St Benedict, the most widely-applied monastic rule throughout north-western Europe, did not literally promote the consumption of fish: it merely required abstinence from the flesh of four-footed animals by all but the sick. In England, its endorsement and strict observance was not universal before the twelfth century. When Simeon, first Norman prior of Winchester (d. 1082), found the monks there eating meat, he persuaded them to change their ways by having the cook prepare exquisite dishes of fish. Thereafter, observance of customary fish-days every Wednesday, Friday and Saturday, and throughout the season of Lent became well established among the English Benedictines and was generally respected through to the Dissolution, though the prohibition of meat-eating on other days was relaxed later in the middle ages. Different religious orders developed dietary regulations of varying severity. Even when strict abstinence from meat was no longer enforced, marine fish remained readily available and cheap and economic pressures ensured that fish continued to make a major contribution to monastic diet right up to the Dissolution. At Winchester Priory, fish formed the main course of the main meal on 165 out of 278 days between December 12th 1514 and September 19th 1515, 59 per cent of the documented days.

Both documentary and archaeological evidence make it abundantly clear that saltwater fish were consumed in far greater quantities than freshwater fish. Notes of purchases of large numbers of herring and cod abound in monastic kitchens' accounts, and in 1491 over 45 per cent of Winchester Priory's total food expenditure was on marine fish. Even on sites far inland, deposits of monastic food refuse have consistently yielded far greater quantities of bones of sea-fish than of freshwater species. In turn, river fisheries provided far more freshwater fish than managed fishponds. Why, then, are fishponds such a prominent feature on many monastic sites?

The answer almost certainly lies in the concept of

FIGURE 34: View of Whitby Abbey over the fishpond.

exclusivity. Fishponds were costly to construct and to maintain. Pike (*Esox lucius* L.) and bream (*Abramis brama* (L.), their most esteemed products, were considerably more expensive on the open market than herring or cod. Grants to monastic communities of fishing rights in rivers and secular ponds sometimes **imposed** conditions that the catch should be reserved for particular feasts and anniversary commemorations of the deaths of members of the patronal family. In the 1090s, William de Warenne, Earl of Surrey, allowed the Cluniac monks of Lewes to fish in his waters for the great feasts and for the memorial of his parents. Another purpose was the entertainment of important visitors. The large fishpond of Battle Abbey was fished out in 1275 in anticipation of the king's arrival.

Fishponds were never intended to supply the entire subsistence needs of monastic communities, let alone to produce revenue from sales. Their primary purpose was to provide more prestigious meals for special occasions. In support of this contention, the yields from monastic ponds remained relatively meagre, primarily because the fish were left to forage on natural resources. Without supplementary feeding, a pond one acre in extent was able to support only about 200 lbs. of bream; but since bream take five years to reach edible size, it could produce only about 40 lbs. per annum. Assuming 175 fish days a year at which each monk would receive a minimum of 0.37 lbs. (0.51 lbs. of unprepared weight) of fish per day in order to meet its entire needs, a small house of ten monks would need to produce 850 lbs. each year, which would require 21acres under water; a large house of 40 brethren would require 91 acres. Furthermore, the needs of guests, monastic pensioners and servants also had to be met. Even allowing for catches from outlying estates, few monasteries in Britain had ponds on this scale.

The chronology of monastic fishponds English monastic chronicles, charters and accounts contain many incidental references to fishponds but they fail to provide a secure guide to the chronology of construction. The earliest purported references to fishponds on any monastic property occur in two charters claiming to record royal grants of land to the Benedictine abbey of Abingdon in AD 958–9 and AD 968. Both charters had boundary inspections attached, referring to the same fishpond. This has been identified with an artificial rectangular pond within the modern parish of Appleton-with-Eaton. Unfortunately both charters are of dubious authenticity, and the bounds are certainly later than their nominal date. Neither, therefore, proves the existence of artificial monastic fishponds as early as the tenth century.

G1. THE DOMESDAY BOOK

The Domesday Survey compiled by order of William the Conqueror in 1086 contains only two records of fishponds at Benedictine abbeys: Bury St Edmunds had two *vivaria vel piscinae*, St Albans one *vivarium piscium*. The Domesday record of fisheries is, however, inconsistent, and it is entirely possible that further monastic ponds may have escaped notice. The appearance in Britain of regular canons and various reformed monastic orders dur-

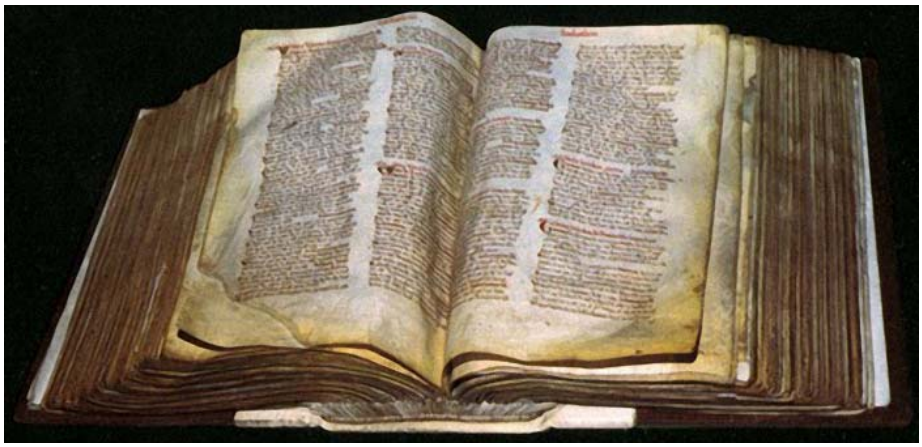

FIGURE 35: The Domesday Book is actually composed of two volumes; here shown is the larger of the two, the Great Domesday book.

ing the twelfth century opened up new links with the continent, which perhaps contributed to the wider adoption of pisciculture. Records of fishponds on monastic properties begin to proliferate only after the middle of the twelfth century.

Many of the earliest examples were pre-existing ponds given to monasteries by lay benefactors. A writ of Henry II permitted the monks of Selby Abbey to have a fishpond "which existed when the abbey was founded," *i.e.*, before 1070. William Ferrers, Earl of Derby, gave the monks of Tutbury a fishpond at Stanfordunder-Needwood around 1170. Religious houses were also often granted special fishing privileges in ponds belonging to their patrons. Geoffrey de Clinton, founder of the castle and priory at Kenilworth, confirmed to the priory canons before 1173–4 the right to fish "with boats and nets" in the large artificial lake alongside the castle on Thursdays. There are many other examples of monastic houses acquiring from secular lords rights in or possession of fishponds before 1200.

The first known record of a monastic initiative in construction is the fishponds made by Abbot Adam (1160–89) on the lands of Evesham Abbey, though unfortunately, the chronicler does not locate them. Fishponds are also recorded on the estates of Pershore Abbey and Fountains Abbey before 1200. References to monastic fishponds become much more numerous during the thirteenth century. To some extent this reflects the increasing range of available sources, but it also coincides with a period of direct exploitation, when enterprising abbots were investing in a wide range of improvements to their lands. Abbot Randulph (1214–29) undertook many new works on the Evesham Abbey estates, including the making of new fishponds at Evesham itself and on at least five outlying demesnes [*i.e.*, lands attached to a manor and retained for the owner's own use]. The Cistercians of Waverley completed construction of a fishpond some 5 km south of the abbey in 1250–51 and the Cistercians of Beaulieu were constructing a causeway alongside their large pond at Sowley in 1269– 70. Though the regime of watermills was not ideally suited to raising fish, Stoneleigh Abbey's millpond at Cryfield was producing perch (*Perca fluviatilis*), roach (*Rutilus rutilus*), bream (*Abramis brama*), tench (*Tinca tinca*) and pickerel (*Esox lucius*) in the 1380s.

Because watercourses so often formed property boundaries, it was a common occurrence for a religious community to be granted land on one side of a stream only. To utilize the valley floor for fishponds, therefore, required negotiations with neighboring landowners. When Byland Abbey decided to construct a new pond in the Wakendale Beck valley in 1234–5, the monks acquired permission to construct a dam and to have a right of way round the western margin of the pond on their neighbor's land for fishing and drawing nets; but if the pond overflowed an adjoining thoroughfare, they would be required to replace the road.

Construction and management of valley-bottom ponds normally necessitated the diversion of the natural stream into a canalized leat [i.e., an artificial water trench]. Such realignments could involve considerable engineering works, as at the priory of Orford. When the surroundings of the Cistercian abbey of Bordesley were first surveyed in the 1960s, it was realized that the entire flow of

FIGURE 36: Great Chalfield Manor and fishpond, near Bradford-on-Avon, Wiltshire. It is a moated manor house built around 1465-1480.

the River Arrow had been diverted out of its natural bed and canalized along the side of the valley for about 1 km to create space for two large parallel fishponds and a separate millpond; subsequent excavation indicated that the river diversion had taken place before about 1180). The creation or enlargement of fishponds usually required the sacrifice of land previously used for other productive purposes, while interference with the natural drainage might cause unintentional flooding nearby. These were frequent causes of conflicts. The Bury St Edmunds chronicler recorded how Abbot Samson (1182–1211),

Raised the level of the fishpond at Babwell […] to such an extent that […] there is no man, rich or poor, having lands by the waterside […] but has lost his gardens and orchards. The cellarer's pasture on the other side of the bank is destroyed, the arable land of the neighbors is spoiled, the cellarer's meadow is ruined, the infirmarer's orchard is drowned through the overflow of water, and all the neighbors complain of it. Once the cellarer spoke to him in full Chapter concerning the magnitude of the loss, but the abbot at once angrily replied that he was not going to give up his fishpond for the sake of our meadow (Butler 1951: 131).

In the 1270s the Augustinian canons of Cirencester enclosed land at Duntisbourne in order to make a new mill and fishponds, provoking complaints from the Benedictine monks of Gloucester, who claimed that the waters encroached over land where they had rights of common pasture. The Gloucester monks were persuaded to relinquish their claim in 1275.

G2: NOBLESSE NOT SO OBLIGING

From this time to the accession of Henry II, considerable progress was made in the cultivation of fishponds. History records the immense sums expended by this monarch in building palaces and castles, and in renovating others in various parts of the country, never omitting those important medieval acquisitions, the fishponds. Half a century later we find they are made a subject worthy of comment in the legislature. Again, in the year 1275, we find in the Statute Book an Act of Parliament passed avowedly to punish with rigorous pains and penalties those found poaching or otherwise damaging them.

In order to show the necessity of this and ulterior laws against poaching and otherwise despoiling fishponds, the following instances are some examples. Destroying the fishponds of noblemen and gentlemen appears to have been a favorite amusement of the mob in the olden times (Nichol, 1795-1811):

In 1328, the new Earl of Lancaster, out of dislike of the proceedings of the king's mother and Mortimer, refused to be present at the Parliament held at Salisbury, where John of Eltham was made Earl of Cornwall, Roger Mortimer Earl of March, Edmund Boteler Earl of Ormond; all of whom, with their adherents, gathered a great army and ravished the lands of the Earl of Lancaster; and, particularly, coming to Leicester on the day before the nones of January, staid there and in the adjacent country eight days, making great havoc and spoils, destroying woods, parks, and fishpools, and carrying away all that they could

FIGURE 37: The expansive grounds located just south of the 78-foot-high great tower erected by William, Lord Hastings, at Ashby de la Zouch Castle contain a series of unusual sunken forms that are the remains of ornamental ponds containing fish.

lay their hands on.

In the petitions to the House of Commons during the year 1649, there is one from the Earl of Rutland, dated March 28, wherein he makes the complaint that a horde of riotous miners had lately entered into his lands, broke up his pleasure-grounds and destroyed his fishponds. This petition evidently referred to his lordship's seat of Nether Haddon, in Derbyshire, where he resided after Belvoir Castle had been demolished by the Cromwellian forces. It is almost needless to add that the fishponds at Belvoir shared a similar late (Nichol, 1795-1811).

In 1381, the mob, excited by Tyler and Straw, demolished John of Gaunt's house and his fine fishponds in the Savoy, London. In the reign of Edward III (1327) a mob destroyed the fishponds of the Abbey of St. Edmondsbury in Suffolk, "and took out such store of fish as they found in the same." In 1377 a dispute between the retainers of the Earl of Warwick and the tenants of the Abbot of Evesham resulted in the fishponds of the latter being demolished by the rabble.

The ponds at Croyland Abbey, Lincolnshire were frequently sacked (Hollingshead, 1577). These were amongst the oldest in the country, having been bestowed upon the monastery by Ethelbald, king of the Mercians, 716AD. They were likewise the most unfortunate, having been perpetually in hot water, either through encroachments, riots or legal squabbles. The secret of this was their extraordinary value; the fish they yielded being worth more than £5,000 per annum in modern currency. We might begin in the year 1280 and follow a multitude of legal and arbitrary cases concerning them, but suffice be it to commence with the year 1415. Thomas Wake, Lord of Laddie, wanted to have some of the Gogeslound ponds, to which he alleged a legal right. The abbot disputed his claim, whereupon the case was tried and the jury found for the plaintiff.

All the jury," said the chronicler, **"who determined the matter by a false, unjust and disinheriting (*ex hereditaria*) presentation, came to violent ends, by palsy, dropsy, phrensy [i.e., frenzy] or other misfortunes, and the foreman who returned the verdict had his tongue swollen so by it that he could not get it back into his mouth, but came to a shameful end."**

From this verdict the abbot appealed and when he won the appeal Wake was condemned in misericordia regis (i.e., the King's mercy). Still the persecution went on against the poor abbot until the 12th of May, 1432, a mob came, armed with swords, sticks, bows and arrows, and fished in the abbot's separate pond out of which they took 1,000 dentrices [pike], 1,000 tencas [tench], 1,000 rochias [roach], and 10,000 anguillas [eels], and carried off the nets and other ingenia [i.e., fish and eel traps] for catching fish, together with 600 dead geese and gulls to the amount of about $15,600 in damages. A special jury was summoned the following year, and the sheriff had orders to fine them in default of not appearing,

FIGURE 38: The Valle Crucis Abbey in Wales. The fishpond provided a ready source of food for the monks who were forbidden by their vows to eat meat. The pond is the only surviving monastic fish pond in Wales, but most monasteries without fishing rights would originally have had one or more such ponds.

and they were all sent to the Fleet Prison in London "save Hugh Cross, of Croyland, who was then with his uncle, Humfrey, Duke of Gloucester, in Picardy."

Thousands of episodes might be mentioned by which we could trace their progress and importance in those so-called dark ages. Even Chaucer tells us in his Franklin's Tale: "Many a luce [i.e., a fully grown pike] and pike had he in stew."

G3. THE MIDDLE OF THE FOURTEENTH CENTURY

Documentation for monastic fishponds declined markedly after the middle of the fourteenth century. Archaeological evidence suggests that pike consumption, reaching a modest peak after construction of the abbey ponds in the early thirteenth century, thereafter declined steadily to the Dissolution. It would be easy to dismiss the later middle ages as a time of declining interest in fish production, as monastic landholders, experiencing the same economic difficulties as lay lords, began withdrawing from direct farming, leasing out their ponds with their outlying demesnes.

A property leased out by Quarr Abbey in 1430 included a fishpond and Winchester Priory's two ponds at Fleet were also leased out by 1491, the prior agreeing to provide the timber necessary for maintenance of the intervening causeway. Whereas Ramsey Abbey continued to derive considerable income in the fifteenth century from leasing its fisheries in the rivers and natural meres of the Fenland, rents from artificial fishponds were generally low. Winchester Priory asked only $50 per annum for the Fleet ponds, little more than the value of the 100 fish which the lessee was required to send to the priory each year. Low rents probably reflected the expectation that the lessee would provide his own breeding stock, exactly as would be the case for leased pasture land.

Despite the general move towards leasing, however, fishponds within the precinct and those belonging to manors which had been retained as residences for monastic officials were usually kept in hand. At Titchfield, land abandoned after the Black Death had been utilized for a new fishpond before 1393 and both here and at Southwick archaeological evidence confirms that the ponds were not only maintained but also enlarged. New ponds were made at Eynsham before 1360, and ponds at Abingdon and Selby were still producing fish into the fifteenth century.

G4. FISHPONDS: LAYOUT AND FORM

There is little difference in characteristics of siting, construction, form or management between monastic and secular fishponds in Britain. The layout of ponds within or just outside monastic precincts depended upon a number of factors, of which the most important were the physical characteristics of the site and the amount of space available. In areas of accentuated relief, ponds were confined to chains along narrow, steep-sided valleys, where dams were easily constructed. Where the site was generally level the course of leats bringing in and removing water required more careful surveying, and more earth-moving was needed to excavate beds and provide retaining banks; but there was greater scope to create more elaborate arrangements of ponds for more convenient management. On the whole the reformed monastic orders settling in remote locations had better opportunities to lay out more extensive arrangements of fishponds, simply because they had more space, whereas the older Benedictine abbeys and the later friaries were

FIGURE 39: Manor House and fishpond, Long Clawson, Leicestershire.

more frequently in congested urban settings.

One important late medieval innovation was the introduction of carp (*Cyprinus carpio*). Carp already dominated continental fish-farming by the early fourteenth century and had been kept in Britain since the fifteenth century; yet no evidence has been found for their presence in monastic ponds before 1530 when the Prior of Llanthony by Gloucester sent a gift of carp to the king. When Prior More placed "certain carp fisshes" in his Worcestershire ponds in 1531–32, he does not seem to have regarded them as a particular success.

G5. EUROPEAN LITERATURE ON FISHPONDS

The culture of fishponds also became one of literary importance. One of earliest manuals for cultivating cyprinids in fishponds was written by the Swedish friar Peter Magni in 1520. He dealt in detail with how to keep crucian carp in ponds. However, it was never printed and therefore did not reach any audience. There are a few printed sixteenth-century treatises on freshwater aquaculture from central Europe. The first, and in point of data, the most important writer on this subject, was Scala (John) Dubravius, Bishop of Olmutz, in Moravia, early in the sixteenth century. He was born at Plitzen, in Bohemia, and died Sept. 6, 1553, having acquired the reputation of being a pious and enlightened prelate. The functions of the episcopate did not prevent him from being an ambassador in Silesia, afterwards in Bohemia and subsequently president of the tribunal touching the troubles of Smalkalde (The *Schmalkaldic* League was a military alliance of Lutheran princes within the Holy Roman Empire during the mid-16th century). He is the author of several works, the most important of these being a history of Bohemia in thirty-three books executed with fidelity and accuracy, and *De Piscinis*, a treatise on fishponds. In the latter he exhausts the entire subject, every minutiae being delineated with a master hand. Nothing escaped his powerful penetration, and parallels were drawn from the ancient authors, more distinctly illustrating any obscure definition where such arose.

But the work was only applicable, in a general sense, to the country which it so faithfully depicted The culture of ponds in Moravia, with all its ramifications, is inapplicable to England, save when such manipulations are altered and modeled to meet the requirements of a different sphere. Nevertheless, it has been the textbook to all subsequent writers on this economy, though altered to meet the several requirements which arose in different cases, which practical experience alone can truthfully indicate. As far as it concerned Moravia, Bavaria and Saxony, it was an infallible guide. One point, however, I cannot omit to mention. In his book he mentions the profits that were in those days derived from fishponds in his native country. He describes those belonging to Janus of Berenstenie, "the rich ruler and alderman of Bo-

FIGURE 40: Scala (John) Dubravius (1486-1553), Bishop of Olmutz and author of *Libellus de piscinis et piscium.*

hemia and Moravia," who he states annually derived three times the amount that Cato received from the ponds of Lucullus, which represent £9,375 per year in today's currency.

The bishop's treatise soon acquired an immense reputation, and became known in almost every country. In 1599, George Churchey, Fellow of Lincoln's Inn (one of the four Inns of Court in London to which barristers of England and Wales belong and where they are called to the Bar), published a translation of it in English, very few copies of which now remain. Dubravius's efforts were emulated by English writers, as follows. In 1590, by Leonard Mascall; in 1686, by Richard Blorne; in 1715, by the Hon. Roger North; in 1727, by Professor Bradley, F.R.S.; in 1800, by the Bight Hon. Sir Joseph Banks, Bart.; in 1804, by Sir Edward Lytton, Bart.; in 1805, by the Rev. Charles Maxwell; in 1806, by J. Loudon, F.R.S.; in 1812, by the Rev. *W*. B. Daniel, and in 1841 by Gottlieb Boccius.

The second manual was published in 1573 (second edition in 1605) by Olbrycht Strumieński (?–1609), a nobleman and manager of fishponds in the vicinity of Kraków. He wrote the book at the request of his friends, who valued his experience in aquaculture very highly. In the introduction he stated that "some respectable persons" had written works in Latin, but he did not know them. Due to the popularity of carp aquaculture, his book was plagiarized by Stanisław Stroynowski and published twice, in 1609 and 1636. These manuals give us insight into how aquaculture was conducted in early modern times.

G6. AFTER THE DISSOLUTION

Monastic fishponds after The Dissolution of the Monasteries (1536–40) was accompanied by much plundering of monastic resources. Some of the men who rose to positions of wealth and power in the wake of the Dissolution acquired former monastic premises for their private residences and redesigned their gardens and fishpond systems. Thomas Wriothesley, 1st Earl of Southampton, acquired Titchfield Abbey in 1537. Almost immediately he added four new fishponds and acquired 500 carp to stock them, hoping that future sales of carp might yield $400 or $600 a year. The ponds continued to supply carp at least up to 1741. In 1542 Wriothesley further stocked the Titchfield ponds with 1,400 fish, including bream, pike, tench and perch, supplied from Sowley Pond, formerly the property of Beaulieu Abbey.

A survey of the site of the Cistercian abbey of Old Warden recorded a substantial dam some 5m high and over 220m long, which would have retained a large lake in the valley immediately south-east of the abbey. This was equipped with a diversion channel, and probably is of medieval origin. Ridge and furrow in its bed may indicate a rotation of fish-rearing and agriculture. However, earthworks of a more intricate complex of small rectangular ponds and channels immediately south of the former cloister buildings seem not to be of monastic origin, and were more probably associated with the gardens of the great house built by Sir John Gostwick soon after he acquired the abbey site in 1537 (Baker 1982).

FIGURE 41: The actions of Henry VIII led to the dissolution of the monasteries during the 16th century and their fishponds were acquired by private estates. This is one of such examples, the fishpond of Warden Abbey in in Old Warden, Bedfordshire.

Earlier assumptions that monastic houses had played a leading role in the development of fish culture in Britain can no longer be upheld, though they undoubtedly made extensive use of methods previously shown to be effective on lay estates. Despite the efforts which went into the construction of monastic ponds, reliance upon fish foraging for their own food limited productivity. There is no evidence for supplementary feeding becoming general practice.

It has often been stated that monastic communities led the way in commercial fish farming but fish were not generally consumed by monks before the late thirteenth century. The view that monastic fishponds could have a commercial aspect is not entirely without foundation, since surviving gardener's accounts from Abingdon Abbey record receipts from sales of surplus fish on two occasions, but this seems to have been a localized and relatively late development, and there is no evidence that such practices were widespread.

H. FISHPONDS IN COLONIAL AMERICA

As mentioned in the previous section, during the seventeenth century, it was common for the estates of the great lords and of the middling gentry to include fishponds. These ponds were stocked with young fish or fry seasonally, and the fish were kept fed until they were needed for the dinner table. When English colonists came to the New World, they abandoned this practice. The development of such ponds in the American colonies during the second half of the eighteenth century marked the culmination of a long process by which British-American colonists adapted to the declining abundance of natural wildlife in long-settled regions. The development of fishponds as an increasingly important and integral component of American mixed husbandry practices in long-settled areas by the era of the Early Republic illustrates colonial American farmers' need and ability to adapt the English system of mixed husbandry to the changing environment of the New World.

In colonial America, as in early modern England, mixed husbandry as a mode of production embraced a wide array of distinct economic activities. "The chiefe and principall point of a good Countrey farme," according to the author of a seventeenth-century farmers' manual entitled the *Countrie Farme*, "is to want nothing, either needful…or available for the profit that may come thereof." Even farmers with small holdings, who could command only the labor of themselves and their families, sought to secure a competency out of their lands through a strategy of diversified production. The farmer/husbandman divided his lands between timbered areas for collecting firewood and building materials, cleared lands for raising grains and garden vegetables, orchards for growing fruit for cider, pastures for grazing livestock and meadows for growing hay. Besides properly cultivating and managing his lands, the ideal farmer also turned his improving energies to the waters within and abutting on his properties.

The *Countrie Farme* continued, "the good householder then shall not esteeme a little of Fish, seeing that of them he may make both a provision of his table, and great gaine unto his purse." Fish-

FIGURE 42: A typical Colonial farm fishpond.

ponds offered one way for the farmer, whether his lands were in England or the colonies, to help assure himself and his household of an economic competency and financial independence.

But for the greater part of the colonial period, until the latter half of the eighteenth century English settlers in North America chose to forgo the construction of fishponds, instead relying upon the bounty of nature to supply them with fish. What coolonial husbandmen of the seventeenth century actually husbanded - rather than their cows, pigs, sheep, or horses - was their labor, and with the superabundance of the natural waterways around them, colonial farmers saw little reason to waste their labor in digging a fishpond.

Early European visitors to the east coast of North America often commented on the superabundance of fish in the continent's rivers, lakes and streams. One visiting Englishmen wrote of streams choked with alewives "in such multitudes as is almost incredible, pressing up such shallow waters as will scarce permit them to swim." Thomas Morton, an English lawyer touring New England in the 1630s, claimed that in Massachusetts the river adjoining the house he was staying in stopped up with so many fish that they could have filled a ship of one-hundred tons and that "wagers have been layed that one should not throw a stone in the water but that he should hit a fish." As late as 1663, English physician John Josselyn declared the rivers and streams of New England to possess "an infinite of fish," and recorded the remarkable bounty of the many lakes and ponds that supplied the proliferating towns of English settlers.

As these examples make clear, the ponds and waterways filled with fish abounded in the areas of North America first settled by the English. But as a matter of custom, the waters of ponds and the fish they contained belonged to the commons, open to all within the community. And since these naturally occurring ponds most often served as boundaries between properties bordering on several parcels of land owned by various individuals, settlers had little incentive to conserve the fish in these communal waters.

H1. EARLY LAWS

It was only as the seventeenth century gave way to the eighteenth that the customary rights of early American settlers to fish resources yielded to the traditional practices of English mixed husbandry. By then the growing population of colonists in the areas settled earliest were beginning to place pressure on the resources of the land and water. In England, laws requiring dams and weirs to be opened to allow the passage of migratory fish dated back to the thirteenth century. Similar American laws passed during the eighteenth century may be interpreted as simply a direct expansion of English law to the new English colonies. But such laws also represent a common response to the shared dilemma of declining populations of migrating fish due to the obstruction of migration paths and to the overutilization of fish in general as a food resource.

By the early eighteenth century, colonial legislatures had begun to pass laws to protect dwindling fish populations. Among them was a 1715 act passed by the Connecticut General Assembly to prevent "stopping or obstructing the natural course of passage of fish in their season." The law prohibited the construction of all "wears [i.e., weirs], hedges, fish gears, disturbances or encumbrances" that might result in three of the colony's

FIGURE 43: A Colonial trout fishery.

largest rivers without first receiving government approval, and in later amendments fish-gates were required to be installed in all dams to allow the seasonal passage of migrating fish. This Connecticut act underwent a long series of revisions over the course of the 60 years from its passage in 1715 through the end of the colonial period. It was renewed regularly, its prohibitions expanded upon and new means of enforcement devised. Like similar legislation passed in other colonies at the same time, this act failed to have its desired effect.

Such acts represent an awareness on the part of the colonial assemblies that the migrating fish populations within its jurisdictions were under pressure and a desire to rectify the situation in order to ensure the continued availability of this resource for the inhabitants under their authority. The first response of colonial legislatures was to regulate the technologies (primarily seines and weirs) employed in harvesting river fish in order to ensure against depletion population and provide as many colonists as possible the "common privilege and benefit" of fishing.

From the 1720s onward, however, the assemblies also began to lessen the pressure on fish populations by granting exclusive rights to fishing along certain stretches of rivers and streams to private individuals. These rights were granted to individuals or partners for the construction of fish-stages [*i.e.*, wooden buildings], presumably with the intention of harvesting river fish not for personal consumption, but for sale at market. The trend towards privatization and commercialization of fishing rights, which had begun in Britain itself in the thirteenth century and which was largely complete by the end of the sixteenth, had now begun in Britain's American colonies.

H2. PONDS ON FARMS

American farmers did not rely exclusively on their representative bodies to secure their access to fish resources. Had they done so, they would have been sorely disappointed as colonial legislation failed to revitalize fish populations. As the eighteenth century progressed, more and more farmers began to construct private fishponds on their property. As wildlife resources declined, colonialists began a long but steady transition from the customary right for all colonists to exploit nature in common to private rights to own and exploit one's own land and the waterways that ran through it. Just as colonists began to feel the need to fence in and provide fodder for their terrestrial livestock as the eighteenth century progressed, they also began to dig ditches and build dams and to exert their energies in rearing fish for the table and for market.

A large farm listed for sale in Ulster County, New York by Mr. John Haskoll in 1739 included a large pasture of improved swampland that had been ditched and drained. A pond had been left in the pasture to provide Haskoll's cattle with a watering hole. Haskoll also kept the pond "well stored with a variety of fine Fish." Digging ditches and draining water represented a considerable investment of time and labor. It was this investment of labor in the improvement process, along with ownership of the property on which the efforts to improve had been expended, that granted Haskoll sole rights to the use of his pond and the harvesting of its fish.

In the seventeenth and eighteenth centuries, a working farmer had to be a jack-of-all-trades.

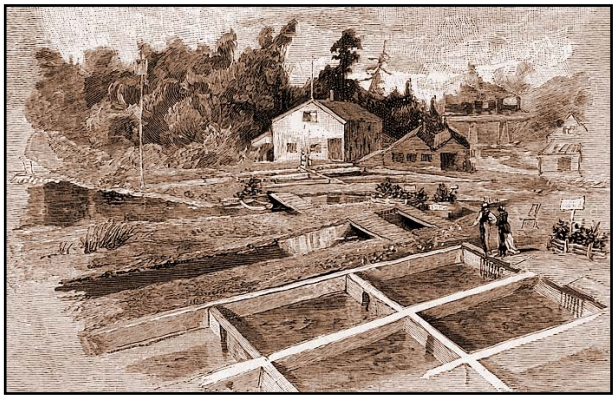

FIGURE 44: Sometimes fishponds were a significant part of farm operations in Colonial times.

Likewise, his ponds were expected to meet diverse needs. Landowners putting ponds to dual use as both fishing and watering holes followed the English example and came to be common practice among colonial husbandmen. A tract of land for sale near Peekskill, New York was advertised as possessing a pond "convenient for Cattle and for Fish." A twenty-five acre lot up for sale in Essex County, Massachusetts contained as "Part of the Premises" a "very commodious Fish Pond, and convenient for watering Cattle."

Where a naturally occurring watering hole was too shallow or otherwise unsuited for the stocking of fish, landowners raised water levels through damming. A farm for sale on Long Island in the 1760s contained a "large watering pond, which with the labor of eight or ten good hands for the space of one day, would raise the water 12 or 14 feet for a fish-pond." Taking advantage of naturally advantageous pools of standing water in the construction of his fishpond allowed the husbandmen to conserve his labor while still asserting his right to the property by improving the waterways on his land.

The ideal fishpond served as an integral part of mixed husbandry's system of diversified production. "Well Timber'd," with "large orchards of fine Fruits," and grain fields besides possessing a pond for keeping fish and watering livestock, John Haskoll's farm represented the ideal of mixed husbandry. Diversified production of fruit, grain, meat and fish provided the farmer with the economic competence that ensured independence, while also providing him with a surplus for sale at market. John Haskoll had not merely accepted the countryside as he found it, his swampland was drained and improved to provide pasture and pond. At their watering hole, cattle mingled with fish, both providing fresh protein for the farmer's table and fresh or salted fish and flesh for sale or trade to either rural neighbors or urban dwellers in nearby villages and towns.

THE DEVELOPMENT OF PRIVATE RIGHTS

By the mid-eighteenth century, the inadequacy of the natural supply of freshwater fish eventually led beyond the mere appropriation of rights to fish natural waterways by private individuals to the construction of artificial pools for first the holding and later the rearing of stocks of food-fish. Fishponds offered the advantages of smoothing out the irregular seasonal supplies presented by runs of migrating fish as well as perhaps offering the farmer the opportunity to farm more appealing species than those that inhabited his waterways naturally.

In the 1740s, a plantation was advertised near Philadelphia that included a "fine Spring where a Fish Pond might be made for little Charge." This Pennsylvania farmer obviously believed that a fishpond would represent a desirable improvement to his lands, one with the potential to help it sell. But the 152 acre lot also offered the benefit of two naturally occurring water ways, "two fine Streams running thro' said Place" with "plenty of Fish in said Runs such as Trout, Mullett, and Pike." Even without the investment of extra time and labor, this parcel offered the potential buyer ready access to food-fish. But here, as at the spring, opportunity existed for human design to improve upon the bounty of nature. "The Fish

FIGURE 45: A 1880s Carriage house barn fishpond.

might be kept in with little cost by putting a Grate" at the point where the two streams joined, creating another pond that would "afford room for the Fish to Play and Feed." As advertised, this plantation had much to recommend it to the industrious farmer.

A notice run in one of the local newspapers in 1784 by a landowner named John Harris living near Providence took a novel approach to appropriating the fishing rights to the brook that ran through his farm. For a number of years would-be fishermen had been crossing Harris' property to fish either in the brook running through his land or in the large pond on which it adjoined. Harris complained that these trespassers had been in the practice of throwing down his fences, using the fence rails and other of Harris's timber for fire, taking and destroying his hay and trampling his grain. While Harris recognized his neighbors' right to fish in the "main" brook where the road crossed over it, he denied their right to fish these public waters from his lands.

In his advertisement, Harris claimed for himself the exclusive right to fish the small brook that ran through his land, intending to offer his catch for sale at the "moderate" price of about $8 per every hundred pounds," though he also promised that "the Poor (that are really so) shall not be sent empty away." Harris justified this appropriation for himself exclusively of fishing rights that had customarily belonged to everyone within the community by pointing out the brook he meant to fish "crosses no Person's Land but my own."

As for the "main Brook" which ran clear through his property and then onto that of his neighbors, Harris promised neither to take fish from it nor to in any way obstruct their passing. Finally, Harris admonished his neighbors that if they did not find these terms satisfactory, he would dig a canal from the small brook to a natural depression on his land where the brook's waters would pool into a fishpond. If his neighbors failed to recognize his own self-declared exclusive rights to the fish swimming in the brook crossing his farm, then Harris was resolved to assert his rights through a more traditional avenue. He would build a canal to water a new fishpond, securing rights to any fish therein as the product of his labors in improving his land.

Essentially, Harris held the fish of the main brook hostage to gain the consent of his neighbors to his claims to the sole right to fish the smaller brook wholly contained within his farmlands. The reason Harris proposed terms for his neighbors' consideration is his apparent reluctance to expend the money and labor that would be necessary to dig the ditch that would water his new pond. Caught between ambiguous claims of private property and customary rights, Harris found it most expedient to compromise.

In the 1790s, an English gentleman touring America commented on a fishpond of between two and three acres in size on the land of an innkeeper named McAllister living in the countryside outside of Harrisburg, Pennsylvania. McAllister's pond sat on a farm of nearly three hundred acres, half of which was covered by woodlands, the rest encompassed by fields of rye, corn, and oats, pastures of clover and meadows of English hay for the maintenance of cattle, an orchard of peach and of apple trees, and a garden vineyard

FIGURE 46: A Colonial fishpond on an estate.

of grapes and strawberries. The farm also maintained its own cider press, a distillery for the production of rye whiskey and peach and apple brandy, a grist mill, a sawmill and an ice-house. In short, Mr. McAllister was the epitome of the gentleman farmer - an owner and improver of property engaged in a great diversity of rural production activities - and adjudged by his English guest to be the "most spirited and intelligent farmer" whom he had met during his travels. McAllister's fishpond yielded "all the kinds of fish which the river produces" presumably satisfying the hunger of the guests who frequented his public house and also possibly providing a surplus of fish for export to the nearby town, packed and preserved in ice from the store in his ice-house.

H4. POND ADVANTAGES

Whether or not McAllister used his pond to produce for the market, either for sale in Harrisburg or for sale in his own inn, he certainly made use of its waters to improve his yield of English hay. Besides yielding fish and providing watering holes for cattle, ponds also had the advantage of providing the farmer with a valuable manure for his grain fields. "The cleaning of ponds frequently is of great use," advised the *Complete Grazier*, "and it is done at no expense, because the mud, serving as manure to the lands more than pays the expense of taking it out." As the seventeenth century wore on and gave way to the eighteenth, successive generations of farming on the same plots of land made manuring as a means of restoring the nutrients to the soil became ever more important. By allowing the waste waters from his pond, rich in the detritus of decaying plant life and fish manure, to flow over his meadowlands, McAllister returned some of the nutrients to the soil that had been lost to haying.

Farmers regularly mowed their meadows annually or bi-annually, storing hay as fodder for their cattle during the winter months. Haying thus removed nutrients from the meadowlands where the grasses were grown, to the barnyard where cattle were fed when unable to be kept in the pasture. The dung collected out of the barnyard was then spread over the grain-fields in the spring, providing fertilizer for that year's crop. Chaff and loose grain, along with offal and blood from the slaughtering of livestock, made up the most common food items given to pond fish, bringing the process full circle and supplementing the nutrient load accumulated in the pond from run-off.

McAllister's pond represented the completion of America's transition from a settler colony of superabundance and common rights to fish resources to a settled nation of recognizably limited resources and private fishponds. This two-century -long process in America represented the continuation of a process towards an extinction of customary rights in favor of private property that had begun in England during the middle ages. The adoption of the rearing of fish in fishponds in concert with livestock rearing and grain cultivation by men such as McAllister by the end of the eighteenth century represented a culmination of American farmers' adaptation to self-wrought changes in the environment of North America's Atlantic seaboard.

Robert Warington (1807-1867): Professional Chemist

AJK Productions, Albert J. Klee, Editor, October 16, 2010

Editor's Note: Although I have written much about Robert Warington (Klee, 2012, 2015, 2016, 2019), it has dealt mostly with aquarium matters, although my short biography of Warington (Klee, 2015) did expand somewhat into his professional life, especially that of his association with the Society of Apothecaries. Recently, however, I have come across a detailed case study by Anna Simmons that provides an example of how chemistry in Great Britain could be commercialized outside the academic environment and how consulting merged into a broader scientific career. To do this, she based her paper on the professional career of Robert Warington (Simmons, 2020). Dr. Anna Simmons is an Honorary Research Associate in the Department of Science and Technology Studies at University College London. Her research and numerous publications explore various aspects of the history of British chemistry and pharmacy from about 1650 onwards, with a particular focus on the laboratories and pharmaceutical trade at the Society of Apothecaries (she has been associated with the Society of Apothecaries for more than twenty years) and the development of chemical careers and professional organizations.

Dr. Anna Simmons

Much of this paper is Simmons' although I have added to it and also edited it to make it more readable by American aquarists. Among other things, I have changed British spellings to U.S. and have replaced certain British terms (e.g., while for whilst). Simmons' paper is an academic one and she uses footnotes for both sources and for comments. Unfortunately, she uses a 7-point font for the footnotes and so they are not only difficult to read but they are voluminous (if they were converted to the 10-point font size of her text they would generally exceed the space taken by the text. Thus I have taken all source references from the footnotes and placed them into a Bibliography section at the end of the paper. Comments in the footnotes have been entered into the text in parentheses except for those that are of little interest to the hobbyist.

The whole point of Simmons' article involves money, money represented by the British pound symbol, £. American aquarists, however, are unlikely to know what these values mean (which change as the year changes) since she does not provide their present-day dollar equivalents. This I have remedied, thus the values given in square-brackets after their £-values are their present-day dollar-equivalents taken from Eric W. Nye's "Pounds Sterling to Dollars: Historical Conversion of Currency," accessed on October 4, 2020. All other square-bracketed text is mine.

INTRODUCTION

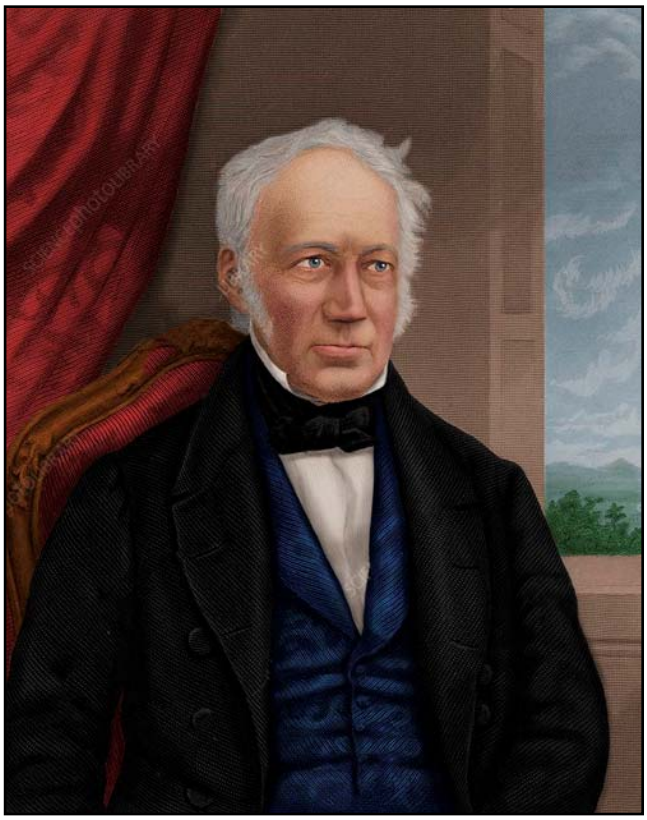
Chemistry was a saleable skill in mid-nineteenth century London and Warington was one of a number of chemists to take advantage of the opportunities available and for which data on his earnings are available. However, there are a number of other prominent chemists at the time for which earnings data is also available and I will start with short biographies of the most important of them.

The Glasgow-born chemist Dr. Andrew Ure (1778-1857) is considered to be the first chemist to earn a living primarily from consulting when, following his

controversial end to his teaching career in Glasgow, he set up in private practice as a consultant in London in 1830. He served briefly as an army surgeon before settling in Glasgow, where he became a member of the Faculty of Physicians and Surgeons in 1803.

On December 10, 1818, he read a paper to the Glasgow Literary Society on some pioneer experiments he had performed with the galvanic current on the body of Clydesdale, a murderer, and suggested that by early stimulation of the phrenic or vagus nerves or the great sympathetic in the neck, life might be restored after suffocation or drowning. These experiments caused a considerable sensation according to the Dictionary of National Biography, and found an echo in Byron's poem Don Juan. The following are some extracts from the published account of these experiments:

The murderer was a middle-sized muscular man of 30. He was suspended on the gallows for nearly an hour, and the experiments were made in the anatomy theatre within ten minutes of him being cut down. There was no dislocation of the neck. Dr. lire connected his galvanic rods firstly with the spinal marrow and the sciatic nerve through deep incisions, whereupon every muscle of the body was immediately agitated with convulsive movements resembling a violent shuddering from cold. On moving the second rod from hip to heel the knee being previously bent, the leg was thrown out with such violence as nearly to overturn one of the assistants, who in vain tried to prevent its extension. The body was also made to perform the movements of breathing, by stimulating the phrenic nerve and the diaphragm. In the judgement of many scientific gentlemen who witnessed this scene, this respiratory experiment was perhaps the most striking ever made with a philosophical apparatus.... Later every muscle of his countenance was simultaneously thrown into fearful action, rage, anguish, horror, despair, and ghastly smiles united their hideous expression in the murderer's face, surpassing far the wildest representation of a Fuseli or a Kean. At this period several of the spectators were forced to leave the apartment from terror or sickness, and one gentleman fainted.



Dr. Andrew Ure (1778-1857) is considered to be the first chemist to earn a living primarily from consulting.

1821 he published his first major book, "Dictionary of Chemistry," a replacement for William Nicholson's outdated Dictionary. It came out two years after William Brande's "Manual of Chemistry," and Ure was accused of plagiarism. Subsequently, Ure accused Dr. William Henry (an eminent vhemisdt) and Dr. Thomas Thomson of plagiarism of his own works. (Dr. Wollaston, a friend of both Ure and Henry, was asked to arbitrate, but compromised by appointing a friend unknown to either of them to do so. His report, a model of tact, proved agreeable to them both and their friendship was later renewed.)

He seems also to have obtained the unofficial offer of the Chair of Chemistry at University College, London, which was in the process of being founded by Lord Brougham, who as Lord Rector of Glasgow University and a great supporter of public education, knew and admired . Ure's pioneer work in this field.

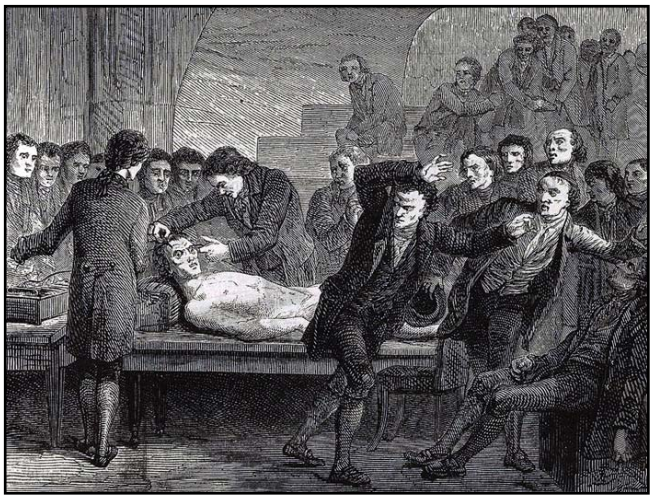
It was probably this possibility which finally decided him to move his family to London, which he did in 1830. The professorship, however, went elsewhere, as the result, it seems, of unexpected opposition fermented by Thomson, the Regius Professor of Chemistry at Glasgow, whose "First principles of Chemistry" Dr. Ure had reviewed somewhat harshly in the *Quarterly Journal of Science and Art* –"…a more arrogant and truly mischievous publication… The Regius Professor is taking Royal liberties with the labours and property of others!" In a private letter to Ure the Editor (William Thomas Brande, 1788-1866) wrote regarding another similar review "I have as usual blunted some of the shafts of your criticism ... just though they are!"

Ure set up in 1830 in private practice as a consultant in science in all its branches, and more particularly as an analytical chemist for commercial purposes. It was said of him by Sir Michael Faraday, after his death, that "his skill and accuracy were well known as well as the ingenuity of the methods employed in his researches'. . . and it has been stated that no one of his results has ever been impugned. His extensive knowledge enabled him to arrive at conclusions, and to demonstrate facts considered impossible by his compeers in science".

Some idea of the variety of his practice and "the amazing and varied fund of knowledge of applied science on which he was consulted from all over the world" (British Medical Journal) can be gained from the following brief list which has been culled from his letters or publications: The disinfecting of ships and their cargoes, bread-baking processes, distilling, a new process of amalgamating zinc and copper, analysis of a metal tool and an ointment found by Sir Gardiner Wilkinson in an Egyptian tomb, infringement of a patent concerned in piano construction, several photographic patents of his own, and the analysis of various types of coal for the Admiralty.

He also visited professionally most of the new Midland industrial areas, and some in France and Belgium, to advise upon technical improvements, chiefly in cotton manufacture, bleaching and dying processes, glass manufacture, and mining; many of the leading industrialists being old pupils of his. In 1833 he was requested by the Lords of the Committee of the Privy Council to undertake experimental researches into sugar refining, and his report was printed by order of the House of Commons, and led to the fixation of the sugar duties. He also undertook for them the investigation of methods of estimating the amount of sugar in sugar-cane juice,, for which he was paid £800 [$101,300]. In the following year he was appointed first consulting analytical chemist to the Board of Customs, a post which he held until his death. His friend Brande, who as Editor of the *Quarterly Journal of Science and Art* was relying increasingly upon his collaboration, secured him the post of Lecturer in Chemistry to the Surrey Institution, and later to the Royal Institution, where he had succeeded Sir Humphry Davy as Professor of Chemistry, and the Apothecaries' Hall.

William Thomas Brande (1788-1866) was born in Arlington Street, London, England, the youngest son of six children to Augustus Everard Brande an apothecary, originally from Hanover in Germany. He was educated first in Kensington and then in Westminster. After leaving Westminster School, he was apprenticed, in 1802, to his brother, an apothecary, with the view of adopting the profession of medicine. He studied medicine at Great Windmill Street Medical School and at St George's Hospital, before being drawn to chemistry following a meeting with Humphry Davy. He then began to lecture in chemistry, based on a sound knowledge of which he acquired in his spare time.



Le docteur Ure galvanisant le corps de l'assassin Clydesdale (Dr. Ure galvanizes the body of the murderer Clydesale).

In 1812 he was appointed professor of chemistry to the Apothecaries' Society, and delivered a course of lectures before the Board of Agriculture in place of Sir Humphry Davy, whom in the following year he succeeded in the chair of chemistry at the Royal Institution, London. In 1821 he was the first to isolate the element lithium, which he did by electrolysis of lithium oxide. From about 1823 onwards, Brande worked increasingly with the Royal Mint, eventually becoming Superintendent of the Coining and Die Department. Brande's *Manual of Chemistry*, first published in 1819, enjoyed wide popularity, and among other works he brought out a *Dictionary of Science, Literature and Art* in 1842. He was working on a new edition when he died at Tunbridge Wells.

It should be mentioned that Robert Warington became interested in what came to be known as the "balanced aquarium principle," reading the following from Brande's "A Manual of Chemistry":

In the year 1778, Dr. Priestley resumed this investigation, and verified his main conclusions by new and satisfactory experiments; he found, however, that it was necessary for their success, that the plants should be in a state of healthy and natural vegetation, and that all plants were not equally efficacious, some indeed appearing rather to deteriorate than improve the contaminated atmosphere. About this time too, Dr. Priestley made the capital discovery of the evolution of oxygen by aquatic plants, growing in water containing carbonic acid; that the presence of light was necessary to this change; that in sun-shine it was most rapid; that it was in great measure independent of warmth; and, lastly, that the bladders of some kinds of sea-weed, (*fucus vesiculosus*), often contained air purer than the atmosphere. The renovation of the air contained in water, requisite for the respiration of fishes, was thus accounted for; and the circumstance of fishes and most other aquatic animals being unable to live for any time in pure water, though exposed to air, satisfactorily explained.

John Thomas Cooper (1790–1854) was an English chemist, notable as a lecturer, chemical supplier and chemical analyst, at a time when interest was burgeoning in chemistry as a discipline of study and application. Cooper was born in Greenwich and studied and, for a short while, practiced medicine. Finding the life of general practitioner stressful and tiring, he turned instead to chemistry to which he applied himself with zeal. Until 1842 he lectured in chemistry at a number of establishments, including the Russell Institution, the Aldersgate School of Medicine, and the Webb Street School of Anatomy and Medicine in Southwark. Cooper acted as a manufacturer and supplier of chemicals, at one time the sole supplier of iodine in Britain. He devised or collaborated to produce a number of tools and techniques for which he won repute, including a hydrometer, an oxy-hydrogen microscope (the gasses providing a bright light-source), a baroscope, a refractometer; he also made improvements in electroplating, electric cell design and microscope mountings.

Cooper was employed as a chemical analyst and appeared at court as an expert witness on a number of occasions. He provided expert services to a Royal Society and Board of Longitude initiative to improve the optical qualities of glass and testimonials of the purity of a new line of brandy to its manufacturers for

Dr. William Thomas Brande (1788-1866).

use in its advertising. He discovered iodoform but did not publish, that honor falling to Georges-Simon Serullas. Cooper was vice-president of the London Chemical Society during its short incarnation. One of Cooper's students, Robert Warington founded the Chemical Society of London, and Cooper was an "energetic early Fellow." Cooper's name and excellent reputation is not entirely free from controversy, however. He is implicated in the support of a patent for the use of hyposulphite of soda to fix daguerreotype images, despite clear indications that he was aware of prior art demonstrated and published by Sir John Herschel.

Michael Faraday (1791-1867) was born in a working class south London neighborhood on September 22, 1791. Faraday was the first to produce an electric current from a magnetic field, and he discovered and named "diamagnetism", a concept that describes why some substances like copper react opposite to the magnetic force when they encounter a magnetic field. He discovered the effect of magnetism on light, and was the inventor of the electric generator and the electric motor. He is also credited with providing the scientific foundation for much of James Maxwell's groundbreaking work with electromagnetism.

Faraday's father was a blacksmith who suffered from chronic health problems that often impeded his labor. As a result, Faraday's family had little money and Faraday got only minimal formal schooling. In fact, he and his siblings sometimes had barely enough to eat. But Faraday had an active curiosity and determination to learn. While working in a London bookbindery as a teenager he was exposed to a wide range of books including textbooks and encyclopedias, and he read everything he could get his hands on. By doing extensive reading Faraday soon educated himself on a variety of scientific subjects, and his life as a scientist began.

In 1812, Faraday attended four lectures at the Royal Institution that were given by a renowned chemist named Humphrey Davy. Afterwards Faraday sent a letter to Davy, expressing a keen interest in the subjects covered in the lecture series and offering his services as an apprentice. A year later Davy accepted Faraday as his laboratory assistant. Davy also took Faraday with him on an extended tour of Europe, where Faraday met some of the most influential scientists of the day. Faraday returned to the Royal Institution in 1815 after 18 months of travel, and there he helped perform experiments with Davy and his colleagues.

Thanks to his association with Davy, the young Faraday gained a thorough scientific education. He soon began to do research and experiments with electricity, and he constructed two mechanisms to generate electromagnetic rotation, which is the force used to power electric motors. In 1821 he published an academic paper on electromagnetic rotation.

Although his time was mostly spent helping Davy, Faraday began to emerge on his own as a chemist and scientist of great importance. He began to give frequent lectures at the Royal Institution, and soon his reputation as a gifted lecturer was firmly and widely established. He published more research papers, including essays about optical illusion, the nature of gas condensation, and methods for isolating the chemical benzene, a chemical that he himself discovered. He is also credited with the discovery of other organic compounds, and he was the first scientist to liquefy a gas previously considered to exist only in a permanent gaseous state.

When his mentor Davy retired in 1827, Faraday took his place as the head of the chemistry department of

Michael Faraday (1791-1867).

the Royal Institute. Upon accepting the position he was able to focus on his own research, and Faraday's most influential and celebrated work began in the 1830s, while he concentrated on experiments with electricity.

In 1831, he discovered electromagnetic induction, a breakthrough that ushered in an entirely new era of technology. With Faraday's discovery it became possible to create such things as electrical generators and motors, and because of the practical nature of his discoveries, he was quickly awarded government grants and positions that enabled him to continue his work with electricity.

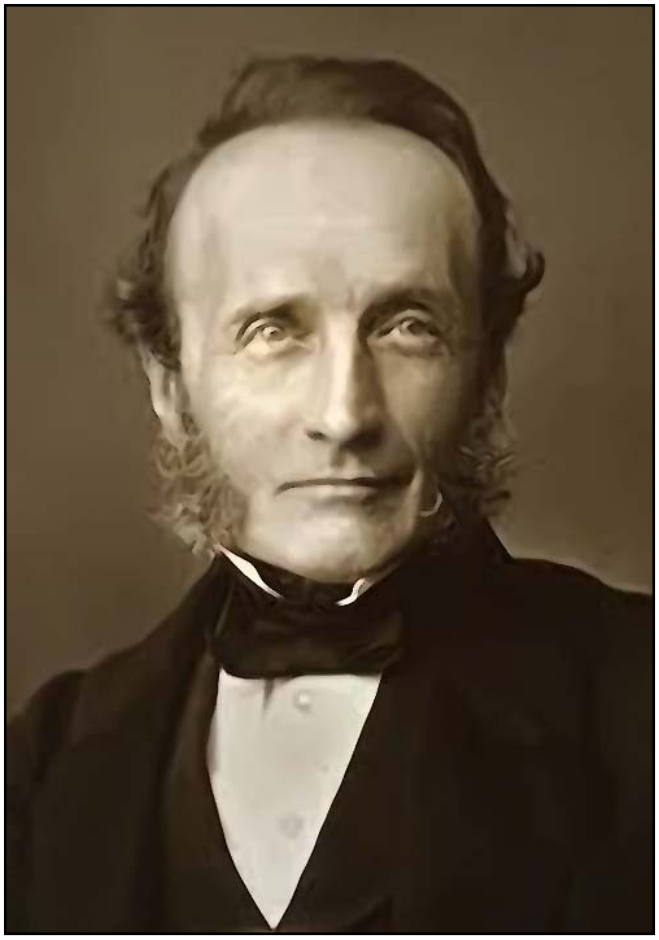
For the next eight years Faraday worked long hours in the laboratory, and the strain of his endeavor eventually took a serious toll on his health. By the end of the decade he was in such poor health that he had to take a break, and his research did not begin again in earnest until 1845. In 1846 he gave a lecture that presented important ideas about the nature of electricity, and these later inspired the historical work of James Maxwell related to electromagnetic field theory.

A number of chemists such Cooper and Brande, built careers as "professional chemists" finding multiple markets for their expertise. In the commercial section of the 1845 London Post Office Directory, Ure is the only individual to describe himself as an "analytical chemist," whilst Cooper styles himself "chemist." Five years later Cooper is one of only two chemists in the publication to use the term "consulting." The other is John Thomas Way (fl. 1820 -1883) who had been appointed Consulting Chemist to the Royal Agricultural Society of England in 1847. Use of "consulting chemist" and "analytical chemist" became more prevalent at this time, as both roles' marketability became established in the metropolis. The section category "analytical chemist" was introduced in the 1854 London Post Office Directory, with eleven listed.

ROBERT WARINGTON

Robert Warington (1807-1867) was a central figure in the mid-nineteenth century chemical community, notably through his role in the foundation of the *Chemical Society of London* in 1841. As demand for chemical services grew, Warington constructed an ultimately lucrative career in chemistry in which consulting played a major part. His formative years laid ideal foundations for establishing himself as a consultant, while his appointment as chemical operator to the Society of Apothecaries' pharmaceutical trade provided the status and infrastructure to sustain this activity.

Throughout the nineteenth century, chemists made up Britain's largest scientific community, practicing a versatile subject with wide-ranging applications. As chemists established themselves as one of the first new scientific professions, independent practice became a central element in their developing identity. When the Chemical Society of London was founded in 1841, chemical consultancy was already a significant component in the careers of many of its founder members. Later defined as "a person qualified to give professional advice or services," the consultants mentioned in this paper were practicing or analytical chemists who independently provided services for fees.



Robert Warington (1807-1867).

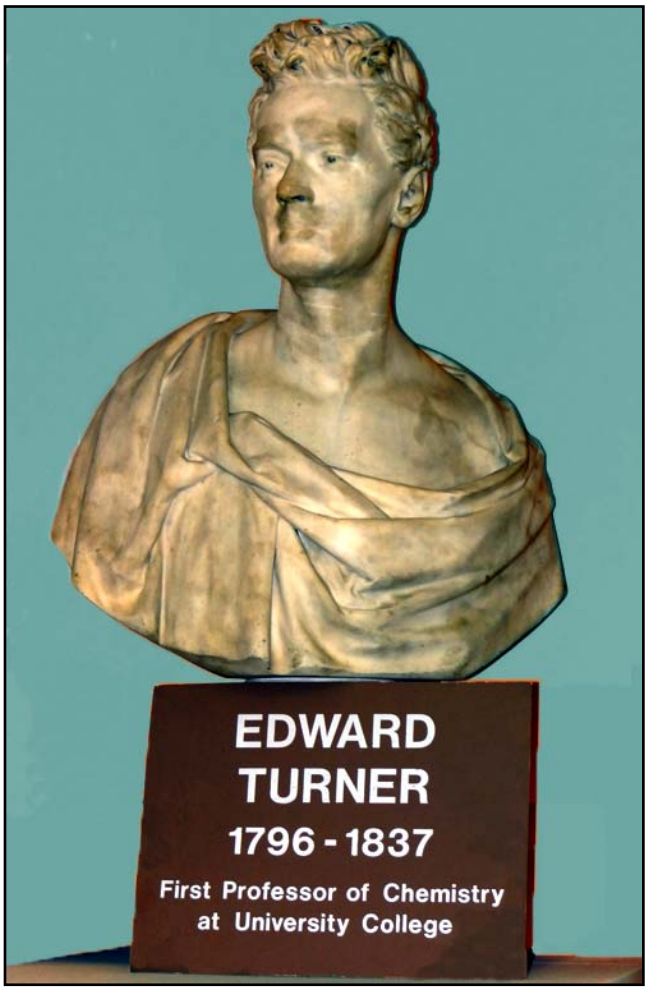
A variety of work was available to the chemist willing to advise on any scientific question. Performing process and product control, advising on chemical practice, and undertaking research were part of the services consultants performed for industrial and commercial clients, as a precursor to the employment of in-house expertise. The role of the expert witness in courts of law could also be a lucrative sideline. The versatility to perform a number of roles, whether for industry, government or private individuals was the key to sustaining work in this sector. Increasing recourse to the skills of the chemist, combined with a desire to supplement income, led to thirty percent of those who joined the three major British chemical institutions between 1881 and 1886 being employed partially in consultancy at some point in their career.

Building on the growing demand for chemical expertise from industrial and commercial clients and government bodies, Warington took on a variety of roles including analyst, chemical referee and expert witness in patent litigation cases. The notion of expertise and the appropriateness of its use has been the subject of scholarly interest in a number of disciplines, with chemical expertise in the metropolitan context in relation to environmental, public health and food quality concerns receiving particular attention. Chemistry was a saleable skill in mid-nineteenth century London and Warington was one of a number of chemists to take advantage of the opportunities available.

WARINGTON'S TRAINING AND EARLY CAREER

Born in Sheerness [a seaport in North Kent, in Southeast England on the Isle of Sheppey, at the mouth of the Thames] on September 7, 1807 to Thomas Warington (1773-1843), a victualler [a person providing or selling food or other provisions] of ships, and Esther Elizabeth Eaton (1779-1861), Robert Warington spent his early childhood moving between ports, and then studied at Merchant Taylors' School in the City of London. Intended to be a land-surveyor, he abandoned this in favor of chemistry, first as a house pupil, then from November 1822 as an articled apprentice for five years to John Thomas Cooper. Warington was to be "instructed in the said trade, science, art and occupation of an Apothecary and Chemist." Few were better placed than Cooper to prepare a student to earn a living in chemistry. Originally trained in medicine, Cooper lectured on chemistry, was a successful manufacturer of potassium, sodium and iodine, and became a widely-respected consulting chemist known for his technical expertise, particularly in the gas sector.

Having completed his apprenticeship, in 1828 Warington became an assistant to Edward Turner, Professor of Chemistry at the newly founded University College, London. Warington remained in this post for three years, took charge of the practical classes that Turner had initiated and published his first research in the *Philosophical Magazine*. Under Cooper and Turner's tuition and guidance, Warington gained experience and connections, with both men having a significant influence on the development of his career. His analytical skills were honed while tutoring students in the practical classes at University Col-



lege, while his early publications reflected Turner's interest in nomenclature. It was Turner who recommended Warington for his first industrial post, with the brewers Truman, Hanbury and Buxton. The firm desired the services of "an able young chemist" at its Black Eagle Brewery in Spitalfields [a district in the East End of London]. Warington started as an under brewer in November 1830 on a basic yearly salary of £156 [$18,900], comparable to clerks' salaries in minor posts in government, commerce and manufacturing. He acknowledged the ongoing debt to his two mentors in "A Series of Chemical Tables," published in 1833, with the following dedication:

To J. T. Cooper, Esq. and Dr. E. Turner, the following tables are respectfully inscribed as a small tribute of respect and grateful feeling for their continued kindness towards him, and the invaluable instruction which he received while under their tuition, by their late assistant and pupil. *R. Warington, 30 Church Street, Spitalfields, 1833*.

Warington's life centered on Spitalfields for most of the 1830s. Initially he resided in staff accommodation at Truman's, but soon he was living at 30 Church Street, the home of George Jackson, surgeon, instrument maker and founder member of the Microscopical Society. In 1835 Warington married Jackson's daughter, Elizabeth, at Christ Church, Spitalfields and the family set up home at 22 Princes Street. His employment in the brewing industry did not prevent his independent pursuit of chemistry and he published papers in the *Philosophical Magazine* on chemical symbols in 1832 and the action of chromic acid upon silver in 1837. Warington and a small number of others were all members of the Spitalfields Mathematical Society in the 1830s. Founded in 1717, the Society had sunk to a very low ebb but Jackson and other friends joined with the hope of raising it out of the mire. Lecture cards show that Warington spoke on lead and its combinations, while his father-in-law George Jackson discussed the construction of thermometers.

Warington's employers were initially unsatisfied with his contribution to the brewery. In 1832 the clerk's salary ledger notes that "if Mr. Warington does not very materially improve in three months we shall dismiss him." In 1836 there was "still room for further activity," with a pay rise to £300 [$35,000] offered "if he exerts himself" but set against a possible reduction to £240 [$29,200]. Although "rather improved" in 1837, Warington was not entitled to the salary increase and his employment record shows that he struggled with aspects of the role such as keeping correct accounts.

James Sumner has used Warington's career at Truman's as an example of how larger breweries were beginning to accept the value of employing "scientific gentlemen," but with mixed results. Nevertheless when Warington left Truman's in 1839 ("having an interest in a patent for making soap") his salary totaled £300 [$33,000] and the firm was "sorry to lose a person whose conduct has been so respectable." Although Warington's surviving papers include a laboratory sketch and projected profits for soap production, it is unclear what became of this proposition. In 1841 he registered a patent for "improvements in the operations of tanning," the first mention of the use of chromium chemicals in the leather trade. He had been working on chromium salts since the early 1830s and later would describe how he was "frequently called upon to examine the value of astringent substances imported into this country for the purposes of tanning."

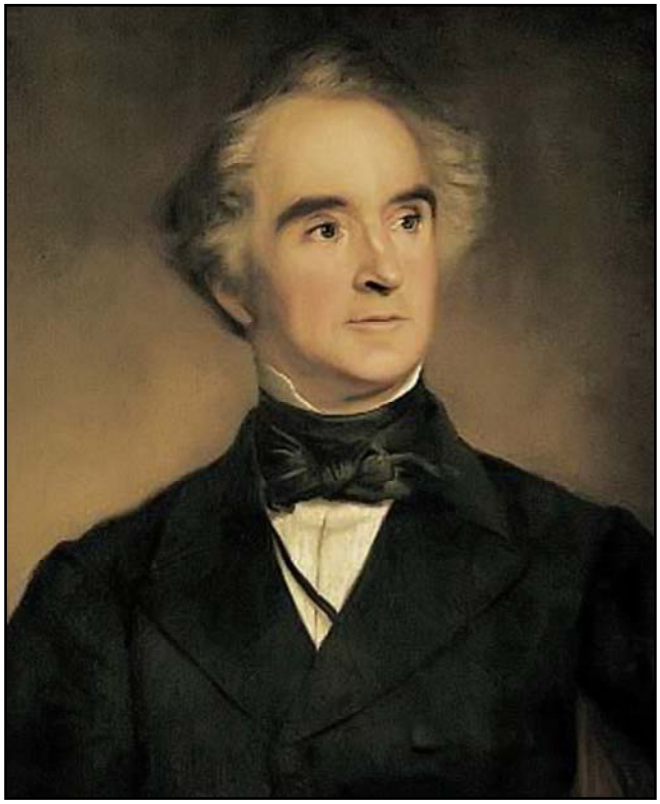
The year 1841 was part of what Robert Warington Junior (1838-1907) would later call "a short period of leisure in the life of my father." During this period Warington Senior began looking for support, ini-

"If you can't helium a sick chemist or you can't curium, you might as well barium."

tially informally then more widely, for the formation of a chemical society in London, an objective achieved in 1841. Proposed by John Thomas Cooper, Warington became Secretary, a post he held until 1851. He remained active in the Chemical Society thereafter, serving as a Council member from 1858-1861 and Vice-President twice from 1851-1854 and 1862-1865. The circumstances of the Chemical Society's foundation, the significant part played by professional chemists and Warington's aim to help unify the chemical community and integrate scientific theory and practice have been related elsewhere but key was Warington's organizational role, which indicated the central position he played in the chemical community, especially in London.

The influence of his personal connections can be seen in the twenty-five attending the Society's first meeting on February 23,1841. They included a nucleus of chemist members from the Spitalfields Mathematical Society and several linked to Warington through consulting activities. Warington's reputation for hard work and patience particularly suited him to such organizational roles. The Microscopical Society had been founded in 1839, with both Warington and his father-in-law George Jackson appointed to its first Council. Warington would later be involved in the foundation of the Royal College of Chemistry in 1845 (serving on its Provisional Committee) and the Cavendish Society, a chemical publishing subscription club, in 1846. He also had an extensive correspondence circle which included the German chemists Justus Von Liebig and Heinrich Will. Liebig and Warington had a close friendship, with Liebig sending Warington a dozen bottles of "genuine Rhein wine" and writing: "Regarding myself I like London perhaps more than any other place, I have in this town so many friends among whom, my dear Warington you are one of those I most esteem."

During this period without a formal post, it appears likely that Warington's primary income came from



Justus Freiherr von Liebig (1803-1873) was a German scientist who made major contributions to agricultural and biological chemistry, and is considered one of the principal founders of organic chemistry.

Heinrich Will (1812-1890) was a German chemist. He worked as the successor to Justus von Liebig from 1853 to 1882 as a professor at the University of Giessen. He is known for a method for the quantitative determination of nitrogen.

consultancy. In 1841 he lived with his wife, father, sister and three children at Percy Villa, South Lambeth, along with three female servants (an indicator of a certain level of prosperity). Warington's father, Thomas, had been engaged in the wine trade since the 1810s, but if his business had been successful at one point, its fortunes had severely declined. In 1841 Warington's parents were living separately and in June 1842 Thomas appeared before the Court for Relief of Insolvent Debtors and was sent to the gaol at Horsemonger's Lane in south London. These financial problems were not new; there had been judgements against Thomas in 1826 and 1832. In the same month as his father was committed to a debtor's prison, Warington returned to full-time employment, a timing which seems more than coincidental. He was appointed chemical operator to the pharmaceutical trade of the City of London livery company, the Society of Apothecaries, a post he held for the remainder of his working life.

THE SOCIETY OF APOTHECARIES AND CHEMICAL CONSULTING

The Society of Apothecaries' drug trade operated from premises surrounding its livery hall in Blackfriars, central London. Here drugs were manufactured in bulk quantities to supply customers both at home and abroad including the Navy, Army and East India Company, as well as hospitals, institutions and medical practitioners. In the year of Warington's appointment, the Society's trade employed fifty staff across manufacturing, wholesale, retail and accounts, with a turnover of £42,000 [$5,020,000]. During his tenure, driven by demand for drugs during the Crimean War, turnover would top £100,000 [$12,000,000]. As chemical operator, Warington had both practical and administrative responsibilities. He was in charge of manufacturing in the laboratories; he tested the quality of drugs produced and purchased; he liaised with the various committees of apothecaries administering the trade; and was the key source of chemical and pharmaceutical expertise

The Gallery of the Society of Apothecaries.

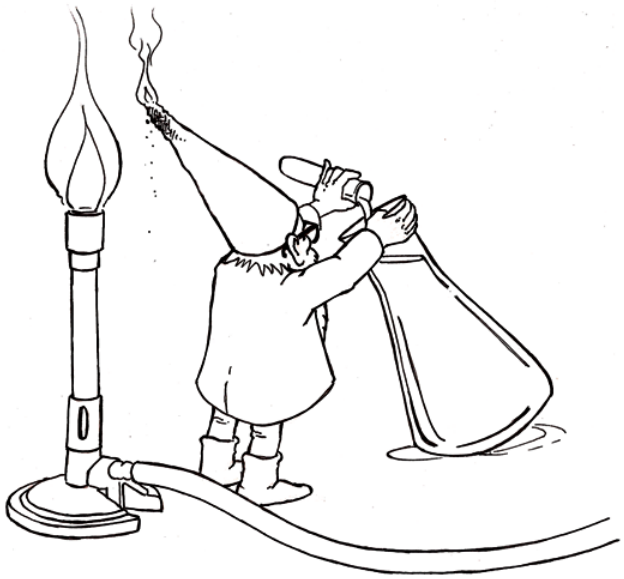
for both the Society and its customers. On September 29, 1842 Warington and his family moved into the chemical operator's house at Apothecaries' Hall. Here the Warington children, Amelia, Robert and George grew up: they were educated at home, forming societies (including a chemical society) that met in their father's laboratory early in the morning before the working day started.

Warington's appointment as chemical operator brought significant advantages, particularly in relation to developing his career as a consultant. With position came premises, while institutional employment brought affirmation and legitimation for his work, key factors in building a reputation for providing chemical services. Accounts of Warington's life emphasize this: "his professional engagements became very numerous during his connection with the Apothecaries' Society." These engagements included work as a scientific adviser in the law courts and from 1854-1861 he was especially connected with questions of water and gas supply. In 1854 four of the metropolitan gas companies, including the Surrey Consumers Gas Company, appointed him chemical referee, a post that he held for seven years. He also analyzed the water of the River Lee when its quality was under investigation in the 1850s.

Moreover, his position at the Society of Apothecaries led to work modernizing the Pharmacopoeia, particularly in regard to standardization and the introduction of chemical tests for purity. In 1851 he revised the translation of the Royal College of Physician's London Pharmacopoeia, which had been left unfinished by the chemist Richard Phillips. He was also consulting chemist to the London and Edinburgh Pharmacopoeia Committees engaged in preparing the first British Pharmacopoeia in 1864 and jointly edited the second edition of 1867, although involvement with the latter was curtailed by illness. By the autumn of 1865 Warington's lungs were seriously affected. Thereafter his presence at Apothecaries' Hall was reduced significantly. He spent the winter of 1865-1866 in Hastings [a seaside town and borough in East Sussex on the south coast of England, famous for the Battle of Hastings in 1066]. His son George (an assistant chemical operator from December 1861) took on many of his father's responsibilities regarding the pharmaceutical trade.

Warington was fortunate to benefit from the established laboratory infrastructure at the Society of Apothecaries, which provided him with well-equipped facilities for a range of chemical activities, including consulting and research. A test room – "a small laboratory fitted up with the requisite apparatus, for minute and delicate investigations and in which Chemical tests and other articles requiring peculiar attention and cleanliness are prepared" – was part of its trading premises. Apothecaries'Hall was also a location at which interested parties could call upon him with requests for advice without the need for public advertisement (Warington does not appear in the London Post Office Directory). He was ideally placed through the networks surrounding the Society's drug trade and his position in London's chemical community to link expertise across government, industry and commerce, as illustrated by the following example.

In 1844 an excise officer visited Warington at Apothecaries' Hall, bringing samples of black and green tea which had been seized in Kennington [a district in south London]. Warington examined these microscopically and "made a number of inquiries



For gnomes who love chemistry, avoiding the Bunsen burner remains a major challenge.

among the influential men in the trade and at the East India House" (one of the Society's major customers). Warington requested further information but never saw the officer again, yet his investigations continued, papers were published and evidence given to the Select Committee on the Adulteration of Food, Drink and Drugs on the subject in 1855. However, by his own admission this research came about "rather accidentally than otherwise." With versatility a key attribute for a consultant, Warington's reputation for pursuing a wide range of scientific interests was an asset. His research covered a myriad of topics, ranging from seaweed to microscopy, glass, mining and volcanoes. In 1846 he was granted a patent relating to improvements in food preservation and in 1850 he invented the balanced aquarium.

Warington could also build on a history of Apothecaries' Hall chemists providing services for clients within the institutional structure of its pharmaceutical trade. For example, through his appointment as Superintending Chemical Operator and Professor of Chemistry at the Society of Apothecaries, William Brande received significant payments for analyzing the impurities in saltpeter imported by the East India Company. Although Warington's consultancy work drew on connections generated by his employment, it extended far beyond the trade's customer base.

Given the extent of his external commitments, it is noteworthy that there is no evidence of any dissatisfaction with his services as chemical operator. When Warington resigned as chemical operator in June 1866, the Society displayed its appreciation, awarding him a pension of £150 [$16,000] per annum "in consequence of his long and able services." There is also no evidence of any financial arrangement between Warington and the Society regarding outside work. It appears that Warington was the sole recipient of any fees charged without incurring any overhead. Such advantages also benefitted many academics engaged in consulting and contributed to tensions between academic and practicing chemists that shaped professional organization in chemistry in the 1870s.

WARINGTON AS A CONSULTANT

Providing chemical services for industrial and commercial clients constituted the largest part of Warington's work as a consulting chemist. At this date few firms employed full-time chemists, so expertise was brought in as chemical answers began to be sought to commercial questions about manufacturing, waste, standards, competitors' activities and intellectual property. Warington's notes provide an insight into how firms used consultants' skills. There is evidence that Warington was approached to help undertake process and product control, analyzing both new and waste products. Such work was not regular, with samples submitted as and when required.

The explosives manufacturers, John Hall and Son of Faversham, requested analysis of a new sort of gunpowder blast, while the printers Routledge sent in alkali in waste dye, water samples and refuse soda ley. Warington's background in brewing led to clients including Beamish and Crawford of Cork, Mackeson's of Hythe, and Bridges and Cuthbert of the Falcon Brewery, Ipswich. Assessing composi-

This is the old Beamish & Crawford brewery in Cork, one of Warington's clients. Established in 1792 this was at one point the largest brewery in the country. Breweries were common clients for the professional chemists of the time.

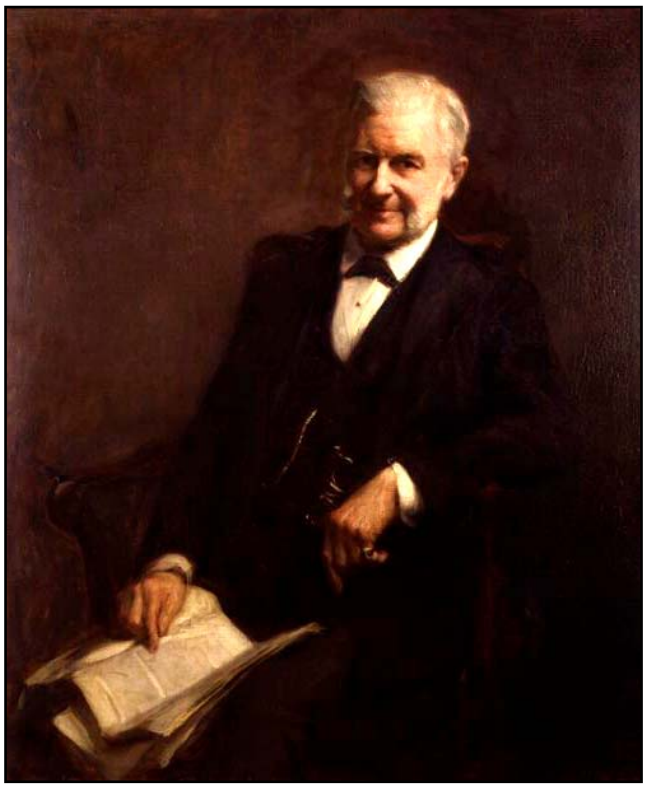
tion, quality, and purity were key concerns, with Warington's skills required to analyze raw materials, assist purchasing decisions and demonstrate the quality of products sold. The merchants Scott, Simpson and Wallis submitted sugar samples from Mauritius, St Kitts, Trinidad and Demerara [now part of Guyana] so that composition could be evaluated against the duty charged. The analysis of Ind Coope beer exported to India and returned was tested for possible contamination from proximity to turmeric.

A more detailed assessment is possible of the consulting services that Warington performed for the south London dyestuffs manufacturers, Simpson, Maule and Nicholson. The law emerged as a major patron of nineteenth-century science providing not only an additional income for many but also generating discussions about accuracy, standards and veracity, and providing a mechanism of judgment in an evolving professional and industrial arena. Simpson, Maule and Nicholson had purchased rights to Medlock's arsenic acid patent for magenta (aniline red) production in 1860. This was the most efficient process (through employing arsenic acid as an oxidant) and gave control of the route to aniline blue and violet. Such was its importance that by the beginning of 1865 the firm had spent around £30,000 [$3,360,000] fighting possible infringers of the Medlock patent. Although the firm employed several chemists in the 1860s, it relied on the consulting services of August Wilhelm Hofmann, supported by a number of members of the inner circle of the Chemical Society, including Warington.

Warington's services were initially engaged in June 1861, when he examined samples of liquid and dry magenta and prepared a report of his findings for the firm. This was shortly after Simpson, Maule and Nicholson had discovered that Wilson and Fletcher of Mile End had been manufacturing magenta using the arsenic acid process and on July 2, a Bill of Complaint was filed in the High Court of Chancery. Warington performed further experiments on samples provided by the firm as the legal process continued, with the case finally beginning in December 1862 in the Court of the Queen's Bench. Warington was amongst the eminent chemists and elite of the Chemical Society who denied that "dry" meant "anhydrous" leading to what has been called one of several "inane and newsworthy confrontations between counsel and witness." However, the chemists, including Warington, were right. When used as adjectives**,** anhydrous in chemistry means having little or no water of crystallization, i.e., water than comes from a crystal substance after heat is applied whereas dried means without water or moisture, said of something that has previously been wet or moist.

It should be noted that such statements underlined the witnesses' motives to support the legal argument rather than scientific fact. Nevertheless, the judgment in June 1863 was in favor of Simpson, Maule and Nicholson and no other firm could manufacture magenta using the arsenic acid process until the monopoly was broken in January 1865.

Warington's experimental notes from 1863 were dominated by work on magenta, blue and violet dyes



Sir Frederick Augustus Abel (1827-1902). Abel was an English chemist and explosives specialist who, with the chemist Sir James Dewar, invented cordite (1889), later adopted as the standard explosive of the British army.

and show how consultants were used by Simpson, Maule and Nicholson to monitor their competitors' activities and protect intellectual property. The firm provided samples of rivals' dyes to Warington from manufacturers including Thomas Holliday and Dan Dawson, both of Huddersfield and Levinsteins of Manchester. Warington also investigated recently patented processes. He performed, for example, a series of experiments relating to Dan Dawson's 1863 magenta patent. Late in 1863 a case began in London regarding infringement by Levinsteins of the aniline blue process of Girard and de Laire (which Simpson, Maule and Nicholson possessed an exclusive license to work in Britain). A sample of Levinstein's Bleu a la Lumiere/Night Blue and other competitors' blue and violet dyes were amongst those examined by Warington in the preceding months.

When the case was heard before the Court of the Queen's Bench in December 1864, Hofmann reported on experiments he had made with Warington, Edward Frankland, Henry Noad and Theophilus Redwood to produce aniline blue, while Warington recounted his analysis of samples of blue dyes received from the plaintiffs. Warington also carried out a series of investigations on arsenic acid in 1864. He was one of many chemists drawn into studying processes and products from a new industrial sector closely tied to metropolitan chemistry and pharmacy, with his activity in this field predating his consultancy role. Warington's work for Simpson, Maule, and Nicholson finished with the Levinstein case.

The end of the relationship was probably due to Warington's declining health (the proportion of consultancy work he undertook for industrial and commercial clients declined significantly after 1864) but also linked to broader factors affecting Simpson, Maule and Nicholson. Medlock's magenta patent was declared void in January 1865 and although Nicholson and Maule (Simpson left the partnership in 1866) tried to have the patent restored, they were unsuccessful and retired from the industry in 1868, while leadership in the British dye industry shifted to northern manufacturers.

THE CHEMICAL CONSULTANT: REMUNERATION AND ROLES IN MID-NINETEENTH-CENTURY LONDON

When Frederick A. Abel's father asked for advice regarding his son's ambition to study chemistry in the 1840s, Warington advised against "on account of the very limited prospects of advancement in the profession." When considering remuneration from institutional employment in isolation, the advice appears accurate. Warington's initial salary as chemical operator at the Society of Apothecaries was £200 [$23,900] and it was not until 1860 that his earnings from the post matched what he received in his final year at Truman, Anbury and Buxton. Warington also never achieved the status which came with an academic appointment: he unsuccessfully applied for the chemistry professorship at St. Bartholomew's Hospital in 1857.

However employment at Apothecaries' Hall was not Warington's only income. By considering how Warington self-defined his occupational status, it is clear that by the 1860s institutional employment was one aspect of his working life. Using "brewer" in the

1830s, a brief period as "gentleman" in 1839 and 1840, and then "chemist" from 1841, by the 1851 Census Warington styled himself as "Chemical Operator to the *Society of Apothecaries* and Professional Chemist." "Professional Chemist" alone is used in the 1861 census and in his will. The use of this term reflected the growing professional identity in the field; it was consulting and analytical chemists who were instrumental in the foundation of the Institute of Chemistry in 1877. The changing terminology also suggests the existence of a generational shift in consultants' roles between the 1830s and 1860s, whereby consultancy evolved from being a supplemental activity to a primary focus.

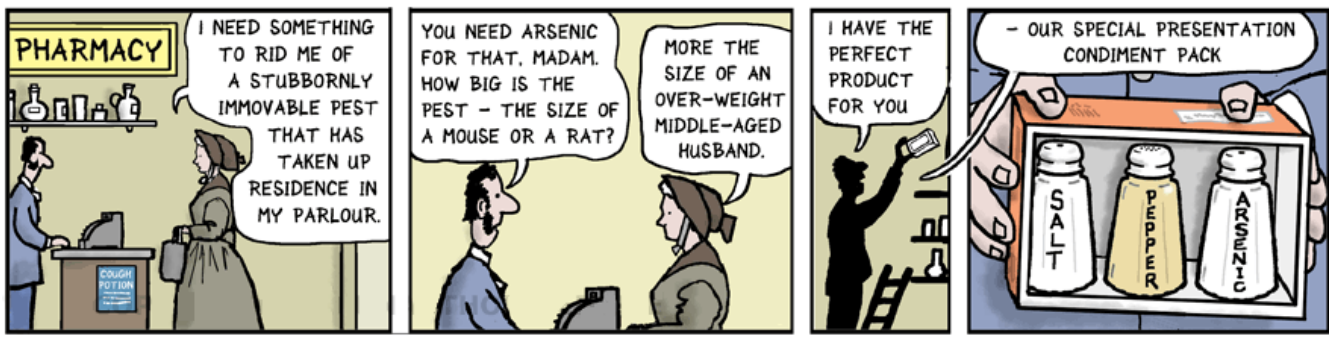
The role of "professional chemist" appears ultimately to have been very lucrative to Warington. Over the course of thirty-plus years of employment at Truman, Anbury and Buxton, and the Society of Apothecaries, Warington's remuneration totaled just over £8,500 [$906,000]. Yet his will was proved at under £16,000 [$1,650,000] on his death, a sum not only substantially more than his lifetime institutional earnings but also significantly greater than that of his contemporaries. William Brande had left £3,000 [$321,000] a year earlier, while Michael Faraday's will was proved at just under £6,000 [$643,000] in 1867, when his yearly salary never fell below £800 [$98,000] after 1836. As Warington's salary from the Society of Apothecaries reached a maximum of £305 [$32,500] in 1861, this shows the extent to which his earnings must have been augmented by other sources, even after accounting for significant variations in outgoings. The size of Warington's estate has led to it being suggested that his emolument at Apothecaries' Hall was supplemented by a private income.

However, given Warington's father's financial problems, family money seems unlikely, especially considering that his brother Thomas, a corn merchant, also faced bankruptcy proceedings in the late 1850s and early 1860s. The significant sum that Warington built up during his lifetime must have come from external engagements, of which the provision of chemical services was a major part. No details of fees charged by Warington survive, but consider those of the Glasgow-born chemist Andrew Ure. His schedule of fees ranged from £1 1s [$112] "for consultation respecting any single point or question of inquiry" to £10 10s [$1,120] for the complete analysis of any mineral water, soil, earth, metallic or other mineral indicated the sums that could be made. Engagement as an expert witness could also be extremely lucrative, as shown by "The Feast of the Blues," an extravagant dinner that Warington and other expert witnesses attended during the Levinstein case.

SUMMARY

The concluding paragraph of Warington's obituary in the Proceedings of the Royal Society begins by encapsulating the strengths he brought to consultancy work: "Mr. Warington was remarkable for his varied taste and constant activity as an observer." However, it went on:

He may be said indeed to have passed from one subject to another with too great a facility and consequently his completed investigations bear but a very small proportion to the number of subjects that he had continually under examination.



Combined with his relatively late election to the Royal Society in 1864, such comments suggest that some of Warington's contemporaries considered that his achievements were not as great as one would have expected from a man of his abilities. Yet such sentiments risk drawing attention away from the esteem in which Warington was held for his practical and organizational contributions to chemistry. His obituary in the *British Medical Journal* ends: "Few men have passed a life of more continuous and honorable usefulness. He died at Budleigh Salterton, Devon [a county in southwest England] on Nov. 12, 1867 universally respected and widely lamented."

As science-based enterprises grew in scale and scope, Warington's breadth of experience, combined with his position at the heart of London's chemical community, meant he was ideally placed to provide chemical services to a range of firms, government bodies and private individuals. Drawing on the networks generated from his training under John Thomas Cooper and Edward Turner, the period living in Spitalfields, and his key role founding the Chemical Society, and supported by the institutional status and infrastructure of his employment at Apothecaries' Hall, Warington constructed a lucrative career in chemistry in which chemical consulting played a major part. In this work, elements of his background in brewing and his experience in pharmaceutical production can be located, while for a number of years work in both water and gas analysis was key. Although many of the services Warington provided for industrial and commercial clients were on an *ad hoc* basis, such activity was a precursor to how specialist advice would be used across different sectors as consultants became a key resource in knowledge management.

MISINFORMATION AND AQUARIUM HOBBY HISTORY

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Facebook Files, November 13, 2020)

Misinformation in aquarium hobby history is not uncommon and some of it has generated a great deal of controversy over the years. The majority of defects are often due to sheer carelessness when slipshod authors erroneously or incompletely record information and do not take the precaution, prior to publication, to proofread their work. More serious errors occur, however, when authors fail to define important terms, fail to check their sources or else rely on secondary sources that contain fallacies.

Failure to consult an original source leaves an author at the mercy of an intermediary's imperfect or biased reading. To avoid being unconsciously influenced by the second-hand user's slant, it is essential to see the full original. Moreover, original sources often reveal pertinent data unseen by and unknown to the lazy secondary borrower. Such misinformation is abundant on the Internet and include Wikipedia, You Tube, social media and other internet sites connected to the aquarium hobby. Such errors are also found in books and magazine articles not on the Web. The purpose of this essay, then, is to examine some of this misinformation and to show how I handled these problems.

THE HISTORY OF THE WORD "AQUARIUM"

The most important word in the history of the aquarium hobby is, of course, "aquarium." The word is Latin, so I'll start with the Romans (see Klee, 2015). Note that the root of aquarium is aqua, which means "water" in Latin and takes on different endings depending upon the gender, declension and whether it is singular or plural. For the neuter gender, for example, in addition to adding the ending -rium to aqua, we find the added endings -ria, riorum, riis, -rio and -rii.

Cato the Elder (234 BC-149 BC was the first author of record to use the word aquarium. Examples from his book, De agricultura ("On Farming" sometimes referred to as De re rustica), written about 160 BC include the following: **situlum aquarium** ("water bucket"), **urceum aquarium** ("water vessel") and **bonumque aquarium** ("well-watered"). Note, however, that aquarium here simply meant "water," not a container of water.

Pliny the Elder also mentioned aquarium in his Naturalis Historia, published circa AD 77–79. In Book 59, Volume 19, he talks about directions for watering certain plants:

Peculiaris medicina raphano, betae, rutae, cunilae in salsis aquis, quae et alioqui plurimum suavitati et fertilitati conferunt. Ceteris dulcium aquarum rigua prosunt. Utilissimae ex his quae frigidissimae et quae potu suavissimae. Translated, this reads,

There is a curative property especially effective for radish, beet, rue and savory in salt waters, which moreover also contributes a great deal to their sweetness and to their fertility. All other plants are benefited by being watered with fresh water, the most useful for the purpose being water from streams, which is extremely cool and very sweet to drink."

With regard to the term, "watering place," in Cicero's Three Books of Offices and Other moral Works, written in 44 BC, we find the following:

Tum Canius inquit, quæ, Pythi, quid est hoc? Hic, ne, tantum piscium, ne tantum cymbarum? Et ille inquit, quid mirum? Quidquid piscium est Syacusis est hoc poco, hic aquatio… Translated, this reads,

Then Canius says, 'What is this, pray, Pythias – so many fish – so many boats?' And he answers, 'What's the wonder? Whatever fish there are at Syracuse are taken at this place; here is their water- place…'

Cicero uses the nominative form "aquatio" here to mean "watering-place; it was not used in the sense of a container to hold fish, or anything else for that matter, although some have mistakenly translated it as being a water trough for cattle. Thus at no time did the Romans use aquarium or its cousins in the sense of a container; rather, it was either meant as water or a place (but not a vessel) that held water.

New Latin (also called Neo-Latin or Modern Latin), was a revival in the use of Latin in original, scholarly and scientific works starting circa 1375/1500 AD. For example, Mercator drew a marine chart in 1569 that portrayed the Great Lakes as accurately as could be drawn at the time. It was noted that river running into the St. Lawrence Gulf had two large branches and at the head of the northern branch was grouped three small lakes just west of which is a very large lake. Beside this lake is written, **"hic mare est dulcium aquarium, cujus terminum ignorari Canadenses ex relatu Saguenaiensium aiunt"** ("this sea is of fresh water; the Canadians do not know its bounds, according to the report of the people of Saguenay"). The "sea" that Mercator was talking about, by the way, is what is now known as Lake Huron.

János Reisinger (1784-1852) received a medical degree in 1806 and from 1810 until his retirement in 1848 he was a professor of zoology and mineralogy at the Faculty of Medicine in Pest, Hungary. In 1830 he wrote a book in New Latin titled Specimen ichthyologiæ- sistens pisces aquarium dulcium Hungariæ **(Ichthyological observations on Hungarian freshwater fish)**. Thus even in New Latin the word "aquarium" was never used in the sense of a container; rather, it simply meant water.

However, none of the foregoing gets us any closer to an explanation of how the word aquarium got into the aquarium hobby, although it had been in use among the botanists for a long time to designate the containers in which aquatic plants were reared. In my essay "The Gardener's Aquarium" (Klee, 2014a), I discussed John Loudon's "An Encyclopædia of Gardening" (Loudon,

"It's OK, everyone makes mistakes. Look at me. I hired you."

1824) in which he showed several examples of containers and artificial ponds he identified as aquaria and suggested that fish might be added to them. Since a gardener's aquarium is nothing more than a receptacle that contains water and aquatic plants, I went on a search to determine who came up with the name and who devised such a receptacle. Working backwards from 1824 down into the 1700s, I found that it was Carl Linnaeus (also known after his ennoblement as Carl von Linné). In his 1742 prologue to his Hortus Upsaliensis, he defined the following terms under the heading of "Aquaria:" **Aquarium fluviatile, Aquarium lacustre** and **Aquarium palustre**, denoting respectively a river pond aquarium, a lake pond aquarium and a marsh pond aquarium. Here is how Linnaeus described the last-named:

Aquarium palustre ad latera truncos horizontales seu parietes habet, aquam a solo separantes, inter illos vero & ipsam humum repletum est spatium humo limosa e paludibus desumta, cui insertae plantae palustres. Translated, this reads,

The marsh aquarium has horizontal sides of tree trunks or walls that separate the water from the surrounding soil; the ground between them is filled with soil from muddy swamps, into which is inserted marsh plants.

Clearly Linnaeus was describing the construction of a vessel containing water and not as a synonym for it. He was not, of course, concerned with fish but with aquatic plants but adding fish is not an alteration, only an extension of the meaning. Thus I considered Linnaeus to be the inventor of the aquarium without any further criteria and dubbed him, **PATER AUTEM AQUARIUM** or **FATHER OF THE AQUARIUM** (Klee, 2019).

At this point we can define an aquarium as a constructed vessel containing aquatic plants and/or fish. The history of the aquarium therefore takes us into pre-historic times when writing had not yet been invented. A new study led by Tsuneo Nakajima of the Lake Biwa Museum in Japan and published in Nature Ecology & Evolution (Hudson, et al., 2019), for example, suggests that the practice of rice fish aquaculture actually began thousands of years earlier than previously believed - around 6200 BC.

COMMENTS ON THE WORD "HOBBY"

Before one starts to discourse about important concepts or ideas, barring that others have already defined them to everyone's satisfaction elsewhere, one must define them. The following appears in the Revised & Expanded edition (really the Second edition) of my book, The Toy Fish (Klee, 2003):

There is also, alas, a problem with precisely what is meant by the word, "hobby." …We may ask ourselves whether Anna Thynne was

THE FOUR STAGES OF THE AQUARIUM HOBBY

STAGE I:
THE TOP-DOWN AQUARIUM
(circa 4000 BC)
Opaque-sided containers.
STAGE II:
THROUGH A GLASS CLEARLY
(late 1530's)
Glass jars: fish kept for ornamental or scientific study purposes.
STAGE III:
OCEAN AND LAKE IN GLASS
(mid 1800's)
Tanks frequently with flat glass sides; aquarium books; commercial aquarium fish and equipment suppliers; object to emulate a small portion of a natural habitat.
STAGE IV:
ASSOCIATION (circa 1900)
Aquarium societies; exhibitions; competitions; aquarium magazines.

a hobbyist, or A.A. Maconochie, or some unknown American who maintained several jars of native fishes during the Presidency of Andrew Jackson, but the answers are in no way clear.

Thus I abandoned the idea of defining "hobby" directly in favor of the concept that I developed in 2004 of the "Four Stages of the Aquarium Hobby" (see accompanying figure) that indirectly defined the hobby by describing it chronologically, a lot easier task (see accompanying image). In the fourth edition of my Toy Fish book (Klee, 2005), however, I bit the bullet and defined the aquarium hobby as: **A subject or pursuit involving fishes, undertaken primarily for pleasure during one's leisure time and to which a person is notably devoted**. This enabled me to assert that the first aquarium hobbyists were the Romans. At the very least, it enabled readers to clearly understand my assertion after reading the remainder of this section of the book. For more details on my quest for definitions, see Klee, 2014b. It is time now to discuss some significant errors in the writing of aquarium history.

JEANNE VILLEPREUX-POWER AND THE MYTH OF THE INVENTION OF THE AQUARIUM

Jeanne Villepreux-Power was a remarkable woman. With little or no formal education, she bested Giuseppe Saverio Poli, considered the "Father of Malacology"; she bested Henri de Blainville, an authoritative, well-known figure in the field; and she bested Baron Cuvier, the famous French ichthyologist. As a result of this, she revolutionized the study of marine biology, a fantastic accomplishment for any one with so little formal education and by a woman in an age where men did not take women seriously. However, over the years we have read countless times on the internet that Jeanne Villepreux- Power was the inventor of the aquarium. Ironically, she is known more for this myth than for her real and more important accomplishments. That she was the inventor of the aquarium simply is not true.

In 1832, Villepreux-Power used had four types of what she called "cages" in her research: Two were made of glass (the first of which was used at home; the second was used for smaller mollusks and was in a frame so that it could be immersed in water) and the third was a cage made out of wood designed to be immersed in water. The fourth, invented to replace the second which proved unsuccessful, was a cage made of clay for smaller mollusks and also designed to be immersed in water.

Although the two glass containers certainly were aquaria, she did not invent them. Because of the use of lead-acid batteries in use at the time, her tanks were readily available locally. She neither built them or designed them; she simply bought them and thus did not invent them (see Klee, 2019).

WHO INVENTED THE AQUARIUM?

To answer this question I needed a new definition, i.e., one for "aquarium." As Newman put it (Newman, 1873),

The birth of the aquarium is of such remote antiquity that we fail to ascertain the date with any certainty. The point at which, any

"No Martin… I make errors of judgment… you just make mistakes!"

vessel containing water and fishes becomes an aquarium is equally open to discussion.

Before one attempts to pin down a "first," one must devise a set of criteria that, like in a patent, defines the concept or idea. The following are the ones I chose (Klee, 2012):

(1) In Great Britain in the early 1850s the de facto definition of an aquarium in the sense of the whole concept, not just the container, was a vessel containing water and plants, plus aquatic animals (excluding, of course, mammals and water fowl) in which the water was not aerated nor changed. Note that fish were not necessarily included. Implicit in this definition was that basis for the aquarium was the relationship between plants and the animals, i.e., that plants absorbed the carbon dioxide that the aquatic animals generated while the animals absorbed the oxygen that the plants generated.
(2) Another part of my requirement for "first" was priority of publication, a criterion required in the 1800's and, for most things, also in the present-day.
(3) To simplify the analysis, I considered four categories for "firsts" in this monograph: freshwater aquarium sans fishes, freshwater aquarium with fishes, marine aquarium sans fishes and marine aquarium with fishes.

Using these criteria, Charles des Moulins - a man mostly overlooked in aquarium hobby history - came in first (1830) for the freshwater aquarium sans fishes, Robert Warington (1850) for the freshwater aquarium with fishes, George Johnston (1842) for the marine aquarium sans fishes and Robert Warington for the marine aquarium with fishes. If, however, we add another criterion, (4) that of the impact on the aquarium hobby in the Nineteenth Century, then Warington remains in the first place for the freshwater aquarium, with Gosse and Warington in a close tie for the marine aquarium title. It is difficult to break this tie, since Warington published first whereas Gosse had the greater impact.

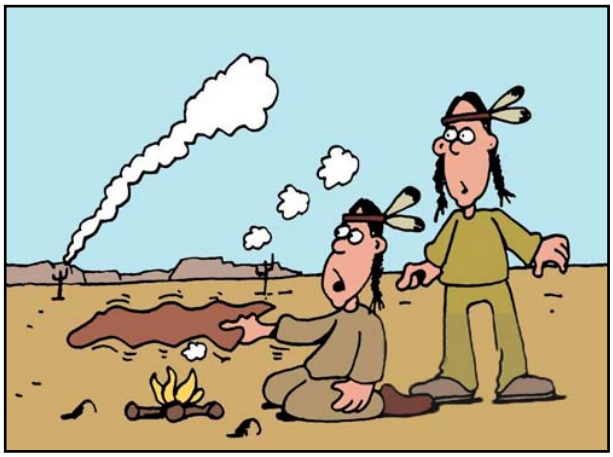
This answered, to my satisfaction at least, the question of who invented the aquarium. If others disagree then they are certainly free to construct other criteria and answer the question differently, but they are obliged to construct them, otherwise their conclusions would be meaningless.

MYTHS ABOUT ROMAN AQUARIA

There are many myths about Roman aquaria and most are due to the absence or inadequate checking of resources. Except where cited, the following is from Bernd Brunner's "The Ocean at Home" (translated from the German version, Wie das Meer nach Hause kam; Brunner, 2003):

These fish were kept in opaque tanks, often made of marble, in front of the house. The first fish to enter the interior of a house in imperial Rome was the sea barbel, a much cherished and expensive breed. Allegedly, they were kept in small tanks underneath the cushions of the guest beds. Around 50 AD, panes of glass were brought to Rome, Herculanaeum, and Pompeii, to replace one wall of the marble tanks; now it was possible to actually see the hustle and bustle of the fish without having to guess their schematic movements from above.

Brunner obtained this information from the book, "Die Arche Mostar" ("Mostar's Ark"), written by Herrmann Mostar (Mostar, 1959). Mostar (1901-



"He never has got the hang of using punctuation!"

1973) was a German writer, poet, columnist and, at times, a narrator, playwright and comedian. He also became Germany's most famous critical court reporter. This particular book deals with animals that have lived together with man, including dogs, cats, cocks, hens, doves, songbirds, fish, but also with the quite undesirable such as flies, spiders, bugs, lice, fleas, rats. Mostar provides a wealth of tales and anecdotes from politics and history, in which animals have played sensational and sometimes even decisive role. Unfortunately, Mostar provided no bibliography and several of his historical statements with regard to fish and the aquarium are questionable, to say the least. Mostar writes:

Well, all these fish [Mostar is referring here to eels, carp and bream] live in Roman water basins that were made from the most precious marble. However, they were still housed outside of the home; the eel had already made it to the fountain. Most likely the first to come into the interior of the house was - to their sorrow - the world-famous mullet. It was considered the tastiest of all fish; that's why you weighed their weight in silver at first and later in gold, but it was also the most beautiful of all fish, resplendent in glorious red, and it was a curse.

Talking now about mullets, Mostar continues:

They put a small tank for them under the cushions of the guest bed, and when it came to the fish course, the head of the house took the fish out of the tank and handed it not to the cook, but to the beautiful Lady of the house or the even more beautiful mistress, and in her slender hands the fish slowly suffocated. Because, alas, it died even more beautiful than when it was alive!

Then, about 55 AD, the first coarse glass panes came to Rome, Herculaneum and Pompeii. Now one could make one wall of the marble basin transparent so that one could see the hustle and bustle of the fish, not just shadowy sliding from above as before, but at the same height with them. And now the ladies and their lords saw the mullet during lovemaking and discovered that love bestowed the same flaming colors of beauty as did death. Where before the fish had so miserably suffocated in their delicate hands they now were in the hands of friends. It was erotic enough for spoiled Rome, eroticism and arousal without cruelty.

However, nothing claimed by Mostar is true (see Klee, 2014c):

(1) Mostar stated that Roman water basins outside the home were made from marble. Higginbotham (Higginbotham, 1997), however, states that seaside fishponds were either excavated in rock or constructed of concrete. Inland ponds were usually built of concrete walls with masonry facings.
(2) No such mention of marble tanks with glass sides were ever mentioned by Cicero, Columella, Horace, Juvenal, Martial, Pliny the Elder, Pliny the Younger, Seneca, Tiberius or Petronius, nor were the remains of such tanks ever found in the

"I realize you like to take time to polish your essay before submitting it to the AHHS, but don't you think four years is a little excessive?"

excavations of Rome, Herculaneum or Pompeii. Neither were they mentioned by Friedländer in his "Roman Life and Manners under the Early Empire" (Friedländer, 1979).

(3) The flat glass produced by the Romans could hardly have served to view fish in any detail as it was very thick, more translucent than transparent and had a distinct greenish color cast to it.

(4) Re the barbed mullets (*Mullus barbatus*) that Mostar maintained the Romans saw spawning, Columella reported that it was difficult to maintain this fish in ponds and even more difficult in an aquarium "since it is a very delicate kind of fish and most intolerant of captivity, and so only one or two out of many thousands can on rare occasions endure confinement" (Columella, De Re Rustica, VIII.17.7). They were kept successfully in salt-water lagoons constructed on the Mediterranean coast, but that is not what Mostar is talking about.

If Brunner had really checked his Mostar source, the combination of a lack of bibliography to support Mostar's claims and his assertion that the change of color in the mullet as it died in a glass was due to courtship or spawning colors would have resulted in Brunner ignoring all of Mostar's claims. One of the most perplexing things about Brunner's book is that the Mostar reference is not in his bibliography, at least not in his English version. I had to learn about Mostar from a query I made to Brunner; otherwise I would have picked up on his oversight a lot sooner.

MYTHS ABOUT ROMAN AQUATIC ENGINEERING

David W. Cheever (1831-1915) was a famous Boston surgeon who contributed essays on medical and natural history topics in the popular vein in the Atlantic Monthly and the North American Review. In an article about the aquarium that appeared in the Atlantic Monthly (Cheever, 1861), he attributed to Martial (he specifically cites Book X, Epigram XXX) the following (Klee, 2014d):

…[Roman] pisciculture was carried so far that fishponds were constructed on the roofs of houses. More practical persons conducted a stream of river-water through their dining-rooms, so that the fish swam under the table, and it was only necessary to stoop and pick them out the moment before eating them; and as they were often cooked on the table, their perfect freshness was thus insured.

Cheever, however, was way off on his translation; I read the epigram in question and I provide the original Latin and my own translation as follows:

Nec saeta longo quaerit in mari praedam, sed a cubili lectuloque iactatam spectatus alte lineam trahit piscis. Si quando Nereus sentit Aeoli regnum, ridet procellas tuta de suo mensa: piscina rhombum pascit et lupos vernas; Natat ad magistrum delicata muraena, nomenculator mugilem citat notum, et adesse iussi prodeunt senes mulli.

The line seeks not its prey in the distant sea, but the fish, caused sight of from above, draws down the line cast from bed or couch. If ever Nereus feels the power of Aeoli, the table, safe-supplied from its own store, laughs at the storm; the fishpond feeds turbot and home-reared bass; to its master's call swims the dainty lamprey; his keeper summons a favorite gurnard, and, bidden to appear, aged mullets put forth their heads.

Note: Nereus, also known as "the old man of the sea," was considered to be a gentle and trustworthy god who never lied. Aeoli (or Aeolus) was the divine keeper of the winds, releasing them only at the command of the greatest gods to wreak devastation upon the world. In some translations the line is said to be cast from a casement (window) rather than from bed or couch. Although I admit that this is a better description I felt obliged to do a more literal translation. Pliny, by the way, also described the leisure practice of fishing from one's bed just by dropping a line out the bedroom window. The proximity of living quarters to fishponds at many of the villas in Italy would have made this activity possible.

Martial therefore says nothing about fishponds on the roof of houses or fish swimming under the dining room table in a stream of water. To make sure that Cheever was not quoting from any of Martial's other epigrams I did a global find among all 1,561 of them in 12 Books using the keywords, Nereus, Aeoli and/or Latin words meaning fish; a number were found but not the one Cheever cited. Being somewhat dubious about Cheever's claim I set out to see if I could find any validation of it in the writings of the authors of the day, such as Cicero, Pliny, Varro and others. In this endeavor, I was unsuccessful.

THE HORTENSIUS MYTH

Although we cannot attribute these two myths–fishponds constructed on the roofs of houses and fish swimming under the table–to Martial, I have come across one of them made by another author, a myth that can be reliably disproved (Klee, 2014d). Quintus Hortensius Hortalis (114 BC - 50 BC), was one of Rome's foremost orators. When he retired he withdrew from politics and passed into a cultivated luxury. The vast wealth he had accumulated was spent on splendid villas, parks, fishponds and costly entertainments. Cicero puts him among the aristocrats solely concerned about their fishponds. Lucius Licinius Lucullus, well-known for having cut a channel through a mountain near Naples to allow the sea to enter his fishponds and stir the water within to prevent stagnation, was for example, a close friend. Hortensius also constructed similar fishponds at vast expense, so designed that the tide caused sea water to flow into them.

One of the references to Hortensius I came across was an 1868 translation of The Ocean World by Louis Figuier. Figuier (1819-1894) was a French chemist and writer on occult subjects. After taking his doctorate in medicine and completing his postgraduate study in chemistry, he was made professor of chemistry at the school of Pharmacy in Montpellier and later exchanged this post for a similar one in the School of Pharmacy of Paris. Many honorary degrees in science and medicine were conferred upon him by various faculties during his career. However, in his research he found himself opposed by Claude Bernard, a French physiologist whom historian I. Bernard Cohen of Harvard University called "one of the greatest of all men of science." As a result of this conflict,

Figuier abandoned his research to devote himself to popular science. Much of the scientific information in the novels of Jules Verne, by the way, was taken from his works. In any event, in The Ocean World I came across this statement in the section under mullets (Figuier, 1868a):

The great rival of Cicero, the advocate Hortensius, who attracted crowds of people to the Forum by his eloquent and elegant discourses, had an inordinate passion for this kind of enjoyment. These little inhabitants of the waters were led by a small canal which was carried under the festive table, and his great enjoyment was to witness the agonies of the unhappy fish just taken from its native element and carried to the table, palpitating with its dying convulsions, as it perished beneath his eyes, he in the meanwhile enjoying a sumptuous banquet.

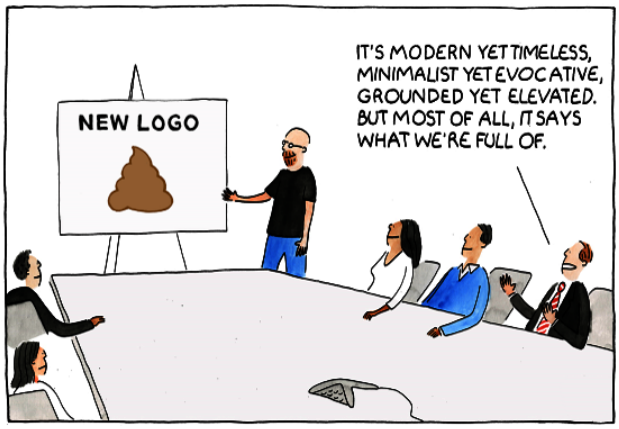
Unfortunately, Figuier provided no in-text references nor did he provide a bibliography. My next thought was that perhaps it was the translator had made an error, not Figuier, so I started a search for the original French version. Alas, there was no such version. On the Title page of The Ocean World, however, was the statement, "Chiefly translated from "La Vie et les Mœurs des Animaux," so I examined this book and found the original French that I was looking for (Figuier, 1868b):

Le rival de Ciceron, l'avocat Hortensius, qui attirait tout le peuple au forum par la beauté de ses harangues, avait une passion désordonnée pour ce petit habitant des eaux. Il faisait venir les rougets dans de petites rigoles jusque sous la table du festin; et il se délectait, assis devant un somptueux banquet, du plaisir de voir un de ces malheureux poissons retiré du bassin et apporté sur sa table, palpitant et agité des convulsions de l'agonie, périr sous ses yeux, en se colorant de mille nuances irrisées.

Keeping in mind that I needed here a more literal translation than an artistic one, I translated it as follows:

The rival of Cicero, the lawyer Hortensius, who attracted all the people in the forum by the beauty of his harangues, had a wild passion for these little inhabitants of water. The mullets were led into a small canal that was carried under the festive table, and he enjoyed sitting in front of his sumptuous banquet, the pleasure of seeing one of those unfortunate fish removed from the canal and brought to the table, and in agonizing convulsions, die before his eyes in iridescent colors of a thousand shades.

Since this didn't differ much from that of Figuier's translator, it was Figuier who was saying that Hortensius brought his fish to the dining room by some sort of water conduit connected to one of his fishponds. However, Figuier's statement could not possibly be true. For proof of this I refer to Marcus Terentius Varro (116 BC - 27 BC), Rome's greatest scholar and a satirist of stature, whose vast and varied erudition in almost every department of literature earned for him the title of the "most learned of the Romans." His only complete work extant, Rerum Rusticarum Libri Tres, has been described as " …the well digested system of an experienced and successful farmer who has seen and practiced all that he records." The following dialogue is taken from this book. Appius Claudius Pulcher was a consul of the Roman



Republic and a good friend of Varro's and this is he, talking to Varro:

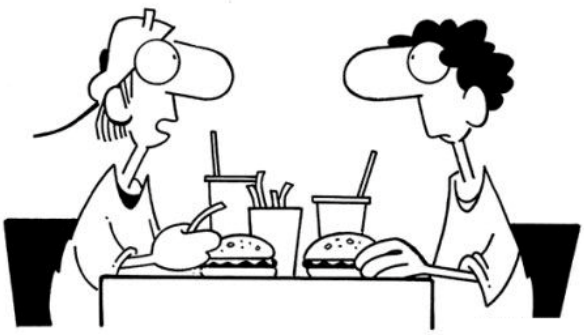
Our common friend Quintus Hortensius had fishponds near Bauli which had cost him a great sum to build, and I know, for I often used to stay with him at his country-house, that he used always to send to Puteoli to buy the fish for dinner. And it was not enough that his fish-ponds didn't feed him, but he must needs, if you please, with his own hands feed them, being more anxious lest his mullets should feel the pangs of starvation than I do lest my asses at Rosea should go hungry. He spent, too, a good deal more on the former than I do on the latter in the matter of both food and drink.

For all I need for the feeding of my costly asses is one little slave, a trifle of barley, and water found on the estate, while Hortensius in the first place kept an army of fishermen to feed the fish, who used constantly to bring him masses of tiny fishes which were destined to serve as food for the big ones. He would buy, besides, salt-fish, and throw it into his ponds, when the sea was stormy, and when, owing to the weather, the market that supplies the fish-ponds (the sea, that is) refused its food, and the live food, the fish eaten by the common people for supper, could not be got to shore with a net. You would sooner, said I, have got Hortensius's consent to your taking his carriage-mules from the stable and keeping them for your own, than a bearded mullet from his fish-pond.

This fanaticism and concern for his bearded mullets became a standing joke throughout Roman society but the point here is that Hortensius was so devoted to his fish that he could not stand to send them off to the banquet table, opting instead to purchase them from the market in Puteoli. He would not have constructed such a conduit from one of his fishponds to his dining table any more than a present-day fish fancier would serve up his pet arowanas through a 3-inch PVC pipe to his dinner guests. Thus, Figuier's account is a myth, nothing more. The coup d'etat was provided by the following review of The Ocean World that appeared in 1868 in The Contemporary Review:

…what is the book? Truly a very patchwork of compilation, utterly without authority as a work of reference! We must admit that the various compilers who have had a share in the volume, have frequently avoided misstatements, while they have popularized the history of the inhabitants of the sea from the zoophyte to the vertebrate fish. Yet we meet with random writing and vague exaggeration more frequently than we expect, even in a French compilation. Thus we are told that the little Janthina shells inhabit the deep sea, and often form banks of many leagues in extent! Another marvelous story is that of a cuttlefish 60 feet long, not counting its arms, which are represented as about 40 feet more and weighing 4,000 pounds, which encountered a French corvette. The fish, according to the illustration taken on the spot and given here, should have been more than a match for the ship. The editor, however, suggests (in, we presume, 'compilation' Latin) that this should be taken cum grano salis.

The reviewer opines, therefore, that Figuier's book is a very patchwork of compilation, utterly without authority as a work of reference, and finishes off by pointing out some errors (I smile at the statement, "…vague exaggeration more fre-



"I forgot to make a back-up copy of my brain, so everything I learned last semester was lost."

quently than we expect, even in a French compilation"). The reviewer goes on to suggest that the only value the book has is as a children's book and even there because of its pictures. Another myth bites the dust, this one by referring to the primary source, not a second one.

GROWING MARINE PLANTS IN ARTIFICIAL SEA-WATER IN A WARDIAN CASE?

The following statement by William Alford Lloyd appeared in his "Handbook to the Marine Aquarium" (Lloyd, 1876):

Mr. Ward had, however, before 1849, made sea-water by artificial means, and had grown marine plants in it.

I was interested in finding the original source for this statement and the first I found was in Shirley Hibberd's "The Book of the Fresh-Water Aquarium or Practical instructions on the Formulation, Stocking, and Management in All Seasons of River Animals and Plants" (Hibberd, 1860):

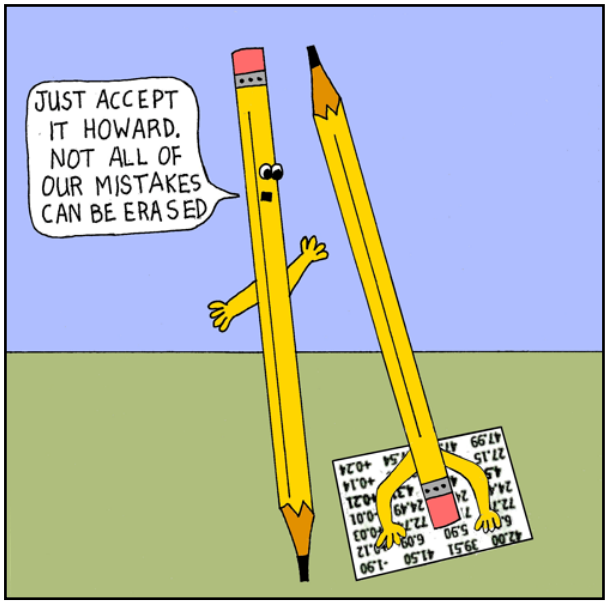
With this opinion I quite concur, and it is agreeable to have to associate Mr. Ward's name with the subject before us, for he was one of the early pioneers, and at a meeting of the British Association at Oxford, 1849, communicated an account of his success in growing marine algae in artificial sea-water.

The British Association that Hibberd referred to was the British Association for the Advancement of Science so I consulted their Annual Report for that year but was unable to find any mention of Ward mentioning artificial seawater. I had noticed that Lloyd stated that this happened BEFORE 1849 and Hibberd stated that it happened IN 1849. As it turned out, with regard to the date Lloyd was right and Hibberd was wrong. I suspected that Hibberd had the wrong date so with a set of key words and phrases I did a Google search and came up with two relevant hits, one in the *Floricultural Cabinet, Florist's Magazine* (Anon., 1847a) and *The Gardener's Chronicle and Agricultural Gazette* (Anon., 1847b). Since the reports were identical, I am reprinting the entry as found in the *Chronicle*:

BRITISH ASSOCIATION. Friday, June 25, 1847. Mr. Ward made some remarks on the results of his plan of growing plants in closed glass cases… Mr. Ward also stated, that not only could land-plants, and the higher forms of vegetation be grown in these cases, but that the various forms of marine Algae had been cultivated in artificial salt water.

This solved the problem, or so I thought at the time, since it was the 1847 meeting of the British Association, not the 1849 one as Lloyd and Hibberd had it. Now all I has to do was to obtain a copy of the 1847 Annual Report and to find Ward's comments. Unfortunately, no matter what words or terms I searched on–Ward, artificial, salt water, etc.–Ward's comments just weren't in these Reports.

I decided to find out what Stephen H. Ward, Ward's son, had to say so I read his paper titled "On Wardian Cases for Plants, and Their Applications" (Ward, 1854). In this paper a note appeared in the appendix that mentioned the idea of growing algae in Wardian cases by means of salt water that appeared in the *Athenaeum* on July 3rd, 1847.



Thus I looked for the *Athenaeum* issue (Anon., 1847c). The *Athenaeum* was large, in newspaper style, set up in three columns and had much more detail than was in the Association's Annual Report. Although the Association did not include the smaller, less important communications in its Annual Report, independent journals like the *Chronicle, Floricultural Cabinet* and *Athenaeum* did. Ward's report, however, read quite differently in the *Athenaeum* from those in the *Chronicle and Floricultural Cabinet* in 1847 (Anon., 1847c):

BRITISH ASSOCIATION.
Friday. July 3.- Section D.
Mr. Ward made a communication on the subject of Growing Plants in Closed Cases. His object was to give the results of a long experience of his plan, as well as to point out some errors with regard to the use of these cases... He also called attention to the fact that all the lower marine Algae might be grown in these cases by means of salt water artificially prepared.

Note that all these reports were written by reporters who worked for–or were paid by–the periodicals in which the reports appeared (in the case of the reports in the *Chronicle* and *Floricultural Cabinet*, it is almost certain that they were written by the same reporter). Periodicals need to publish information as soon as possible and the associations involved published their information annually. Furthermore, the associations of the day did not publish everything (group discussions, for example, were not included in their Annual Reports) so reporters would attend meetings of these individual sections and take their own notes.

Thus, a reporter for a botanical magazine would be sure to attend the meeting of the Botany part of the meeting where he would take notes of informal discussions and exchanges he thought might be of interest to his readers, Ward's comments above being an example. Different reporters, of course, would produce reports of the same exchanges that would agree roughly but not exactly.

The last line of the two reports above highlights a discrepancy between the *Athenaeum* version and the other two, the *Chronicle*, stating that "…the various forms of marine Algae **had been cultivated** in artificial salt water" and the *Athenaeum* stating that "…all the lower marine Algae **might be grown** in these cases by means of salt water artificially prepared." [the boldfacing is mine]." The difference between "had been grown" and "might be" is significant. If it is the latter, then Ward had not actually kept marine algae in artificial seawater, and even if it is the former, Ward did not claim that he had been the one who did. The best that can be said is that, on the record, Ward is the first to evince an interest in using artificial seawater in the marine aquarium, not that he himself had done it.

However, by using deductive reasoning, we can come to a more satisfying conclusion. If Ward or someone he knew had cultivated marine algae in artificial sea water, then he certainly would have mentioned it and included the answers to the usual questions of who, when and where. As he didn't, then Ward was only suggesting that it might be done and the rather lengthy material in the *Athenaeum* was the correct version of what he said at the British Association meeting of 1847 at Oxford.

It is clear that Hibberd most likely got his information from one of the gardening magazines

available in 1847, which would include the *Floricultural Cabinet and Florist's Magazine* and *The Gardeners' Chronicle and Agricultural Gazette*, but not from the *Athenaeum*. He was booby-trapped by using unreliable sources. He was correct, however, in noting that the citation did come from the meeting of the British Association at Oxford; the meeting in 1849, by the way, was at Birmingham.

CONCLUSION

I have shown a number of instances of misinformation appearing in aquarium hobby history writing falling under the headings of (1) failing to define important terms, (2) failing to check their sources and (3) relying on secondary sources that themselves contain fallacies. Unfortunately, the errors described have become widely disseminated all over the planet and into many different languages.

Admittedly these errors are not going to cause any really significant problems for society, but when it happens in other areas, such as education, it is a far more serious case. For example, in 2002, publishers submitted high school U.S. History books for State of Texas approval and the education establishment missed most factual errors. The firm, Educational Research Analysts, found 249 undetected factual errors in four high school U.S. History books after the state approval process certified them error-free. This was despite the publishers' claims to have beefed up their fact-checking, despite the Texas Education Agency's emphasis on verifying their accuracy to the State Textbook Review Panel, and despite an $80,000 Texas Tech review team backing them up. Four examples:

[William H.] Seward had some trouble persuading the House of Representatives to approve the [Alaska Purchase] treaty. (From "The Americans: Reconstruction to the 21st Century," McDougal, 2003.) The Senate, not the House, approves treaties.

1492 Columbus first reaches North America. (From "The Americans: Reconstruction to the 21st Century," McDougal, 2003.) Columbus never reached North America. He explored Caribbean islands and the northern coast of South America.

The Dred Scott case was only the second one in American history in which the Supreme Court reversed a federal legislative act. (From "The Americans: Reconstruction to the 21st Century," McDougal, 2003.) The 1857 Dred Scott decision did not reverse the Missouri Compromise, because the 1854 Kansas-Nebraska Act had already repealed it.

James Monroe was the last president to have fought in the Revolutionary War. (From "American Nation in the Modern Era," Holt, 2003.) Andrew Jackson, not James Monroe, was the last president to have fought in the American Revolution.

THE AQUARIUM AS A HYBRID SPACE BETWEEN ANIMAL HOBBIES AND EXPERIMENTAL ZOOLOGY

by Christian Reiß

(Aquarium Hobby Historical Society, Files Section, February 12, 2011)

This essay is part of Christian Reiß's PhD project (Friedrich-Schiller-Universität Jena) on the history of the Mexican axolotl (*Ambystoma mexicanum*) as an experimental animal in the life sciences. First I'll provide explanations of some of the terminology he used. Reiß frequently refers to the term "life sciences" in his article. Life sciences comprise the branches of science that involve the scientific study of life and organisms – such as microorganisms, plants and animals including human beings. This science is one of the two major branches of natural science, the other being physical science, which is concerned with nonliving matter. Biology is the overall natural science that studies life and living organisms, with the other life sciences its subdisciplines. However, in the context of this article is concerned only with the aquarium and its effect on zoological; research. Reiß uses the term "fancy" alone and also terms such as "animal fancying," "aquarium fancying" and similar terms. In all these instances I have used "hobby" instead.

Reiß also uses the term "hybrid spaces," which is best explained by the following example.

In 1872, August Weismann (he studied how the traits of organisms developed and evolved in a variety of organisms, mostly insects and aquatic animals, and proposed the theory of the continuity of germ-plasm, a theory of heredity) started his research project on the Mexican axolotl. He wanted to find out in the context of his experimental studies on evolution whether the irregular and rare transformation from axolotl to amblystoma August Duméril (Duméril, 1866) had observed ten years earlier in Paris (Fig. 1) was caused by environmental influences or the internal phyletic force suggested by other zoologists.

What he at first considered to be a straightforward *experimentum crucis* (crucial or critical experiment), which would ultimately show that evolution happened gradually and was driven by natural selection, turned out to be much more complicated. His first experimental attempt failed and all axolotls died. Only after he handed the project over to the naturalist Marie von Chauvin did the experiments turn out to be successful (Chauvin 1876). Her initial interest was in the natural history of insects, but she soon acquired a reputation as a talented and experienced animal breeder (Siebold, 1876).

Chauvin used the aquarium as an experimental tool, altering the environmental conditions according to the axolotls' reaction. For her experiments, she kept five axolotls in an aquarium that was set up like a lakeshore, that is, only a part was filled with water. To induce the transformation, she slowly lowered the water level so that the animals could only submerge at one spot. During the experiments, Chauvin showed great skill in observing the reaction of the axolotls to the experimental treatment, adjusting the further steps accordingly.

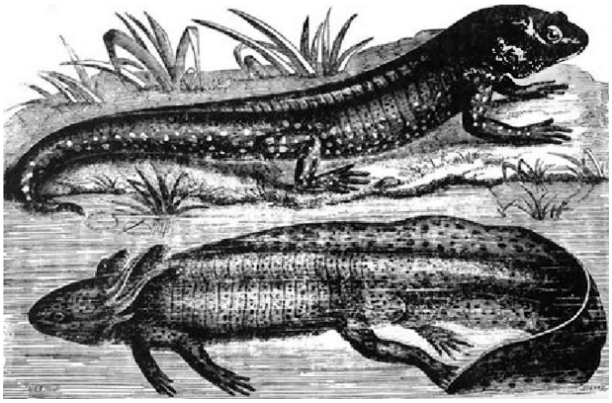

Figure 1: Bottom: Axolotl, Top: Amblystoma. As depicted in one of Auguste Duméril's publications (Duméril, 1866).

The result was the transformation of all five animals. In the course of a subsequent series of experiments she conducted over ten years, she managed to control the axolotls' transformation with the help of the aquarium to the extent that she could start it, stop it, and even reverse it up to a certain point (Chauvin 1883a, 1885). These axolotl experiments were part of a larger experimental system on amphibian metamorphosis, adaptation, and reproduction, on which she also published in the fancier journal Isis.18 While the aquarium was often just used as a gateway, which brought new species into research spaces, Chauvin took full advantage of the aquarium as an artificial environment and turned it into an instrument allowing her to manipulate ontogenetic processes (i.e., processes that are based on visible morphological characters) in several amphibian species.

The following is my translation of his own summary of Reiß's work.

Despite its widespread use in the life sciences, the aquarium has so far received little scientific and technological historical attention. This is not least due to the fact that the aquarium and its history have so far largely been viewed as non-scientific.

Contexts as diverse as acclimatization, amateur natural history and middle-class popular culture played an important role. At the same time, the development of the aquarium is also closely linked to the history of the life sciences. With a view to the second half of the 19th century, I understand the aquarium as a techno-natural assemblage in which technology, culture and nature are connected to an artificial natural space. Its history begins in British amateur natural science and the French acclimatization movement. In Germany in the late 19th century, the aquarium developed into a mass phenomenon.

At the same time it found its way into the life sciences, where it was used as a gateway, instrument and environment. As it turns out, the aquarium is a highly engineered technology that emerged from a combination of different traditions and brought life to the life sciences.

The following is the portion of his dissertation that it of most relevance to the aquarium hobby. I have edited it slightly to make it more readable for American aquarists. *Albert J. Klee, Ph.D., Editor.*

THE AQUARIUM AND THE HISTORY OF SCIENCE

Even though it was and still is an integral part of laboratory research in the biomedical sciences, the aquarium leads a shadowy existence in the history of science and technology. The rare opinions given by historians of science are short and unambiguous. For David Allen, the aquarium was a "plaything of fashion" (Allen, 1996, pg. 394) and the aquarium hobby an "extra-intellectual interest" (Allen, 1994, pg. 122) in the context of British amateur natural history. Andreas Daum describes the aquarium hobby as yet another variety of popular science in nineteenth century Germany, in which "non-professional nature lovers [aimed] for fulfilment and organization" (Daum 2002: 108). This article contributes to these and further works that focus on the aquarium's role in

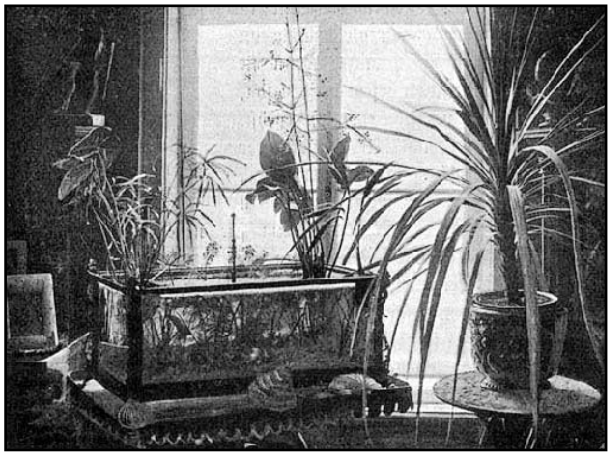

Figure 2: The aquarium as a techno-natural assemblage, integrated into the urban home (Bade 1899, pg. 72).

nineteenth and twentieth century popular culture (Schlebrügge, 2005/ Lorenzi, 2009/ Kranz, 2010/ Brunner 2011/ Hamera, 2012). At the same time it challenges the bias towards an extra-scientific history of the aquarium by emphasizing the aquarium's hybrid nature as an object in popular and laboratory culture.

The aquarium is such a functional space and a technology-in-use in twentieth and twenty-first century laboratory culture. Hence there must be a history of its emergence and stabilization and a historical link to its history in the nineteenth century. And this connection must either provide a feedback from Daum's popular science into the professional realm, or the aquarium must have been more than Allen's profane "plaything of fashion."

Closer inspection reveals that both scenarios apply and that the aquarium indeed has a history of science. It is not just exclusively a history of science, but also a history of fanciers, of animals, of industrial and urban technology and of nature constructed. It is the history of a technology that developed from a broad desire to bring nature into cities, into domestic spaces and – last but not least – into scientific spaces.

THE BRITISH AQUARIUM CRAZE AND THE SALTWATER AQUARIUM

In The Naturalist in Britain, David Allen reconstructs the history of the aquarium and the aquarium craze in Britain in the 1840s and 1850s, linking it to a number of other subfields of British amateur natural history (Allen, 1994). By way of explaining the spreading of the aquarium and the nature of the aquarium craze, he points to two central factors. First, it was the removal of the excise duties on glass (*ibid.* pg. 122) that made products of plate glass, including the aquarium, accessible to a broader audience. Second, there was a social change in the public for natural history, i.e., an emerging educated and prosperous middle class that turned enthusiasm into a craze.

The Aquarium hobby in Britain was materially and practically linked to a set of activities, which all consisted of collecting organisms or parts of them and arranging and displaying them in different kinds of boxes. While in academic natural history, these activities had a long tradition and were based on a taxonomic and classificatory epistemology, amateur crazes followed a different logic.

Driven by the writings of Philip Henry (Gosse, 1856) and following on the heels of seaweed and fern hobbyists, the aquarium offered a new opportunity for members of the emerging middle class to enjoy nature, advance their (scientific) education, and develop and display their aesthetic sensibility. The aquarium hobby originally meant to go to the coast during ebb tide – British aquarium hobby concentrated mainly on saltwater aquaria – to collect plants and animals from the tidal pools and then arrange them in aquaria. With its rising popularity and almost becoming a must-have for the salon, the aquarium became a commodity with a growing industry offering everything from fresh saltwater to fully equipped and even regularly maintained aquaria (Brunner, 2011). The most prominent aquarium trader was W. Alford Lloyd, whose Aquarium Warehouse in London had 15,000 animals in stock (Lloyd, 1858 and Alexander, 2005). To secure a steady supply of fresh water, plants and animals, traders like Lloyd took advantage of the rapidly developing railroad system in Britain, which connected the coast with inland cities like London and allowed a fast and stable transport of the sensitive freight (Schivelbusch, 1978). The rising popularity together with the new infrastructural possibilities owing to industrialization meant that soon "… great stretches of the coast were largely stripped of their attractive inhabitants" (Allen, 1994, pg. 124).

Even though the enthusiasm evaporated as fast as it had emerged, seeing most aquaria abandoned (Brunner, 2011), it left a lasting legacy by laying

the foundations of aquarium technology and practices, and thus of techno-natural assemblages. Furthermore, public aquaria made their way to the European continent as a new attraction for the masses. Following the bankruptcy of his aquarium warehouse with the end of the craze, W. Alford Lloyd became the most eminent expert for public aquaria in Europe, constructing aquaria for the *Jardin zoologique d'acclimatation* in Paris (1860), the *Zoologische Garten Hamburg* (1864), and the *Stazione Zoologica* of Naples (1874).

In addition, it sparked the proliferation of the aquarium as a research technology in the life sciences. While during the first half of the nineteenth century, scientific research with and on aquaria largely remained an isolated endeavor conducted by people like Robert Warington (Hamlin, 1986), Anna Thynne (Stott, 2003) or Jeanette Villepreux-Power (Brunner, 2011) the use of aquaria became widespread among British anatomists and zoologists (Elwick, 2007) from the 1850s onwards. Thus, not even the British aquarium tradition should be considered a purely amateur movement or as popular science. The amateur-professional dichotomy that already received substantial criticism (Daum, 2002/ Nyhart, 2009 and Phillips, 2010) does not hold for the situation in France and Germany either.

The history of the British aquarium craze and of the public aquarium reflects a specific tradition in the aquarium hobby which is intimately tied to a broad cultural (re-)discovery of the ocean at the beginning of the nineteenth century (Corbin, 1994, Rozwadowski, 2005 and Schwarz, 2005). Saltwater aquaria became the focus of this tradition, serving as imaginative spaces of the mysterious and undiscovered wonders of the ocean. In addition, the geographic specificities of Great Britain as an island with a big ratio of coastline to area and the resulting short distances between coast and inland cities simplified their set-up and maintenance.

THE CONTINENTAL COUNTERPART: ACCLIMATIZATION, AQUACULTURE AND THE FRESHWATER AQUARIUM

The situation in continental Europe differed from Great Britain in several ways. Due to the geographic differences – less coastline per area and hence long distances between coast and most inland cities – saltwater aquaria never became as popular and common as in Great Britain. Even though adept enthusiasts managed to set up and maintain saltwater aquaria for several years without changing water, the organisms populating the aquarium nevertheless eventually died and had to be replaced by new ones. As breeding turned out to be almost impossible for most marine organisms, fresh supply had to come directly from the sea.

This corresponds to the fact that, especially in France and Germany, the aquarium hobby was much more rooted in the acclimatization movement with its specific agendas among science, enthusiasm and commerce. The acclimatization movement emerged in France and Great Britain at the end of the eighteenth century (Osborne, 2000). Due to the rapidly increasing circulation of organisms along colonial networks animals, plants and humans were frequently exposed to new environments, and the influence of different environments on organisms came into focus. Acclimatization was the attempt to deal with and even to take advantage of this influence. In Great Britain this meant the transfer of organisms between similar environments, while the French approach assumed that organisms could, to a certain degree, be bred to adapt to different environments (*ibid.*).

The *Société Imperiale d'Acclimatation*, the first acclimatization society founded in Paris in 1854, set its agenda accordingly (Osborne, 1994). It announced prizes (consisting of medals and considerable sums of money) for the successful introduction and breeding of a wide range of organisms that were considered agriculturally and eco-

nomically promising in various ways. Its activities were directed both at France as well as at the colonies and included attempts to acclimatize alpacas, zebras, bustards, new silkworm species, new wax-producing insect species and quinine bark in France, edible fish in Algeria and "an animal to Martinique that could exterminate the fer-de-lance (*Bothrops lanceolatus*) living there."

These examples illustrate the Société's policy ranging from projects in France to ones in the colonies, and from agriculture to pharmacy. In parallel to stimulating acclimatization efforts by its members, the *Société* founded a zoological garden. The *Jardin Zoologique d'Acclimatation* was opened in 1860 and designed as a mix between an acclimatization laboratory and public animal display. In the *Bois de Boulogne* outside Paris, which had been landscaped under the direction of Baron Haussmann into a park in 1852, the *Société* built what was soon regarded as the ideal of a modern zoological garden. Financed by stock shares and a large network of powerful members, the *Jardin* was the manifestation of the acclimatization ideology.

The French acclimatization movement must be understood as part of a much broader regenerative movement, which Napoleon III turned into a state policy during the Second Empire. Projects ranged from Baron Haussmann's urban renewal of Paris to reforestation projects all over France, following the idea of "making facts of nature into instruments of human progress'' (Kinsey, 2006: 536). Acclimatization was a complex set of practices that linked "science to animal display, urban renewal, agricultural improvement and France's colonial mission" (Osborne, 1994, pg. 13).

One of these projects was scientific aquaculture, the attempt to "elevate the last unconquered region of the planet – its aquatic wilderness – to a level of domestication" (Kinsey, 2006: 527). The aqua-cultural revolution, like any other regenerative project at this time in France, was carried by heterogeneous interest groups "including scientists, bureaucrats, sportsmen and entrepreneurs" (*ibid*. pp. 552). State and private actors aimed for the rational and scientific reorganization of the use of aquatic species and tried to acclimatize foreign species in French waters, including salt- and freshwater "fish, mollusks, and even leeches for medical purposes" (*ibid*. pp. 528). For their Jardin, the Société commissioned W. Alford Lloyd to build an aquarium, which included both saltwater and freshwater tanks as well as facilities for fish, oyster and frog culture.

While committed to the improvement of nature in general, and human food sources in particular, the spectacle of the exotic and ornamental held a prominent place on the acclimatization agenda as well. As a result, aquaria did not only become an integral part of the *Jardin* but also objects for private homes (Lorenza, 2009). Compared to Great Britain that created a different blend of aquarium culture, the specific mixture of economic and ornamental motives, the inclusion of freshwater aquaria, and especially the close association with imperial networks and acclimatization shifted the attention away from the one-way relation between the ocean and the aquarium toward the breeding and circulation of aquarium organisms within techno-natural assemblages.

THE AQUARIUM IN GERMANY

The French acclimatization movement - and especially its *Jardin Zoologique d'Acclimatation* - soon acquired European fame, and similar societies and zoological gardens were founded across Europe. Germany was one of the countries where [French] acclimatization found a large following. Zoological gardens were opened or reorganized (Wessely, 2008), societies founded, journals published and a broad affinity to animal keeping and breeding emerged.

While acclimatization and its encompassing improvement agenda turned out to be rather short-

lived in Germany, the educational and leisure aspect of animal keeping and breeding acquired increasing prominence. This development was amplified by the particular German tradition of non-academic natural history (Nyhart, 2009). In this context, Emil Roßmäßler, the German counterpart to Philip Henry Gosse, promoted the aquarium and set the agenda for German aquarium culture (Roßmäßler, 1856, 1857 and Daum, 2002). As in Great Britain and France, aquarium enthusiasts were members of the middle class with the necessary resources in money, time and education (Daum, 2002).

After the initial boom between the 1870s and 1890s, the hobby saw another upswing in the interwar period. During these years, the aquarium found a new audience among members of the working class, and large numbers of proletarian clubs were founded (Hohl, 2001).

The rapid expansion of the field in the late nineteenth century is apparent in the growing number of increasingly specialized journals and the formation of clubs or *Vereine*. Until the 1870s, *Der Zoologische Garten, Zeitschrift für die gesamte Tiergärtnerei* (The Zoological Garden, Journal for the Entire Field of Zoo Keeping), founded in 1859, was the most important journal in the field of animal hobbyists. Originally the journal of the Frankfurt zoological society and its zoo, it soon became the central publication for zoological gardens, acclimatization and animal breeding in Germany. In 1876, *Isis, Zeitschrift für alle naturwissenschaftlichenLiebhabereien, Verkehrsblatt für naturgeschichtlichen Kauf und Tausch* (Isis, Journal for all Scientific Hobbies and Natural Historical Trade and Exchange) was launched. It specialized in the needs of the ever-growing private animal hobbyists, serving as a platform for the exchange of practical information and to connect animal buyers and sellers (Paepke, 2007a). The journal *Natur und Haus, Illustrirte Zeitschrift für alle Naturfreunde* (Nature and House, Illustrated Journal for all Friends of Nature) founded in 1892 and its follow-up *Nerthus: Illustrierte Wochenschrift für Tier- und Pflanzenfreunde, Organ für Sammler und Freunde aller naturwissenschaftlichen Zweige* (Nerthus: Illustrated Weekly for Friends of Animals and Plants, Institution for Collectors and Friends of all Scientific Branches), launched in 1899, were directed at similar audiences (Daum, 2002).

Isis was only published until 1889, but one year later, in 1890, *Blätter für Aquarien- und Terrarien-Freunde, Illustrirte Halbmonatsschrift für die Interessen der Aquarien- und Terrarienliebhabei* (Journal for Aquarium and Terrarium Enthusiasts, Illustrated Half-Monthly for the Interests of Aquarium and Terrarium Enthusiasts), was launched as the first journal exclusively for aquarium and terrarium hobbyists. This project was initiated by Bruno Dürigen, the co-founder of Isis and one of the most prolific figures in the field of German animal keeping and breeding (Paepke, 2007b), and Ernst Bade, former editor of *Nerthus* and a leading figure in the German aquarium and terrarium scene who ran his own commercial aquarium breeding business in Berlin. The journal's title points to a characteristic of German aquarium culture – the close connection between the aquarium and the terrarium, often subsumed under the umbrella term vivarium. This meant a generally more inclusive approach with a broader array of animals, ranging from fish, amphibians, and reptiles to insects and plants, as well as a more complex set of habitats, which often combined aquatic and terrestrial spaces.

In 1902 the *Blätter* was renamed *Blätter für Aquarien- und Terrarienkunde, Illustrirte Wochenschrift für die Interessen der Aquarien und Terrarienkunde* (Journal for Aquarium and Terrarium Studies, Ilustrated Weekly for the Interests of Aquarium and Terrarium Studies) and switched from bimonthly to weekly publication. While the latter indicates the growing number of authors and readership, the change in the title from Freunde (enthusiasts) to Kunde (studies) points to the effort of enthusiasts to be taken seriously in their activities, which they understood as a form of production of knowledge complementary to the

sciences (Nyhart, 2009). In 1909, *Natur und Haus* merged with *Blätter* and in 1939 *Blätter* merged with its competitor *Wochenschrift für Aquarien und Terrarienkunde* (Weekly for Aquarium and Terrarium Studies), founded in 1904.

Aquarium clubs started to appear in the late 1870s. By 1911, 284 clubs existed and could be found in every large German city (Hohl, 2001a). In the same year German aquarium and terrarium hobbyists saw a further institutionalization with the foundation of the *Verband der Aquarien und Terrarienvereine* (Association of Aquarium and Terrarium Clubs) (*ibid*., 2001b).

This continuing specialization and institutionalization of the aquarium and terrarium hobby found no complement in France and Great Britain. Aside from monographs that were regularly published in all three countries, only Germany saw the development of highly specialized, practice-oriented journals and a national network of clubs (Daum, 2002). Clubs mostly worked as local communication platforms where a common interest cultivated sociability in the exchange of practices, technologies, knowledge and organisms. Hobbyist journals fulfilled the same function at national and sometimes international level, connecting likeminded enthusiasts and the growing number of professional aquarium suppliers and acting as platforms on which knowledge and practices were further negotiated, stabilized, exchanged and archived. Especially in the second half of the nineteenth century, when the keeping and breeding of organisms in aquaria and terraria was still developing, clubs and journals were crucial in developing, stabilizing, and making accessible the necessary knowledge and technologies. The following examples demonstrate this process of tinkering and stabilizing techno-natural assemblages as well as their integration into middle-class life worlds in nineteenth-century Germany.

Water ventilation was the most crucial aspect of running an aquarium. Although hydraulic/pneumatic devices (often in combination with a fountain (Fig.3) or spring mechanisms driving a paddle wheel) had been available from early on, enthusiasts were constantly experimenting with alternative mechanisms, like small steam engines (Buck, 1875) or the growing infrastructures of urban supply. Adolf Sasse, who ran the biggest aquarium shop in Berlin, even made a trip from Berlin to Lübeck to study the apparatus constructed by Heinrich Lenz, director of the local natural history collection, who used the water pressure from the recently installed urban water supply system for ventilation (Sasse, 1878).

In Sasse's description of his own efforts to install this apparatus in his apartment, several conflicts of integrating techno-natural assemblages become visible. The new apparatus had the advantage of replacing the old pump system, which was rather bulky and used to spray water. As Sasse emphasized, "nobody was happier than my wife" (*ibid.* pg. 143) about its disappearance. Still, the new apparatus consisted of a rubber pipe, which ran through three rooms and connected the water tap in the kitchen to the aquaria. In the end it was the landlord who ended "this municipal *perpetuum*

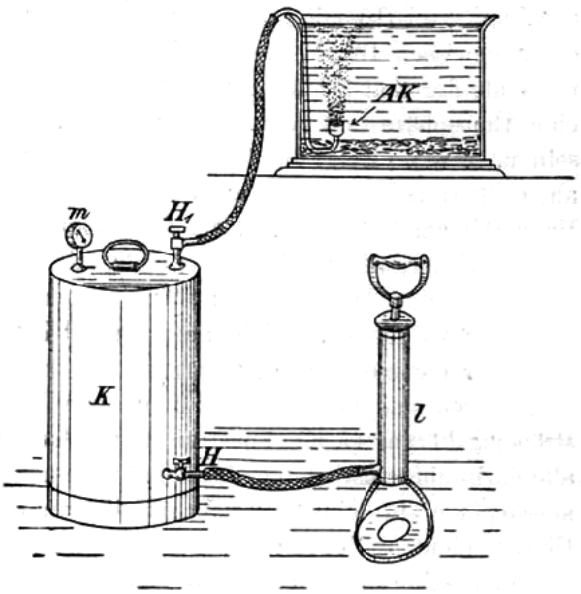

Figure 3: Construction plan for an aeration device using an air pump (Zernecke 1897, pg. 41).

mobile" (*ibid.*), complaining about the water running day and night. Sasse had to return to his old pump system. The kind of ventilation device developed by Lenz did not become commercially available until 1908 (Hohl, 2001a).

As these examples show, the process of creating a shared space for human and non-human animals went beyond mere technical feasibility and had to meet different interests. The decorative aspects of the aquarium often conflicted with the necessities of maintenance and functionality. The boundary between human and non-human subspaces turned out to be problematic in various ways. *Blätter* editor Ernst Bade (Bade 1897) brought these boundary issues to the fore when he discussed the following dilemma. If the aquarium is not filled up to the top lip, the water surface leaves a strip of dirt, which over time is more and more difficult to remove and blemishes the aquarium. Yet filling up the aquarium to the seam, one runs the danger that the fish jump out.

Last but not least, the aquarium hobby had to be integrated into family life. In a text on aquaria for children from 1899, the author discussed the question why children rarely shared their father's enthusiasm. He identified one reason in the way the aquarium was integrated (or rather, not integrated) into family life. While it often formed the center of the household, dominating the needs of wives and children, "no wife, no child is allowed in the vicinity of the aquarium, let alone to touch it" (Dankler 1899: 94).

In the course of this mediation between the diverse interests of aquarium animals, family members and landlords, the aquarium became socially and domestically integrated and the techno-natural assemblage developed into a stable and increasingly ready-made infrastructure (Fig. 2). As the aquarium hobby found a growing audience, a market developed that was served by a growing number of suppliers. To give just one example of its dimensions: between 1905 and 1912, the company A. Glaschker in Leipzig sold 100,000 aquaria (Hohl, 2001b: p. 117).

THE AQUARIUM IN THE SCIENCES

The process of integrating the aquarium did not only take place in domestic spaces. For a number of partly overlapping reasons, life scientists started to keep animals as well. While many life scientists were fanciers themselves, there were also practical and methodological reasons that created a growing demand for living animals. Even though the aquarium was likewise used in scientific institutions in France (for instance at the *Musëum d'Histoire Naturelle* in Paris) and Great Britain (Elwick, 2007), the highly diversified German aquarium culture and the development of the life sciences in Germany in the second half of the Nineteenth century (Coleman, 1971) constituted an especially fertile ground for proliferating the aquarium in the life sciences.

Physiology achieved growing institutional independence and especially experimental physiology developed a research agenda that intensified its consumption of research animals (Nyhart, 1995/ Dierig, 2006). When in 1877 Emil DuBois-Reymond had his new physiological institute built in the center of Berlin, he included a ranarium, that is, a facility to breed frogs, so as to have a steady supply of frog muscles for his electrophysiological experiments (Dierig, 2006). In turn physiologist Elie de Cyon considered the aquarium as the best way to secure this steady supply and he noted that every "experimental scientist should personally make sure that the animals are held under living conditions that fit their nature the most" (de Cyon, 1876, Pg. 29). As de Cyon emphasized, the growing urban infrastructures could be easily used for this purpose (Dierig, 2006).

In parallel, anatomy and zoology shifted from a systematic to a morphological framework (Nyhart, 1996). Instead of studying particular anatomical structures in particular species (often

using particular specimens from a collection) to comparatively understand the taxonomic relation of these species, morphology used a number of species from one group as exemplars to understand the history and thus the development of a structure in the whole group. Gradually, the scope expanded to increasingly fundamental principles and ever-larger taxonomic groups.

Since this research was based on the investigation of the successive steps of morphological development, it needed the successive developmental stages of often several animal species. Accordingly, the large collections of dead and preserved specimens gradually lost their significance in this context. Like experimental physiologists, zoologists started to rely on species that were either of great abundance locally or could be kept and bred rather easily (Hopwood, 2011). Hence availability slowly outpaced taxonomy.

In this context, experimental embryology emerged as a new field of research. It was a science of, or better, at the sea, with roots in the morphological questions of *Entwicklungsgeschichte* (developmental history). After primarily developing at marine stations that were founded on all European coasts in the 1870s and 1880s, it heavily relied on easy access to eggs and larvae of mostly marine invertebrates (Groeben, 2008). As a consequence, decades into the twentieth century, several generations of zoologists and anatomists traveled at least once a year to one of the stations, the most famous being the Stazione Zoologica of Naples (Fantini, 2000).

And finally, life history studies, though often less visible, always played an important role in zoology (Nyhart, 1996). Following the publication of Darwin's Origin of Species, the interrelations between organisms and their environment became an important area of research that was increasingly carried out in the emerging hybrid spaces of techno-natural assemblages.

Especially in the context of experimental embryology and the research style developed at the marine stations, the aquarium gained significance. But this observation should neither suggest that the aquarium was imported into science as ready-made technology, nor that there was a clear distinction between amateur and scientific uses of the aquarium. Lynn Nyhart has already brought to attention the importance of "practical naturalists" (Nyhart, 2009, pg.108) for the life sciences and the role played by the "everyday business of keeping the animals alive." Not only people generally considered as amateurs contributed to scientific knowledge; also scientists participated in activities generally considered as amateurish.

Aquarium enthusiast and scientist were often identities of the same person, sometimes being almost unconnected but sometimes being closely interwoven on the practical level. Probably one of the most (in)famous examples in this context is Paul Kammerer. He started out as an aquarium/ terrarium enthusiast in his youth, became a corresponding member of the Berlin club *Triton* (Rieck/Mau, 2008, pp. 60) and published in the *Blätter* (Kammerer, 1901). In 1902, he started to work at the *Biologische Versuchsanstalt* in Vienna, also known as the Vivarium. It is no coincidence that Kammerer, known for his special aptness for breeding and keeping amphibians (Rieck/Bischoff, 2001/ Gliboff , 2006/ Berz, 2009), worked at this institution which was in all aspects designed for keeping, breeding and experimenting with animals (Reiter, 1994/ Gliboff, 2006/ Berz, 2009). But he kept close contact to the aquarium movement, acting as editor for the *Blätter* from 1908 until 1909.

Other examples include Valentin Haecker, Professor of Zoology at the University of Halle, who had a close relationship to the *Vivarium-Halle*, one of several local clubs. Some of his doctoral students were members of this club and did their experimental research on aquarium animals (Roßmäßler-Vivarium 2006). Werner

Schnakenbeck, for example, published his breeding experiments with the Mexican axolotl in the Blätter (Schnakenbeck, 1922a), and his experimental research on the same animal in scientific journals (1922b, 1923). In Jena, Friedrich Maurer, Professor of Anatomy, Ludwig Plate (Levit/Hoßfeld, 2006), Ernst Haeckel's successor as Professor of Zoology, Karl Hobstetter, Professor of Veterinary Medicine and Julius Schaxel (Reiß 2007), Associate Professor of Zoology, were all members of the local club *Wasserrose e.V.* [e.V. under German law is a Körperschaft (corporation), which is defined as being a legal entity which is separate from its members, i.e. not a partnership], 1913, Jena. The fact that many university libraries in Germany hold a wide variety of aquarium journals further demonstrates the close ties between the academic life sciences and the intermediary realm of enthusiasm.

GOLDFISH: MUSINGS, MEMORIES AND MORSELS

by Albert J. Klee, Ph.D.

(*Aquarium Hobby Historical Society*, Facebook Files, June 10, 2021)

A1. EARLY ATTEMPTS TO DATE THE INTRODUCION OF THE GOLDFISH INTO THE U.S.

In 1836, James Ellsworth De Kay had been entrusted with the stupendous task of covering "both botany and zoology" for a Natural History survey of New York State. The years of research that followed resulted in the publication of five volumes from 1842 to 1849. In these he had described more than 1,600 species of animals, including mammals, birds, reptiles, amphibians, fishes, molluscans, and crustaceans, introducing common names as far as possible.

De Kay (his name was spelled also as DeKay, even by him at times) was born in Lisbon, Portugal in 1792. When he was two years old his family moved to New York; both his parents died, however, while he was still quite young. He attended Yale from 1807 to 1812, but was expelled before completing his degree when he threatened a college tutor with a club. Later, he studied medicine at the University of Edinburgh, receiving his MD in 1819.

De Kay returned to Oyster Bay, New York, giving up medicine for the study of natural history. On the outbreak of cholera in New York City, De Kay hastened to give his services to the afflicted, although the practice of his profession was repugnant to him. He became involved with the Geological Survey of New York, which was initiated in 1835, and as a result, from 1842 to 1844 he published the multi-volume Zoology of New York, or The New-York Fauna covering: mammals, birds, reptiles and amphibians and fish.

I mention this because when I first started my research into aquarium hobby history in 1960, one of my goals was to find out when and who brought the first goldfish to America. At the time, the earliest mention was in De Kay's "Zoology of New-York" (1842, De Kay):

The Golden Carp, or Gold-fish, as it is more generally called, was introduced from China into Europe in the early part of the seventeenth century, and probably shortly after found its way to this country. They breed freely in ponds in this and the adjoining States. They are of no use as an article of food, but are kept in glass vases as an ornament to the parlor and drawing-room. They are said to display an attachment to their owners, and a limited obedience to their commands.

This, however, was hardly a definitive statement about the first importation of the goldfish into America so I attempted to find where De Kay obtained his information. With regard to Western Europe (and I include England here) there were a

James De Kay (1792-1851).

number of dates under general consideration at the time I started my research, i.e., 1611, 1691 and 1728. My reasoning for considering the first importation into Western Europe was that when the goldish was first introduced into Western Europe it would not have been long after that it was imported into the United States. Philip Henry Gosse's book, "The Aquarium, an Unveiling of the Wonders of the Deep Sea", for example was published in London in 1855 and was reviewed in the *North American Review* three years later in the July 1858 issue. Even in the 1700s it only took the British six weeks to ferry an army across the Atlantic!

Since De Kay reported that the goldfish was introduced from China into Europe in the early part of the seventeenth century, he most likely was thinking of the 1611 date. This appeared in D. Marcus Bloch's famous book, "Oeconomische Naturgeschichte der Fische Deutschland" (Block, 1784):

At present goldfish are esteemed not only in England, Holland and Denmark, but also in different cities of Germany. They were brought to the first country in the year 1611, and in 1728 they were already widely known.

Bloch cited as his source Thomas Pennant's, "British Zoology" (Pennant, 1776) but Pennant's comments, however, were as follows:

These fish are now quite naturalized in this country, and breed as freely in the open waters as the common carp. They were first introduced into England about the year 1691, but were not generally known till 1728 when a great number were brought over, and presented first to Sir Mathew Dekker, and by him circulated round the neighborhood of London, from whence they have been distributed to most parts of the country.

However, in those days the dates of publication were always in Roman numerals and it is easier to mistake MDCXCI for MDCXI, the Roman numerals for 1691 and 1611, respectively (just remove the last C from the first date).

Therefore, Bloch's date was clearly a misprint (Hervey and Hems, 1948), although it was accepted by many authors. I was now down to only to two dates, 1691 and 1728, neither of which agreed with De Kay's assertion that the goldfish was imported into Europe in the early 1600s. At this point I put aside the problem (for about 44 years!).

A2. DE KAY'S INTERESTING COMMENT

However, De Kay was not a complete loss. I uncovered the following in the preface of his book:

In 1788, Schoepff, an army surgeon, who was in this country during the war of the revolution, published in the Transactions of the Friends of Natural History at Berlin, a memoir entitled "Descriptions of North American Fishes, chiefly from the waters of New-York." His paper is for the most part a meagre catalogue of species from New-York and the Gulf of Mexico, mostly identical with those previously described by Linnaeus. In common with many of the observers of that period, he had such a slavish deference to the great reformer of natural science,that he scarcely dared to pronounce upon the validity of a species unless it had received the Linnaean stamp of authority.

Johann Schoepff (1752-1800).

This explains why *Fundulus heteroclitus* never wound up being named *Fundulus killfish*! At this point I copied this material but never got around to publishing it until now.

B. FAST FORWARD TO 2004

On May12, 2004, Albert Pawloski, a new member to the Aquarium Hobby Historical Society of America (AHHS) hosted on the Yahoo groups, asked a question regarding Samuel Pepys. I answered the same day, remarking towards the end that the fish viewed at the house of "Lady Pen" was a goldfish. This started a controversial thread, debating whether the fish was a goldfish or a paradise fish. By this time I had added much to my knowledge of this subject and on May 13, 2004 I posted the following (Note: any personal comments I have made with regard to the posts are enclosed in SQUARE BRACKETS and in a DIFFERENT type):

Post by Albert Klee, May 13, 2004
Based on the shorthand manuscript [by Lord Braybrooke] in the Pepysian Library, Magdalene College Cambridge, transcribed in 1825 by Mynors Bright, and edited in 1893 Henry B. Wheatley, the complete quote is as follows:

Thence home and to see my Lady Pen, where my wife and I were shown a fine rarity: of fishes kept in a glass of water, that will live so forever; and finely marked they are, being foreign.--[Gold-fish introduced from China.]--So to supper at home and to bed, after many people being with me about business, among others the two Bellamys about their old debt due to them from the King for their victualling business, out of which I hope to get some money.

In his various editions of Pepys' diary, Lord Braybrooke made a large number of notes but in many instances the notes were altered and added to from later information. This is the case with regard to the goldfish note in brackets. Therefore we do not know whether to attribute this note to Braybrooke, John Holmes of the British Museum who assisted Lord Braybrooke, Henry B. Wheatley, or to one of the many authorities Wheatley consulted during his own editing.

It seems strange that, if it were a paradise fish, Pepys would have commented on either the striking coloration of the fish or its conspicuous finnage. All throughout the diary Pepys commented on both English and foreign fisheries and would have, for the day, a commanding knowledge of fish in general. On the other hand, Pepys comment that they were "finely marked" suggests a paradise fish more than a goldfish.

It should be noted that my interest in the Pepys affair was not in the first introduction of the goldfish into the Western Europe but in whether the fish Pepys saw was a goldfish or a paradise fish. However, this did prompt me to post the following.

Post by Albert Klee, May 13, 2004
Finding the date of the first importation of goldfish into the Western world is difficult, to say the least. In his "A History of British Fishes," London, 1836, William Yarrell states the following:

The date of the first introduction of the Gold-

Samuel Pepys (1633–1703).

en Carp, or Gold and Silver Fish, as they are more frequently called, is differently stated by authors: 1611, 1691, and 1728, are each recorded as the particular year in which they were first brought over. The earliest seen in France were sent there for Madame Pompadour. A correspondent in Loudon's Magazine of Natural History, vol. iii. page 478, considers "that they were probably introduced into Portugal at an early period, after the people of that country had discovered the route to the East Indies by the Cape of Good Hope, as they appear to be now completely naturalised there, and abound in many of their streams, whence they are brought to us by trading vessels from Lisbon, St. Ubes, &c. in large earthen jars, and may be had at a very easy rate before they get into other hands."

In his "Natural History of British fishes: their structure, economic uses, and capture by net and rod," London, 1880, Frank Buckland had this to say about the goldfish:

This fish originally came from some lakes near the mountains of Tchanghou-the-Kiang. It is said to have been introduced into England in 1611, in the ninth year of the reign of James I. Another story is that it was introduced from China to St. Helena, and thence brought to England in 1728, the second year of the reign of George II. I have searched in vain to find any authority for any of these statements, and should be very much obliged for the information.

Some aquarists cite Gustave Loisel (1864-1933) in his "Histoire des menageries de l'antiquite a nos jours," Paris, 1912 where he states that goldfish were introduced into England by 1611, Portugal in the 18th century, and from there through to France and other European countries. However, the Portuguese had, with the concurrence of the Chinese, established themselves in Macao in 1549 and not only started to raise birds but also "red fishes" and, by 1611, it is known that they were shipping goldfish from Macao to Portugal. Loisel, therefore, is not a reliable source.

It is of some interest to note that in 1643, that Jesuits established themselves in Hang Zhou, China, where their church was located close by a "local farm of red fishes." This took the fancy of a man known only by his last name of Martini, who took an interest in the fish and brought back 10 of them to Holland.

The 1611 date of importation into England actually was advocated by the great German ichthyologist, M. F. Bloch, and we know that the 1728 date is associated with the importation of the goldfish into France presumably as a present to Mme. de Pompadour, although the de Goncourts, the historians of the mistresses of Louis XV, have failed to trace any records of this event. The latter, therefore, may just be another aquarium myth. Sir John Hawkins, the noted editor of Izaak Walton and Charles Cotton, wrote in 1760:

There has also been lately brought hither from China those beautiful creatures, Gold and Silver Fish. These fish are usually kept in ponds, basins and small reservoirs of water,

Francis (Frank) Trevelyan Buckland (1826–1880).

to which they are a delightful ornament; and I have known a few of them kept for years in a large glass vessel like a punch-bowl.

No matter how one interprets the word "lately," Hawkins was certainly not talking about any importation earlier than the 1728 date.

Re the Paradise fish, it is known that it was introduced into Paris, France, in 1868. It was introduced in this country in 1876, long after goldfish were introduced here. In 1852, for example, a Chinese merchant named Fang Tang immigrated to the United States and opened up a teashop in San Francisco. In addition to selling silks and porcelain, he also sold goldfish that he had brought over with him.

Post by Harro Hieronimus, May 13, 2004
Sorry, but I don't believe that [here Harro is questioning the 1911 date]. That's 200 years too early for this fish. It's unlikely that fish were imported which had to be caught in the wild. Goldfish had been kept in bowls (not like that ones we know today, but larger ones like large cups to be observed from above) since then.

[Harro had to be right but I wasn't happy about it. If Bloch was wrong then the next "popular" date was 1691 and this would have placed the importation of the goldfish into Western Europe much later than Pepys' visit to Lady Pen on May 28, 1665 and I would have had to abandon my planned refutation of Pepys' fish being a goldfish. I vacillated about this a bit until I suddenly remembered my research 44 years previously when I discovered that Bloch erroneously reported Pennant's 1691 date as 1611. I was about to write a post about this when Lee Finley posted the following:]

Post by Lee Finley, May 16, 2004
The early goldfish importation topic is one dear to my heart and I am glad to see it being fleshed out on AHHS. I would like to make a couple of comments and the first one regards the oft stated import date of 1611 (as noted in Al's post).

Hervey and Hems in their book "The Goldfish" (I am working from the revised 1968 edition) offer the following (page 79): "Bloch [in his book] records that goldfish were introduced into England in 1611, and he cites Pennant's British Zoology as his authority. But, as Pennant gives the year as 1691 it is clear the Bloch's 1611 is a misprint, even if we did not know that misprints were very common in eighteenth-century books."

Hervey and Hems go on to also question the 1691 date, but this is (admitted by them) based on somewhat shakier ground involving a potential transposition of Roman numerals in a date from another source. If their thoughts on this are correct, the date should have been 1711.

But, Hervey and Hems do cover their bases somewhat by noting "That there is some indirect evidence to show that goldfish [from Macao]....reached London in 1692." And, they also wisely state that "A few isolated specimens may even have been brought to England by travelers or sailors in the middle of the seventeenth century."

**Jack Hems (?1911-1989).
In his younger days he had been friends with and worked together in London with George Bernard Shaw.**

The authors also offer some question to the exactness of the 1728 date for importation. They base this thought on a checking of the records of the ship [The Houghton] reported to have brought the goldfishes to England. According to the authors, the ship did not return to England until 1730. A small point, but it is one well worth considering for history purposes.

The main problem in trying to lock down dates for various goldfish imports, to my mind, is the paucity of (and extreme difficultness in locating) original source materials. In regards to this, I would like to make a few comments on the 1728 date (which is admittedly, to my mind, not a date of "first importation").

A couple of years ago I was fortunate to obtain an original copy of the November, 1765 "The Royal Magazine" [Great Britain]. Included in this issue is an article, as part of a natural history series, on goldfish. Unfortunately, no author is listed. The article credits the "Houghton Indiaman" as the ship bringing "...a large number of them [goldfish]..." to England in 1728. This, I must assume, is the same ship as noted by Hervey and Hems. One statement in the article stands out to me: "These fish were not generally known in England till the year 1728..." I see no interpretation for this other than they were known in England prior to 1728 (or 1730, following Hervey and Hems)...just not "generally". Although this article is not any more specific, it does keeps taking us "backwards" in the origin of goldfish imports into England. I am one who believes that there were multiple (mostly unrecorded, no doubt) shipments of goldfish to England, and elsewhere, in the seventeenth Century. Just trying to find written records of these is the challenge. (There was also a nice hand colored engraving of a goldfish accompanying the article. I have placed a scan of this in a photo album on the AHHS site for your possible interest. It is titled "Goldfish 1765").

A personal comment or two on the Hervey and Hems book: From the starting point of investigating Western goldfish history it certainly should be considered a primary source. But I will emphasize "starting point", as many problems and poor information are evident. Their section on goldfish history in America is nothing short of atrocious. And, based on the fascinating material posted on this site by Al regarding Martini taking 10 goldfish to Holland in 1643, Hervey and Hems also fall very short in this area by offering an import date of "...1753 or 1754."

Well, off for now. I will follow up in a separate post with some comments on goldfish in America.

Excerpt from a Post by Lee Finley, May 17, 2004

In a wide variety of North American literature of the 1820's and 1830's, and later, it is not difficult to find mention of goldfish. They were already living wild in many places and were also firmly established as pets (by 1833 there was a person in the environs of Boston who was producing and

Lee Finley has been an aquarium hobbyist for at least 47 years. He has regularly written on various aquarium topics over the past 40 or so years and has over 345 published articles to his credit. He is considered to be one of the most accomplished historians of the aquarium hobby.

selling a dry goldfish food made from flour and egg yolks). Prior to this time frame, finding information becomes a bit more of a challenge.

Joseph Schlagheck, a pet dealer from Toledo, Ohio, noted in a charming little 1919 book titled "Gold Fish And Their Friends And Song Birds" that goldfish were imported "In 1786, or thereabouts...." "...by some Hollanders..." Although an interesting date, this was without question late in the game. Possibly this "introduction" referred to some more "fancy" goldfish.

I recently found an interesting early reference to gold fish that has a connection to Rhode Island (where I live). It seems that one Godfrey Malbone (who is described as being either the wealthiest, or one of the wealthiest, men in town) built in the middle 1840's his Newport RI country house on a sloping 600 acre parcel at the entrance to the harbor, that was described as being "...famous as the finest residence in the colonies." Malbone, who was a strong Tory (yet had a secret tunnel built to bring in some goods, thereby avoiding having to pay duty on them), made his money from a combination of slave and molasses (to be converted into rum) trading. At the time this was known as the triangle trade....the colonies were the base and west Africa was used for gathering slaves and the West Indies for sugar. The ornamental gardens at his home are described as "elaborate" and, in addition to numerous native plants and trees, boasted much tropical vegetation (for the summer at least!) from the Caribbean islands. Artificial ponds were included in the gardens, and in these swam "...silver and gold-fish..." No hint as to the origin of these fish is given, but it does firmly place goldfish into the middle eighteenth Century of North America.

[These posts pretty well finished the Pepys discussion and that of the first goldfish introductions into Western Europe issues on the Yahoo site. In summary, two things came out of it. (1) I found a record of the first importation of the goldfish into Western Europe and (2) Lee found a record of the first importation of the Goldfish into the United States.

With regard to Godfrey Malbone, I had discovered this information independently but only published my findings in the foreword, "A Perspective on the Early Aquarium Hobby in America," in the Third Edition of my Toy Fish book, a six-year project that started in 2003 and ended in 2009. Unlike Lee's post I presented references and whittled down the date to 1747 as the earliest introduction of goldfish in America. As they took very different approaches, it is interesting to compare Lee's version with mine (which is also in the Fourth edition of "The Toy Fish."

With regard to Martini, this involved research over a period of two years. There is a detailed discussion of his life and his importation of the goldfish into Holland in 1643 in my essay, "The Mystery of Lady Pen's Fish (Klee, 2016).]

This is an oil painting by John Greenwood made between 1752-1758. It depicts a humorous scene in a tavern in Surinam, with many merchants and sea captains from enjoying themselves. The work was commissioned by the subjects while visiting the important trading ports in Surinam in the 1750s, probably for their own amusement. Two sailors are dancing, giving a dancing lesson to the young Godfrey Malbone in the brown coat.

Note: I have long considered Lee Finley and James Atz the finest aquarium hobby historians I have ever known. Over the years Lee and I have occasionally been competitive but we shared things as well. For example, as I was pursuing the holdings of the Library of Congress while these exchanges were taking place, I noticed that they held an article with goldfish in the title published in 1800. I told Lee about this and that I was ordering a hard copy of it. When I received the article, it was about goldfinches, not about goldfish! I was astonished that the Library of Congress had made a mistake like that. I was out about $11 dollars for it but both Lee and I got a big laugh about it.

Before I go on to the next section, the following is the post made by Ted that started the AHHS in style as a Yahoo Group.

Post by Ted Coletti, April 12, 2002
Welcome Charter Members and Visitors to the very first message post of the newly formed AQUARIUM HOBBY HISTORICAL SOCIETY (AHHS; pronounced "Oz," which is where many of us reside at times).

As AHHSies (pronounced "Ozzies") we have a quirky but important task ahead of us: to record and interpret the history of this North American aquarium hobby.

It has been nearly 150 years since New Yorker William Emerson Damon and his sister visited P.T. Barnum's "aquarium" in the mid-1850's and became the first known U.S. aquarium hobbyists (feel free to debate this point–that's why we exist). So much has changed since that time, but only a handful of historical narratives exist about the hobby. Almost non-existent are biographical sketches of personalities
who have developed this great pastime of the little glass box. That's where we come in.

The interest in the history of the aquarium hobby is definitely growing. Thanks to both the current "aging" demographics and subsequent "need" for nostalgia; the advent of the New Millennium, which ironically draws so many of us to the past; and the availability of vintage aquarium literature, equipment, and other memorabilia through the internet. Oh yeah...Wayne and Lee, you've helped spark this new interest too with your writings and dramatic performances (although I think the nude version of your play at one of the recent Conventions was lost on most of us).

So...Is there something you've always wanted to know about a person, place, or event in hobby lore? Do you have a question about a piece of rare aquarium literature? Maybe you want a walk-on at Wayne & Lee's next performance?

LADIES & GENTLEMEN, LET'S START THE HISTORICAL RECORD!
Ted

Ted Coletti has been a hobbyist for over 30 years. A writer and teacher by passion, Ted has penned over 200 articles and columns, and a book, and has presented programs on various topics around the country. In 2002 he founded the Aquarium Hobby Historical Society of America. The Group meets on Facebook and has close to 1,000 members. He maintains a collection of historic hobby literature and artifacts.

[Bel lavoro, Ted! Ti dobbiamo tutti un grosso debito di gratitudine per tutto quello che hai fatto per la storia dell'hobby dell'acquario].

C1. THE REPUBLIC OF LETTERS

Although it had a long history, the Republic of Letters emerged in the 17th century as a self-proclaimed community that stretched across national boundaries but respected differences in language and culture. These communities that transcended national boundaries formed the basis of a metaphysical Republic. The circulation of handwritten letters was necessary for its function because it enabled intellectuals to correspond with each other from great distances.

One person would write of a discovery to someone else, who would then pass it along to others. This network built organically over time, consisting of people from all over the continent, England, and eventually America, primarily in Philadelphia. It was not directed from a central place, and there was no inherent hierarchy. Anyone could contribute, and many ideas that might have been considered fanciful, or perhaps even crackpot, were able to make their way into the network. The filtering of these ideas for quality came in a sort of emergent democratic process; if you thought an idea was good, you passed it along to others. If it was clearly mad, you did not bother. It was by no means a perfect method, and many potentially useful notions were relegated to the wastebaskets of the elite. But, importantly, it did not rely on any centralized authority to make decisions about what was important.

The Republic consisted of scholars and scientists who worked as professors, secretaries, courtiers, physicians, lawyers or whoever was rich enough to support themselves. They formed a flexible, self-regulating and international conglomerate of networks spanning the whole of Europe. People became part of this community by the very act of writing letters: those scholars who failed or refused to establish sustained lines of communication could not be reckoned as citizens of this Republic. It was like social media today: if you are not connected, you are not part of it, however 'social' you might be as a person outside the medium of communication.

Its members shared information about work-in-progress and published books; they gossiped about colleagues and recommended students, they reflected on the politics of universities, princes, and the church, and they reported on family matters and their health. Letters were meant to be answered: reciprocity was a vital principle, and the letter writers honored the cult of communication. Idealism and pragmatism converged in the tendency of scholars and scientists to ignore political and religious differences with their correspondents. They often even avoided making explicit that they respected other people's different backgrounds, as it was wiser not to draw attention to what divided them. After all, for the exchange of texts, objects and ideas, it was more effective to seek common ground with one another than to stress differences. Thus, modesty, friendliness, openness, constancy, patience, forgiveness and industry were upheld as the moral codes of the Republic of Letters although it was not always effective; cases of insults, plagiarism and other code violations did occur at times.

C2. JAMES PETIVER

For upwards of thirty years after 1685, James Petiver (1665-1718) was the proprietor of an apothecary shop London. During these years this address became familiar to brother apothecaries, shipmasters, merchants, planters, physicians, sur-

James Petiver (1665-1718)

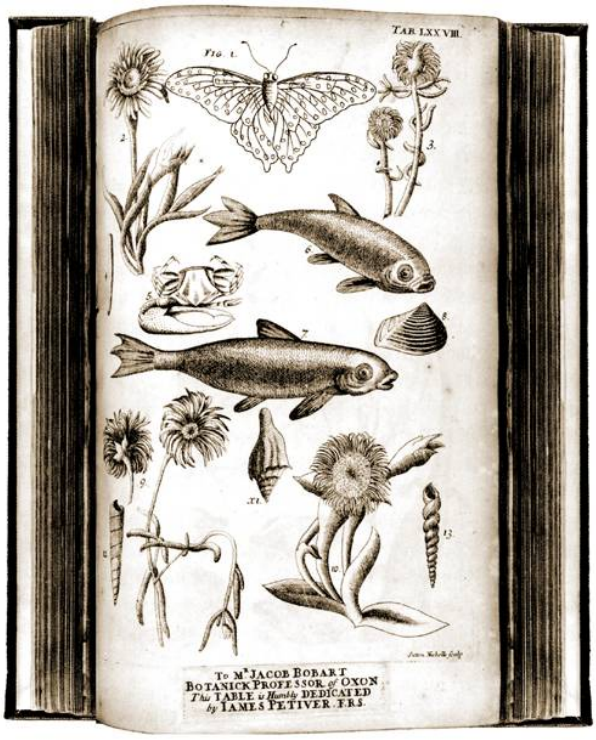
geons, ministers of the gospel, consuls, ambassadors, privy councilors, peers of the realm and foreign gentlemen of various degrees extending from Moscow to the Cape of Good Hope and from the British Colonies in the New World to the Spanish settlements in the Philippines.

From this shop were dispatched thousands of letters and queries, occasional bits of medical advice together with shipments of drugs and nostrums, newssheets, scientific pamphlets and books, frequent consignments of brown paper, wide-mouthed bottles and detailed instructions for amateur naturalists and collectors who had set forth–or were on the point of setting forth – to nearby English counties or to far-off foreign lands. To this shop were addressed other thousands of queries – most of them pertaining to the scientific identification, description, classification, use, habitat, collection, and preservation of botanical specimens and other items of natural history – and hundreds of consignments of seeds, dried plants, insects, serpents, birds, fishes, and small animals for the collections of Mr. Petiver and his friends, whose appetites for such things were insatiable. In this shop were assembled, besides the stocks of herbs and medicines common to a busy and prosperous apothecary, one of the largest and most varied collections of specimens of the natural history of the world that existed in England during the early years of the eighteenth century.

Almost no one who went abroad, especially if he were formally educated or professionally trained (whether in scientific subjects or not), was immune from Petiver's entreaties. Friends, friends of friends, customers in his shop at the Sign of the White Cross, fellow apothecaries, physicians, surgeons, ship captains, merchants, planters, and missionaries – all were asked to collect for Petiver and to enlist the services and correspondence of other persons dwelling in the lands they visited. Petiver supplied them with detailed, printed instructions as to what to collect and how to preserve and pack the specimens for shipment to England.

But not everyone was enthusiastic in their appraisal of Petiver. Their principal criticism stemmed from Petiver's practice of describing and of making illustrations of insects and other items in natural history from imperfect specimens. In his eagerness to collect rarities, Petiver had long been inclined to ignore imperfections and to be content with the most haphazard accounts of the origins and habitats of items received. In some measure, these shortcomings followed inevitably upon the dependence which Petiver and most of his fellow naturalists of that day placed upon dried specimens collected by amateurs who, in many cases, were incapable of supplying scientific data with regard to habitats, growth cycles, and the like.

Petiver was short-tempered and on at least one unhappy occasion he lost one of his best scientific correspondents because of an intemperate pen. The case was that of Samuel Brown of Fort St. George, with whom Petiver had conducted an exceptionally rich exchange since 1690. In 1698, after Petiver had angrily accused Brown of negligence and want of gratitude, as well as with tampering with one of Petiver's shipments intended for another person. Brown wrote sadly to point



From Petiver's *Gazophylacium naturae et artis* showing the silverfish and goldfish he obtained from China.

out that the ship by which he had intended to send his collections to Petiver had been "unexpectedly dispatched from Bengali (and did not return again)"; that he had inspected the shipment which had been misdirected (being intended for the Cape of Good Hope) only in the hope of speeding its delivery to the proper consignee; that "'twas the will of Providence to take from me the friendship of the only person in England whose Correspondence I coveted & on whom I could firmly confide"; and that "I intend to make a clear house and to have no more to do with Botany."' In spite of Petiver's apology for his "passionate expressions" born of disappointments "which my nature cannot easily brooke," he found his scientific correspondence with Brown to be terminated.

In 1703, Petiver had embarked upon putting together a book entitled *Gazophylacii Naturae et Artis*, *Decades Decem* with engravings of animals, insects, plants, and fossils, with short descriptions of them, and with the usual "gratefull" acknowledgments to donors. Five of these "Decades" appeared between 1702 and 1706. In 1711, Petiver stated in the second volume that he possessed "China Silver-tail" and "China gold-tail" fish "brought hence alive." John Henry Gray explained the names in his book, "China: A History of the Laws, Manners, and Customs of the People" (Gray, 1898):

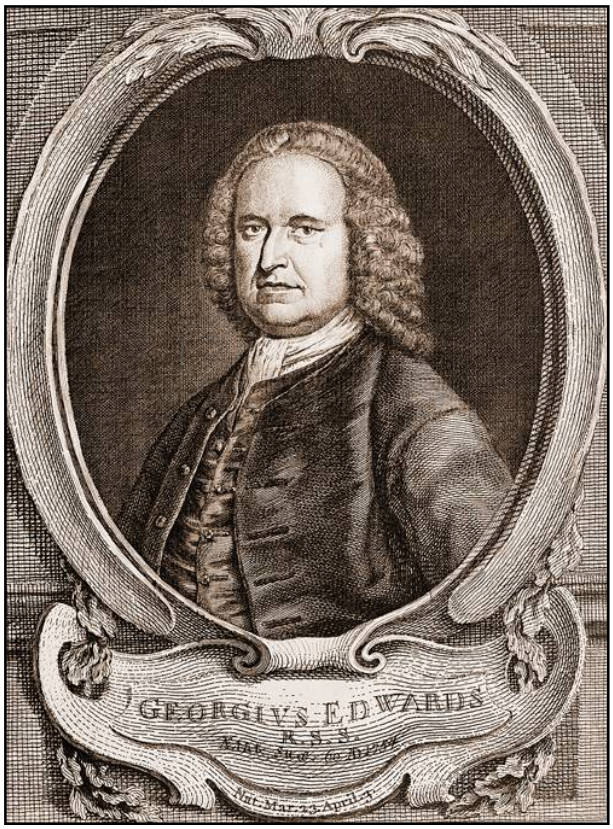
During the first four hundred days of their existence, the fish are black. For several days after this period they are marked with gold or silver spots. Eventually this speckled appearance gives place to that bright golden hue, for which the gold-fish of China are so justly celebrated.

The *Cyprinus auratus*, or gold carp, is the most beautiful gold-fish which the Chinese possess. It is indigenous to the country and, according to Pennant, was introduced into England towards the close of the seventeenth century....In China, silver-fish are of greater value than gold-fish, a circumstance which is probably due to their comparative rarity.... The Chinese do not value gold-fish which have dorsal fins. When provided with such an appendage, they are called Tsak-Yu-Chu. Those which are of greatest value in their estimation are the Chan-Chu-Tun, or pearly-scaled fish.

Therefore, this importation of live goldfish in 1711 is the first recorded for England. It is not known from whom he got his goldfish, where they came from or how they were sent to them. As Roos points out, Petiver knew James Cuninghame, an East India Company surgeon in China so is possible that the fish made their way to London with a member of this group but as it is only a surmise these questions remain unanswered (Roos, 2019).

C3. GEORGE EDWARDS

George Edwards (1694-1773) was a Fellow of the Royal Society and Fellow of the Society of Antiquaries in London who rejected his early formal training and potential career in business to pursue his passion in natural history. His publisher, describes him as follows (James Robson, 1776):



George Edwards (1694-1773).

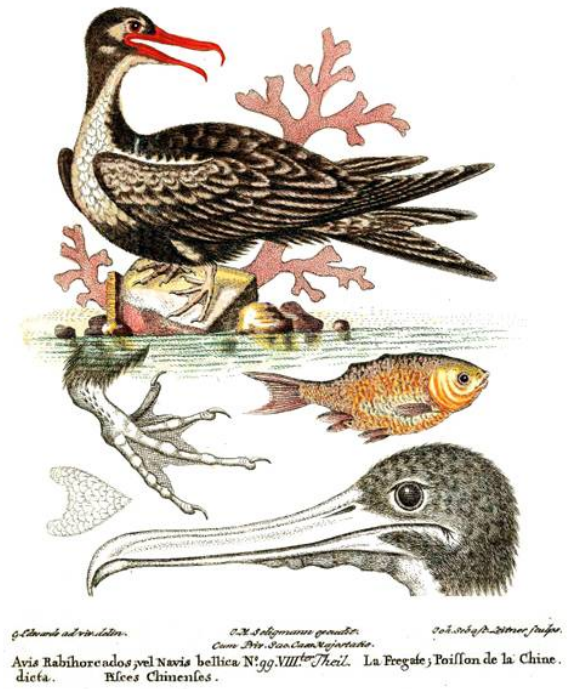
Mr. Edwards was of a middle stature, rather in-clined to corpulence: of a liberal disposition and a chearful conversation. All his acquaintance experi-enced his benevolent temper, and his poor neigh-bours frequently partook of his bounty. His diffidence and humility were always apparent, and to persons who had a taste for studies congenial to his own, he was a most entertaining as well as communicative companion.

His dedication and talent as a draftsman and naturalist was evident, thus gaining the attention of Sir Hans Sloane, President of the College of Physicians and the Royal Society. Sir Hans offered Edwards the post of Librarian of the Royal College of Physicians in London, and enlisted him to draw the natural curiosities of Sloane's private museum. This connection became the inspiration for Edward's two masterful achievements, the first being "A Natural History of Uncommon Birds," published between 1743 and 1751 (it was sold for £15,000 in 2019). This work looked not only at birds, but also at mammals, fish, reptiles and insects. However, the ornithological part of the book made up the majority and is the part for which Edwards earned his reputation. The descriptions written by Edwards were celebrated for their accuracy, so much so that Linnaeus would later use them to name around 350 bird species when preparing his *Systema Naturæ*.

His subsequent work, "Gleanings of Natural History," was produced between 1758 and 1764. These two works illustrated and documented many previously unrecorded specimens of birds, reptiles and insects held in England's private collections up to the mid eighteenth century. A monumental achievement, Edwards documented – both in English and in French – painted, engraved and hand-colored every one of the fine compositions in this Pre-Linnaean natural history opus. Such was the impact of "Natural History" and "Gleanings" that Edwards is considered to have almost single-handedly popularized the art of bird and animal illustration, and is thus known as "The Father of British Ornithology." Although not a field naturalist, Edwards placed many of his birds and animals in landscaped settings, which was unusual for the time. In other compositions birds are elegantly perched on stylized branches in a classic Georgian format, more decorative than realistic, but charming nonetheless. The following describing goldfish and providing some dates is taken from his 1751 "A Natural History of Uncommon Birds":

Out of a great number of these fishes, which were variously coloured and variegated, I have chosen the four subjects represented here of their natural bigness, tho' there are some larger, and others a good deal less. The largest I have met with measur'd eight inches in length, and near three inches in depth over the thickest part of its body; this had no fin on its back. Ii have observed many of the small ones also to be without fins on their back. These fishes are shaped pretty much like the carp, of which genus I take them to be a species; their nostrils rise out of their

Drawings of China goldfish From George Edwards' Natural History of Uncommon Birds and of Some Other Rare and Undescribed Animals (1743-1751).



A picture of George Edwards' study of a frigate bird with a Chinese goldfish below.

heads like the ends of little pipes. All that I have seen had three pair, or six fins, on their under sides; on the upper sides some are without, and others have them in various forms, as represented in these figures; some of them have angle tails, and others have them double, and joined together on the upper edge, as the third figure from the top shews. The upper figure is blue on the back, and back-fin; the rest of the fish is of a gold-colour; these colours break into each other on its sides; the tail is dark brown. The second fish is all over of a gold-colour, except a black spot on the head. The third fish hath its upper side, double tail, and lower fins of a gold-colour; the belly of silver; which two colours mix confusedly on its sides; it has some black spots on its fins and tail. The lowermost, or fourth fish, hath its upper side dusky, and its under of a silver-colour, which soften into each other on its sides; its fins and tail are dusky.

His Grace the late Duke of Richmond had a large Chinese earthen vessel full of these fish, brought alive to England. I drew some of them for his Grace, who permitted me to make draughts for myself, with leave to make them publick. The first account of these fishes being brought to England may be seen in Petiver's Works, published about Anno 1691. See his Catalogue, 186, Piscis Chin. Caudâ argenteâ, Plate 78, Fig. 6 and Catalogue 187, Piscis Chin. Caudâ aureâ , Plate 78, Fig. 7.

The second Duke of Richmond, Charles Lenox (1701-1750), was born at just the right time for someone with an enquiring mind. The Age of the Enlightenment transformed scientific thinking and dominated the eighteenth century. Richmond was part of a large circle of friends and relations whose influence can still be felt today. The Duke had a menagerie where he kept many exotic animals including a lioness, tigers, bears, monkeys, eagles and ostriches. Much of Richmond's influence was through his patronage of authors, particularly in the field of natural history. By acting as

The second Duke of Richmond, Charles Lenox (1701-1750).

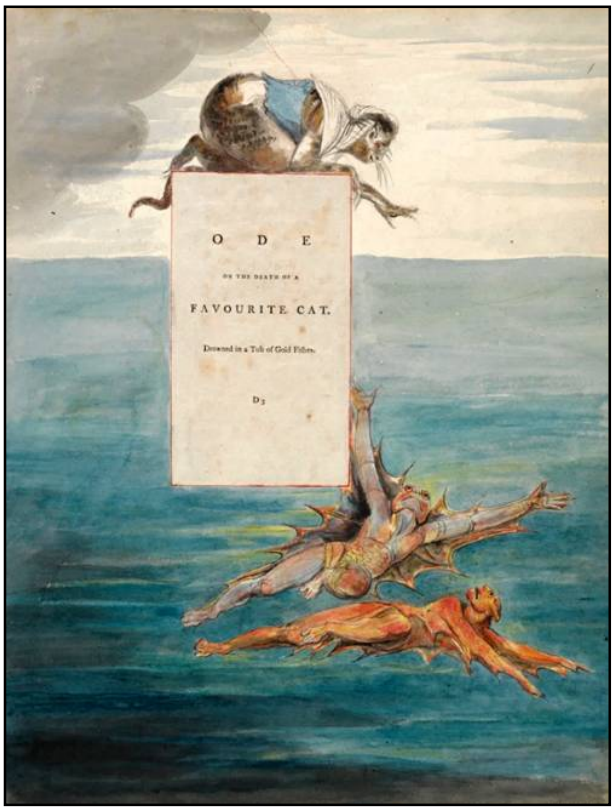
Historian and author Horace Walpole (1717-1797).

a subscriber, he was not only supporting people financially, but also encouraging and fostering talent. He was a subscriber to Mark Catesby's a *Natural History of Carolina*, published in two volumes in 1731 and 1743. This ground-breaking publication opened peoples' eyes to the beauty of American flowering trees and shrubs meticulously observed in Catesby's colored engravings. Another author Richmond supported was George Edwards whose *Natural History of Birds* was published between 1743 and 1751. As French was the international language, Edwards also published a two-volume French edition, *Histoire Naturelle de Divers Oiseaux* (*Natural History of Various Birds*), the first volume (1745) being dedicated to the duke and the second volume (1748) to the duchess.

The historian and author Horace Walpole (1717-1797) also had a large Chinese jar of goldfish located in the Great Cloister of his Strawberry Hill house. Walpole's approximately nine-acre garden at Strawberry Hill, re I) developed between 1749 and 1797, featured a collection of Gothic architectural elements, most notably a small chapel, as well as flower beds, a series of ponds, and other sculptural and decorative features. Everything that he turned his mind to in Strawberry Hill he regarded in a spirit of comic delight. He stood outside himself, like a spectator, and nothing gave him more pleasure than to figure himself as a master of the ceremonies among the bantams, and the squirrels and the goldfish. In one of his letters he describes himself and Bentley fishing in the pond for goldfish with

"nothing but a pail and a basin and a tea-strainer, which I persuade my neighbours is the Chinese method." This was in order to capture some of the fish for Bentley, who "carried a dozen to town t'other day in a decanter."

The large Chinese jar of goldfish located in the Great Cloister of Walpole's Strawberry Hill house.



William Blake, illustration for "Ode on the Death of a Favourite Cat," in 'The Poems of Thomas Gray (1797-98), watercolor with pen and black ink and graphite on paper with inlaid letterpress page.

In 1747 Thomas Gray (1716-1771) commemorated the passing of his friend Horace Walpole's cat with the tragicomic poem "Ode on the Death of a Favorite Cat Drowned in a Tub of Goldfishes." Walpole had asked Gray for an epitaph for his favorite pet and Gray responded with a poem, the first verse of which Walpole had engraved on the Chinese vase (the "tub" of the poem's title) in which the dearly departed cat met her watery end. This poem gained Gay the recognition as a poet he had long been seeking for. Edwards continued with his report in "A Natural History of Uncommon Birds":

They were not generally known in England till the Year 1728, when a large number of them were brought over in the Houghton Indiaman, Captain Philip Worth, Commander, and presented by him and Manning Lethieullier, Esq; to Sir Matthew Decker: Since which Time they have been propagated in ponds by several curious gentlemen, in the neighbourhood of London. They may be esteemed a domestick fish; they vary infinitely in their colours and marks, as do all domestick animals; they have been propagated and greatly increased in the Island of St. Helena, from whence they are now brought by all our India ships that touch there. They keep them in small ponds and basons in China, for the amusement of the Ladies, and other curious persons. Those propagated with us are generally of a deader colour than what are brought from China, or St. Helena. In a few years it is probable, we finally have them in our rivers. The last author that has mentioned this fish is Linnaeus. See his Fauna Suecica , published at Leyden, 1746. He calls it Cyprinus Pinna Ani duplici, Cauda trifurca, exoticus Piscis aureus Chinensium.

Sir Matthew Decker (1679-1749) was born in Amsterdam in 1679 and came to London in 1702 where he established himself there as a merchant. He was remarkably successful in his business life, gaining great wealth and having many honors conferred upon him. He was a director of the East India Company and ultimately its chairman, sat in parliament for four years as member for Bishops Castle, and was High Sheriff of Surrey in 1729. He was created a baronet by George I. in 1716. Decker's fame as a writer on trade rests on two tracts. He proposed to do away with customs duties and substitute a tax upon houses. He also suggested

This is the drawing of the goldfish (upper right) in Linnaeus' *Fauna Suecica* of 1746.

Sir Matthew Decker (1679-1749).

taking the duty off tea and putting instead a license duty on households wishing to consume it. The second advocated the license plan in an extended form; urged the repeal of import duties and the abolition of bounties, and, in general, showed himself such a strong supporter of the doctrine of free trade as to rank as one of the most important forerunners of Adam Smith. The Decker estate at Richmond was described as follows:

The longest, largest, and highest Hedge of Holly I ever saw, is in this garden, with several other Hedges of Ever-Greens, Visto's cut through Woods, Grotto's with Fountains, a fine Canal running up from the River. His Duckery, which is an oval Pond brick'd round, and his pretty Summer-House by it to drink a Bottle, his Stove-Houses, which are always kept in an equal heat for his Citrons, and other Indian Plants, with Gardeners brought from foreign Countries to manage them, are very curious and entertaining. The house is also very large a -la-modern, and neatly furnished after the Dutch way.

Note that Edwards refers to Petiver's publication date as being 1691 (MDCXCI in Roman numerals) but the correct date is 1711 (MDCCXI in Roman numerals). Hervey and Hems present a plausible argument for this error, i.e., that Edwards accidentally transposed the C and X when he recorded the 1691 date. In any event, we can assume that the goldfish were well established (rather than just a few) by 1728.

C4. THOMAS PENNANT

Thomas Pennant (1726 –1798) was a naturalist, writer and antiquarian well known for his published accounts of pioneering tours throughout the British Isles and one of the foremost zoologists of his time. He was educated in Wrexham and Oxford. Pennant's publications on natural history include such works as *British Zoology*, the *History of Quadrupeds*, and *Arctic Zoology*. He was a fine observer in the field, and collected specimens of plants, minerals, birds and animals. But his knowledge of the natural world also came from a wide international network of leading scientific figures of his day – his correspondents included figures such as Linnaeus, Joseph Banks

Sir Thomas Pennant (1726 –1798).

and Gilbert White of Selbourne. He was a passionate antiquarian, with an interest in the Roman remains and artefacts around Chester and a deep curiosity about the British past. An enthusiast for economic improvement and a champion of burgeoning industry (he opened a lead-mine on his own estate) Pennant was politically conservative, becoming more reactionary in the decade of unrest after the French Revolution. His writings nonetheless reveal a thoughtful and generous-spirited man with a social conscience, who was deeply moved by the conditions of poverty he encountered on his travels.

The following is taken from the goldfish section in his "British Zoology" (Pennant, 1760):

These fish are now quite naturalized in this country, and breed as freely in the open waters as the common carp.

They were first introduced into England about the year 1691, but were not generally known till 1728 when a great number were brought over, and presented first to Sir Mathew Dekker, and by him circulated round the neighborhood of London, from whence they have been distributed to most parts of the country.

In China the most beautiful kinds are taken in a small lake in the province of Che-Kyang, Every person of fashion keeps them for amusement, either in porcellane vessels, or in the small bafons that decorate the courts of the Chinese house. The beauty of their colors, and their lively motions, give great entertainment, especially to the ladies, whose pleasures, by reason of the cruel policy of that country, are extremely limited.

In form of the body they bear a great resemblance to a carp. They have been known in this island to arrive at the length of eight inches; in their native place they are said to grow to the size of our largest herring. The nostrils are tubular, and form fort of appendages above the nose: the dorsal fin and the tail vary greatly in shape: the tail is naturally bifid, but in many is trifid, and in some even quadrifid; the anal fins are the strongest characters of this species, being placed not behind one another like those of other fish, but opposite each other like the ventral fins.

The colors vary greatly; some are marked with a fine blue, with brown, with bright silver; but the general predominant color is gold of a most amazing splendor; but their colors and form need not be dwelt on, since those who want opportunity of feeing the living fish, may survey them expressed in the most animated manner, in the works of our ingenious and honest friend Mr. George Edwards.

Pennant repeated Edward's error in reporting the first goldfish importation into England as 1691 and so Pennant is not really a source. However,

Catherine Maria Fischer (1741–1767), known as "Kitty Fisher," was a prominent British courtesan. This painting was made in 1765 by Nathaniel Hone and is probably the first of these iconic goldfish bowl images.

he indirectly caused a dating problem that I will address in the next section.

C5. MARCUS BLOCH

Marcus Elieser Bloch (1723-1799) was a German physician and ichthyologist, but academic prowess was anything but inevitability in his life. His parents, being very poor, gave him hardly any education so that on arriving at manhood he was almost illiterate, and till the age of nineteen could not even read German. Some knowledge of Hebrew and rabbinical literature enabled him, however, to obtain a teacher's position in the house of a Jewish surgeon in Hamburg. Here he learned German thoroughly and mastered some Latin, taking up also the study of anatomy. Scientific enthusiasm being thus aroused, Bloch went to Berlin, where, with remarkable zeal, he devoted himself to the study of all branches of natural science and medicine, being supported by some relatives. After taking the degree of Medical Doctor at Frankfort-on-the-Oder in 1747, Bloch settled in Berlin where he subsequently worked as a physician.

Bloch was well into his fifties when his ichthyological hobby became his main academic focus. He concentrated on local fish in the beginning, publishing a couple of minor books on the subject. In about 1781-3 he began to release what would ultimately become the most important (and beautiful) study of fish published in the 18th century. It was one of the first wide-ranging ichthyology works that both provided detailed species descriptions and adhered to Linnaean principles. Although inaccuracies surfaced (particularly with non-German fish) and observations were eventually superseded, the series was generally serviceable and regarded as the standard for a century or more.

Between 1782 and 1795 he published his *Allgemeine Naturgeschichte der Fische* (General Natural History of Fishes), a 12-volume, beautifully illustrated comprehensive work on fishes. The first three volumes describe fishes in Germany and were entitled *Oeconomische Naturgeschichte der Fische Deutschlands* (Economic Natural History of Fishes in Germany); the remaining volumes dealt with fishes from other parts of the world and were entitled *Naturgeschichte der ausländischen Fische* (Natural History of Foreign Fishes). The overall series was enormously popular. Investors helped defray the publication costs of the second half of the series by sponsoring individual illustration plates which bear their names (just one of these books just sold for over $80,000 at an auction). Bloch's 432 hand-colored engravings are fair attempts at reproducing the bright natural coloring of the fish and some of the illustrations were heightened with gold, silver or bronze filings to imitate the metallic sheen of scales. Bloch published a couple of other multivolume series on fish, thereby cementing his place as one of the most important historical figures in eighteenth century ichthyology.

In Bloch's "Oeconomische Naturgeschichte der Fische Deutschlands" (Bloch, 1784), when talking about goldfish he writes:

Nach ersterem Lande ward er im Jahr 1611

Marcus Elieser Bloch (1723-1799).

gebracht, und 1728 war er daselbst schon allgemein bekannt. (It was brought to the former country in 1611, and in 1728 it was already well known there.)

He cites as the source Pennant's "British Zoology," Part III, p. 374, but as I explained in section A1, Pennant wrote 1691, not 1611 so this is either a misprint or an error. Unfortunately these two errors – 1611 and 1691 – have often been cited as the first introduction of the goldfish into England instead of the correct date of 1711.

D1. LINNAEUS AND THE GOLDFISH

Linnaeus was already interested in plants from early childhood. His father Nils Linnaeus had a lovely flower-garden with a remarkable number of plant species. However, he also kept domestic pigeons, which was still a rare habit among clergymen at that time. The young Linnaeus went as a poor student to Uppsala University in 1728 and studied medicine and natural history. As a student in Uppsala he kept many native birds, bought from local bird catchers, in his student room. A friend wrote that Linnaeus' room was "filled with branches and he kept 30 different kinds of tame birds there." Linnaeus himself wrote that he had tits, larks, sparrows, siskins and others in his chamber.

After graduating in Uppsala in 1732, Linnaeus went to Harderwijk in the Netherlands to get a doctoral level degree in medicine. This Dutch university was famous for awarding degrees very quickly and he was finished in two weeks (reminds me of our current slew of university diploma generators who grind them out for $25 each!). Instead he could focus on networking and improving his standing in the scientific world at that time. He was also employed as a curator at a private botanical garden and menagerie owned by George Clifford, director of the Dutch East India Company. The menagerie had many exotic animals, among them many birds and thus Linnaeus became well acquainted with parrots and other exotic birds. He returned to Sweden in 1738, becoming a physician in Stockholm. During his year in Stockholm he also kept birds at his home.

In 1741 the 34 year old Linnaeus was appointed Professor at Uppsala University and soon he also became responsible for the Botanical Garden (nowadays known as Linnaeus' Garden) in the city. He had to modernize the garden but also had to make a new home there where he and his wife raised a son and several daughters. He was obviously well acquainted with native birds in captivity, and in his zoological lectures he gave many interesting details about the qualities of many native birds as cage birds based on his own experiences. Starting in 1747, in his printed travelogue, Linnés föreläsningar öfver djurriket ((Linnaeus' lectures on the animal kingdom) he used several pages to describe not only these hybrids, which fascinated him, but also a kind of care-sheet for canaries (Lonnberg, 1913).

In 1750, at the age of 43 Linnaeus was appointed as Uppsala University's rector. In the 1750s Linnaeus had finally settled down. At his home near the Garden he had an extensive orangery and a large animal building. The Garden was well-established and he attracted many students not only from Sweden but also from abroad. Linnaeus had an enormous network and corresponded with everyone of importance within the scientific

Carl Linnaeus (1707-1778).

world. At the end of the 1750s he also started to acquire exotic mammals and birds to add to his menagerie. He already had peacocks in his garden and he also tried to keep a raccoon. To this he added various monkeys, lemurs, coati, agouti and other mammals, as well as parrots and other birds. Note that there is no mention of fish at this time, goldfish or otherwise).

During the summer his monkeys lived in "monkey huts." These were poles with a sort of little hut or house at the top. The monkeys were chained to the pole and could run up and rest or sleep there according to their desires. The first time I have seen a quotation from a reference incorporated into the title of the reference is in "Deras mistande rör mig så hierteligem: Linné och barns sällskapsdjur" ("Their loss touches me so dearly," *Linnaeus and his pets*), this is "This quote where Linnaeus is bemoaning the death of one of his pets reinforces the idea that he really cared for his animals (Svanberg, 2007).

D1. LINNAEUS RECEIVES PRESERVED GOLDFISH

In Sweden, the goldfish had been known since the 1740s. In 1739, Linnaeus helped found the Royal Swedish Academy of Science; he became the first Praeses (a Latin term meaning "placed before or "at the Head") of the academy by the drawing of lots. With the help of Swedish ambassador Nils Palmstierna, the Academy received a preserved goldfish that was described by Linnaeus in the *Proceedings* from the Academy in 1740. Interestingly enough, Linnaeus also published some information about its care. It was still a fish in Scandinavia kept in bowls, not in ponds, and it was recommended that it be given fresh water two or three times a week. It should be fed with biscuit, egg yolks, dried lean pork and small snails. It is however unclear if Linnaeus had any personal experience of live goldfish (which he actually might have had from his years in the Netherlands). However, the information he gives about the care of goldfish bears witness that he had at least received information from someone who knew. One of the depicted gold fish was obviously a fantail.

A close-up of one of the monkey huts.

Two of Linnaeus' "monkey huts"

Linnaeus never ceased to be fascinated by the beauty of the goldfish. In 1744, the merchant Carl Gyllenborg donated "Chinese goldfish" to Linnaeus, but they were preserved in ethanol. Linnaeus was eager to get hold of live fish. In November 1745, he wrote instructions for his pupil Christopher Tärnström that he should bring back goldfish for the Queen from his tour to East India. However, Ternström unfortunately drowned in south-east Asia and was never able to complete the task. Linnaeus's enthusiasm for the goldfish was undiminished. He received further preserved goldfish for his zoological collections from the royal court and King Adolph Fredric and his Queen probably kept goldfish in the ponds at the royal palace of Drottningholm.

D2. LINNAEUS' SECOND ATTEMPT TO OBTAIN LIVE GOLDFISH

In 1759, another opportunity arose for Linnaeus to obtain live goldfish. One of his pupils, the physician Pehr Bjerkén, was staying in London and kept up a lively correspondence with Linnaeus. He asked Bjerkén to find goldfish for him. Linnaeus became very enthusiastic when he received a letter telling him that Bjerkén had traced down a goldfish breeder, a colleague in England, Dr. Richard Guy. Guy was a physician in London known for (1) His essay on scirrhous tumors and cancers and (2) the histories of cases cured by him by means of Mr. Plunkett's medicine. The following is a review of Guy's essay that appeared in The Critical Review (Anon, 1759):

…such a precaution may be the more necessary in Mr. Guy, whose design in this essay is to recommend a nostrum for the cure of scirrhous and cancerous tumors. The bare mention of a secret remedy, or specific, is sufficient to impeach a man of ignorance and empiricism, unless he takes some such method to promulgate his knowledge. He accordingly, in the preface, gives us to understand, that he has been exposed to many invidious reflections of this nature. He tells us that as soon as he became acquainted with the surprising efficacy of Mr. Plunkett's medicine, he was seized with a desire to know the secret; which he accordingly purchased for a valuable consideration, under such restrictions as disable him from making it public, even though he should be disposed to throw away a considerable sum of money for the good of mankind. For our parts, we think he has a natural right to make the most of his own purchase; and if the medicine should be found really specific in those disorders, the legislature, upon proper application, will, no doubt, make it worth his while to discover it for the benefit of his country.

Guy charged about £50 to £100 for his cures; his medications proved quite profitable and so he was quite wealthy. At the time Sweden was experiencing quite a number of cancer cases in their population and the Swedish Health Commission was assigned the task of seeking better solutions. Bjerkén was impressed with Guy's successes:

The most important thing I can now name, and which I wish it were in my power to make public, is to sit down to cure the cancer. However, one of my neighbors in London, the surgeon Richard Guy, has made quite a reputation which deserves all possible attention. Dr. Guy bought a medication from a widower named Plunket, who inherited it from his father and grandfather, and who earned large sums of money from it in Ireland and in the surrounding country. Its reputation has increased in many different ways on a daily basis, especially since Guy improved his method of application and recently made complete cures on several persons of wealth and wealth, who have been under the care of the best doctors, as incurable. I have met several of his poorer patients, whom I never thought he would be able to help, who, however, have been

Pehr af Bjerkén, (1731-1774).

completely cured, without the slightest problems but always with the daily decrease of the cancer. The medication is applied externally to the cancer locally, as a simple vegetable in the form of a green powder, which for the sake of more convenience is applied in the form of unguent with some general digestive, and exchanged every other day or the 3rd day. It does not seem to attack the healthy part, but only the cancer itself, which gradually loosens; in fact, all its roots fall out after 4 or 6 weeks and leaves a good healthy wound behind, which is considered a general wound that needs no further need of the medication. He is a very modest and quiet man and has no natural gifts for a quack or charlatan.

Thus the Swedish Health Commission contacted Guy directly to purchase a quantity of Plunkett's medicine. This they did but he wanted £3000, which was considered a bit steep; furthermore he insisted that the medication itself was useless; it had to be applied by following Guy's methods. The biggest sticking point was that Guy would not reveal the composition of the medication. Nevertheless, he Commission agreed to these terms and the cost was paid – in public funds – by the Swedish Treasury.

When this news came out there was a public uproar about State paying so much for what some considered was nothing more than a nostrum. That Guy kept the ingredients of his powders a secret didn't help any. During this time Bjerkén acted as an intermediary between the Health Commission and Guy. By 1772 there were some cures or improvements in patient's conditions so that things quieted down except for the ingredients of the powder provided by Guy. Guy had confided in Bjerkén but swore him to secrecy. However, after Guy's death Bjerkén revealed that Plunkett's medicine consisted of *Clematis flammula*, fennel, sulfur and white arsenic, which with egg yolk was made into a sort of dough although it could also be used dry. Although physicians had long used arsenic for cancers and tumors, interesting enough, I found that *Clematis flammula* is also used today. I found several articles, including one of which was published in 2019 that I quote from here, "Overall, our data showed that *Clematis flammula* is a promising antitumor agent…," (Geusmi, 2010). Now back to Richard Guy and goldfish.

Guy had a pond at his country estate with 50 to 60 goldfish. He of course was very careful about what was then a rare fish, but Bjerkén persuaded him to donate a couple to the world-famous professor in Uppsala. Bjerkén brought them back by ship to Gothenburg. Linnaeus wrote impatiently in September 1759, "Do please send the goldfish already tomorrow with a vessel to Uppsala; they do not freeze that easily; so I will be able to once again see them, something I have dreamed of all my days but never hoped. Let the skipper ask what price he wants, only I get them alive". He finished the letter, "God give I had them alive in my orangery."

Bjerkén sent the goldfish together with detailed information about how to take care of them.

ABSTRACT, Letter 7 October 1759, Stockholm to Carl Linnaeus: Pehr af Bjerkén tells Linnaeus that he sent the goldfishes and the orang-outang with Johan Pihlström last week and that he hopes they have arrived safely. af Bjerkén tells Linnaeus in detail how to take care of the goldfishes and stresses the importance of changing the water and keeping

Horatio Henry Couldery (1832–1918)[1] was an English animal painter and illustrator noted especially for his depictions of domestic cats, kittens and dogs.

the tanks clean. af Bjerkén tells Linneaus that Richard Guy is a surgeon and a wealthy man and gives Linnaeus his address. af Bjerkén also tells Linnaeus that he has bought a secret drug against tumours for £3000 from Guy. At his estate in the country Guy has a big pond with 50 – 60 goldfishes and because of Linnaeus's good reputation he has given Linnaeus the biggest ones. af Bjerkén believes he might be able to get even more of them for Linnaeus. af Bjerkén tells Linnaeus that he corresponds with Guy and gives him Guy's address in London.

In October 1759, one fish was already dead, but the other specimen survived at least the winter and was alive the next year. Guy promised to provide Linnaeus with further specimens.

ABSTRACT, Letter 31 December 1760, Stockholm to Carl Linnaeus: Pehr af Bjerkén writes that in his latest letter Guy has promised to send new goldfishes to Linnaeus and that Daniel Solander will arrange the shipment.

The following year, Guy kindly sent new goldfish to Linnaeus, the famous naturalist Daniel Solander (botanist on Captain James Cook's first voyage and librarian for Joseph Banks, president of the Royal Society) arranging the shipment. In January 1761, Linnaeus writes to Bjerkén:

ABSTRACT: Letter 23 January 1761, Uppsala to Pehr af Bjerkén, Stockholm: Linnaeus writes to thank Pehr af Bjerkén for his letter [af Bjerkén to Linnaeus, 31 December 1760 and to tell him that he has not received a letter from Richard Guy. Linnaeus has, however, written to Guy to thank him for the goldfishes.

It is, however, unclear if Linnaeus received any more live goldfish from Guy after 1760 (Svanberg, 2007). Job Baster (1711-1775) was a Dutch physician and naturalist who devoted himself almost entirely to the study of medicine and natural history. In 1758, Baster was given a beautiful property loaded with trees and two large ponds. He called it Zonnehof (Sunshine Farms). As a new pond owner, Baster decided to try his hand at breeding Goldfish. A versatile scientist, Baster exchanged letters with the leading biologists of his time and the first twelve fish arrived thanks to a contact in England. Unfortunately, all the goldfish died. The following year, Baster got eighteen more fish. Two died, but the rest survived. Thirteen years later, Baster owned more than a thousand goldfish. He was a Linnaeus worshiper and in 1751 he wrote the following letter to Linnaeus:

Letter November 29, 1751, Zierikzee to Carl Linnaeus, Uppsala
Job Baster has for a long time wanted to establish a contact with Linnaeus, and through Ulrich Hemmingson he has got an opportunity to contact Linnaeus and to make himself known. He is very much devoted to Linnaeus's methods and very willing to do what Linnaeus may ask of him. Every now and then, Baster receives seeds or new plants from friends living in the western continents, and sometimes also from East India. If Linnaeus would be pleased to be informed of or to receive a share of those, Baster will be glad to do his best in that direction.

Statue of Job Baster (1711-1775) holding a goldfish. Baster was a Dutch physician and naturalist who devoted himself to the study of medicine and natural history.

The house where Linnaeus lived is in the garden and is now a museum. In the 1920s the garden was restored to its Linnaean character. Constructed between 1742 and 1743 the Orangery was designed (with an advanced heating system) to house plants unable to tolerate Sweden's harsh winter climate.
FOREGROUND: Lacustre or Lake pond.
MIDGROUND: Orangery attached to house.
BACKGROUND: Linnaeus' house.

Some years later Baster wrote another letter to Linnaeus, this time concerning goldfish:

ABSTRACT, Letter September 1, 1763?, Zierikzee to Carl Linnaeus, Stockholm:
Baster has a lot of goldfish in his ponds, and they have withstood the winter cold. Baster will be glad to send some to Linnaeus if he can find some means to send them quickly and safely.

This was the only letter regarding goldfish that Baster sent to Linnaeus so it is commonly assumed that he could not find a suitable way to send them. However, a more plausible reason is that by 1763, Linnaeus had already secured sufficient live goldfish, either from Richard Guy or from someone else.

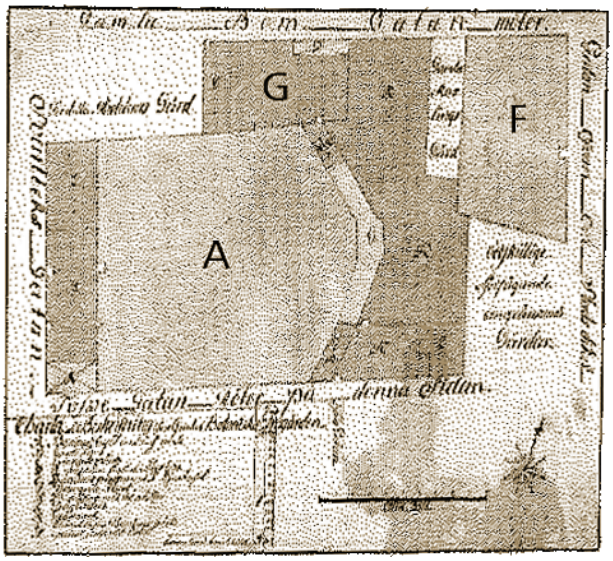
D3. GOLDFISH IN THE LINNAEUS GARDEN?

In an article on *Linné On Line*, the anonymous author states (Anon., 2008):

However, there were also animals in Linnaeus' garden. Parrots shouted here, imitating Linnaeus' voice: "Blow your nose!" Monkeys played around and a raccoon wanted to be petted. Peacocks strolled about displaying their beautiful plumage. Goldfish swam in the pond.

However, there are no written materials cited in the article that support such a claim about goldfish and I doubt very much that it is true. For one thing, if Linnaeus had live goldfish in hand he would have placed them in his orangey, not in the Botanical Garden. Linnaeus was concerned that although goldfish might be adversely affected by the cold winters in Sweden, they would be protected in the warm orangery. They also would be further protected against predators in the Garden's open ponds. Lastly, Linnaeus would have wanted the goldfish to be nearer to him where they could be more easily observed.

If Linnaeus had goldfish in the Botanical Garden in Uppsala, he would not only be the one who



A: Linnaeus' house; G: Orangery; F: Animal Quarters.
The Botanical Garden is north of the Orangery and not seen in this diagram. Linnaeus was concerned that Guy's goldfish would not survive Swedish winters and so he planned to place them in the Orangery.

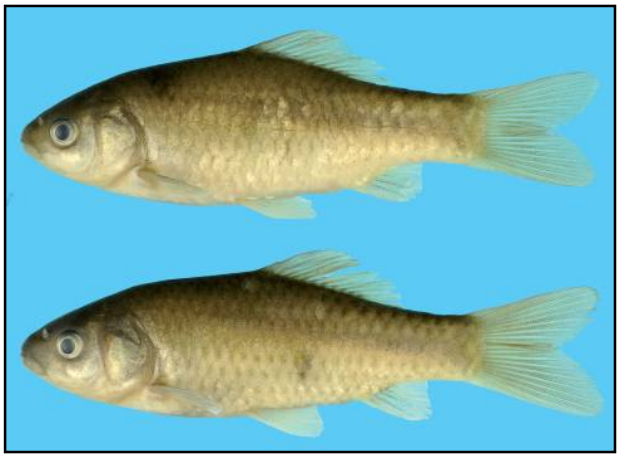
coined the defined the word "aquarium" for all posterity, he would also have been our first aquarist in the sense of keeping fish and aquatic plants together in a container of water. Incidentally, in her book on goldfish Roos refers to the *Linné On Line*: "Linnaeus kept a number of fish in the botanical gardens of Uppsala University, trading information about fishy varieties with the Dutch naturalist Job Baster who bred them [goldfish] in open air ponds," citing Baster's letter of September 1, 1763. There is nothing in this letter, however, that mentions any of this.

E. MORSELS

(1) There has been considerable confusion concerning the taxonomic status of the goldfish. Many authors have recognized two subspecies in its native range: *Carassius a. auratus* (the goldfish, Chinese goldfish, or Asian goldfish) from Asia, and *Carassius a. gibelio* (the Prussian carp, gibele carp, or European goldfish) from Eastern Europe (Raicu et al., 1981). Others have concluded that the goldfish is a subspecies of the crucian carp *Carassius carassius* (i.e., *Carassius c. auratus*). More recently, it has been reported that *C. auratus* is a tetraploid derivative of *C. carassius* (Jenkins and Burkhead, 1994). There are many mutant goldfish varieties and this exhibit a broad range of body forms and colors. Howells (1992b) reported that some exotic fish experts believe that "goldfish" typically observed in U.S. waters is actually a crucian carp x goldfish hybrid. In addition, goldfish commonly hybridizes with common carp *Cyprinus carpio*, giving rise to individuals that are intermediate in morphology between the two parent species. The goldfish has been widely and repeatedly stocked in the United States from many points of origin, including both Asia and Europe. As such, U.S. populations represent a complex of morphologically and taxonomically diverse forms.

(2) Recently, *Carassius praecipuus*, a dwarf new species, was described from a hill stream in the upper Nam Ngum watershed in Mekong drainage in central Laos. It is distinguished from all other members of the genus by the short dorsal fin, a small number of branched dorsal-fin rays, lateral line scales and gill- rakers. The largest available specimen was 62mm (about 2.5 inches standard length). This is the first species of the genus discovered outside East and North Asia and Europe. The upper Nam Ngum watershed includes a part of the Plain of Jars, which had been hypothesized to have allowed the movement of a number of fish lineages between the rivers flowing to the Gulf of Tonkin and the Mekong drainage. It gets its name from the Latin adjective praecipuus, -a, -um, meaning "which is not common," an allusion to the unexpected presence of a *Carassius* in the Mekong drainage and the very low dorsal-fin ray, lateral line scale and gill-raker counts.

(3) Following the rules of the International Commission on Zoological Nomenclature (ICZN), when a species name is combined with a generic name other than the original one, the name of the author of the species-group name, if cited, is to be enclosed in parentheses (the date, if cited, is to be enclosed within the same parentheses), i.e., *Carassius auratus* (Linnaeus, 1758). On page 91 of Roos' goldfish book she states "…those goldfish lived, immortalized by Linnaeus in his *Systema naturae* featuring his new system of binomial nomenclature to classify every living creature. Linnaeus gave them their scientific name, *Carassius auratus*." This, of course is not true. The genus *Carassius* was proposed by the Swedish ichthyologist Sven Nilsson in 1832 and Linnaeus died in 1778.



***Carassius praecipuus*, a dwarf new species of Carassius.**

THE DAWN OF THE AQUARIUM HOBBY IN AMERICA

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Facebook Files, October 2, 2021)

Some things are difficult to define, and the aquarium hobby is one of them. For example, the aquarium hobby in England in the 1850s was not the same aquarium hobby in the United States in the 1950s. After some reflection I realized that the history of the aquarium hobby can be described in four separate and fairly distinct stages – and this solved the problem. After all, an aquarium is nothing more than a vessel that holds water and a hobby is nothing more than a pastime pursued for pleasure. Accepting these terms in their broadest interpretations, therefore, allows us to proceed in the most meaningful and useful way, i.e., by looking at the stages of the hobby as they occurred and developed over time, and this is shown on page 2 of my "Toy Fish" book (Klee, 2014). Stage Four is called "ASSOCIATION," which is characterized by the existence of aquarium societies, competitions and magazines associated with the hobby. This essay is concerned with the beginning of Stage Four in the later part of 1893 to 1914, an era I call "The Dawn of the Aquarium Hobby in America" or Dawn Era for short. This chronology is summarized in the accompanying table but added are five dates of some early introductions of fancy goldfish in the period 1872-1880. The starting date I have selected for the Dawn Era in this essay is 1892, the ending period being the end of 1914 (see the accompanying table for the timeline).

Although the common goldfish was first imported in this country in the mid-1750s, they will not be discussed in detail in this essay as they are mostly pond fish or isolated specimens in the ubiquitous goldfish bowl where, sooner or later with inattention or improper care, the crime of piscicide relegates them to a watery grave. However, a few facts about them will be helpful as fancy goldfish are bred–at considerable expense–from common goldfish, and it should be remembered that common

IMPORTANT DATES IN THE DAWN OF THE AQUARIUM HOBBY IN AMERICA	
1872	The first fancy goldfish imported into the United States were seven fantails called 'Kingiyo's.' These were brought from Japan in 1872 by Martin Gillet Gill and one of these was presented to the New York Aquarium in that year.
1876	The first official World's Fair to be held in the United States, the Centennial International Exhibition of 1876, was held in Philadelphia. Mulertt's goldfish won numerous awards here.
1877	In April of 1877 the *New York Aquarium Journal* reported that they had just imported two specimens of what they called the "Japanese Telescope fish." Although they were recently brought directly to the Aquarium from Germany, they originally came from Japan. In the following May 1877 issue, the *Journal* provided additional information about the fish.
1878	Rear Admiral Daniel Ammen made the second importation of the veiltail in 1878. These were bred on his estate at Ammendale, Maryland and fish of that lot were presented to the United States Fish Commissioner and extensively bred at the government nurseries in Washington and distributed in large numbers by them for a number of years. A few of the Ammen stock were brought to Philadelphia from Ammendale and were bred in ponds for several years, the output being sold in that city for rather high prices. Subsequently, large numbers of Japanese goldfish were brought into the United States by private fanciers and by regular dealers; other importations were made from Europe.
1880	Gill stocked the fountain that was at Baltimore's Sesqui-Centennial Celebration held October 11-19, 1880 and was bought by the City of Baltimore, through him. Henry Bishop of Baltimore got what fish were left in the fountain. The others had died for want of proper care and interest.
1892	*THE AQUARIUM*, edited by Hugo Mulertt, first published in Cincinnati in the year 1878 to 1881 or 1882 (exact year not known), and then in 1892 in Brooklyn, NY.

IMPORTANT DATES IN THE DAWN OF THE AQUARIUM HOBBY IN AMERICA Continued.	
1893	Five aquarists of New York City met on March 12, 1893 in that city and formed an aquarium society. The society was called "*Triton*" of New York. Baron von Schlichting was elected its president. This was the forerunner of the *New York Aquarium Society*.
1893	On May 31, 1883 a second aquarium society was formed in New York City. The society was called "*Salamander*." Dr. A. von Duering was elected president and Mr. H. V. Letkemann secretary.
1893	The World's Columbian Exposition (also known as the Chicago World's Fair) opened on May 1, 1893. At the close of the fair, William P. Seal returned home to Philadelphia with what was known as the "World Fair's fish." Supposedly, with this fish began the famous line of American, or "Philadelphia" Veiltail goldfish.
1894	"The Amateur Aquarist," by Mark Samuel.
1888	"The Goldfish and its Systematic Culture with a View to Profit: A Practical Treatise on the Fish, its Propagation, Enemies, Diseases, and Care of the Fish in Captivity," by Hugo Mulertt.
1897	"The Fishes of the Fresh and Brackish Waters in the Vicinity of New York City," by Eugene Smith.
1898	William Poyser stated that J. Hope was the originator of the goldfish fancy in Philadelphia and that he first introduced Japanese fish in that city in 1898 (the same year the Philadelphia Aquarium Society was established) at a price within reach of all. Poyser purchased his first goldfish from Hope about that same time. When and where Hope got his fish is not known.
1898	John Cugley and a few hobbyists started to assemble on a regular basis and one of these regulars, H. G. Burrows suggested that the group organize and conduct meetings in a regular way and so, with the aim of setting up a permanent organization, the very first meeting was held at the Colonnade Hotel in Philadelphia on May 5, 1898. Burrows, who was elected President, proposed the name by which the society was henceforth known, i.e., The Aquarium Society of Philadelphia. Other officers elected were: Harry Folwell, Vice President; George Cugley, Secretary; and E. Thalag, Treasurer. On June 14, 1898 the practice of meeting at members' homes was started.
1898	"Aquaria," by Charles N. Page.
1902	"The Goldfish and its Systematic Culture: a Thorough Guide for Goldfish Keeping and Goldfish Breeding in the House and Out-of-Doors, the Construction and Care of the Parlor Aquarium and Ponds for Breeding," by Hugo Mulertt.
1902	"The Home Aquarium…How to Care for It," by Eugene Smith.
1908	"Fresh Water and its Inhabitants," by Otto Eggeling and Frederick Ehrenberg.
1908	"Goldfish Aquaria and Ferneries," by Chester Reed.
1908	"Goldfish Breeds and other Aquarium Fishes: A Guide to Freshwater and Marine Aquaria, their Fauna, Flora and Management," by Herman T. Wolf.
1909	"The Aquarium: Devoted to Aquarium Culture and Window-gardening: Information for the Care of the Parlor Aquarium," a pamphlet by Hugo Mulertt.
1909	"Japanese Goldfish: Their Varieties and Cultivation," by Hugh M. Smith.
1911	The *Brooklyn Aquarium Society* was formed early in 1911, chiefly from the membership of the *New York Aquarium Society* residing on Long Island.
1911	The *Chicago Fish Fanciers Club* was established in 1911 but was nosed out by a few weeks by the Brooklyn club.
1911	The *BULLETIN OF THE BROOKLYN AQUARIUM SOCIETY* appeared, Editors De Voe, Lienau and Wilco, published by *The Brooklyn Aquarium Society*, Brooklyn, New York.
1911	"Aquaria Fish," by Frank Lee Tappan.

IMPORTANT DATES IN THE DAWN OF THE AQUARIUM HOBBY IN AMERICA Continued.	
1911	"Aquaria Fish," by Frank Lee Tappan.
1912	*THE AQUARIUM*, Editors: Eugene Smith and others; publishers included at the start were *The Brooklyn Aquarium Society, The Chicago Fish Fancier's Club, The New York Aquarium Society* and *The Philadelphia Aquarium Society*. Others as the time passed included the *Milwaukee Aquarium Society, Boston Aquarium Society, Philadelphia Goldfish Society, Minneapolis Aquarium Society*, and *San Francisco Aquarium* Society. However, both the San Francisco and Boston groups had undergone reorganizations before 1917 and therefore were by that date, different societies. Also, the Chicago Fish Fanciers Club had incorporated as the Chicago Aquarium Society.
1913	March 1913 the New York Aquarium Society had changed its name to "*The Aquarium Society*."
1914	"Domesticated Fish," by Walter Lannoy Brind, New York City.
1914	"The Care of Home Aquaria, by Raymond C. Osburn.

goldfish were sold in quantity in this country before and after the Dawn Era.

A1: SOMETHING ABOUT GOLDFISH

The following is taken from Charles Darwin's book, "The Variation of Animals and Plants under Domestication" (Darwin, 1868); however note that he defined monstrosities as a "considerable deviation of structure in one part, either injurious to or not useful to the species, and not generally propagated."

Gold-fish (Cyprinus auratus) were introduced into Europe only two or three centuries ago; but it is believed that they have been kept in confinement from an ancient period in China. Mr. Blyth suspects from the analogous variation of other fishes that golden-coloured fish do not occur in a state of nature. These fishes frequently live under the most unnatural conditions, and their variability in colour, size, and in some important points of structure is very great. M. Sauvigny has described and given coloured drawings of no less than eighty-nine varieties. Many of the varieties, however, such as triple tail-fins, &c., ought to be called monstrosities; but it is difficult to draw any distinct line between a variation and a monstrosity.

As gold-fish are kept for ornament or curiosity, and as "the Chinese are just the people to have secluded a chance variety of any kind, and to have matched and paired from it," we may feel nearly confident that selection has been largely practised in the formation of new breeds. It is however a singular fact that some of the monstrosities or variations are not inherited; for Sir R. Heron kept many of these fishes, and placed all the deformed fishes, namely those destitute of dorsal fins, and those furnished with a double anal fin, or triple tail, in a pond by themselves; but they did "not produce a greater proportion of deformed offspring than the perfect fishes."

This observation was important as it had a great deal to do with Darwin's belief that these abrupt changes were not inherited. Charles Lyell, important in the foundation of modern geology, influenced Darwin so deeply that Darwin envisioned evolution as a sort of biological uniformi-

Figure 1: Genetic deformity in a bubble-eye goldfish.

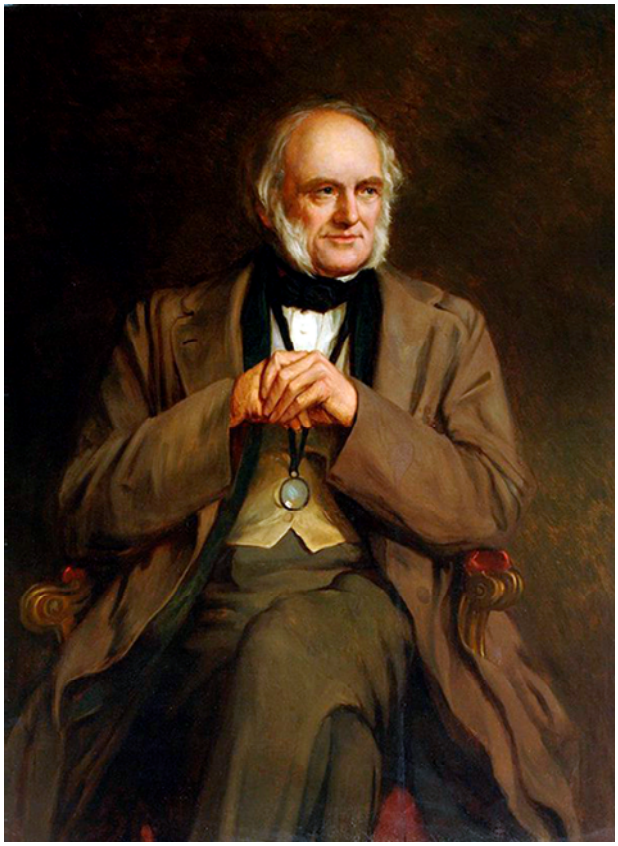

Figure 2: Charles Lyell (1797-1875). Lyell helped to arrange the simultaneous publication in 1858 of papers by Darwin and Alfred Russel Wallace on natural selection, despite his personal religious qualms about the theory.

tarianism, the theory that changes in the earth's crust during geological history have resulted from the action of continuous and uniform processes. Darwin argued that evolution took place from one generation to the next before our very eyes, but it worked too slowly for us to perceive. In a letter Darwin sent to Lyell dated February 23, 1860 (Anon., 2002) he stated that in the case of goldfish it is not a case of abrupt origin of new forms. "On the whole, I still feel excessively doubtful whether such abrupt changes have more than very rarely taken place."

It is known that, if left untended, in a few generations goldfish revert to their wild type. However, within the same generation of fancy goldfish this reversion can be seen starting; typically, 90% of a new brood of fancy goldfish must be culled and discarded. This is expensive for breeders since the newly-hatched first must be fed foods like brine shrimp and then brought to a size where they can be evaluated. To continue with Darwin's comments:

Passing over an almost infinite diversity of colour, we meet with the most extraordinary modifications of structure. Thus, out of about two dozen specimens bought in London, Mr. Yarrell observed some with the dorsal fin extending along more than half the length of the back; others with this fin reduced to only five or six rays; and one with no dorsal fin. The anal fins are sometimes double, and the tail is often triple. This latter deviation of structure seems generally to occur "at the expense of the whole or part of some other fin;" but Bory de Saint Vincent saw at Madrid gold-fish furnished with a dorsal fin and a triple tail. One variety is characterized by a hump on its back near the head; and the Rev. L. Jenyns has described a most singular variety, imported from China, almost globular in form like a Diodon, with "the fleshy part of

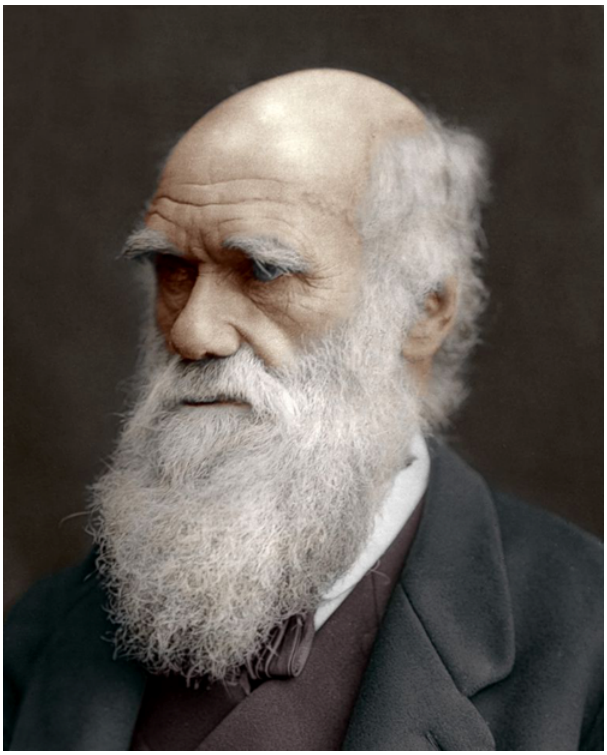

Figure 3: Charles Darwin (1809–1882).

the tail as if entirely cut away; the caudal fin being set on a little behind the dorsal and immediately above the anal." In this fish the anal and caudal fins were double; the anal fin being attached to the body in a vertical line: the eyes also were enormously large and protuberant.

Darwin's comment that "Passing over an almost infinite diversity of color, we meet with the most extraordinary modifications of structure," suggested that goldfish provided a rich resource for investigating the genetics of diverse morphological features. The study of variation under domestication in goldfish supplied Darwin with the idea of selection, whether natural or artificial, as the driving force behind evolution.

A2. SCIENCE AND THE GOLDFISH MARCH ON

Goldfish have been subjected to over 1,000 years of intensive domestication and selective breeding. A recent article (Chen, et. al., 2020) resequencing 185 representative goldfish variants and 16 wild crucian carp revealed the origin of goldfish and identified genomic regions (*i.e.*, regions of genes) that have been shaped by selective sweeps linked to its domestication. Comprehensive collection of goldfish varieties enabled the researchers to associate genetic variations with a number of well-known anatomical features, including features that distinguish traditional goldfish clades. Additionally, they identified a candidate causal gene for the first well-known case of Mendelian inheritance in goldfish–the transparent mutant. The datasets that were generated may help to elucidate the evolution of goldfish and goldfish varieties and may provide a resource for a wide range of studies with important implications for the use of goldfish as a model for vertebrate and fish genetics.

A SNP (snip) is a DNA sequence variation that occurs when a single nucleotide (adenine, thymine, cytosine, or guanine) in the genome sequence is altered and the particular alteration is present in at least 1% of the population. An example of a SNP is the substitution of a C for a G in the nucleotide sequence AACGAT, thereby producing the sequence AACCAT. Fish have many SNPs; for example, a total of 8.4 million candidate SNPs were identified in the channel catfish (*Ictalurus punctatus*).

Modern datasets often have a very large number of variables. This makes it difficult to inspect each of the variables individually, due to the practical fact that the human mind cannot easily digest data on such a large scale. When a dataset contains a large number of variables, there is often a serious amount of overlap between those variables. Principal component analysis (PCA) is a statistical method that allows one to "regroup" the variables into a smaller number of variables, called components. The goal of PCA is to regroup these variables in such a way that the first (newly created) component contains a maximum of variation. The second component contains the sec--largest amount of variation, etc. The last component then contains the smallest amount of variation. Thanks to this ordering of components, it is possible to retain only a few of the newly created components while still retaining a maximum amount of variation. We can then use the components rather than the original variables for data exploration.

Using the principal components of SNP variation, seven different types of goldfish were found to be clustered, i.e., common goldfish, Wenyu-Oranda, Telescope, Wen-pompon, Eggfish-Lionhead, Egg -pompon and Chinese-ranchu (Chen et al., 2020). Using the first two components, Figure 4 shows

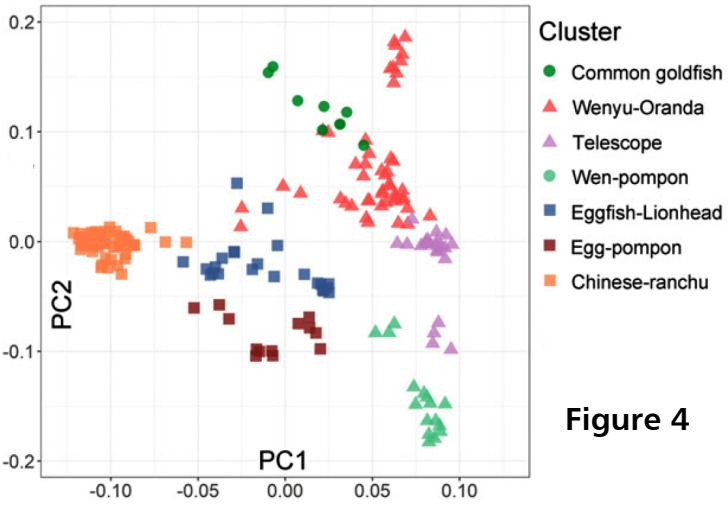

Figure 4

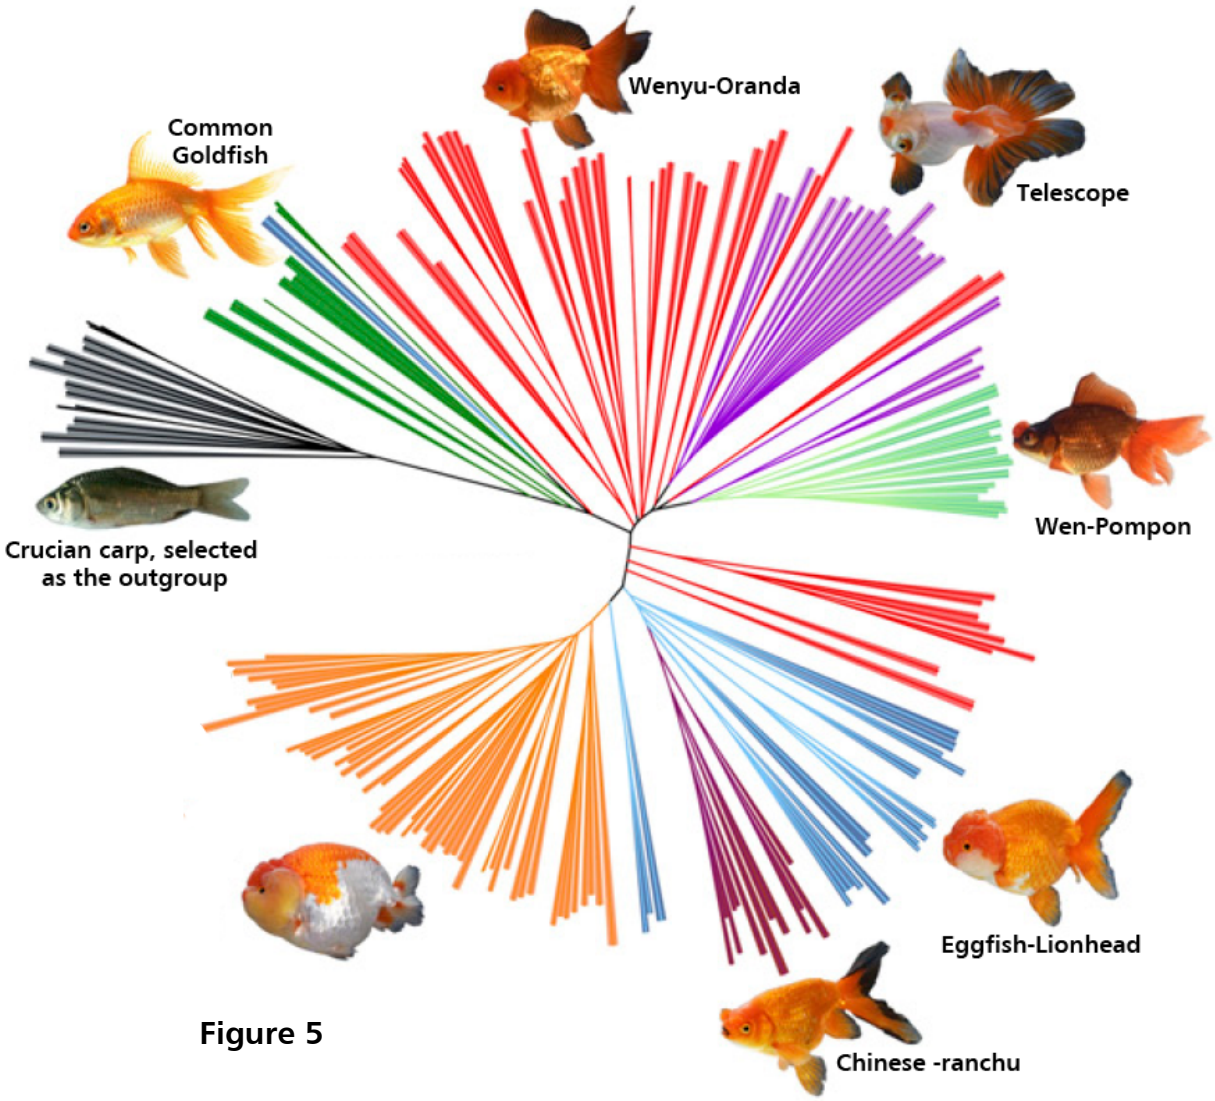

Figure 5

these seven clusters. A different technique, based on the genetic distance calculated from the SNPs, shows the clustering more clearly and also shows images of each type (Figure 5). The branch color indicates membership in one of the eight classified goldfish populations, eight because it also contains the crucian carp, used as an outgroup, which was not used in the principal components figure.

B1. THE FIRST VEILTAIL GOLDFISH OF RECORD

The tea importing firm of Martin Gillet & Co. was founded in Baltimore, Maryland by Martin Gillet in 1811, just 35 years after the Declaration of Independence (Anon., 1912). A gentleman of the old school, the founder of the venerable firm felt that the importing of tea would be not only lucrative, but would bring much honor from the housewives of the young republic. The War of 1812 afforded the opportunity of selling teas to the Government, and thus the business prospered from the very start. In 1822 Mr. Gillet's daughter, Miss Elina Adams Gillet, married Owen A. Gill, who was taken into partnership. Martin Gillet, the founder, died in 1814, and Gill carried on the business alone until his sons became of age and took their places in the business world with him (Phillips, 1979).

In 1862 the first to be admitted was Martin Gillet Gill. As a youth of 18, Gill first traveled to Paris and England aboard the ship of a tobacco trader, subsequently undertaking three round-the-world trips over the course of his 69 years. Gill rose

Figure 6: Martin Gillet Gill.

through the ranks of his grand-father's tea importing firm and as a representative of the company, he went to China and Japan in the capacity of tea-taster and remained in the Orient for seven years. During his stay in Japan it was reported that Martin traded arms to the Mikado in his struggle with the Tycoon government, and amidst this turmoil he conceived the idea of the teabag, a product later sold as "He-No tea."

The first fancy goldfish imported into the United States were seven fantails called 'Kingiyo's.' These were brought from Japan in 1872 by Gill and one of these was presented to the New York Aquarium located at 5th St. and Broadway, established by W. C. Coup and Reiche and Brothers in 1876 (Anon., 1876). The fish more properly were called "Kingyos," but the Germans called them "Schleirschwanze" (Veiltails in English).

Starting from Japan in 1875 with eighty-eight fish, the captain of the steamer took great interest in his efforts to introduce the fish to America and built a tank on the steamer to accommodate them. He took in a supply of river water but it was soon found that the motion of the ship dashed the fish against the sides of the tank and many were lost. To obviate this, a smaller tank was built and suspended like a compass, thus counteracting the motion of the ship. However, notwithstanding all the care bestowed on them, only fifteen arrived in San Francisco, all in a very weak condition. Of these, eight subsequently died.

There were also numerous troubles in bringing the fish across the continent. At one place in Nebraska the train was stalled in the snow for several days and Gill had the fish packed in snow to keep them to show the people at home, but to his surprise seven of them survived this hard treatment and lived to breed in ponds he had in his yard in the city. He afterward stocked the fountain that was bought by the City of Baltimore for the Sesqui-Centennial Celebration held October 11-19, 1880. After the celebration was over, many of the fish had died for want of proper care and interest. However, Henry Bishop of Baltimore got what fish were left alive in the fountain.

B2. HENRY BISHOP

Henry Bishop was born Hanover, Germany in June 1846 and in boyhood, he had made birds and fish a study. In 1862, at the age of 16, he came to the United States and in 1869 married his wife, Mary,

Figure 7: Image of the Kingyo in the *New York Aquarium Journal* of November 1876.

who had emigrated from Germany in 1866. They had a son, Henry Bishop, Jr. and two daughters, Hermina and Marie.

Bishop landed in New York City and I will let him tell what happened next (Bishop, 1886):

Although of German birth, I say "We Americans," for I landed on these shores when scarcely sixteen years old, and five months after went on American vessels, where I served in the capacity of cabin boy, and later as carver and steward, and took the greatest pains in mastering the English language and adopting the ways of the American people in general. This I have brought to such perfection that on Election Day I vote twice unless it can be plainly seen that my man will have an overwhelming majority. Of this voting as often as you can I sing in my song, in another part of this book, entitled "Rock, Cradle, Rock," the third verse of which is as follows:

"When twenty-one then you are a man,
Vote soon and often as you can
For the party which pays the best–
Be easy, let your conscience rest."

I won't take Bishop to task for this since in those days there was no difference between Baltimore's political structure and that of New York City's Tammany Hall (and I was also laughing a lot when I read it!). Actually, this work has been selected by scholars as being culturally important, and is part of the knowledge base of civilization as we know it. Since it is in the public domain, the book is readily available as a reprint.

It is not known why Bishop moved from New York to Baltimore but in 1880, Germans made up the majority of the foreign-born population of Baltimore at 58% of all foreign born residents. 16.9% (56,354) of Baltimore were foreign born, 32,685 of them Germans. The German-born immigrant population in Baltimore peaked in 1890, when German-born Baltimoreans numbered 41,930 out of the total population of 365,863. We don't know when Bishop arrived in Baltimore, Maryland, but the following is taken from his book (Bishop, 1886):

It is but twelve years ago, June 17,1874, when I opened the little Bird Store No 49 East Baltimore street, with but little cash, no credit and no more knowledge of the business other than that of an *enthusiastic* private bird fancier. During my occupation as hotel clerk and steward in previous years, I had as much as two hundred dollars' worth of birds and aquariums at one time, just for my private amusement, and to parents I would say this, should your son have a natural fancy for such household pets, let him have full sway, as it will keep him out of mischief. Nothing adds so much to making a house cheerful and the inmates happy–especially ladies and children– as a song-bird, a talking parrot or a choice aquarium, and any of these can always be had at my store, or from my agents In other

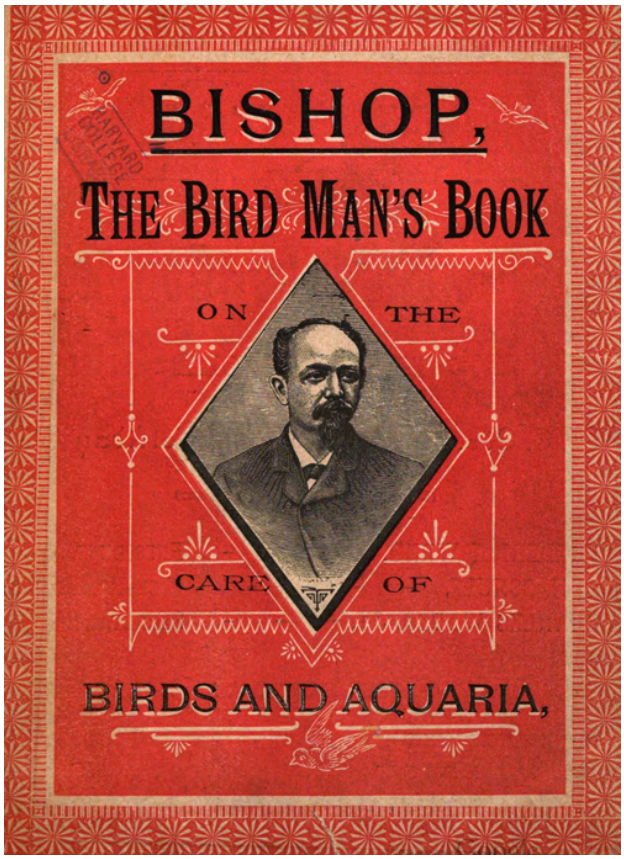

Figure 8: Henry Bishop's 1886 book.

cities, in the most approved styles and at prices so low as to surprise every visitor.

Susan G. Pearl, on the Board of Directors of Prince George's County Historical Society as Historian, discovered that in 1890, Edwin A. Newman of Washington, D.C., purchased approximately 80 acres of land that lay to the east of the Maryland Agricultural College, separated from the college by the Washington-Baltimore Road (Pearl 2018). It was well watered by the Paint Branch, a tributary of the Eastern Branch of the Potomac. The construction of the Baltimore & Ohio Railroad some 50 years earlier had caused this wetland area to form ponds and a small lake in this area. Newman envisioned the development on his new property of a resort community which he named Lakeland, with the lake (a triangular body of water of approximately 5 acres as a community amenity. He called this amenity Lake Artemesia, after his wife, Clara Artemesia Newman. He had the area platted and subdivided, laying out streets, installing gas lights, curbs and gutters, and began to sell lots. The five-acre Lake Artemisia was stocked with bass, but later her father rented the lake to a family that used it for raising goldfish..

Part of a 1903 lease among the Prince George's County land records was from the Aquarium Fisheries Company of Prince George's County, Inc. (Edwin Newman, president) to Henry Bishop, for 26 ½ acres of land and water - "for the purpose only of a goldfish farm or hatchery… all lands, ponds, lakes or bodies of water now existing or hereafter to be constructed in the subdivision of Lakeland, with rights of ingress and egress to and from…" Bishop had the right to use "water of the Paint Branch and to conduct it to and from said ponds, lakes and bodies of water." The owner of the land, Aquarium Fisheries Company, retained the right to collect ice from the ponds.

The lease was to extend for 10 years, from 1 May 1903 to 30 April 1913. Three years later, in June 1906, another document was filed in the Prince George's County land records, this one dealing with Lake (or Pond) #5 which Bishop had constructed on the west side of the tracks, south of the train station in an area which had not been developed with housing. This document permitted Bishop to construct two more lakes adjacent to one of the Lakes within the next seven years (i.e., up to the end of the original 1903 lease). Henry Bishop was not able to carry out the larger plans for his fisheries project; he died in 1907, and the obituary from the *New York Times* credits him with having developed

…the largest goldfish industry in the country. His breeding lakes at Lakeland cover acres. From them he supplied parks in New York, Detroit, Washington, and other cities with specimens. He also shipped these fish to New York and other places to be used for destroying the larvae of mosquitos."

After Henry Bishop died, Henry Bishop, Jr. had no interest in maintaining the bird and aquarium business. However, within a fairly short time the United States government was operating the fisheries at Lakeland (Kelly, 2017). There is a government report from 1915 reporting the success of

Figure 9: An interior image in Bishop's book.

Figure 10: Henry Bishop (1846-1907).

fish breeding in the Lakeland ponds. And there are several interesting reports from the *Washington Post* (1924) that indicate that the government was still running a productive fishery there at that time. One 1924 article informed fishermen that Uncle Sam was going to keep all streams within 100 miles of Washington well stocked with favorite fish.

On the road to Baltimore, near the Maryland Agricultural College (sic), the government has leased a tract of land which will be used for the breeding of fish for use in stocking the streams throughout a large part of the East. Utilizing a pond system that had been used for raising goldfish, the bureau of fisheries has 23 acres…under water for breeding purposes. The millions of crappie, bluegill, bream, and large-mouthed black bass…will be distributed in the creeks and rivers of Maryland, Virginia, West Virginia, North Carolina, Delaware, New Jersey, Pennsylvania and New York. The bureau stocked the 23 acres of ponds with 105 black bass, 8 crappie, and 12 catfish. Six months later, exactly 34,255 crappie, 2945 catfish, and 37,085 black bass had put in appearance…"

In the same year, the *Washington Post* recorded the visit by Herbert Hoover, then Secretary of Commerce, to the Lakeland fisheries (The Bureau of Fisheries operated under the Department of Commerce from 1913-1939):

The secretary visited each of the half dozen ponds. He helped draw in seines of small bass . . . part of the supply of 200,000 fish . . . which have been hatched at Lakeland from 250 large-mouthed bass with which the ponds were stocked.

As the 20th century reached its midpoint, Lakeland had become a comfortable black residential suburb, and the lakes and ponds were becoming overgrown, but they had clearly been an exceptional source of fish during the first part of the century due to Henry Bishop. In the 1907 Report of the Director of the Aquarium to the Board of Managers, under Acknowledgments" was the following statement (Townsend, 1908):

The late Henry Bishop, of Baltimore [Bishop died on November 3, 1907]**, presented fifteen Japa-nese goldfish of the large and handsome varieties so successfully bred by himself.**

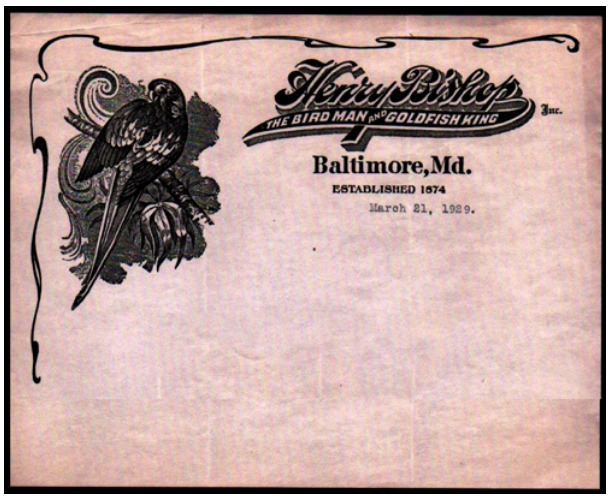

Figure 11: The Henry Bishop letterhead.

Bishop, therefore, bred more than one variety of fancy goldfish–probably veiltails and telescopes. It is possible–but hardly likely–that some of these fish might have even been bred from the veiltails he rescued from Baltimore's 1880 Sesqui-Centennial Celebration, but they probably were responsible for his early interest in fancy goldfish.

B.3 THE FIRST TELESCOPE EYE GOLDFISH OF RECORD

In April of 1877 the *New York Aquarium Journal*, under "Recent Additions," reported that they had just imported two specimens of what they called the "Japanese Telescope fish." Although they were recently brought directly to the Aquarium from Germany, they originally came from Japan (Anon., 1877a):

Like the Kingiyo they are a species of carp, the name being given to them on account of the peculiar form of the eye. On examination it will be seen that these organs, instead of occupying a cavity, are placed at the extremity of two abnormal protuberances. It is a well-known fact that certain insects are endowed with the same peculiarity, and can simply by the turning backward of these projections see behind them. In addition to this peculiarity of eye structure these fish have also the "three tails," similar in general form, though less marked, than in the Kingiyo.

In the following May 1877 issue the *Journal* provided the following additional information (Anon., 1877b):

LING-TSING-YU

A glimpse at the new arrival, Ling-Tsing-Yu, is all that is needed to inform the visitor of its origin. None but the Japs could raise such a grotesque looking beauty, and, having raised it, none but a Jap could christen it with such a name. Those familiar with the graceful beauty, the Kingiyo … will note the resemblance in many particulars between it and its rival, the Ling-Tsing-Yu. Whether these mystical three syllables, when interpreted, mean the "big-eyed-fish," we will not venture to affirm. Certain it is, however, that in addition to the long wavy tail which is the special adornment of the Kingiyo, we have the extra wonder of the projecting eyes, which have caused this fish to be called in plain English the Telescope Fish. The Ling-Tsing-Yu is a species of Golden carp. Its body has all the bright colors of the gold-fish, and adds to this the wonder of the triple tail, and the still greater wonder of the eyes. These latter are mounted on stalks projecting from the sockets, as shown in Figure 12, and are the result of breeding and culture. Although the Kingiyo was our first love, the still greater wonder now on view is a sign that the manager of the Aquarium means that each succeeding conquest in the realm of Neptune shall be greater than the last.

Figure 12: The LING-TSING-YU bubble-eye goldfish at the New York Aquarium in 1877.

B4. THE VEILTAIL IMPORTATIONS CONTINUE

When Ulysses S. Grant was a little boy, he almost drowned. His best friend, Danny Ammen, saved his life. In a very real sense, then, we have Daniel Ammen to thank for the preservation of the Union, the destruction of slavery and the accomplishments of a president. (Or, as Grant joked in a letter to Ammen fifty years after being rescued, "You are responsible for the many trials and difficulties I have passed through in the last half century. But I am of a forgiving nature and I do forgive you.")

Rear Admiral Daniel Ammen, U. S. N., had a varied career. In May 1864, while in charge of some 220 conscripted seamen sailing from New York to Aspinwall on the California passenger steamer Ocean Queen, he suppressed an open mutiny. Most of the draft were miserable creatures, raked up from the shipping agencies, and the time being at the height of the war, such a set of people were much more dangerous on board a passenger ship with ladies and children on board than tons of dynamite would have been. A mutiny occurred within thirty-six hours after the vessel sailed from New York, and some of the mutineers actually had the captain and chief engineer by the throat when Am-mon shot the ringleader dead in his tracks. The officers of the ship then fired, killing another prominent muti-neer. The dangerous mutiny was quelled.

During his career and after retirement, he was involved with designing a number of crafts and weapons for the Navy, including the ram Katahdin for harbor defense and a cask life raft that became standard design for life boats in the naval service.

Ammen made the second importation of the veiltail in 1878 on a Pacific Mail Line Steamer from Japan. These were bred on his estate at Ammendale, Maryland and fish of that lot were presented to the United States Fish Commissioner and extensively bred at the government nurseries in Washington and distributed in large numbers by them for a number of years. A few of the Ammen stock were brought to Philadelphia from Ammendale and were bred in ponds for several years, the output being sold in that city for rather fine prices. Subsequently, large numbers of Japanese goldfish were brought into the United States by private fanciers and by regular dealers; other importations were made from Europe.

B.5 VEILTALE FABLES AND THE "WORLD FAIR'S FISH"

The Veiltail goldfish has several stories about its origins in America. One of these tales talks about Imperial Goldfish being sent to Chicago from Japan to be exhibited at the World's Columbian Exposition (also known as the Chicago World's Fair), which opened May 1, 1893. It was told that these fish became sick, with most of them dying. A few were rescued by William P. Seal (Seal, 1915), who was placed in charge of the construction of the aquarium before the Fair was opened in 1893, but resigned his position as special agent in charge of the aquarium on December 31, 1892. At the close of the fair, Seal returned home to

Figure 13: Rear Admiral Daniel Ammen (1820-1898).

Philadelphia with what was known as the "World Fair's fish" and later sold it to Franklin Barrett. Supposedly, with this fish Barrett began the famous line of American or "Philadelphia" Veils. Actually, however, the Barrett Veiltail strain was produced from a Japanese Fringetail and a Chinese Telescope Eye with a short but very square tail. John Cugley of Philadelphia had imported these Telescope Eye fish and shared them with Barrett to establish a very good line of American veiltails.

The true facts are as follows: The Wisconsin Fish Commission bought two hundred imported Japanese Fantail goldfish for their exhibit at the Columbian Exposition. Unfortunately, these were infected by the disease commonly known as tail- or fin-rot and died off very rapidly. When all were dead but seven they were given to Seal to experiment with by James Nevin, Superintendent of the Wisconsin Commission. This was before the opening of the Exposition. Seal succeeded in saving three or four of them which he brought to Philadelphia. Two of them, a male and a female, one the pure pearl fish (it was white) subsequently exploited as the "World's Fair Fish" and pictured as red in color, were sold to a Philadelphia fancier for fifteen dollars. However; this fish at that time had not attained anything like the later development of its fins. In fact, at that time it was no better than thousands of others that were imported every year and sold at low prices. At the time, fish like this cost 13 dollars a hundred at San Francisco. Thus although this particular fish began its career in the United States with a value of thirteen cents, with its owner spreading a tale of its cost it finally attained a mythical newspaper value of five thousand dollars. It was not exhibited at the World's Fair, and would only have attracted attention as one of a tankful if they had lived.

B.6 THE BREEDING OF FANCY GOLDFISH

Regarding the breeding of fancy goldfish, I'll refer to Al Foster, one of the most recognized specialists of this century (Radford, 2004). First he advises the beginner who just wants to maintain a strain (it should be mentioned that I have done some minor editing of the text):

To keep a strain of goldfish, you should keep at least a couple of dozen fish all the time. These fish should be old enough to breed, i.e., 2- and 3-year old fish. Most peo-ple, however, don't have enough water space to keep a strain go-ing [a common suggestion is for the first fish, 20 gallons of water and for each one afterwards, 12 gallons]**. Also, most are too soft-hearted to do all the culling. If you don't cull, then you end up crowding the fish and they just don't develop. If you can get to a store that has adult fish you can usually pick out a pair by standing and watching the way that they act for a while. Once you have a pair, the breeding takes care of itself. If the water is clean, they will lay eggs by themselves. You can read in any book how to do it. That means changing water sometimes on a daily basis for the first couple of weeks.**

He then describes his own set-up and methods:

Figure 14: Al Foster, one of our expert fancy guppy breeders in the United States.

I have 2 fish rooms in the house and a building outside where I keep my fish over winter. I also have about 20 ponds. Most of the fish that I breed in the house are in 200 gallon tanks containing 10 or 12 adult fish. There will be several Ranchu in them, but usually a few small Ryukin also, maybe even a few single tailed males. The big males, Veils especially but Ranchu also, don't chase the females very well. However, the younger males chase like crazy. When I walk into the fish room in the morning, I know immediately if any of the females have eggs because the smaller males are chasing them all over. The big males on the other hand are waiting to see if I will feed them.

When I see that there are fish with eggs, then I will take the female and the desired male and hand strip the eggs. I hatch out the eggs and raise them for a month, feeding them all the brine shrimp that they can eat. In fact, I keep live brine shrimp in the tank with them all the time regardless of whether this means feeding them three times a day, twice a day or whatever. Al-most daily before I feed them, I siphon out two-thirds of the water, including anything that they haven't eaten and any fish waste. I then fill it back up and feed them again.

A vital part of Foster's operation is culling:

When they are about a month old, I cull them using big white porcelain bowls just like they have in China. I first put these fish in about an inch of water. Next I take a 100-watt bulb with a little reflector and place it about a foot over the water. Then I pick out all the fish that have double tails that match. (These are the fancies that I am talking about, i.e., anything with a double tail.) You usually find out that this takes about 90% of the fish out of the batch right away, no matter what variety of goldfish. If you are breeding Veils, you only take the ones that have perfect matching tails. If you are breeding Ranchus, you get a lot of tripod tails so you get rid of all of these fish. When finished all the selected fish are put back in the same aquar-ium. There may have been 40 gallons of water with 2000 fish at the start. Now, after 10 minutes, there are 40 gallons of water with 200 fish. I feed the same amount that I was feeding the day before. Don't worry; they eat it.

I have found that even with all the water that I have, I end up with a lot of fish that no one wants. I learned to be real ruthless right away. If they don't have a double tail, then you don't want to raise them. It doesn't mat-

Figure 15: Foster recommended culling with a vengeance. Center: Fry with faulty tail fin; Center: Right with good tail fin shape but it is divided; Right: Fry with fins fully divided.

ter how good they look from the side. You've got fish that are just going to foul up your whole set-up. What do I do with the 90% I cull? I dump them right back in the big 200 gallon aquarium with all the adult fish. Within 10 minutes, they are gone. It is the best natural food for the adults. On the bad side, I figure that by culling time, I have probably fed them about $25 of newly hatched brine shrimp.

The fish double in size almost twice a week. They grow so fast I usually go through them a second time. Now no matter what variety of goldfish it is, I usually raise only about 1% of the fry. People are under the illusion that I have thousands and thousands of Veils. If you count all the ones that hatch out of the eggs, I do. However, when you count the ones that people see in a book, this narrows it down to that 1%.

This section shows that the breeding of fancy goldfish had little to do with the Dawn Era of the aquarium hobby in America. It was just too expensive and time-consuming to compete with the introduction of tropical fish. Veiltails were never produced by a large number of individuals; the centers of veiltail breeding were Philadelphia and New York where it appears that many fancy goldfish hobbyists were for the most part well-off financially, very competitive in their shows, and did not readily share information with potential show competitors. When tropical fish became available to the general public, the goldfish hobby did not have a large healthy hobbyist base with which to compete and goldfish quickly became secondary to tropical fish in popularity.

In the 1920's, the veiltail goldfish abounded in both the US and Britain. There is no certainty as to how precisely the veiltail got to England but it flourished there in the hands of breeders like Captain Betts, Frank Close, Joe Linnale and George Fern. Barrett shipped his fish to others and without doubt some of these shipments were International. Two articles in 1950 about Charles Whitehead, in the *Portsmouth Evening News* and the *London Evening Standard*, indicate that he was either a source or the origin of the English veiltails. Whitehead likely obtained his first veiltails from the US just prior to WWI. By comparison, in the United States the veiltail was almost lost until the 1970's. The recovery of the Veiltail in the US brings to mind the names of John Anderson and Al Thomma as key proponents of the resurgence of the variety. Al Thomma was able to obtain stock from John (Andy) W. Anderson of Philadelphia who possessed fish from the original Barrett line. Anderson worked for Innes Publishing as advertising editor and publisher of Innes' *The Aquarium*.

C.1 THE PHILADELPHIANS

Hugo Mulertt became an increasingly popular presence in the Philadelphia aquarium scene at the end of the nineteenth century. The Centennial International Exhibition of 1876, the first official

Figure 16: A page from Cassel's catalog.

Figure 17: The Mulertt Aquarium details.

World's Fair to be held in the United States, was held in Philadelphia, Pennsylvania, from May 10 to November 10, 1876, to celebrate the 100th anniversary of the signing of the Declaration of Independence in Philadelphia. Officially named the International Exhibition of Arts, Manufactures, and Products of the Soil and Mines, it was held in Fairmount Park along the Schuylkill River on its fairgrounds. Nearly 10 million visitors attended the exposition, and 37 countries participated in it. Mulertt's goldfish had won numerous awards at the Centennial exhibition and at Philadelphia Aquarium Society fancy goldfish competitions. However, to complete this discussion of Mulertt it is necessary to explore the activities of Jacob Cassell.

Cassel was born into a family of farmers in Montgomery County, Pennsylvania sometime around 1849. In 1873, he married Harriett Pattern and the couple moved to Philadelphia where Cassel opened the Fair-Hill Terra Cotta works. In Cassel's time there were about six such works operating in the southeast Pennsylvania region. Four of those six were producing utilitarian objects, primarily sewer pipes, and one was producing some utilitarian wares as well as some garden equipment. Cassel, the sixth, was producing primarily floral and garden equipment and, uniquely, aquaria.

Cassel was primarily a garden supplier. About 70% of his twenty-five different forms advertised in the 1877 Fair-Hill trade catalog were garden related; only 25% were related to the aquarium trade. In the 1870s, 1880s and 1890s, the census and city directories list "terra cotta" or "florist" as Cassel's occupation. Similarly, most of his advertisements appeared in garden catalogs or garden sections of newspapers. By 1898 he still retained a show room in Philadelphia but began listing his occupation as "aquarist" or "aquariums." He developed what he called the "Mulertt Aquarium, the basic frame of which was not, as was most common in those days with rectangular aquaria, composed of metals. Instead it was made of an earthenware ceramic like terra cotta. Rather than being cut, folded and soldered like the metals, therefore, the earthenware was poured into a design mold, dried, fired and painted.

For decoration, the earthenware frame of the Mulertt aquarium was covered in artificial logs, stacked in a half-moon shape to cover the frame of the aquarium. This was painted to simulate moss. The rectangular pedestal was similarly constructed using two artificial logs, one on either side of the base. Two flat, semi-circular pieces of glass were inserted in the frame on either of the round sides. The artificial logs were set outside of the aquarium frame so as not to obscure viewing the fish. Overall, the tank could only hold about 1.5 gallons of water but as it was extremely decorative, it proved to be a best-seller for Cassell.

Cassel most likely broke into the aquarium industry because of the products he was already creating. His terra cotta forms were created from molds of a particular shape that could be used for any number of forms. In the case of the Mulertt Aquarium, Cassel used the same mold to create a nearly identical flower vase. The Mulertt Vase was featured in the same 1877 trade catalog, but in the garden department section. It featured the same half- moon shape constructed from stacked faux logs and a faux log pedestal. It varied in that instead of glass viewing portals on either side, the

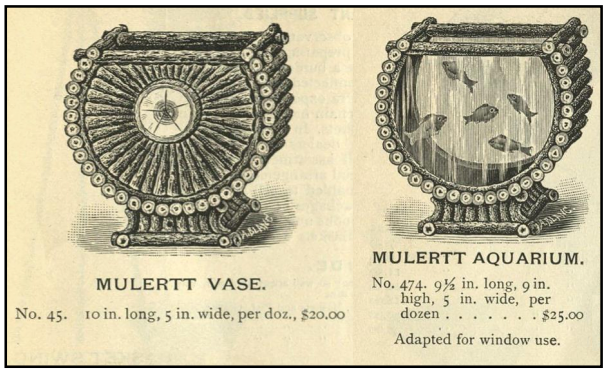

Figure 18:
The Mulertt Aquarium and Vase compared.

space was filled with rustic style logs radiating outward from a central star. Otherwise, the products are identical. It is likely the design for the aquarium preceded the vase because the name of the design referenced Hugo Mulertt, who was the most famous living aquarist at the time. Mulertt, however, most likely was not happy with Cassel's design as he was a champion of the much larger flat-sided aquariums that became the standard in the aquarium hobby. Despite beginning as a florist and garden supplier, as the Philadelphia Aquarium Society emerged Cassel became more deeply engaged with aquarists, and his aquarium designs became the icon of the flourishing aquarium district in the city.

In the March 1913, William Poyser wrote:

J. Hope was the originator of the goldfish fancy in Philadelphia. He first introduced Japanese fish in that city, some twenty years ago, at a price within reach of all. The Editor purchased his first goldfish from Mr. Hope about that same time [i.e., 1893, the same year the Philadelphia Aquarium Society was established].

Hope advertised in 1913 that he was a **"herpetologist, an Importer of rare Reptiles and Batrachians, Natural History Objects, etc. Also all varieties of curio fish on hand and supplied. Dealer in Birds, curious animals, dogs and Angora Cats and kittens–Pets of every kind."**

At least seven aquarium operations were located within a three block radius of Arch and 10th streets by 1910 including: Jacob C. Cassel, Fair-Hill Terra Cotta Works Showroom (Arch and 7th), William T. Innes, aquarium publisher (Cherry and 10th), Cugley and Mellon, fancy fish purveyor (Arch and 12th), and the Philadelphia Aquarium Society Headquarters (Arch and 13th). Thirty years earlier when Cassel had just opened his showroom, none of the others surrounded him. As time moved on, other important firms were established in the city, such as those operated by Harry P. Peters, William L. Paullin, Franklin Barrett and the General Aquarium Company of America.

Cugley and his partner, George Mullen, operated primarily as bird dealers but like Cassel, became increasingly involved in the fancy fish trade. Over the course of the first decade of the twentieth century, they advertised their Telescopic varieties and fancy aquaria in nearly every issue of the Philadelphia Inquirer. In 1897, Cugley imported a paradise goldfish from Japan that had the body and fin development of the Telescope, with the large tubular eyes pointed forward, a shortened head and long snout, moderately large paired fins and a double tail. The skin was covered with wart-like growths or papillae, which caused the thin scales to curve and stand from the sides as though they were ruffled, thus giving to the fish somewhat the appearance of being covered with barnacles, hence it was called the "Barnacled Paradise goldfish." Its scales were unevenly overlapped so that they appeared somewhat scattered, like those of the mirror carp, although they entirely covered the body of the fish. The singular appearance of these fishes led American breeders at first to suppose them to be diseased, but later they were recognized as a variety of the Japanese Telescope, the distinctive peculiarity being the scale formation. Other paradise gold-

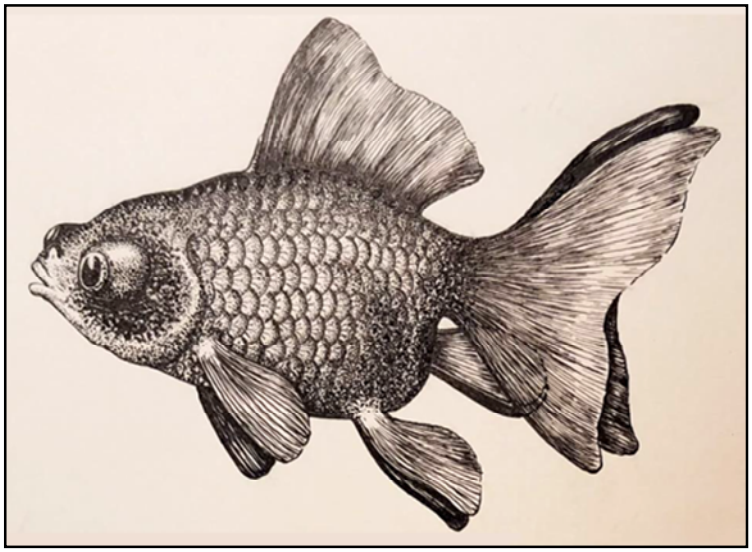

Figure 19: George Cugley's Japanese Barnacled Paradise Goldfish, drawn by Herman T. Wolf, February 6, 1902.

fish had been imported before, but they were exceedingly rare and challenging to bring home successfully.

These dealers provided impetus and equipment to the burgeoning aquarium hobby in Philadelphia. Harry P. Peters, member of the Philadelphia Aquarium Society, auctioneer, exhibitor and contestant in goldfish competitions, and Master of Ceremonies at aquarium events was William T. Innes' favorite among the dealers and he once described him thusly:

Now if there is any one large bouquet to be awarded, let us give credit where credit is due. Every organized effort has a leader. Without his energy and personal self-sacrifice nothing much would be accomplished. Since the inception of these shows fourteen years ago Harry P. Peters has been right there with his shoulder to the wheel and his hand in his pocket. Some years it seemed there would be no show until Harry got out his big whip and commenced to crack it. This was one of those years. He organized us this year and put the show across big without as much help as he should have had, and so, Mr. Harry Peters, we make a low bow and hand you the big bouquet with one hand and a cake with the other.

One thing that Philadelphia did not have, however, was a public aquarium, whereas many of the early aquarium societies did have one. That these were tremendous attractions and started many a visitor to start keeping aquarium fishes is exemplified by the following that appeared in the *Scientific American*:

ASTONISHINGLY GREAT INTEREST IN AQUARIUM.

The New York Aquarium had a greater number of visitors during the year 1909 than ever before, the attendance being 3,803,501, an average of 10,417 a day. These figures show that the Aquarium has a greater patronage by the public than all the other museums of the city, including the Zoological Park, combined, and 1,800,000 more, for the same period, than the New York Hippodrome, which has probably the largest attendance of any theatre in the city. These figures are unequaled by those of any other museum in the world for which statistics are available.

I can understand how the New York Aquarium was responsible for introducing many people to the aquarium hobby in that city since that is how I myself started. Eighty years ago, as a youngster living there, I made many trips on the subway from my home in the Bronx to the Battery (the southern tip of Manhattan Island) where the aquarium was situated.

C.2 THE PHILADELPHIA AQUARIUM SOCIETY

In the small pet shop on Ninth Street operated by John Cugley, who was the first to import calico telescope goldfish from Japan, a few hobbyists started to assemble on a regular basis to discuss the problems of this new hobby since detailed information was lacking, information that only experienced aquarists could answer. One of these regulars, H. G. Burrows, suggested that the group organize and conduct meetings in a regular way and so, with the aim of setting up a permanent organization, the very first meeting was held at the Colonnade Hotel in Philadelphia on May 5, 1898. Burrows, who was elected President, proposed the name by which the society was henceforth known, i.e., The Aquarium Society of Philadelphia. Other officers elected were: Harry Fol-

Figure 20: New York Aquarium Staff , 1909.

well, Vice President; George Cugley, Secretary; and E. Thalag, Treasurer. The object of the society was simply, "The scientific management of the aquarium and the amateur breeding of aquarium fish." In that the breeding of goldfish was stressed, the Philadelphia group set goals quite different from those of The Aquarium Society of New York established two years earlier. Active membership in the Society cost $6.00 per year (equal to about $160 today!) and Associate membership cost $3.00 (equal to about $80 today). For the first three meetings the average attendance was ten and by the end of the year, the total membership stood at eighteen.

On June 14, 1898 the practice of meeting at members' homes was started. In August of 1898 the Society was visited by Max G. Hammerschlag of The Aquarium Society of New York and thus, inter-society contacts were started. One interesting observation was that, independent of the New York group, the Philadelphia society also wrestled with the problem of commercialism. Their By-laws, however, stated explicitly: "It must be definitely understood that no member shall use the Society as an advertising medium." By the end of 1899 the Philadelphia group, perhaps influenced by the New York club, realized that its dues were too high. In order that the charter members not lose their initial investment, the Society disbanded on January 10, 1900, dividing the $20.40 cash on hand among fifteen members.

All but two members immediately reorganized as a new association, adopting the old constitution and bylaws as a whole but reducing the dues to $1.20 per year. However, since one of the problems in acquiring new members was that the old constitution and bylaws had been based upon those of academic or more erudite associations such as the Philadelphia Academy of Natural Sciences; this was no way to attract new members who were only interested in keeping and breeding the colorful new tropical fish that were being introduced into the aquarium hobby, so the new constitution and bylaws were modified to reflect this.

These changes were successful. In March of 1900 the Philadelphia club held the first competitive aquarium exhibition in America. It was held in the home of one of its members, Mr. E. Hoffman of 1813 South Third Street. The fish, goldfish only, were divided into three classes: under one year, one to three years and over three years. Ribbons were awarded by popular vote, not by judges selected for that purpose. By January of 1908 it had 128 active members (exceeding that of the New York club), a number of whom resided in neighboring cities. Its purpose at this time was the propagation of the finer breeds of the goldfish and the keeping of freshwater aquaria. Set topics of interest were discussed, exhibitions took place, prizes were awarded and inquiries from any source were invited and answered." Its meetings were held monthly, except June, July and August.

However, there was in no way a similarity between The Aquarium Society of New York and the Aquarium Society of Philadelphia. The former was an organization whose interest encom-

Figure 21: Therese Krones (1801-1830 was an Austrian actress of much ability and grace in comic parts. The portrait here showing the iconic goldfish bowl with a women was painted in 1824 by Ferdinand Georg Waldmüller.

Figure 22: Franklyn Barrett's Scaled Fringetail, Columbian World's Fair Prize Fish, Herman T. Wolf, February 6, 1902.

passed all aquarium fishes; the latter focused mainly on goldfish.

Because the number of aquarists interested in the new fishes started to significantly outnumber the goldfish fanciers, The Philadelphia Goldfish Society had broken off from the *Philadelphia Aquarium Society* in May of 1913, although the break was friendly and many kept memberships in both clubs. The new association was to specialize in goldfish, leaving all the other fish to the older organization.

In January 1914 the Philadelphia Aquarium Society started publication of a quarterly publication known as *Aquarium News and Notes*. It was a quarterly publication with its officers 1913-14 as follows: H. R. Lippincott, President; Charles Paxson, Vice-President; Hiram Parker, Treasurer; L. M. Dorsey, Jr., Secretary; Board of Governors: Hiram Parker, Geo. W. Price, C. Abram Provost, Wm. L. Paullin, and Wm. T. Innes, Jr. Publication Committee: Horace E. Thompson and Walter Lee Rosenberger (Chairman and Editor. I do not know how long it was published but the last issue I have in hand is the October 1915 issue which was Volume II, No. 8.

As time passed on, both the Philadelphia Aquarium Society and the Philadelphia Goldfish Society had disappeared. I

There are many reasons why the goldfish fad was passing. An article in the March 1911 issue of the *Guide to Nature* by Innes tells the story but as it is long, I'll summarize it here and include the complete article in the Appendix. I should explain that by "fringetail" Innes means what he later coined as a "veiltail." Innes also mentions "scaleless" goldfish; these are thin or transparently scaled fish.

He starts by observing that The Chinese are a people fond of the grotesque, i.e., a kind of beauty in ugliness. He goes into some detail talking about the telescope varieties of the goldfish where the idea is one of the grotesque kind of hideous urchin of the aquarium, beautiful in its ugliness, if you are trained to see it in that way. He notes that nine people out of ten on first seeing telescopes are horrified.

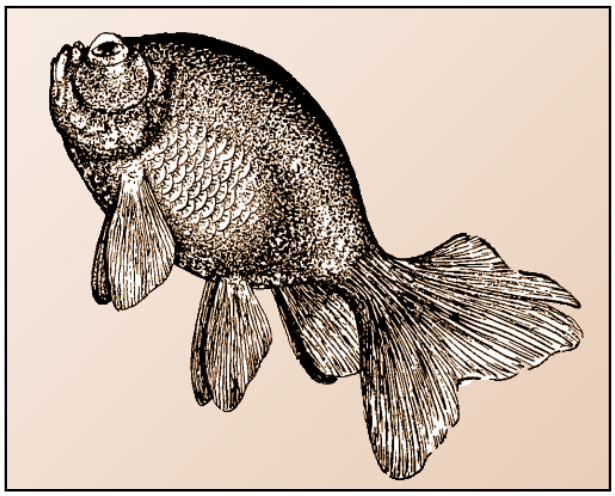

Figure 23: The Chinese Celestial Telescope goldfish, an example of an ugly Chinese breed. Herman T. Wolf, February 6, 1902.

There had been a breeding change of the telescope over time for large fin development and short body–two points clearly belonging to the ideas of grace and beauty. However, in working for these points, eyes and particularly color had fallen by the wayside. This had also produced a fish that had everything against it physically. The Chinese telescope with its great, bulging, near-sighted eyes, combined with the weakening influence of inbreeding, had trouble enough to keep alive. But combine with these disadvantages those of over-development of fins, together with the air-bladder, spawning and intestinal difficulties that go with short-bodied fish and you have a creature weighted down with handicaps. The short life and early loss of reproduc-tive power on the part of the males accounted in large measure for the difficulty in breeding large quantities of young from which to make selections, thus giving aquarists less and less opportunity to make experimental combinations.

The fish that was truly and legitimately graceful and elegant was the Japanese fringetail. The Japanese were among the most artistic people in the world and it was they who realized the possibilities of the beauty of a short-bodied fish with flowing and graceful fin development. With this fish too goldfish breeders had recently fallen behind, partly because more attention had been given to telescopes and partly because the scaled fish had gone out of fashion.

However one might very much enjoy seeing a good scaleless fringetail, it was not a practical fish. The scaleless fish had fins so weak that the dorsal could not be held erect after it had reached first-class development, and the long tail usually hung in a string instead of gracefully flowing be-hind the fish. Usually the fin develop-ment during the first year was not suffi-cient to be considered handsome. In the second year the fish looked its best, for the fins had become larger and in some cases were not yet broken. In the third and fourth years, when the fins should have been at their best, they were in the scaleless fish almost invariably dragged and broken. With the scaled fish this was not so apt to be the case. The fins were much more strongly ribbed and were carried in good form for several years. It is a fact that aquarists did not now see the very high, sail-like dorsals and the extremely long and good-conditioned tails of a few years back.

The best fin development was acquired at from three to four years of age, but if the fins at this age were not sufficiently firm to maintain their form, it hardly seemed to be worthwhile. Furthermore the scaleless fish was weaker and more sensitive to cold, and by breeding the scaleless fringetails together the depth of color was gradually lost. The fish with scales mottled red and white or solid red was very pleasing in color and possessed so many advantages over the scaleless variety that it should have been rescued from the inattention into which it had recently fallen.

Figure 24: William T. Innes attending to his goldfish, September/October issue of *The Guide to Nature*.

This ends my short version of Innes' article. Therefore, although it cannot be denied that the advent of tropicals put a serious dent in the goldfish hobby, the goldfish hobbyists themselves have to shoulder a good portion of the responsibility.

The following data summarizes the demise of the interest in goldfish over the early years of the aquarium hobby:

GOLDFISH ARTICLES		
PUBLICATION	PERCENAGE	YEAR
Guide to Nature	50%	1911
The Aquarium	31%	1913
The Fish Culturist	8%	1929

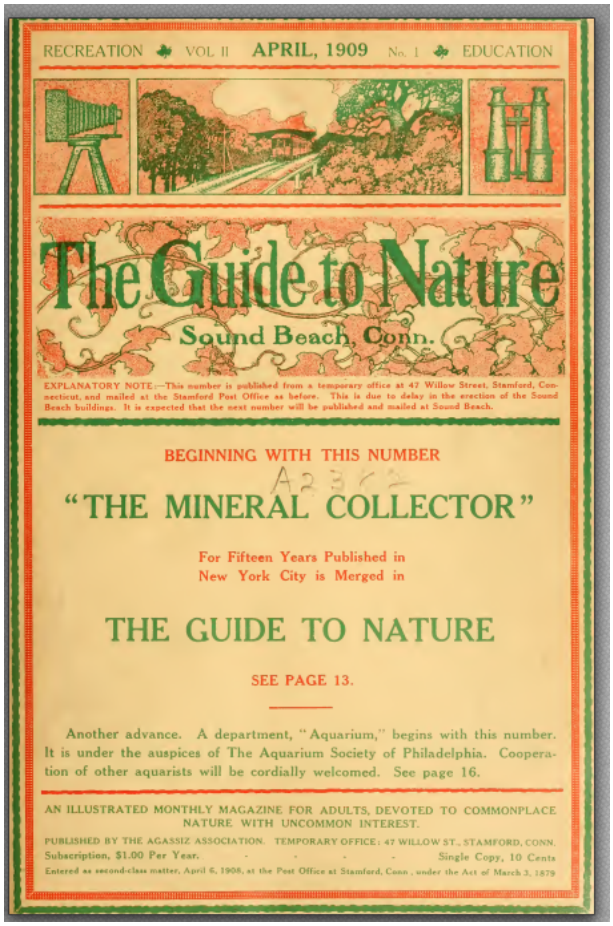
C.3 THE GUIDE TO NATURE

In April 1908, the *Guide to Nature*, published by the Agassiz Association as its official journal, appeared on the scene. A year later the publication was divided into different departments, such The Outdoor World, Popular Astronomy, Mineralogy, Correspondence and Information, The Agassiz Association, Literary and Biographical and The La Rue Holmes Nature Lovers League.

In the April 1909, *The Mineral Collector*, for fifteen years published in New York City, merged in *The Guide to Nature* as a new department but of far greater interest to aquarists was that another new department, the Aquarium, began. The cooperation of other aquarists was cordially welcomed. It was sub-listed as being under the auspices of The Aquarium Society of Philadelphia with Herman T. Wolf as its Editor. Wolf wrote the first piece, "The eyes of Chinese Goldfish" and M. R. Lippincott of Collenswood, N.J. wrote the second one titled "Wooden-Framed Household Aquaria."

Herman Theodore Wolf was born on October 13 1855 in Philadelphia, PA, to Carl Christian Wolf and Elizabeth Wolf (nee Weislogel). Both his father and his mother were born in Germany. On May 16 1883, at age 27, Herman married Louise Wolf (nee Kohler), also born in Pennsylvania. They had one daughter, Helen Emilie Wolf, born in 1887. By profession Wolf was a jeweler and jewelry salesman. On November 2, 1924 at age 69, Herman died in Lower Merion Township in Montgomery County, Pennsylvania, a suburb of Philadelphia and part of the Philadelphia Main Line ("Main Line" refers to the Pennsylvania Railroad train line that was built in the area beginning around the 1850s).

In 1901, Herman T. Wolf was an officer of the Philadelphia Society and a brother of Rudolf Wolf who, by his extensive importations, was largely responsible for establishing Philadelphia as the center of the fancy goldfish hobby in America. He had suggested a series of topics on goldfish and allied subjects that the Philadelphia Aquarium Society might entertain in discussions. As Secretary of the club, Wolf took detailed notes and these led to the writing of a manuscript. Wolf tried to get the work published but to no avail and



RECREATION VOL II APRIL, 1909 No. 1 EDUCATION

The Guide to Nature

Sound Beach, Conn.

EXPLANATORY NOTE.—This number is published from a temporary office at 47 Willow Street, Stamford, Connecticut, and mailed at the Stamford Post Office as before. This is due to delay in the erection of the Sound Beach buildings. It is expected that the next number will be published and mailed at Sound Beach.

BEGINNING WITH THIS NUMBER

"THE MINERAL COLLECTOR"

For Fifteen Years Published in New York City is Merged in

THE GUIDE TO NATURE

Another advance. A department, "Aquarium," begins with this number. It is under the auspices of The Aquarium Society of Philadelphia. Cooperation of other aquarists will be cordially welcomed. See page 16.

AN ILLUSTRATED MONTHLY MAGAZINE FOR ADULTS, DEVOTED TO COMMONPLACE NATURE WITH UNCOMMON INTEREST.

PUBLISHED BY THE AGASSIZ ASSOCIATION. TEMPORARY OFFICE: 47 WILLOW ST., STAMFORD, CONN.
Subscription, $1.00 Per Year. Single Copy, 10 Cents
Entered as second-class matter, April 6, 1908, at the Post Office at Stamford, Conn., under the Act of March 3, 1879

Figure 25: The April 1909 issue of *The Guide to Nature* .

was at the point of burning the whole thing when he mentioned the fact to Innes in 1906. After reading the manuscript, Innes offered to publish it. Innes' father typeset the entire 385-page book by hand and Innes himself printed it on a small job press. The work took almost two years, appearing finally in 1908 as *Goldfish Breeds and Other Aquarium Fishes*. It was well written and beautifully illustrated. Wolf was an excellent artist and, for many years, several of his large drawings of goldfish types hung on the walls of the meeting room of the Philadelphia Society until 1909 when they were stolen. To the author's credit, the book was a masterpiece and it would not be an overstatement to say that Wolf's book was one of the great aquarium works of all time. But apart from this, it must be said that Innes' contribution was also a masterpiece. It was set in type and printed as was no aquarium book before it. It, of course, established Innes' reputation in the aquarium hobby as a publisher of aquarium literature and started his ascendancy to prominence within his own Society and in the hobby in general.

In the March 1909 issue the following review of the book appeared in the Literary and Biographical Department:

Goldfish Breeds and Other Aquarium Fishes. Their Care and Propagation. By Herman T. Wolf. Philadelphia, Pennsylvania: Innes & Sons.

This is a new and thoroughly up-to-date book on the aquarium and its inhabitants. It represents the total experience of the aquarium enthusiasts comprising the Aquarium Society of Philadelphia and the scientific knowledge of a number of members of the famous Academy of Natural Sciences. The author is an active member of both organizations and as secretary of The Aquarium Society for a number of years had ideal opportunities for writing just such a complete and practical book. In addition, Mr. Wolf is an artist of unusual ability. His illustrations of aquarium life are extremely natural and beautiful. Altogether this is far the best aquarium book that has ever appeared in any language and should be owned by every aquarist and naturalist. Every point mentioned is taken up thoroughly and practically. The book is 7 x 10y2 inches, fine paper, gilt top, 390 pages and contains 280 life- size illustrations, including a frontispiece in colors. The illustrations alone are worth the price of the book, $3.00.

An article in the May 1909 issue of *The Guide to Nature*–"The Propagation of Aquarium Fishes"–shows the types of fish being kept and/or bred in Philadelphia at the time:

The constantly growing demand for the highly developed breeds of Chinese and Japanese goldfishes, as well as the paradise fish, gourami, chanchito, climbing perch, archer perch, fighting fish and other labyrinthine or air-breathing fishes ; and the golden ide, green and golden tench, bitterling, carausche [i.e., the crucian carp]**, zebra fish and other beautiful indigenous, exotic and tropical forms, that**

Figure 26: Herman Burgin, President of The Philadelphia Aquarium Society in 1910.

may be domesticated and kept in household aquaria, has opened a field of industry in the United States which promises profitable returns to the culturist, who, with an understanding of needs and requirements and adequate facilities, will devote himself to their propagation.

The Aquarium Department was edited by Wolf in 1909 in the April, May, June, July, September/ October and November issues. The Department was missing from the magazine until the April 1910 issue when it appeared in the September/ October issue edited by Herman Burgin, President of The Philadelphia Aquarium Society. In the June 1910 issue it appeared but without mention of who edited it; the material in it, however, was by Innes. The Aquarium Department then was missing for the remainder of 1910. It was mentioned twice more, in the March 1911 issue and in the April 1913 issue, both times written by Innes, again without mention of editorship. In summary, the Aquarium Department was mentioned in 10 issues of *The Guide to Nature* during this time, 6(2) from Wolf, 1(1) from Burgin and 3 (2) from Innes, the numbers in parenthesis referring to the number of times goldfish articles appeared first. Thus in these 10 issues, five of them led off with goldfish articles and five led off with non-goldfish articles.

D.1 THE AQUARIUM MAGAZINE (Mulertt), 1892-1897

This section concerns Hugo Mulertt and the commercial aquarium hobby magazine he published while in Brooklyn, New York City. Because there was another aquarium magazine published during the dawn Era timeline with the same title, I have placed his name in parenthesis after the title. Since I have written much material about Mulertt, I summarize his activities here on the following page.

It is astonishing that after he settled in Brooklyn, Mulertt was successful in balancing all of these activities simultaneously. However, the main point here is that Hugo Mulertt was most certainly part of the dawn of the aquarium hobby in America. His was the first commercial aquarium magazine published during this period and it was excellent for its day.

The magazine itself had colored front and back covers (unfortunately the colors were drab and usually of an ugly green or mustard hue) made from a thin cardboard material that did not stand the test of time although the interiors pages were, as the Bard said," made of sterner stuff." The topics covered included native fishes, aquatic plants, aquariums, types of aquariums, fish physiology and aquatic invertebrates. Imported tropical fishes were scarce except for one about the Betta and another about the Brazilian Zebra Fish (called *Heros fasciatus* by Mulertt but *Cichlasoma facetum* in later aquarium books).

Mulertt wrote the following interesting account of his experiences in setting up exhibition aqua**The two main points to be kept in view when**

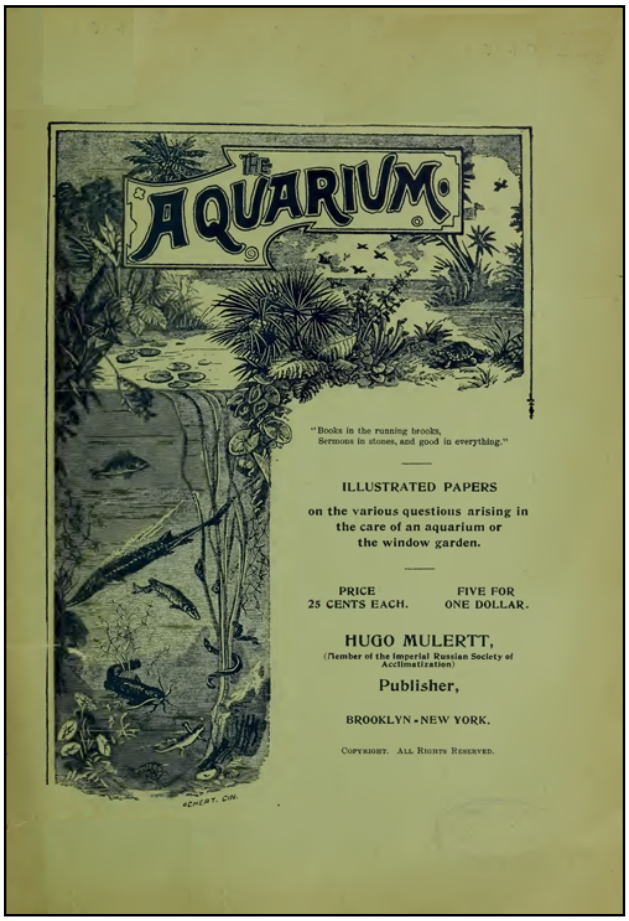

Figure 27: Mulertt's *The Aquarium* magazine.

HUGO MULERTT TIMELINE	
1848	Mulertt is born in in the town of Delitzsch, near Leipzig, Germany.
1863	He spends this year in England.
1864	He emigrates to the United States and finds employment in a commercial nursery in New Jersey.
1865	The civil war was at its height and Mulertt enlists in the cavalry and fights under Generals Sheridan and Grant for the cause of the Union.
1865	Mulertt works on Southern plantations where during that time he supplies many plant and animal specimens to the institutions of learning in Europe.
1872	He leaves his position as horticulturist at the Bellevue High School in Virginia and spends nearly two years in foreign traveling, visiting nearly every point of interest in Europe.
1874	Returning to the United States he settles in Cincinnati, Ohio where he was in business for fifteen years at 502 Race Street as a florist and aquarist.
1876	Mulertt's goldfish won numerous awards at the first official World's Fair to be held in the United States, the Centennial International Exhibition of 1876 held in Philadelphia.
1877	The Cassel Fair-Hill Terra Cotta Works produces the "Mulertt Aquarium."
1878	The first issue of his magazine, *The Aquarium,* was published.
1883	His primary work, "The Goldfish and its Culture," is published, for which he was acknowledged as an authority on four continents.
1885	The "Imperial Russian Society for the Acclimatization of Animals and Plants" elects him a corresponding member.
1876	The same Society awarded him their Great Silver Medal, a distinction which had in their days been bestowed upon Alexander von Humboldt and Philipp Franz von Siebold.
1888	This was the last year he spent in Cincinnati, leaving his store near the end of the year for Brooklyn, New York City where he started an aquarium business from his home.
1889	Mulertt obtains the position of Curator at the Harriet L. Packer Institute, a school for the education of girls.
1892	Mulertt renews the publication of his magazine, *The Aquarium*.
1894	He starts writing a monthly column called "The Aquarium" in the "*American Gardening, A Journal of Horticulture*."
1895	This was the first issue where advertising appeared in Mulertt's magazine.
1897	In this year the last issue of *The Aquarium* was published.

constructing a series of tanks for public use, aside from the proper location of them of course, are: (1st) to secure proper protection to the collection against injury by spectators, caused either through ignorance or by an inborn inclination for destructiveness; and (2nd) to allow ample elbow-room behind the tanks ("behind the scene" would be quite proper here) for the aquarist, that he may be able to work about and arrange the tanks, and wait upon his charge at any time undisturbed.

We experienced sad losses when, many years ago, we first began to display collections of aquatic life to the public. At first, when we innocently displayed our collection entirely unprotected, we mourned the loss of choice specimens that had been stolen. The water was frequently spoiled by people feeding the animals with almost anything possible and impossible, including preserved fruits and ice cream; even the small boy with the proverbial "pin-hook" fastened to a thread was represented. At one time a boy attracted quite a

crowd around one of the aquariums, because he used a certain kind of bait that hooked nearly any fish he desired, and the policeman in charge of that part of the hall–why, he enjoyed it as much as the rest of them, and declared that the next time he would go out fishing, he would use that same kind of bait.

We knew, at least we thought so then, how to stop fishing and feeding our specimens. All that was required was a wire netting over the tanks. So we had these made with dispatch, and when we covered our collection with them we felt that their safety was secured. But little did we know inquisitive man (we do not say woman). To look at an animal in captivity, no matter what element it is in, without at least trying to poke it seems to be impossible for a great many people. The spectators would now poke their parasols or fan-handles through the screens, and when the mesh of the screens proved too small for these, some did not find it too much trouble to use their hat-pins for the purpose. It gave them so much pleasure when they hit them "right close to the eye."

The feeding-fiend misunderstood the meaning of the screens entirely. Of course, no one but "city folks" could think of preventing these dear little fishes from partaking of their luncheon–consisting principally of home-made pie. They would go to the trouble of breaking it into sufficiently small pieces and force it through the meshes. Two young ladies we will never forget, as we caught them in the act, busily engaged, both on the same tank, feeding the fish with sponge cake using the protective (?) screen for a grater.

Good-natured and polite, we stopped their proceedings, and were informed by them that we need not fear any bad effects, because they had baked the cake themselves, it being no "bought stuff". We had no doubt as to the quality of the cake, for the fish had literally filled themselves up with it and we were compelled to renew the water of this tank at once. If we inform you that the tank held a barrelful, you can measure our appreciation of home-made Kentucky sponge cake. These few examples were caused by sweet innocence; but when one drops a box of sulphur matches, chewing tobacco, and, in one case, a chunk of unslaked lime (which he had to bring from outside the exposition grounds), into a tank, or cuts the glass with the diamond of a ring, we think it is done with bad intent.

On another occasion we had our display guarded by iron railings, made of gas pipe. It is true this kept the observer at a safer distance, but it likewise made the display less interesting, especially to the younger generation. On succeeding occasions we displayed our collection in show-window fashion. This arrangement guarantees entire satisfaction, both to the exhibitor and the observer. We used this method first in 1879, and it has shown that it covers all wants.

Figure 28: A girl looking into a goldfish bowl by Carl von Bergen (1853-1933).

In order to obtain the most striking effects, the tanks should be in convenient height to the eyes of the observer; the shape of the tanks should be long, rather than high, with sufficient depth (toward the rear) to admit the formation of a proper background.

The all-important light is controlled by adjustable screens. Very beautiful effects can thus be secured with either daylight or artificial light. For lighting up the tanks at dark, the light should enter the water from above the surface of the water, and as much from the front as possible, keeping it (the light itself) out of the spectator's view. The outside space, the walk or passage in which the observer is, should be but dimly lighted, if lighted at all. The effect that is produced in this way is somewhat similar to that produced by a small bull's-eye lantern fastened in front of your hat. There will be no shadow between you and the object you desire to observe.

The accompanying sketch (Figure 29) of one of Mulertt's aquatic displays will give the reader a pretty clear illustration of an example of his work. The tanks are set flush behind a wall and in the middle is a pond with a fountain open to visitors (unfortunately making it possible for them to toss food into it and for small boys to fish in it!).

Mulertt occasionally provided short stories, often unusual, related to fish; the following is an example.

One of the supplying pipes of the city water works in a city in Germany needed frequent cleaning of the rapid growing water weeds. Several efforts to give the pipe a thorough cleaning failed until a man was struck with the capital idea to use a fish to make a connection between the two tanks. A carp was put into a small vessel and on his dorsal fin a thin but strong line, which was varnished to prevent the water from soaking into it and thus making it too heavy for the fish, was fastened. The vessel was now held close to the pipe and the fish entered it. The distance he had to travel was six hundred feet. He had to go straight forward, as his size prevented him to turn himself around. Several times it was noticed, by the line, that he stopped, but when he had reached the second half of the distance he had to travel, the water had a stronger fall and he did not try to

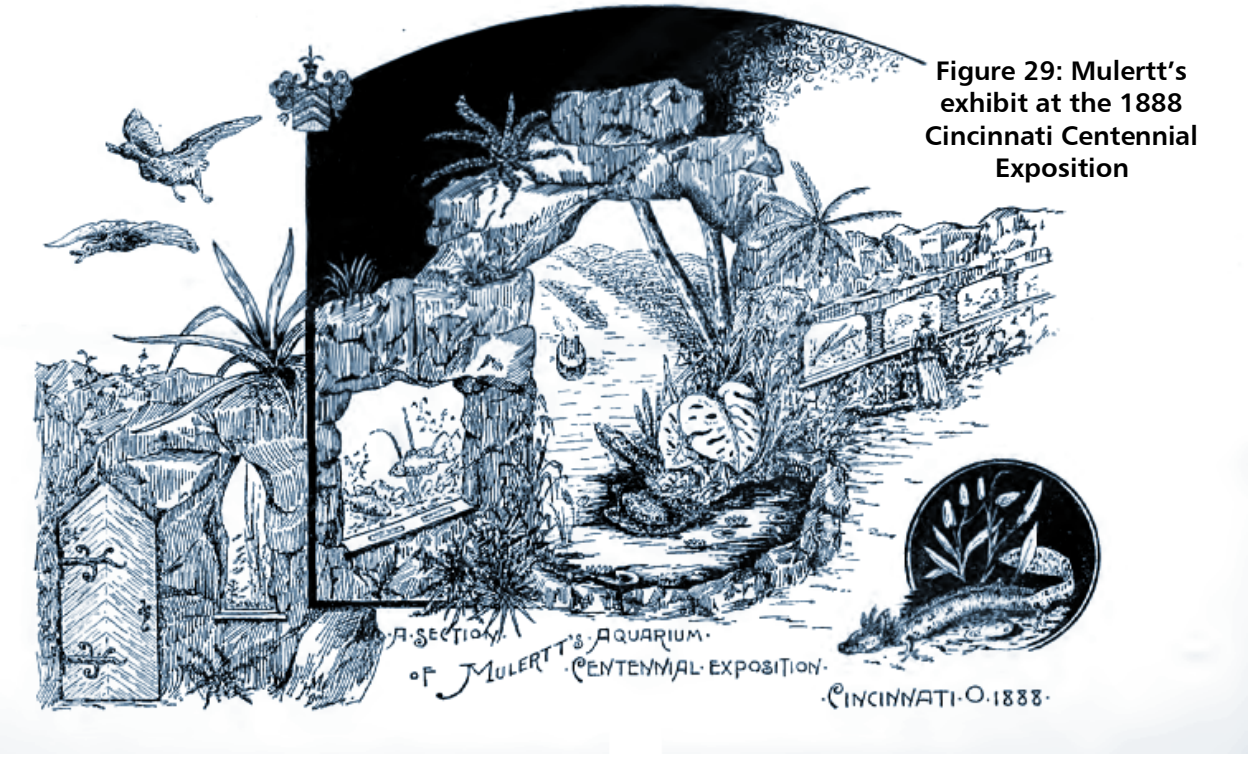

Figure 29: Mulertt's exhibit at the 1888 Cincinnati Centennial Exposition

stop any more. He arrived at the other end after two hours with the line still attached to his dorsal fin. He was very weak from his work and was easily caught. A stronger rope was now pulled through the pipe and with this, a wire cable was put there stationary on which brushes could be run through when necessary. The poor carp did not live long enough to be used as the customary Christmas dish, but had to be killed soon after he had performed his valuable service.

D.2 THE NEW YORK AQUARIUM SOCIETY

Early in 1893, five persons who had by chance become acquainted founded a small society, and although by 1896 was no longer in existence, was the mother of first aquarium society in the country. Its members had two things in common: (1) a love of aquarium fishes and (2) they all spoke German. Because the new organization was the only aquarium society at that time it was called simply, "The Aquarium Society." Only some years later, when other societies had formed throughout the country, was its name changed to "The New York Aquarium Society."

The New York Aquarium Society originally embraced a membership from the five New York boroughs as well as from the adjacent part of New Jersey; Eugene Smith was its Founder and first President. The New York Aquarium Society is thus the oldest in the field and experienced the usual vicissitudes of all pioneer organizations. The Philadelphia Society, numerically the strongest, was formed independently of New York in 1898; however, even up to 1912 it devoted its energies mainly to goldfish culture. Other early aquarium societies included the Brooklyn Aquarium Society, formed early in 1911 chiefly from the membership of the New York Society residing on Long Island. It was very successful and had established a small monthly bulletin in its own interests. The Chicago Fish Fanciers Club also was established in 1911 but was nosed out by a few weeks by the Brooklyn club.

D.3. THE AQUARIUM MAGAZINE, 1912-1914

In April of 1912, Volume I, No. 1 of *The Aquarium* appeared on the scene. As Eugene Smith put it,

Keenly realizing the benefits of association, it was felt that closer touch with the work of others was needed and mutual help could not be better obtained than by creating an organ of intercommunication. This not only would assist the several societies but would also serve to bring into touch many distant but nevertheless interested persons not connected with any society. The Brooklyn Society very wisely and generously took this larger view of the matter and agreed to merge their bulletin with the present magazine.

The societies in this consortium at the time consisted of The New York Aquarium (President, Isaac Buchanan), The Philadelphia Aquarium Society (President and Local Editor, Wm. T.

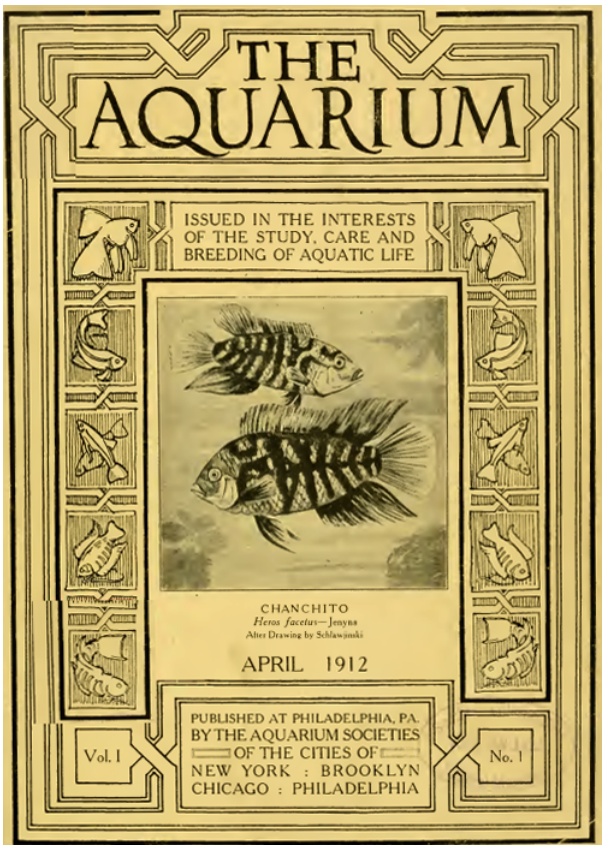

Figure 30: The first issue of The Aquarium magazine (1912-1914).

Innes, Jr.), The Brooklyn Aquarium Society (President, W.F. DeVoe) and the Chicago Fish Fanciers Club (President, F.S. Young); in June 1912 the Milwaukee Aquarium Society (President C.G.B. Schenck) joined the consortium.

Because of his illness, William T. Innes edited the September 1912 issue; the last issue Smith edited was November 1912. In January 1913, William Poyser took over as Editor due to Smith's death and for the first time, the editorship fell to the Midwest (Poyser was from Hammond, Indiana).

The consortium membership was augmented by The Minneapolis Aquarium Society (November 1912), the Boston Aquarium Society (November 1912) and The Philadelphia Goldfish Society (December 1913). It should be noted that on March 1913 the New York Aquarium Society had changed its name to "The Aquarium Society."

In September 1913, Will S. Hilpert (Chicago Fish Fanciers' Club) had taken over as editor of *The Aquarium* from Poyser. The onus of publishing had fallen to the Chicago group and the difficulties of publishing the magazine were summarized by the editor, J.W. Gage in December 1913:

LABOR WITHOUT REWARD

There has been more or less criticism regarding the magazine which would not be so prevalent if subscribers and advertisers took into consideration the fact that the entire labor of getting out the magazine is purely a labor of love. No one connected with the publication is paid a penny, yet the work involved in getting suitable articles, editing them, soliciting advertisements and keeping the accounts is no small task. It means work and time, both of which are cheer fully given by those in charge - still most of us feel a certain pride and satisfaction for honors bestowed upon us, even though the honors are mere titles of office.

As *The Aquarium* aged, many drawings and photographs were employed and the covers were in color. Yearly subscriptions were one dollar and single issue 10 cents. The Aquarium was an excellent magazine and many famous aquarists contributed to it, including Eugene Smith, R.W. Schufeldt, William T. Innes, Frank Tappan, S. Chichester Lloyd, Fred G. Orsinger, C.H. Heede, W.F. DeVoe, W.A. Poyser, John Treadwell Nichols, Frederick Schneider, C.G.B. Schenck, Harry Peters, William A. Paullin, L.M. Dorsey and Floyd S. Young. It was truly a remarkable endeavor by these aquarium societies.

E.1 AQUARIUM EQUIPMENT AND SUPPLIES

Although there were many patents awarded during the Dawn Era of 1892 to 1914, they overwhelmingly involved the design of aquaria. There were a few that dealt with filtration, heating or aeration but none of them were ever marketed. This is unfortunate since patents show how they work and provide drawings that facilitate understanding. Why weren't there more such patents? The answer is that the equipment need for aquarium application were already invented and you can't get a patent on someone's previous work. The best we can do is to scan the advertisements of this period to see if they provide more information or, if one is lucky, examine some of these antique apparatus that still exist.

E.2 WATER-DRIVEN AIR PUMPS

Walter Brind of New York City advertised the German K.D.A. air pump for $9 in the January 1913 issue of The Aquarium and the General Aquarium Company of Philadelphia did the same in the June 19, 1913 issue. An explanation of how the K.D.A. pump works can be found in my article on the early history of aquarium aeration (Klee, 2013).

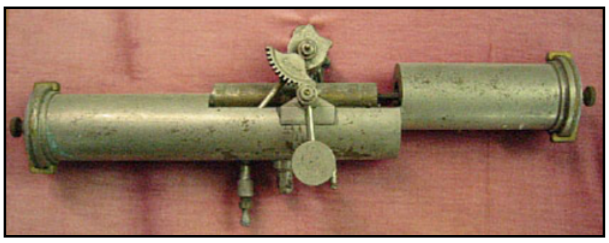

Figure 31: The K.D.A. water-driven air pump.

Figure 32: The "Little Wonder" was a water-driven air pump like the K.D.A. pump but it was based upon a different mechanism.

In addition to the K.D.A. air pump, the General Aquarium Company was in addition the selling agents for the US-made "Little Wonder" pump ($17.50) that also was water-powered. This was made by the Bishop-Babcock-Becker Company of Cleveland, Ohio who advertised the pump in the December 1913 issue of The Aquarium (Figure 32). The pump used a method that started with a chamber with a float inside (Figure 33).

Figure 34: An old aquarium air pump showing the armature (i.e., the coil below the rotor which is a permanent magnet.

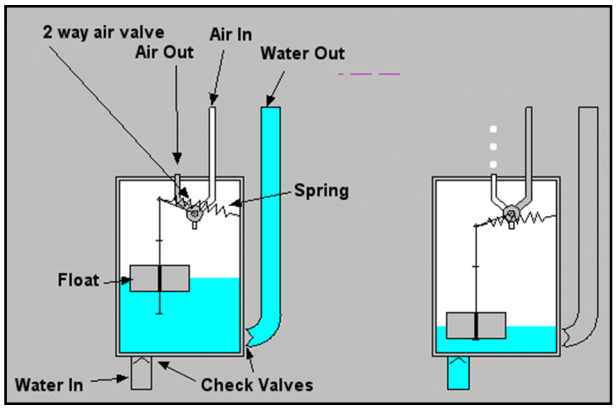

Figure 33: The "Little Wonder" system.

The chamber is under the water level. On startup, water enters the chamber through a check valve, then compressed air pushes the water out a 2nd check valve, up into the tank. When the water level gets low, a float closes off the incoming air, and opens a vent to let the air inside the chamber escape. The chamber refills with water, and either the same or another float switches the air valves back, and the cycle starts again.

E.3 ELECTRIC MOTOR DRIVEN AIR PUMPS

In electrical engineering, an armature is the component of a motor which carries alternating current. The armature windings interact with the magnetic field in the air-gap; the magnetic field is generated either by permanent magnets, or electromagnets formed by a conducting coil. The armature's role is twofold. The first is to carry current across the field, thus creating shaft torque in a rotating motor. The second role is to generate an electromotive force (EMF). In the armature, an electromotive force is created by the relative motion of the armature and the field. The EMF opposes the armature current, and the armature converts electrical power to mechanical power in the form of torque, and transfers it via the shaft.

Figure 34 shows an old aquarium air pump of the 1890s. The armature, i.e., the coiled wire, is shown just below the rotor which is, in this case, a permanent magnet. Although the rotor looks as if it was a gear, the grooves provided the air gap in which the magnetic field was formed.

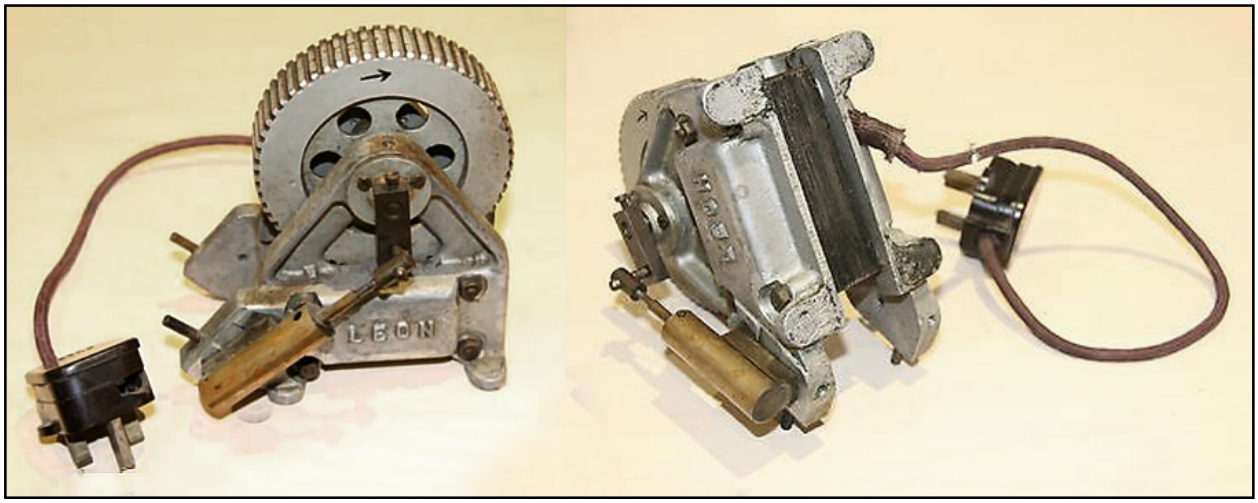

Figure 35: LEFT: The Leon air pump n its upright position; RIGHT: The pump turned upside-down, showing the coiled armature between the four corners of the stand.

Figure 35 shows two views of the Leon air pump, the one on the left being an overall view and the one on the right a look at the underside showing the coiled armature between the four corners of the stand.

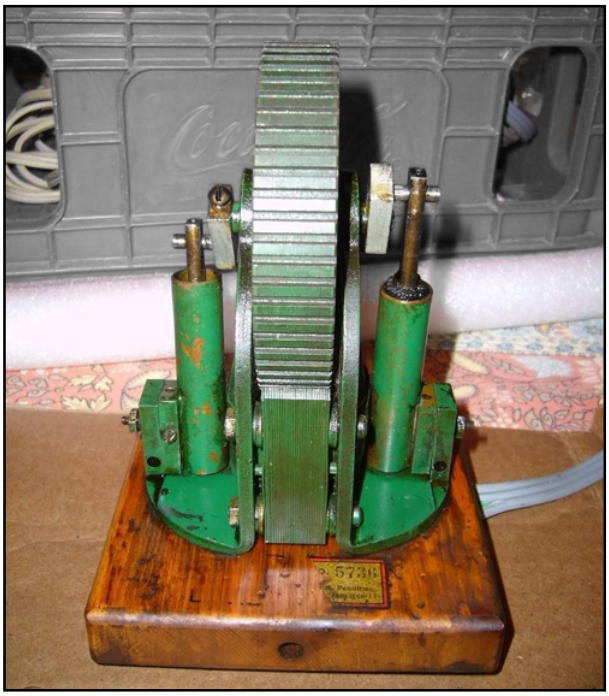

Figure 36: The Tankaire used "wobbler" type cylinders and valves similar to those used on many model steam engines.

The Tankaire (Figure 36) used a rotor that drove a piston on each side. The pump used "wobbler" type cylinders and valves similar to those used on many model steam engines. Later induction pumps such as the Marco used a much thinner rotating wheel. How the wobbler type works is shown in Figure 37 The rotor turns as a result of the induction motor. One end of the piston rotates around a pin attached to the flywheel. As the fly-wheel rotates, the piston goes back and forth, pushing out air to the aquarium when the piston end is in the low position and pulling in air when it is in the high position. Both the Leon and Tankaire pumps were on the market circa 1908.

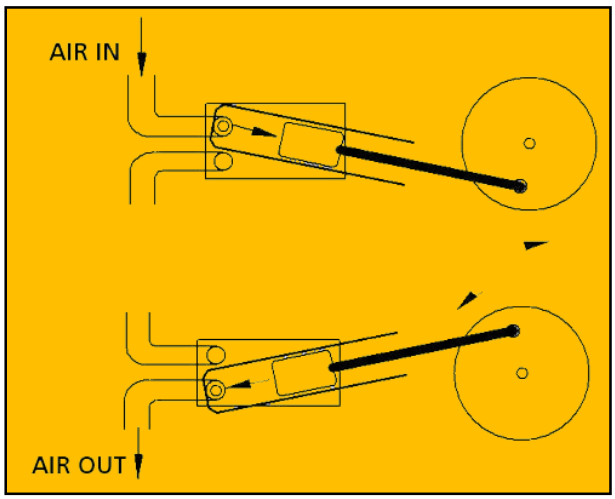

Figure 37: How the pistons work.

Figure 38: The "Eureka Electric Air Pump," made by the Bishop-Babcock-Becker Co.

The Bishop-Babcock-Becker Company also produced an induction motor double-piston air pump that looked much like the Leon and Tankaire pumps that were just described. It was patented in 1913 under the name "Eureka Electric Air Pump" (Figure 38), but it is not known what year it came on the market. Its appearance suggests that it was larger and better-made than the other pumps.

E.4 HEATING SYSTEMS

Because of the expense of individual tank heaters, aquarists having many tanks usually heat the room the tanks are in rather than separately. Those who want to heat a single tank in the Dawn period, however, did not have available the electric heaters that are common today so they had to construct heating systems themselves. These systems are of two types: direct heating systems and water-circulating systems. The first five of the six shown in Figure 39 are of the first type and involved making holes in the bottom of the tank; the last is a water-circulating system where no holes were required. All were heated with Bunsen burners as the households of the day were often supplied with gas for heating and/or lighting. My book, "The Toy Fish, etc.," (Klee, 2014) shows many types of heating systems devised during this time.

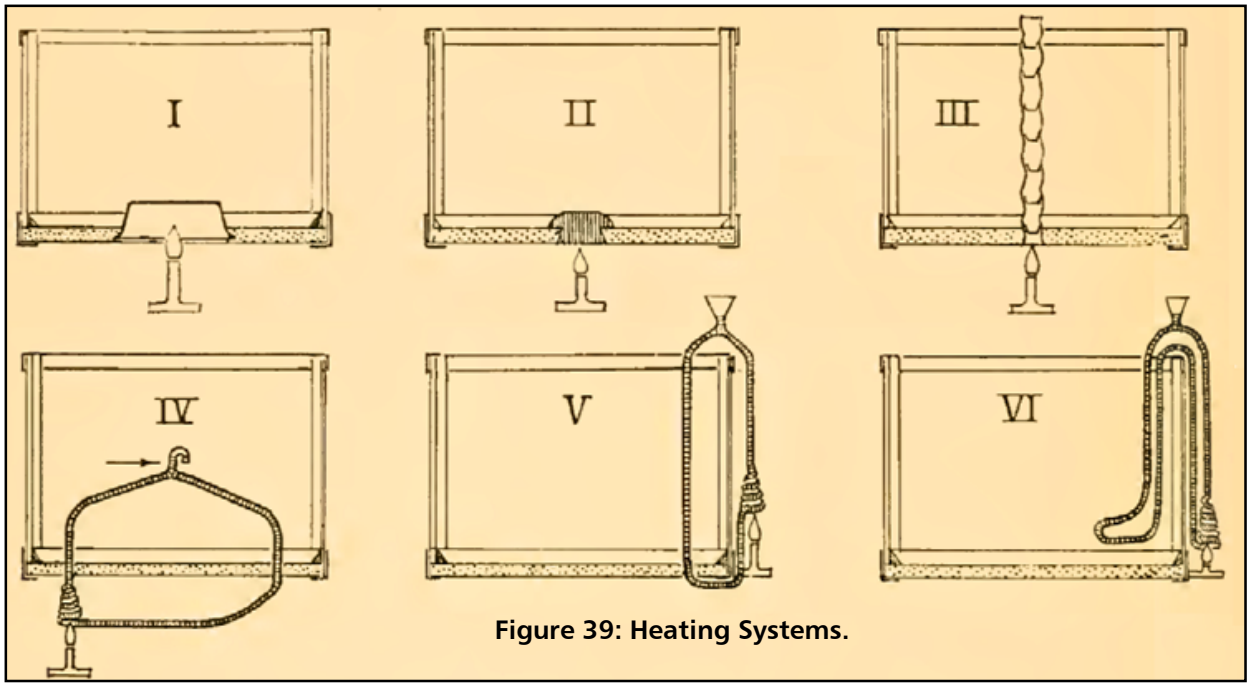

Figure 39: Heating Systems.

E.5 FILTRATION

Filtration, however, was virtually unknown during this period and the popularization of filtration would have to wait until 1932 when the first inexpensive inside box filter was placed on the market. However, the Treasurer of the Chicago Fish Fanciers' Club, Carl Fossetta, devised the first airlift outside filter. His equipment is shown in Figure 40. Water was drawn through a perforated glass tube, down a rubber hose to a triple-necked Wolff bottle. The Wolff bottle, used by chemists, contained the gravel used as the filtering medium. The filtered water passed through an airlift, up through a rubber hose and then back to the tank. The third neck of the Wolff bottle was used for back-washing the gravel. In principle this is identical to the outside airlift filter systems used much later.

E.6 FISH FOODS

The manufacturers of commercial fish foods kept their ingredients close to their vests but some of them mentioned Daphnia and Cypris, along with "cereal." Harry Peters of Philadelphia sold his fish food, Greenriver Fish and Baby Fish Food and advertised that it contained 17 ingredients plus Daphnia. Mulertt sold two foods and advertised that all goldfish and other carp-like fishes, also paradise and some catfish, were best fed regularly on "IXL" and occasionally on " Nero," and sunfish , eels and other carnivorous fish, also salamanders and turtles, should be fed regularly on "Nero."

Otherwise, aquarists made do with their own food preferences. The natural foods, Daphnia, Cyclops, Cypris and worms were the best, but aside from these, fish eggs, raw or boiled, finely scraped fish flesh of the fresh or salt water varieties, oysters, clams, shrimp, or lobster meat, smoked fish, such as herring, whitefish or salmon were used with more or less success. After these came animal foods such as beef, veal, lamb or game of any sort, used either raw or boiled, but in all cases scraped, dried or pulverized. A popular food for small fish or fry that have pasted the yolk-sac stage was the yolk of a very hard-boiled egg, fed in a fluid or powdered state. When fishes were fed with meat, care was taken to have it cut or scraped into smaller pieces.

E.7 THE FISH SOLD DURING THE DAWN ERA

Tables 1 and 2 (next page) show the fish offered by two different full-page advertisers in *The Aquarium* in its October 1912 issue. The list of fish in the ad by The Nature Shop at 579 W. 181st Street, New York City is impressive. The list of fish in the ad by Franklin Barrett at 4815 D Street, Olney, Philadelphia is less so since it mainly offers only fancy (read "expensive") goldfish. This clearly shows the large difference in demand between the Philadelphia and New York City aquarists and this holds true for aquarists in Philadelphia and any other city at the time for that matter.

This not to say that there wasn't a market for fancy goldfish in New York City. In the Nature Shop add is added below the list the statement that

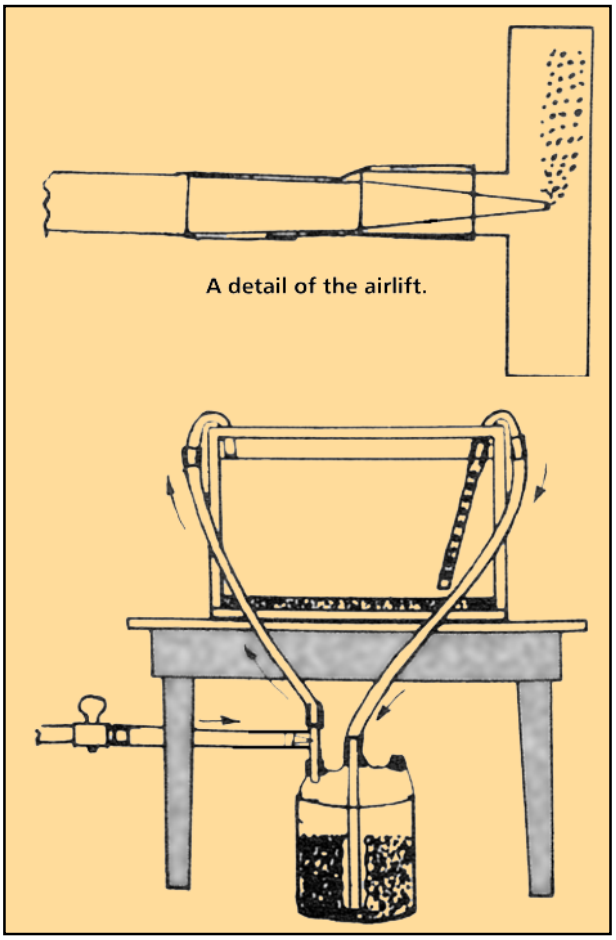

Figure 40: The Carl Fossa Filtration System.

TABLE 1: LIST OF FISHES FOR SALE BY THE NATURE SHOP, NEW YORK CITY

Anabas scandens	Mollienesia latipinna
Barbus conchonius	Ophiocephalus striatus
Barbus semifasciolatus	Paratilapia multicolor
Badis badis	Paratilapia species
Betta rubra	Pantodon buchholzi
Betta splendens	Platypoecilia maculata
Callichthys callichthys	Platypoecilia niger
Callichthys marmoratus	Platypoecilia rubra
Cichlasoma nigrofasciatum	Platypoecilia species
Danio rerio	Poecilia poecilioides
Danio malabaricus	Poecilia species
Gambusia affinis	Polycentrus shomburgkii
Gambusia caudimaculata	Polyacanthus dayi
Gambusia holbrooki	Pseudoxiphophorus bimaculata
Gambusia nicaraguensis	Rivulus flabellicauda
Gambusia rachowi	Trichogaster fasciatus
Girardinus reticulatus	Trichogaster lalius
Gymnogeophagus gymnogenys	Tetrogonopterus lineatus
Haplochilus chaperi	Tetrogonopterus guppyi
Haplochilus panchax	Tetrogonopterus rubilus
Haplochilus rubrostigma	Tetrogonopterus ulreyi
Haplochilus sexfasciatus	Xiphophorus brevis
Hero facetus	Xiphophorus helleri
Macropodus viridiauratus	

TABLE 2: LIST OF FISHES FOR SALE BY FRANKLIN BARRETT, PHILADELPHIA

Common	Celestials
Scaled	Lion's Heads
Scaleless	Shubunkins
Comet	Paradise
Fantail	Golden Orfes
Fringetail	Golden Tench
Telescopes	Gambusia affinis

We are constantly getting in new varieties of fish, so if there are any species that you want, let us know, and we will quote prices. We always have on hand a nice collection of common and rare Gold Fish at prices that are right; also aquarium plants, snails, tadpoles, etc.

Barrett did, however, did list the following twenty five aquatic plants that he sold: Cabomba, Myriophyllum, Anacharis, Sagittaria, Ludwigia, Vallisneria, Hornwort, Potamogeton, Snow Flake, Water Poppy, Water Hyacinth, Salvinia, Water Fern, Lace Leaf, Water Lettuce, Umbrella Palms, Cyperus Papyrus, Cyperus, Alternifolius, Gracilis, Laxus Folva, Variegated, Boston Ferns, Pteris Ferns, Water Lilies. I venture to say that this was because there was a longer history of aquatic plants being kept by goldfish fanciers since many of them were aquatic gardeners from whence the word "aquarium" came.

F. RES GESTAE

Res Gestae is a Latin term which means "things done." *Res Gestae Divi Augusti* ("The Deeds of the Divine Augustus"), for example, is a monumental inscription composed by the first Roman emperor, Augustus, giving a first-person record of his life and accomplishments. Another *res gestae* is *Pater patriae* ("Father of his country"), sometimes used by the Romans to designate distinguished statesmen.

Figure 41: Caesar Augustus (63 BC–AD 14), also known as Octavian, was the first Roman emperor. Res *Gestae Divi Augusti* ("The Deeds of the Divine Augustus") is a monument inscription composed by him.

Figure 42: Antoine Laurent Lavoisier (1743–1794), "The Father of Chemistry."

Discoveries and innovations often are the work of multiple people, resulting from continual improvements over time; however, certain individuals are remembered for making significant contributions to the birth or development of a field or technology. Historically, persons have been dubbed, mostly in Western societies, as being the father, mother, founder or similar of a particular field or invention. Two examples are Ada Lovelace: "The Mother of Computer Programming" and Antoine-Laurent Lavoisier, "The Father of Chemistry." These are honorary titles given to people by a person or group for specific accomplishments, most of the time unofficially.

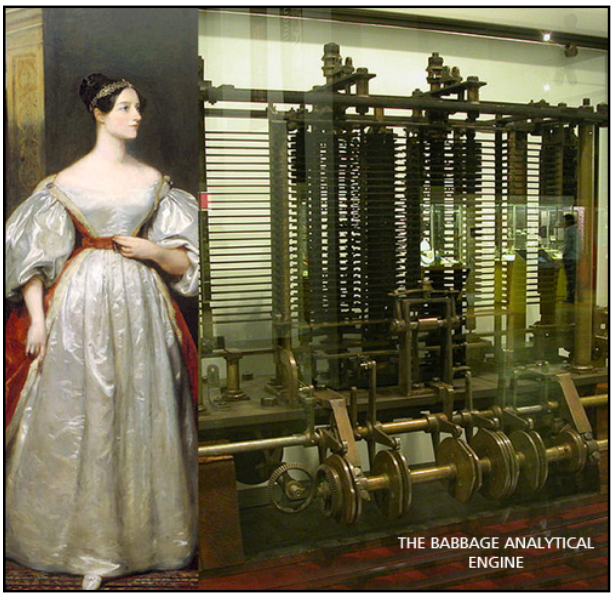

Figure 43: Ada Lovelace (1815-1852). She was the first to recognize that Charles Babbage's proposed mechanical general-purpose computer, the Analytical Engine, had applications beyond pure calculation, and to have published the first algorithm intended to be carried out by such a machine. As a result, she is often regarded as the "Mother of Computer Programming."

To date, I have named four of them myself, i.e., The Grandfather of the Aquarium Hobby in America (Hugo Mulertt), The Father of Aquarium Photography (Dr. Robert W. Schufeldt), The Father of the Fancy Guppy (Charles Visel), and The Father of the Aquarium (Carl Linneatus). In my writings I have mentioned many other "fathers," but these are the four I myself have named. It is now time to honor Eugene Smith for his important contributions to the development of the aquarium hobby in America and I have named him, "Father of Aquarium Societies in America."

G. SUMMARY

As the aquarium hobby marched on with time, aquariums became more popular as many houses had an electricity supply after World War I. Electricity allowed artificial lighting, as well as cheaper and more efficient aeration, filtration, and heating of the water. It ushered in more and more aquarium societies, new commercial aquarium magazines, advanced air pumps, (somewhat) better heating devices and sturdier tanks. One right after another, new to the hobby tropical fish species were imported as transportation became better and cheaper. I won't go into the changes that occurred after World War II since most readers will know them well enough.

Over time, there has been an increasing appreciation of the value of an aquarium in providing many health benefits such as reducing stress, blood pressure and heart rate. In addition, the process of keeping a successful aquarium exposes the aquarium keeper to a vast array of scientific information, principles, processes and methods. Nonetheless, there is an irrepressible and sentimental longing or wistful affection for the past, and I commend those aquarists that paved the way for the rest of us.

SPECIES & NAMES

by Albert J. Klee, Ph.D.

(*Essays on Aquarium Hobby History*, January 4, 2022)

This essay was sparked by my interest in two excerpts I found in a pair of books that should be known to serious aquarists interested in aquarium history. The first was something I found in Charles Kingsley's book, "Glaucus; or, the Wonders of the Shore" (Kingsley, 1855). Glaucus was a deity of the sea. According to Ovid, he was a fisherman who found an herb that brought dead fish to life, so he decided to try it himself. As a result, he became immortal, but he grew fins, and his legs stuck and melded in a fish tail. As a creature of water, he could no longer walk the earth with earthly feet, but despite his sorrow, the other sea deities like Oceanus and Tethys welcomed him with open arms and taught him the skill of prophecy.

A1. CHARLES KINGSLEY

The son of a country parson, Charles Kingsley was born on June 12, 1819. After attending several schools he entered Magdalene College, Cambridge in 1838 where he was more sportsman than scholar. Shortly after graduation in 1842, he was ordained an Anglican priest. In 1842 he became rector of Eversley, the parish he served until his death in 1875. In 1859 Kingsley was appointed chaplain to Queen Victoria, and in 1860 he became Regius Professor (in the United Kingdom the holder of a university chair founded by a sovereign, especially one at Oxford or Cambridge instituted by Henry VIII, or filled by Crown appointment of modern history at Cambridge). A man of so varied activities was hardly a scholar, but Kingsley's lectures, more about men than politics or economics, were popular. In 1861 he tutored the Prince of Wales, later Edward VII, in history.

Kingsley was a tall, thin, excitable man with a stammer. His enthusiasms pulled him in many directions, just as they drew famous people, including royalty, to him. Among his friends was Philip Henry Gosse. In 1848, he was one of the founders of Christian Socialism. To support the movement he wrote many articles over the signature "Parson Lot" and two novels, *Alton Locke* (1850), about the plight of the urban worker, and *Yeast* (1851), about the ills of the rural poor. However, Kingsley's opinions were far more Christian than socialist. Certainly he never wanted to upset the established social order.

Turning to history, Kingsley wrote two historical novels, *Hypatia* (1853) and *Westward Ho!* (1855). He also grew interested in biology and wrote *Glaucus* (1855), a nonfictional description of the wonders of the shore. Kingsley was a poet too. However, perhaps his best-loved book was *The Water-Babies* (1863), a children's story in which he combined his interests in natural science and religion. In 1869 Kingsley resigned his professorship of history and was appointed canon of Chester (a title given by the bishop to a priest or lay person to mark their special contribution to the church. They are important in the Church of England and men of the highest caliber); in 1873

Charles Kingsley (1819–1875).

he became canon of Westminster. He died on Jan. 23, 1875.

A2. A THEOLOGICAL CONTROVERSY

Kingsley for the most part was a good person but from the first, he had been anti-Roman Catholic (and consequently, anti-Irish as well). In 1864, while holding the Chair of History at Cambridge, Kingsley published a review of J. A. Froude's "History of England" (a work with strong anti-Catholic bias) and made the statement that Cardinal Newman had declared that 'truth' was not a matter of great importance to Roman clergy. John Henry Newman (1801–1890) was an English theologian, scholar and poet, first an Anglican priest and later a Catholic priest and cardinal, who was an important and controversial figure in the religious history of England in the 19th century. He was known nationally by the mid-1830s and was canonized as a saint in the Catholic Church in 2019

Newman took great offense at this, leading to an exchange of pamphlets and a public apology by Kingsley for misrepresenting Newman. What began was a correspondence between himself and Kingsley which started in private but rapidly became a veritable pamphlet war in which it was soon very clear that Kingsley was completely out of his depth. Sir Henry Wotton (1568-1639), an English poet and diplomat wrote *disputandi pruritis ecclesiarum scabes* (literally "an itch for disputation is the mange of the churches). If Wotton had been alive at the time I wonder what his comment would be then! (Wotton is also known for his definition of an ambassador: "an honest man sent to lie abroad for the good of his country."

Most of the pamphlets by Newman in this exchange were later published under the title, Apologia Pro Vita Sua ("apologia" then meant "defense," not "apology" as it does today), and it ranks just below Augustine's Confessions as one of the great works of religious self-analysis in the canon of Western literature. It starts off by taking Kingsley apart thoroughly and with a certain relish. But now to my main point, which involves Kingsley's "Glaucus; or, The Wonders of The Shore."

A2. GLAUCUS; OR, THE WONDERS OF THE SHORE

The following is an 1856 anonymous review of the book:

It is a very difficult thing to write a good review, more especially on subjects of a scientific nature: the review must not be too learned, or it will have too few readers; it must not betray ignorance of the subject by the writer, or it is simply useless. "Glaucus," if considered as a review, shares both these faults; it is much too learned, and at the same time reveals to us an alarming extent of ignorance in the writer on the subject of natural history. Yet, few works published during the past year have been more read than "Glaucus"; go where you will, talk to whom you will, everyone has seen "Glaucus," and speaks approvingly of it; some, indeed, suggest, that it would have been better "if so and so had been omitted," or object to a passage in this page or a sentence in that; but,

Cardinal John Henry Newman (1801–1890).

taken as a whole, it is very seldom that a work receives so cordial a welcome. Now, what is the secret of this success? Mr. Kingsley had acquired fame as a writer on other topics before he touched upon natural history; and though apparently very ignorant of this latter subject, still he brought all the trained skill of the author, and all the weight of a pen of no mean calibre, to bear upon the topic he chose to advocate. Imagine the excitement that would be caused if Macaulay or Dickens were to bring out a book on natural history; all the world would read it, to see what they could have to say on the subject; and we presume it has been with much the same motive that all the world has read Kingsley's "Glaucus."

Glaucus was one of the earliest books I picked up during my early days of delving into the history of the aquarium hobby. I was, however, not tempted to read every page since the book is saturated with theological arguments like the following:

…we meet with many a Christian passage in scientific books, which seems to us to go, not too far, but rather not far enough, in asserting the God of the Bible, as Saint Paul says, "not to have left Himself without witness," in nature itself, that He is the God of grace. Why speak of the God of nature and the God of grace as two antithetical terms? The Bible never, in a single instance, makes the distinction; and, surely, if God be (as He is) the Eternal and Unchangeable One, and if (as we all confess) the universe bears the impress of His signet, we have no right, in the present infantile state of science, to put arbitrary limits of our own to the revelation which He may have thought good to make of Himself in nature. Nay rather , let us believe that, if our eyes were opened , we should fulfil the requirement of Genius, to see the universal in the particular," by seeing God's whole likeness, His whole glory, reflected as in a mirror even in the meanest flower ; and that nothing but the dullness of our own sinful souls prevents them from seeing day and night in all things, however small or trivial to human eclecticism, the Lord Jesus Christ Himself fulfilling His own saying, " My Father worketh hitherto, and I work ."

Even though Kingsley in part is arguing in favor of science, which I am of course in accordance with, a little of this ecumenical exuberance goes a long way. He provides little detail in setting up a saltwater aquarium, referring to Gosse's 1854 book instead (Gosse, 1854). One example is the following:

Buy at any glass-shop a cylindrical glass jar, some six inches in diameter and ten high, which will cost you from three to four shillings; wash it clean, and fill it with clean salt water, dipped out of any pool among the rocks, only looking first to see that there is no dead fish or other evil matter in the said pool, and that no stream from the land runs into it. If you choose to take the trouble to dip up the water over a boat's side, so much the better.

Unfortunately, this is bad advice. It would have been better to have recommended the reverse, i.e., a cylindrical glass jar, some ten inches in diameter and six inches high.

Nonetheless, after a more careful reading I was more impressed with some of his advice and although the following excerpt is long, it says a lot for raising children:

Glaucus or Wonders of the Shore, Plate 2.

I have been sketching an ideal but one that I seriously recommend to the consideration of all parents; for, though it be impossible and absurd to wish that every young man should grow up a naturalist by profession, yet this age offers no more wholesome training, both moral and intellectual, than that which is given by instilling into the young an early taste for out-door physical science. The education of our children is now more than ever a puzzling problem if by education we mean the development of the whole humanity, not merely of some arbitrarily chosen part of it. How to feed the imagination with wholesome food, and teach it to despise French novels, and that sugared slough of sentimental poetry, in comparison with which the old fairy-tales and ballads were manful and rational; how to counteract the tendency to shallow and conceited sciolism [*i.e., superficial knowledge*]**, engendered by hearing popular lectures on all manner of subjects, which can only be really learnt by stern methodic study; how to give habits of enterprise, patience, accurate observation, which the counting-house or the library will never bestow; above all, how to develop the physical powers, without engendering brutality and coarseness, —are questions becoming daily more and more puzzling, while they need daily more and more to be solved, in an age of enterprise, travel, and emigration, like the present.**

For the truth must be told, that the great majority of men who are now distinguished by commercial success, have had a training the directly opposite to that which they are giving to their sons. They are for the most part men who have migrated from the country to the town, and had in their youth all the advantages of a sturdy and manful hill-side or sea-side training; men whose bodies were developed, and their lungs fed on pure breezes, long before they brought to work in the city the bodily and mental strength which they had gained by loch and moor. But it is not so with their sons. Their business habits are learnt in the counting-house; a good school, doubtless, as far as it goes: but one which will expand none but the lowest intellectual faculties; which will make them accurate accountants, shrewd computers and competitors, but never the originators of daring schemes, men able and willing to go forth to replenish the earth and subdue it.

And in the hours of relaxation, how much of their time is thrown away, for want of anything better, on frivolity, not to say on secret profligacy, parents know too well; and often shut their eyes in very despair to evils which they know not how to cure . A frightful majority of our middle class young men are growing up effeminate, empty of all knowledge but what tends directly to the making of a fortune; or rather, to speak correctly, to the keeping up the fortunes which their fathers have made for them; while of the minority, who are indeed thinkers and readers, how many women as well as men have we seen wearying their souls with study undirected, often misdirected; craving to learn, yet not knowing how or what to learn;

cultivating, with unwholesome energy, the head at the expense of the body and the heart; catching up with the most capricious self-will one mania after another, and tossing it away again for some new phantom; gorging the memory with facts which no one has taught them to arrange, and the reason with problems which they have no method for solving; till they fret themselves into a chronic fever of the brain, which too often urges them on to plunge, as it were to cool the inward fire, into the ever restless sea of doubt and disbelief.

It is a sad picture. There are many who may read these pages whose hearts will tell them that it is a true one. What is wanted in these cases is a methodic and scientific habit of mind; and a class of objects on which to exercise that habit, which will fever neither the speculative intellect nor the moral sense; and those physical science will give, as nothing else can give it.

A3. KINGLSEY'S COMMENTS ON THE NAMING OF NEW SPECIES

The following is the section that provided part of the impetus for my writing this essay. Here Kingsley is describing the values in strolling along or in the seaside looking for desirable specimens perhaps to take home–usually anemones, invertebrates and fishes.

But what is even this to the delight of finding a new species?—of rescuing (as it seems to you) one more thought of the divine mind from Hela [i.e., *Odin's first born; she served as Executioner and Goddess of Death as she and her father made their way through the Nine Realms bringing death, destruction and conquest along for the ride*]**, and the realms of the unknown, unclassified, uncomprehended? As it seems to you: though in reality it only seems so, in a world wherein not a sparrow falls to the ground unnoticed by our Father who is in heaven.**

The truth is, the pleasure of finding new species is too great; it is morally dangerous; for it brings with it the temptation to look on the thing found as your own possession, all but your own creation; to pride yourself on it, as if God had not known it for ages since; even to squabble jealously for the right of having it named after you, and of being recorded in the Transactions of I-know-not-what Society as its first discoverer:—as if all the angels in heaven had not been admiring it, long before you were born or thought of.

Wow! This is a viewpoint that I never before considered, but I will leave it to the reader to discover to whom it might apply. However, this is a good time to discuss the hurdles in the history of naming fish species. In the past, when an ichthyologist discovers or receives a fish that he thinks is a new species, he does some research to determine whether it has been named previously. This is a risky business, fraught with the possibility that someone else has beaten him to it. If he is satisfied that it is new he writes a paper and submits it to the editor of a professional journal.

After World War II, however, there was a splurge of new species being discovered and named, placing a severe economic burden on these professional journals, most of which were sponsored by educational organizations such as universities. One of the results was that it took longer and longer to get the article published and some publications even started to charge the author if the paper were accepted.

A stamp from East Germany. Cardinal Tetra (*Cheirodon axelrodi*) (Germany, Democratic Republic (DDR) 1966)

A4. THE CHEIRODON AXELRODI DISPUTE AND ICZN RULES ON PUBLICATION

In 1956, specimens of a small characin were sent independently to Leonard P. Schultz by Herbert Axelrod, who originally acknowledged that the specimens had been received from a New Jersey fish dealer on 10–11 February 1956, and to George S. Myers and Stanley H. Weitzman by William T. Innes and Paramount Aquarium (Myers and Weitzman, 1956). Both Schultz (1956) and Myers and Weitzman (1956) published a description of the species in February 1956, and, after a heated debate and split vote, the International Commission on Zoological Nomenclature (ICZN) ruled on the priority of the name *Cheirodon axelrodi* Schultz (ICZN, 1957; Opinion 485). In the letters concerning this case, however, no one has been able to answer why Vol. 4, No. 4 of the *Tropical Fish Hobbyist* should carry the precise date 20 February 1956, and the succeeding one reverts to the similar form, May-June 1956. In any event, the general feeling to this day is that the ICZN had been duped.

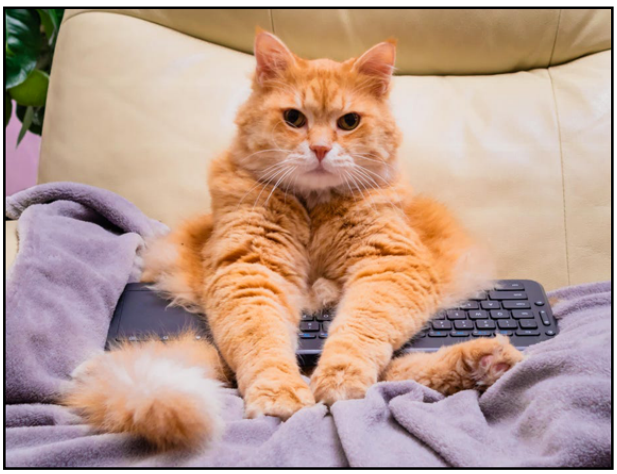
Hyphessobrycon cardinalis Myers & Weitzman was clearly published as a voluntary act of publication in a journal normally serving as a vehicle of taxonomic publication–the Stanford Ichthyological Bulletin– dated 21 February. *Cheirodon axelrodi* Schultz, on the other hand, does not appear to have been deliberately published by its author. Schultz sent a personal letter to Axelrod who published the article on his own responsibility in the *Tropical Fish Hobbyist*, a lay journal which, unappreciated at the time, satisfied the ICZN's publishing rules which roughly were as follows: Article 8 of the ICZN specified the following for what constituted a published work. A work was to be regarded as published for the purposes of zoological nomenclature if it complied with the requirements of the Article and was not excluded by the provisions of Article 9 (this discussed what does not consist of published work). A work had to satisfy the following criteria:

1. It must be issued for the purpose of providing a public and permanent scientific record,
2. It must be obtainable, when first issued, free of charge or by purchase,
3. It must have been produced on paper, by a printing method (such as letterpress, offset printing) or by hectographing or mimeographing.

This led to a breaking of the log jam in publishing new names. It not only relieved the author of any financial burden but publication now was a lot faster.

A5. ICHTHYOLOGY AFTER WORLD WAR II

After World War II there was a general decline in systematics and taxonomy, the science dealing with the identification, description, naming and classifying of organisms. Ichthyology today is not in vogue in universities, especially not in taxonomic ichthyology. As a result, it is difficult to acquire tenure, much less the grants necessary to fund the collecting trips that are required. Also, most taxonomists are faced with editorial resistance to publishing their work in the high impact journals that will secure tenure and promotion and allow them to continue their work and contributions. I personally know two who are in this unenviable position, whiling their way to teaching anatomy or some other biological course where students are not as scarce. For a young ichthyologist to make a name for himself, it is not enough to name new species. One way out is to take one or more species and create new taxa for them. As a result, genera long familiar to aquarists now are split into one or more genera or even subgenera.



A new member of the Aquarium Hobby Historical Society preparing his latest post.

The terms "lumpers" and "splitters" were introduced more widely by George G. Simpson in his 1945 work *The Principles of Classification and a Classification of Mammals*. As he put it:

…splitters make very small units–their critics say that if they can tell two animals apart, they place them in different genera…and if they cannot tell them apart, they place them in different species. … Lumpers make large units–their critics say that if a carnivore is neither a dog nor a bear, they call it a cat.

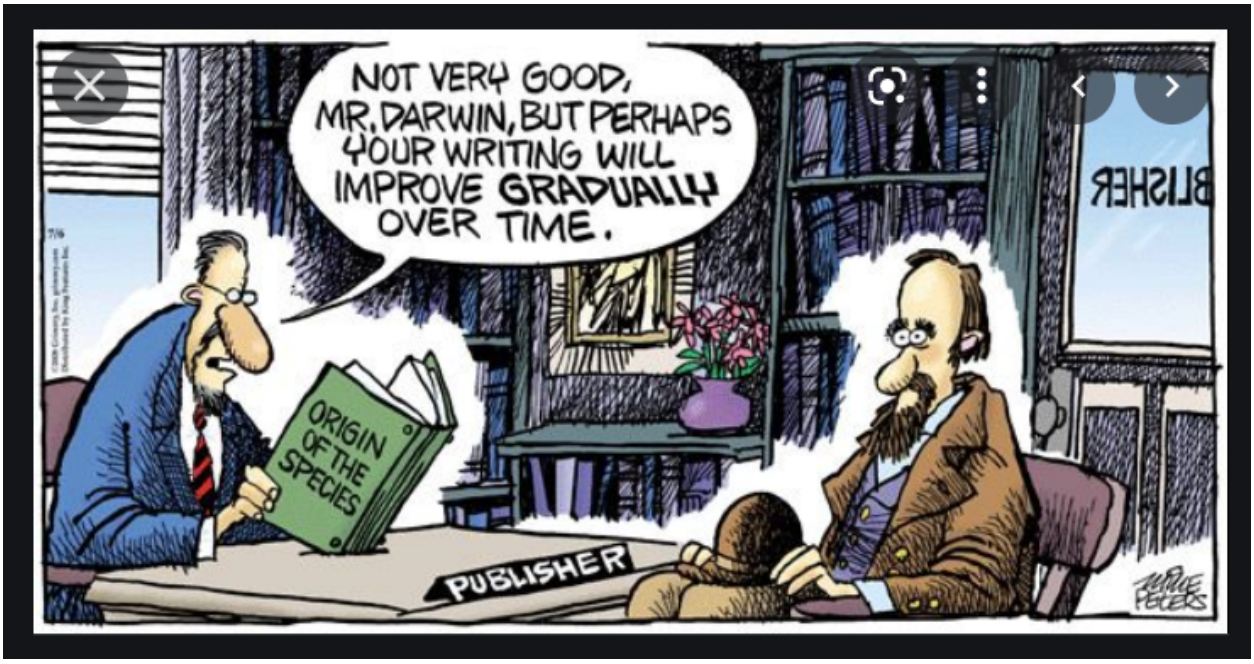
Both the *Oxford English Dictionary* and the Wikipedia article for "Lumpers and splitters" credit the first use of the terms to none other than Darwin, on the strength of a letter he wrote to his friend Joseph Dalton Hooker in 1857:

I am got extremely interested [sic and Boldfaced emphasis in the original] **in tabulating according to mere size of genera, the species having any varieties marked by Greek letters or otherwise: the result (as far as I have yet gone) seems to me one of the most important arguments I have yet met with, that varieties are only small species–or species only strongly marked varieties. The subject is in many ways so very important for me; I wish much you would think of any well-worked Floras with from 1000–2000 species, with the varieties marked. It is good to have hair-splitters & lumpers.**

Hooker's priority was to establish a reputation as a philosophical naturalist (i.e., one who believes the doctrine that the natural world is all there is), and to do so he embarked on a survey of global vegetation patterns. He believed that taxonomic "splitters" hindered his ambition to create natural laws for botany (and hence establish it as a prestigious science) by generating a multitude of redundant synonyms for every plant variety. Despite the fact that Darwin's ideas apparently promised a justification for splitting, they also offered a philosophical justification for Hooker's taxonomic practice, and so he enthusiastically championed his friend. However, splitting is not the main reason for the plethora of species described after World War II.

A6. TAXONOMIC PUBLISHING ENTERS THE DIGITAL AGE

The ICZN for dealing with paper publications first appeared over fifty years ago–in 1961–and the earliest attempt at a formal code of nomenclature had been proposed by Hugh Edwin Strickland another 120 years before that. Despite all this time, the Code as it pertains to paper publica-



tions has still not been perfected, and revisions continue to be proposed and published. Indeed, some of the issues the code grapples with (such as what does or does not constitute "publication") are, in the end, probably not universally soluble, because they deal with factors such as judging ethical behavior that cannot be expressed in simple formulae applicable to every situation. So it should hardly be expected that rules for electronic publication should have immediately attained perfection when not even those for paper publication, with 170 years or more of a head start, have not yet done so. In any event, following four years of highly charged debate, the rules for publication of scientific names of animals have been changed to allow electronic publications to meet the requirements of the stringent ICZN.

In a landmark decision, the ICZN has passed an amendment to its rules that will accept an electronic-only publication as "legitimate" if it meets criteria of archiving and the publication is registered on the ICZN's official online registry, ZooBank. ZooBank is a central, authoritative and comprehensive resource for scientific names in zoology. It provides an authoritative online, open-access, community-generated registry for zoological nomenclature, as a service to taxonomists, biologists, and the global biodiversity informatics community. With ZooBank in place there will be access to a single reference list of animal names, and so discussions about priority species and habitats can proceed with greater clarity and speed. The criteria mentioned above include:

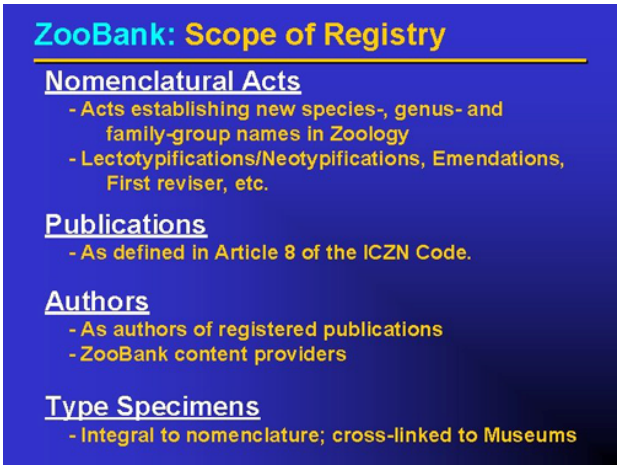
1. Wide accessibility;
2. Issued for the permanent scientific record (online posting for a limited time is not accepted);
3. Fixed content and layout (e.g., a protected PDF file, not an editable Word file);
4. Date of publication must be stated in the work itself (i.e., paper or book); a note on the journal's webpage is not sufficient;
5. Work (i.e., a paper or a book) must be registered in ZooBank, the Official Registry of Zoological Nomenclature (http://zoobank.org), and contain evidence that such registration took place (e.g., exact date of registration or/and registration number); registration of new animal names is not mandatory, but encouraged (paper publications, on the other hand, do not yet have to be registered);
6. ZooBank registration entry must give the name and internet address of an organization other than the publisher that is intended to permanently archive the work in a matter that preserves content and layout, and is capable of doing so (this does not need to be stated in the published work itself; such archives are currently Bioline International, Biotaxa, CLOCKSS, Harvard Digital Repository Service, Hathitrust, LOCKSS, National Digital Heritage Archive of the National Library of New Zealand, Portico®, PubMedCentral®, and Virginia State Publications Depository Program);
7. ZooBank registration entry must contain the ISBN or ISSN number (the former identifies editions of books and the latter is used for serials such as journals, magazines and newspapers).

Currently, ZooBank accommodates the registration of four different kinds of data objects:

1. Nomenclatural Acts: Published usages of scientific names for animals, which represent nomenclatural acts as governed by the ICZN Code of Nomenclature. Most of these acts are original descriptions of new scientific names for animals, but other acts may include emendations, lectotypifications (a lectotype is a specimen chosen as the type of a species or subspecies if the author of the name fails to designate a type**)**, and other acts as governed by the ICZN Code.

2. Publications: Publications that contain Nomenclatural Acts, as defined above.

3. Authors: Anyone who is an author of one or more Publications (as defined above), or who is a contributor to ZooBank content.



4. Type Specimens: Type specimens for scientific names of animals. The registration of Type Specimens is considered provisional and is not yet fully implemented in ZooBank.

The accompanying image shows what ZooBank looks like when I entered "Chromaphyosemion" in its search box. Clicking on entries leads to addition information regarding the species.

The decision about electronic publication has not been without controversy because the rules of the ICZN are considered, and intended, to be among the most rigorous for scientific publication. The task of keeping correct information on animal names is immense and critical, as almost all information on the living world is linked through names. Animals comprise the vast majority of the world's recognized living species and currently stands at around 1.9 million, growing at a rate of about 20,000/year. For each of these groups there are as many as 2–10 legitimately published names due to past debate and poor information exchange. Estimates of the total of living animal biodiversity are 4–20 times this number (8–50 million species), with fossils adding many more. When the task of cataloguing biodiversity approaches completion, this vast amount of information will be linked through names.

The new decision means that the difficulty in naming some species such as the case of *Darwinius masillae* can be avoided. In 2009 a fossil discovery was announced that was supposed to profoundly change our views on human evolution. The 47 million year old fossil nicknamed "Ida," was published in the electronic journal *PLoS One*. The publishers had an 11th hour realization that this publication would not be legitimate under ICZN rules. The name could even have been scooped by an unscrupulous author. A "special paper copy" of the journal had to be published, which would not be needed under the new rules.

The ICZN ruling is explicit that while the publication can exist in an electronic-only format, it must still be published through a recognized scientific journal. Purely web options such as blog posts, forums, Wikimedia, Wikipedia, Scratchpads and other potentially ephemeral, unarchived web-only sources still do not qualify as legitimate electronic publications under the new ICZN rules.

It should be noted that it is currently not the purpose of the Code nor is it in the purview of the ICZN to police taxonomy. Taxonomy is a scientific endeavor, whereas nomenclature is not. The Code should be used as those names which are regarded as being established and

accepted by which to determine whether taxon names are nomenclaturally available for use in subsequent publications. But this is precisely where a dilemma exists. The Code is by definition not scientific, but it generates a set of nomenclatural rules for taxonomy and is only useful if there are scientists willing to use the rules. Thus, a name that slips through the (admittedly imperfect) scrutiny of peer review or names generated *en masse* by poorly executed taxonomy automatically enter nomenclature. All it takes is the observance of a few very simple criteria for a taxon name to become available according to the Code. Under these circumstances, it is possible to produce large numbers of names that are Code compliant but have no scientific basis; the Code expects these names to be considered in the same manner as science-based names.

A7. TAXONOMIC VANDALISM

Much of what is in this section and section A6 is due to Hinrich Kaiser (2013), Darren Naisch (2013) and Benjamin Jones (2017). These are lengthy–and also a bit complicated–documents so I have edited them to make them more readable to aquarists. Those wishing to read their complete contents can access them using the above entries in my bibliography.

In taxonomic herpetology there has recently been a troubling development with the emergence of what Hinrich Kaiser, Professor of Biology, Victor Valley College described as pseudoscientific works, in which taxonomic decisions are reported whose methodology fails on basic scientific principles based on modern concepts of publication in science (i.e. demonstrated scientific methodology including a list of specimens examined, scientific publication outlet and peer review with inclusion of editorial oversight). In a textbook definition, Kaiser states:

Pseudoscience attempts to look like actual science so that its assertions might appear valid. However, unlike science, pseudoscience begins with a claim and looks only for things that support it. Controlled experiments are never done. In fact, direct tests of any kind even if possible, are generally avoided. Pseudoscience is indifferent to facts and tries to persuade with appeals to emotion, sentiment, or distrust of established knowledge. Unlike real science, pseudoscience does not progress; nothing is revised or learned. These pseudoscientific works also run afoul of the Code of Ethics appended to the Code.

Recently, Australian snake enthusiast Raymond Hoser has presented over 500 new taxon names in 20 issues of his self-edited and probably non-peer reviewed *Australasian Journal of Herpetology* (*AJH*); Hoser is invariably the only author. As mentioned previously, taxonomy is a scientific endeavor, whereas nomenclature is not. It is currently not the purpose of the Code, nor is it in the purview of the International Commission on Zoological Nomenclature, to police taxonomy. The

American herpetologist Hinrich Kaiser prepares specimens at his makeshift research station at East Timor.

Code should be used as a statement which is assumed to be true without question, and which does not require proof by which to determine whether taxon names are nomenclaturally available for use in subsequent publications.

But as Kaiser points out, this is precisely where a dilemma exists. The Code is by definition not scientific, but it generates a set of nomenclatural rules for taxonomy, and is only useful if there are scientists willing to use the rules. Thus, a name that slips through the (admittedly imperfect) scrutiny of peer review, or names generated *en masse* by poorly executed taxonomy automatically enter nomenclature. All it takes is the observance of a few very simple criteria for a taxon name to become available according to the Code. Under these circumstances, it is possible to produce large numbers of names that are Code compliant but have no scientific basis; the Code expects these names to be considered in the same manner as science-based names.

Hoser uses the Code as a 'name-laundering scheme': his mass-produced names go in and 'clean' names come out. The more names that are put through the system, the greater is the likelihood that some will by coincidence stand if science eventually produces supporting facts. None of these names have a rigorous scientific foundation, which would at the very least require a certain amount of specimen work to validate holotypes along with careful first-hand examination of comparative material (either using museum specimens or molecular data). Hoser does neither; he resorts to bulk citations of all literature on a given taxonomic group, including particularly those papers that feature unnamed branches on relationship trees, and creates a new taxon name for any node that falls in line with his ideas. These passages generally include disclaimers, similar to the following from Hoser to which are appended 151 citations that are not shown here:

Where it is appropriate to rely on earlier published material, this is not necessarily rehashed herein. This is especially in terms of when the relevant material is widely available to readers on the worldwide web '(internet).'

Although Hoser violates multiple areas of ethics in his publications his deportment is not a problem for the Code since the Code of Ethics (which is violated by intemperate behavior) is unfortunately only an Appendix, and not mandatory.
Vandals churn out names of so-called "new species" in their journals, often when the scientific evidence to support a discovery is lacking. And if the names are properly constructed and accompanied by characteristics that are "purported" to distinguish the species, they become valid under the Code. As long as you create a name, state intention that the name is new, and provide just the vaguest description of a species, the name is valid.

A8. METHODS OF TAXONOMIC VANDALISM

Taxonomic vandalism usually isn't subtle. Oftentimes, vandals will explicitly steal others' science to support their so-called "discovery." They don't do any of the research and they don't own any of

Raymond Hoser.

the research. One of the most common lines of evidence they steal is what's known as the phylogenetic tree.

Phylogenetic trees, not unlike family trees, reveal how different animal specimens are related to each other based on their genetics; specimens that are genetically similar are grouped together. In some cases, those groupings represent species that have yet to be named, which scientists call "candidate species." Researchers commonly publish phylogenetic trees on the road to discovering a new species and then use those published trees as evidence for that species' uniqueness.

However, gathering enough evidence to make a discovery can take months or even years. Meanwhile, culprits like Hoser swoop in. Once the tree is publicly available, vandals use it as evidence to justify a "discovery," which they quickly publish in their personal journals. Vandals go through literature and comb through phylogenetic trees, find a group in the phylogenetic tree that could be named, and quickly give it a name.

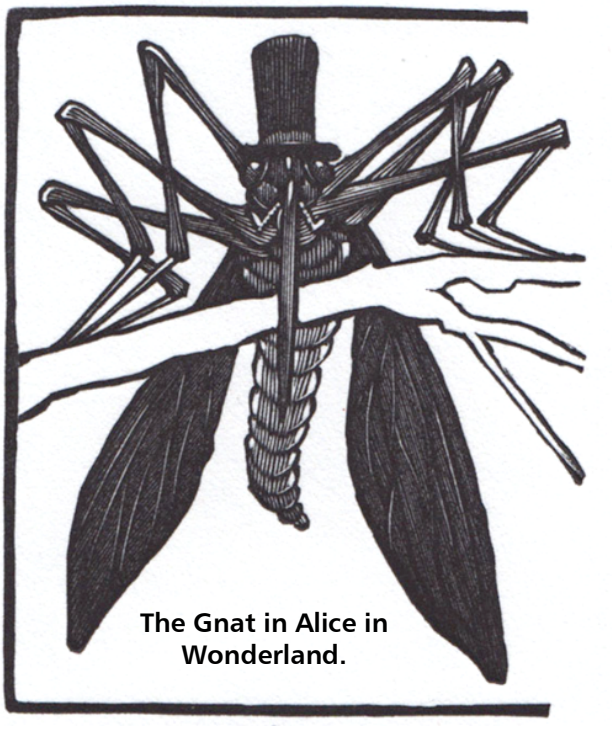
It's difficult to pinpoint the total number of species named by these vandals, but it has been estimated that there are tens of thousands. Hoser readily admits that he has used this approach to name tens–if not hundreds–of taxa. "I managed to name about 100 genera [of snakes] by basically looking at phylogenetic trees," Hoser said. Among them was the African spitting cobra, *Spracklandus*.

Another approach is based on a theory called "allopatric speciation," or the evolution of new species through geographic isolation. The theory states that when animal populations are physically separated without opportunities to interbreed, they can grow genetically distinct. Over time, the populations can become separate species—meaning, in simplistic terms, that they can't successfully reproduce with each other. This is a widely-accepted theory, but not proof in itself. Without DNA samples and a detailed examination of several individuals from each population, it's not so much a discovery as it is a clue.

Taxonomic vandals have been known to take full advantage of this theory to make "discoveries." To find and name new species, they will search for geographic barriers that cut through the range of an existing species, such as rivers or mountains. If the species populations look different on either side of the barrier–on one side they're red and on the other side they're blue, for example–vandals will automatically declare them two separate species although there is no scientific underpinning of that statement. Hoser, Kaiser writes, uses both existing phylogenetic trees and allopatric speciation to justify generating "new" species names.

B1. DEFINING SPECIES

"What sort of insects do you rejoice in, where you come from?" the Gnat inquired.
"I don't *rejoice* in insects at all," Alice explained, "because I'm rather afraid of them — at least the large kinds. But I can tell you the names of some of them."
"Of course they answer to their names?" the Gnat remarked carelessly.
"I never knew them do it."
"What's the use of their having names," the Gnat said, "if they won't answer to them?"
"No use to *them*," said Alice; "but it's useful



The Gnat in Alice in Wonderland.

to the people that name them, I suppose. If not, why do things have names at all?"
"I can't say," the Gnat replied. "Further on, in the wood down there, they've got no names."
[Lewis Carroll, 1962, pg, 225]

The definition of "species" is a tricky one. Depending on a person's focus and need for the definition, the idea of the species concept can be different. Most basic scientists agree that the common definition of the word "species" is a group of similar individuals that live together in an area and can interbreed to produce fertile offspring. However, this definition is not truly complete. It cannot be applied to a species that undergoes asexual reproduction since "interbreeding" does not happen in these types of species. Therefore, it is important we examine all of the species concepts to see which are usable and which have limitations. The following are species concepts by various authors from 1789 to 1859.

JEAN-BAPTISTE LAMARCK
"*Species*: in botany as in zoology, a species is necessarily constituted of the aggregation of similar individuals which perpetuate themselves, the same, by reproduction." [Vol. 2, *Encyclopedie Methodique*, 1786]

ANTOINE-LAURANT DE JUSSIEU
"Just so many plants agreeing in all their parts, or being consistent in their universal character, and born from and giving birth to those of like nature, are the individuals together constituting a species, [a term] wrongly used in the past, now more correctly defined as the perennial succession of like individuals, successively reborn by continued generation." [*Genera plantarum secundum ordines naturalis disposita*, 1789]

GEORGES CUVIER
"... the word species means the individuals who descend from one another or from common parents and those who resemble them as much as they resemble each other." [**Annales du Museum d'Histoire Naturelle,** 1812]

RICHARD OWEN
"The proposer of the new species now intends to state no more than he actually knows; as for example, that the differences in which he founds the specific character are constant in individuals of both sexes, so far as observation has reached..." [*On the Osteology of the Chimpanzee and Orang Utan*, 1835]

PHILLIP HENRY GOSSE
"It is often difficult in practice to determine the difference or identity of species; as we know of no fixed principle on which to found our decision, except the great law of nature, by which specific individuality is preserved – that the progeny of mixed species shall not be fertile *inter se*." [*An Introduction to Zoology*, 1844]

GEOFFROY SAINT-HILAIRE
"The species is a collection or a succession of individuals characterized by a whole of distinctive features whose transmission is natural, regular and indefinite in the current order of

French naturalist Jean-Baptiste Lamarck (1744-1829). Lamarck was an early proponent of the idea that evolution occurred and proceeded in accordance with natural laws.

things." [*Histoire naturelle génerale des règnes organiques*, vol. 2, 437, 1859)]

B2. EARLY CONCEPTS OF SPECIES

There was a concept of species before there was any clear idea of what they might be (Templeton, 1989). Species were identified in the 15th century that are still regarded as species, and there wasn't the slightest hint of an explanation in the air at the time. And it's an old concept, too, although the first simply biological definition of "species" (a Latin word that means "form" or "appearance") waited until 1686. The earliest taxonomist to achieve a species definition was the English naturalist and botanist John Ray (1627–1705). In his major work *Historia Plantarum* (Ray, 1686) he stated:

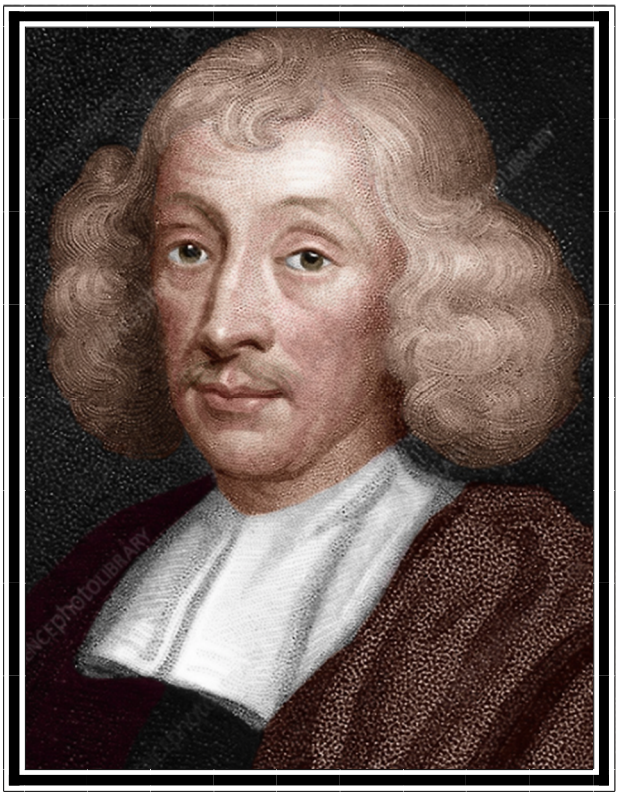
No matter what variations occur in the individuals or the species, if they spring from the seed of one and the same plant, they are accidental variations and not such as distinguish a species permanently; one species never springs from the seed of another nor vice versa.

Therefore, Ray attempted to define species as groups of plants that truly breed within their limits of variation. Ray additionally said of a species:

After long and considerable investigation, no surer criterion for determining species has occurred to me than the distinguishing features that perpetuate themselves in propagation from seed. Thus, no matter what variations occur in the individuals or the species, if they spring from the seed of one and the same plant, they are accidental variations and not such as to distinguish a species ... Animals likewise that differ specifically preserve their distinct species permanently; one species never springs from the seed of another nor vice versa.

Ray's definition was based on a simple observation: progeny resemble their parents. Species are those groups of organisms that resemble their parents. A version of it can be found in Epicurus' disciple, Lucretius (Smith, 1975)]:

If things could be created out of nothing, any kind of things could be produced from any source. In the first place, men could spring from the sea, squamous fish from the ground, and birds could be hatched from the sky; cattle and other farm animals, and every kind of wild beast, would bear young of unpredictable species, and would make their home in cultivated and barren parts without discrimination. Moreover, the same fruits would not invariably grow on the same trees, but would change: any tree could bear any fruit. Seeing that there would be no elements with the capacity to generate each kind of thing, how could creatures constantly have a fixed mother? But, as it is, because all are formed from fixed seeds, each is born and issues out into the shores of light only from a source where the right ultimate particles exist. And this explains why all things cannot be



John Ray (1627–1705).

produced from all things: any given thing possesses a distinct creative capacity.

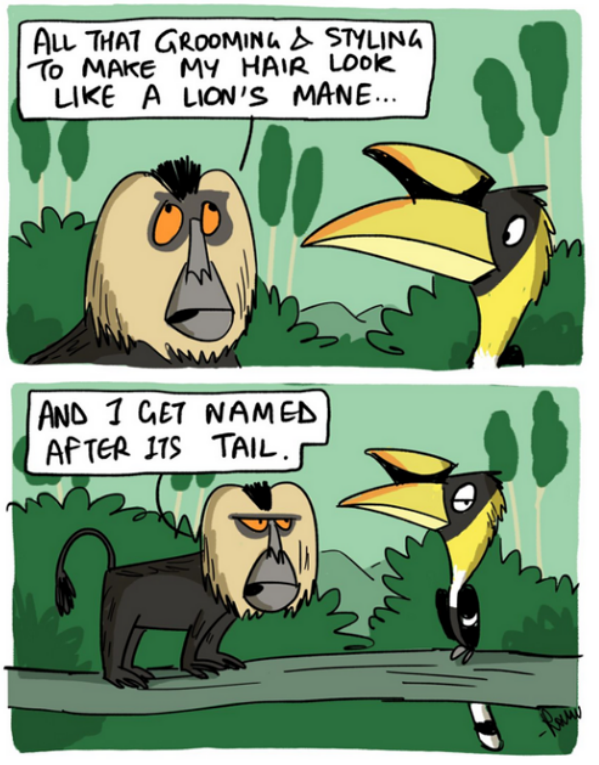
Linnaeus (1707–1778), whose work nearly 50 years later was the most eminent and momentous in the taxonomy field, adopted a broader concept, providing a new definition of species. In his work *Species Plantarum* (Linnaeus, 1753), using mainly the floral structure and sexual characters, Linnaeus described briefly and systematically approximately 5900 species of plants known to man then. Thus he used a sexual or "natural system" for defining species. The Linnaeus concept was simple, applicable and was accepted widely.

Both the Ray and the Linnaeus approaches in defining species were typological; i.e., they believed that under natural intraspecific variations exists a fixed unchangeable type of each species and this refuted the Ancient Greek idea of transmission of species (i.e., that a species was a collection of objects that had a common underlying "essence") that was widely believed in those days (Briggs and Walters, 1984).

De Candolle (1778–1841), who was the first to introduce the word taxonomy through his book *Théorie Élémentaire de la Botanique* (De Candole, 1813), defined species as "a collection of all the individuals which resemble each other more than they resemble anything else, which can by natural fecundation produce fertile individuals, and which reproduce themselves by generation, in such a manner that we may from analogy suppose them all to have sprung from one single individual." He divided plants into two major groups, non-vascular and vascular plants. A book in seven volumes covered all species of cotyledons in the world including 161 families and 58000 species was his main and most important work which is called *Prodromus Systematis Naturalis Regni Vegetabilis* (1823–1873). Most taxonomists after him, before the next phase of taxonomy, used De Candolle's system, although sometimes with modifications.

Years later, in his theory of evolution with Wallace (Darwin and Wallace, 1859) even before his famous book *On the origin of species by means of natural selection,* Charles Darwin (1809–1882) considered species as the fundamental units of evolution, starting a new era of species definition. Darwin emphasized the fact that species could be produced rapidly if the conditions were appropriate and in the absence of such conditions, species might remain unchanged for a long time. It should be noted that all Darwinian theories and studies were carried out before the establishment of genetic science. The following is from Darwin writing about species (*On the Origin of Species*, 1859):

Hereafter we shall be compelled to acknowledge that the only distinction between species and well-marked varieties is, that the latter are known, or believed, to be connected at the present day by intermediate gradations, whereas species were formerly thus connected. Hence, without quite rejecting the consideration of the present existence of intermediate gradations between any two forms, we shall be led to weigh more carefully and to value higher the actual amount of difference between them. It is quite possible



that forms now generally acknowledged to be merely varieties may hereafter be thought worthy of specific names, as with the primrose and cowslip; and in this case scientific and common language will come into accordance. In short, we shall have to treat species in the same manner as those naturalists treat genera, who admit that genera are merely artificial combinations made for convenience. This may not be a cheering prospect; but we shall at least be freed from the vain search for the undiscovered and undiscoverable essence of the term species.

If things could be created out of nothing, any kind of things could be produced from any source. In the first place, men could spring from the sea, squamous fish from the ground, and birds could be hatched from the sky; cattle and other farm animals, and every kind of wild beast, would bear young of unpredictable species, and would make their home in cultivated and barren parts without discrimination. Moreover, the same fruits would not invariably grow on the same trees, but would change: any tree could bear any fruit. Seeing that there would be no elements with the capacity to generate each kind of thing, how could creatures constantly have a fixed mother? But, as it is, because all are formed from fixed seeds, each is born and issues out into the shores of light only from a source where the right ultimate particles exist. And this explains why all things cannot be produced from all things: any given thing possesses a distinct creative capacity.

For Darwin, "species" was an undefinable term. In an 1856 letter to his friend Joseph Hooker, Darwin wrote:

It is really laughable to see what different ideas are prominent in various naturalists' minds, when they speak of 'species'; in some, resemblance is everything and descent of little weight – in some, resemblance seems to go for nothing, and creation the reigning idea – in some, sterility an unfailing test, with others it is not worth a farthing. It all comes, I believe, from trying to define the indefinable.

That hasn't stopped scientists in the 150 years since then from trying, however. When scientists today sit down to study a new form of life, they apply any number of more than 70 definitions of what constitutes a species–and each helps get at a different aspect of what makes organisms distinct. In the Appendix I have supplied a list of other distinct species concepts. The listing is somewhat technical but I provide it to show some of the many definitions that have appeared in the literature.

Darwin even dreamt of a time when a revolution would come about in biology. He proposed that one day, biologists could pursue their studies without ever worrying about what a species is, or

Sir Joseph Dalton Hooker (1817-1911) was a British botanist and explorer in the 19th century. He was a founder of geographical botany and Charles Darwin's closest friend.

which animals belong to which species. Indeed, some contemporary biologists and philosophers of biology have taken up this idea, and suggested that biology would be much better off if it didn't think about life in terms of species at all.

Scrapping the idea of a species is an extreme idea: it implies that pretty much all of biology, from Aristotle right up to the modern age, has been thinking about life in completely the wrong way. The upshots of this new approach would be enormous, both for our scientific and philosophical view of life. It suggests that we should give up thinking about life as neatly segmented into discrete groups. Rather, we should think of life as one immense interconnected web. This shift in thinking would fundamentally reorient our approach to a great many questions concerning our relation to the natural world, from the current biodiversity crisis to conservation.

And, in a way, this kind of picture may be a natural progression in biological thought. One of the great discoveries of evolutionary biology is that the human species is not special or privileged in the grand scheme of things, and that humans have the same origins as all the other animals. This approach just takes the next step. It says that there is no such thing as "the human species" at all.

B3. THREE SIMPLIFIED CONCEPTS OF SPECIES

Regardless of the many species concepts listed in the Appendix, it is possible to distill them into the following three main ideas.

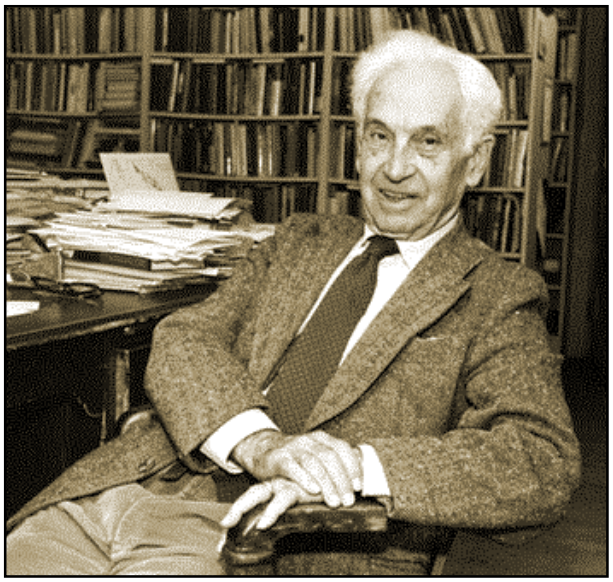
1. BIOLOGICAL SPECIES

The most universally accepted species concept is the idea of the biological species. This is the species concept from which the generally accepted definition of the term "species" comes. First proposed by Ernst Mayr, the biological species concept explicitly says, "Species are groups of actually or potentially interbreeding natural populations which are reproductively isolated from other such groups." This definition brings into play the idea of individuals of a single species being able to interbreed while staying reproductively isolated from each other (Mayr, 1942).

Without reproductive isolation, speciation cannot occur. Populations need to be divided for many generations of offspring in order to diverge from the ancestral population and become new and independent species. If a population is not divided, either physically through some sort of barrier, or reproductively through behavior or other types of prezygotic or postzygotic isolation mechanisms, then the species will stay as one species and will not diverge and become its own distinct species. This isolation is central to the biological species concept.

2. MORPHOLOGICAL SPECIES

Morphology is how an individual looks. It is their physical features and anatomical parts. When Linnaeus first came up with his binomial nomenclature taxonomy, all individuals were grouped by morphology. Therefore, the first concept of the term "species" was based on the morphology. The morphological species concept does not take into account what we now know about genetics



Ernst Walter Mayr (July 1904-2005) was one of the 20th century's leading evolutionary biologists. He was also a renowned taxonomist, tropical explorer, ornithologist, philosopher of biology, and historian of science. His work contributed to the conceptual revolution that led to the modern evolutionary synthesis of Mendelian genetics, systematics, and Darwinian evolution, and to the development of the biological species concept.

and DNA and how it affects what an individual looks like. Linnaeus did not know about chromosomes and other micro-evolutionary differences that actually make some individuals that look similar a part of different species.

The morphological species concept definitely has its limitations. First, it does not distinguish between species that are actually produced by convergent evolution and are not really closely related. It also does not group individuals of the same species that would happen to be somewhat morphologically different like in color or size. It is much more accurate to use behavior and molecular evidence to determine what is the same species and what is not.

3. LINEAGE SPECIES

A lineage is similar to what would be thought of as a branch on a family tree. The phylogenetic trees of groups of related species branch off in all directions where new lineages are created from speciation of a common ancestor. Some of these lineages thrive and live on and some become extinct and cease to exist over time. The lineage species concept becomes important to scientists who are studying the history of life on Earth and evolutionary time.

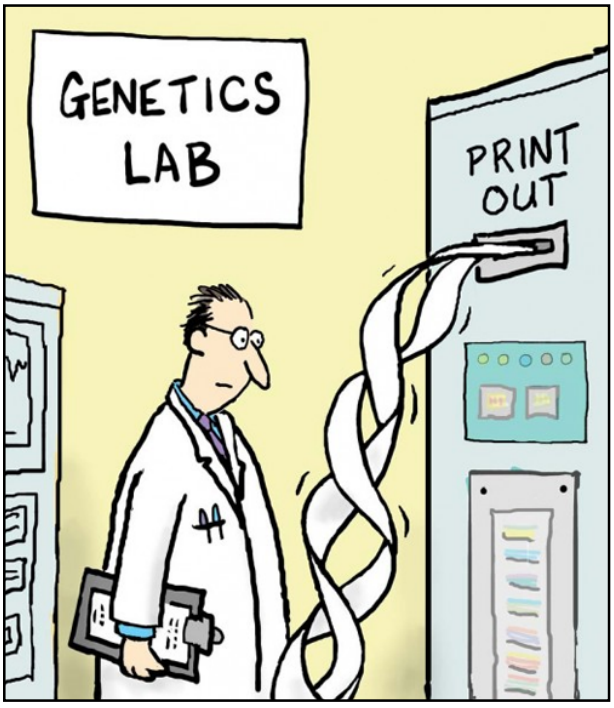
By examining the similarities and differences of lineages that are related, scientists can determine most likely when the species diverged and evolved compared to when the common ancestor was around. This idea of lineage species can also be used to fit asexually reproducing species (and there are examples even among fishes, e.g., *Rivulus marmoratus*)). Since biological species concept is dependent upon reproductive isolation of sexually reproducing species, it cannot necessarily be applied to a species that reproduces asexually. The lineage species concept does not have that restraint and therefore can be used to explain simpler species that do not need a partner to reproduce.

B4. DNA ENTERS THE PICTURRE

In a way, this plethora of definitions helps prove Darwin's point: The idea of a species is ultimately a human construct. With advancing DNA technology, scientists are now able to draw finer and finer lines between what they consider species by looking at the genetic code that defines them. How scientists choose to draw that line depends on whether their subject is an animal or plant; the tools available; and the scientist's own preference and expertise. Now, as new species are discovered and old ones thrown out, researchers want to know: How do we define a species today? Let's look back at the evolution of the concept and see how far it's come.

The most classic definition of species is a group of organisms that can breed with each other to produce fertile offspring, an idea originally set forth in 1942 by evolutionary biologist Ernst Mayr whom I have mentioned above. While elegant in its simplicity, this concept has since come under fire by biologists who argue that it didn't apply to many organisms, such as single-celled ones that reproduce asexually, or those that have been shown to breed with other distinct organisms to create hybrids.

Alternatives arose quickly. Some biologists championed an ecological definition that assigned species according to the environmental niches they fill such as this animal recycles soil nutrients and this predator keeps insects in check. Others



asserted that a species was a set of organisms with physical characteristics that were distinct from others (e.g., the peacock's fanned tail and the beaks of Darwin's finches).

The discovery of DNA's double helix prompted the creation of yet another definition, one in which scientists could look for minute genetic differences and draw even finer lines denoting species. Based on a 1980 book by biologists Niles Eldredge and Joel Cracraft, under the definition of a "phylogenetic species" (i.e., the concept of a species as an irreducible group whose members are descended from a common ancestor and who all possess a combination of certain defining or derived, traits), animal species now can differ by just 2 percent of their DNA to be considered separate.

Back in 1996, the world recognized half the number of species of lemur there are today. (Today there are more than 100 recognized lemur species. Advances in genetic technology have provided a much more detailed picture of the world's species and their health. These advances have also renewed debates about what it means to be a species, as ecologists and conservationists discover that many species that once appeared singular are actually multitudes. Smithsonian entomologist John Burns has used DNA technology to distinguish a number of so-called "cryptic species"–organisms that appear physically identical to members of a certain species, but have significantly different genomes. In a 2004 study, he was able to determine that a species of tropical butterfly identified in 1775 actually encompassed 10 separate species.

In 2010, advanced DNA technology allowed scientists to solve an age-old debate over African elephants. By sequencing the rarer and more complex DNA from the nuclei of elephant cells, instead of the more commonly used mitochondrial DNA, they determined that African elephants actually comprised two separate species that diverged millions of years ago. "You can no more call African elephants the same species as you can Asian elephants and the mammoth," David Reich, a professor in the department of genetics at the Harvard Medical School, a population geneticist and lead author on the study, told *Nature News* (Gilbert, 2010). What does it mean to be a species? Genetics is changing the answer.

In the wake of these and other paradigm-shifting discoveries, Mayr's original concept is rapidly falling apart. Those two species of African elephants, for instance, kept interbreeding as recently as 500,000 years ago. Another example falls closer to home: Recent analyses of DNA remnants in the genes of modern humans have found that humans and Neanderthals–usually thought of as separate species that diverged roughly 700,000 years ago–interbred as recently as 100,000 years ago.

So are these elephants and hominids still separate species? This isn't just an argument of scientific semantics. Pinpointing an organism's species is critical for any efforts to protect that animal, especially when it comes to government action. A species that gets listed on the U.S. Endangered Species Act, for example, gains protection from any destructive actions from the government and private citizens. These protections would be im-

David Emil Reich is an American geneticist known for his research into the population genetics of ancient humans, including their migrations and the mixing of populations, discovered by analysis of genome-wide patterns of mutations.

possible to enforce without the ability to determine which organisms are part of that endangered species.

At the same time, advances in sequencing techniques and technology are helping today's scientists better piece together exactly which species are being impacted by which human actions. "We're capable of recognizing almost any species [now]," says Mary Curtis, a wildlife forensic scientist who leads the genetics team at the U.S. Fish and Wildlife Service's Forensics Laboratory. She has a demonstrated history of working in US Federal wildlife law enforcement field and is skilled in Population Genetics and data analysis, Molecular Biology and Freshwater Fisheries Biology, Her lab is responsible for identifying any animal remains or products that are suspected to have been illegally traded or harvested. Since adopting DNA sequencing techniques more than 20 years ago, the lab has been able to make identifications much more rapidly, and increase the number of species it can reliably recognize by the hundreds.

"A lot of the stuff we get in in genetics has no shape or form," Curtis says. The lab receives slabs of unidentified meat, crafted decorative items or even the stomach contents of other animals. Identifying these unusual items is usually out of the reach of taxonomic experts using body shape, hair identification and other physical characteristics. "We can only do that with DNA," Curtis says. Still, Curtis, who previously studied fishes, doesn't discount the importance of traditional taxonomists. "A lot of the time we're working together," she says. Experienced taxonomists can often quickly identify recognizable cases, leaving the more expensive DNA sequencing for the situations that really need it.

Not all ecologists are sold on these advances. Some express concerns about "taxonomic inflation," as the number of species identified or reclassified continues to skyrocket. They worry that as scientists draw lines based on the narrow shades of difference that DNA technology enables them to see, the entire concept of a species is being diluted. "Not everything you can distinguish should be its own species," as German zoologist Andreas Wilting told the *Washington Post* in 2015 (Gebelhoff, 2015). Wilting had proposed condensing tigers into just two subspecies from the current nine.

The study reinforces evidence that tigers are perhaps the least diverse big cat in the world. It also supports a theory that there was a massive population decline after a super-eruption took place in Sumatra about 73,000 years ago, leaving only a single ancestor for all modern tigers from the South China area.

But in a field where one of the biggest goals is to preserve the diversity in tigers, convincing people that tigers aren't really that diverse can be a challenge. This is not the first time tiger taxonomy has been challenged, but earlier proposals have had trouble gaining ground due to a lack of evidence.

At the heart of the debate is a concept called "taxonomic inflation," or the massive influx of newly recognized species and subspecies. Some critics blame the trend in part on emerging meth-

Mary Burnham Curtis, expert Wildlife Forensic Scientist working in the US Federal wildlife law enforcement field. Skilled in Population Genetics and data analysis, Molecular Biology and Freshwater Fisheries Biology.

ods of identifying species through ancestry and not physical traits. Others point to technology that has allowed scientists to distinguish between organisms at the molecular level.

Other scientists are concerned about the effects that reclassifying once-distinct species can have on conservation efforts. In 1973, the endangered dusky seaside sparrow, a small bird once found in Florida, missed out on potentially helpful conservation assistance by being reclassified as a subspecies of the much more populous seaside sparrow. Less than two decades later, the dusky seaside sparrow was extinct.

CONCLUSION

The nature of species is controversial in biology and philosophy. Biologists disagree on the definition of the term 'species,' and philosophers disagree over the ontological status of species (ontology is the branch of philosophy that studies concepts such as existence, being, becoming and reality and includes the questions of how entities are grouped into basic categories and which of these entities exist on the most fundamental level).

A proper understanding of species is important for a number of reasons. Species are the fundamental taxonomic units of biological classification. The concept of species plays an important role both in and outside of biology. Within biology, species are the fundamental units of biological classification. Species are also units of evolution—groups of organisms that evolve in a unified way. Outside of biology, the concept of species plays a role in debates over environmental law and ecological preservation. Environmental laws are framed in terms of species and even our conception of human nature is affected by our understanding of species.

APPENDIX: A SUMMARY OF 26 SPECIES CONCEPTS

There are numerous species "concepts" (i.e., conceptions of "species") at the research and practical level in the scientific literature. (Mayden 1997) has listed 22 distinct species concepts along with synonyms. Authors have been added where they can be located in addition to Mayden's references, and instead of his abbreviations an attempt has been tried to give the concepts names, such as biospecies for Biological Species, etc. (following George 1956), except where nothing natural suggests itself. There have also been several additional concepts since Mayden's review, which is added here the views of Pleijel and Wu, and several new revisions presented in Wheeler and Meier (2000). Also added are some "partial" species concepts - the compilospecies concept and the nothospecies concept. Two phylospecies concepts are distinguished here that go by various

names, mostly the names of the authors presenting at the time (as in the Wheeler and Meier volume). To remedy this terminological inflation, they have been christened here as the Autapomorphic species concept and the Phylogenetic Taxon species concept.

1. AGAMOSPECIES

Synonyms: Microspecies, paraspecies, pseudospecies, semispecies, quasispecies, genomospecies (for prokaryotes Euzéby 2006) Principal authors: Cain (1954), Eigen (1993, for quasispecies) Specifications: Asexual lineages, uniparental organisms (parthenogens and apomicts), that cluster together in terms of their genome. May be secondarily uniparental from biparental ancestors.

2. AUTAPOMORPHIC SPECIES

See: Phylospecies Principal authors: Nelson and Platnick (1981); Rosen (1979) Specification: A geographically constrained group of individuals with some unique apomorphous characters, the unit of evolutionary significance (Rosen); simply the smallest detected samples of self-perpetuating organisms that have unique sets of characters (Nelson and Platnick); the smallest aggregation of (sexual) populations or (asexual) lineages diagnosable by a unique combination of character traits (Wheeler and Platnick 2000).

3. BIOSPECIES

Synonyms: Syngen, speciationist species concept Related concepts: Biological species concept, Genetic species, isolation species Principal authors: John Ray, Buffon, Dobzhansky (1935); Mayr (1942) Specifications: Inclusive Mendelian population of sexually reproducing organisms (Dobzhansky 1935, 1937, 1970), interbreeding natural population isolated from other such groups (Mayr 1942, 1963, 1970; Mayr and Ashlock 1991). Depends upon endogenous reproductive isolating mechanisms (RIMs).

4. CLADOSPECIES

Synonyms: Internodal species concept, Hennigian species concept, Hennigian convention Principal authors: Hennig (1966; 1950); Kornet (1993) Specifications: Set of organisms between speciation events or between speciation event and extinction (Ridley 1989), a segment of a phylogenetic lineage between nodes. Upon speciation the ancestral species is extinguished and two new species are named.

5. COHESION SPECIES

Synonyms: Cohesive individual (in part) (Ghiselin and Hull) Principal authors: Templeton (1989) Specifications: Evolutionary lineages bounded by cohesion mechanisms that cause reproductive communities, particularly genetic exchange, and ecological interchangeability.

6. COMPILOSPECIES

Synonyms: None Related concepts: Introgressive taxa Principal authors: Harlan (1963), Aguilar (1999) Specifications: A species pair where one species “plunders” the genetic resources of another via introgressive interbreeding.

7. COMPOSITE SPECIES

Synonyms: Phylospecies (in part), Internodal species (in part), cladospecies (in part) Principal authors: Kornet (1993) Specifications: All organisms belonging to an internodon and its descendents until any subsequent internodon. An internodon is defined as a set of organisms whose parent-child relations are not split (have the INT relation).

8. ECOSPECIES

Synonyms: Ecotypes Related concepts: Evolutionary species sensu Simpson, Ecological mosaics Principal authors: Simpson (1961); Sterelny (1999); Turesson (1922); Van Valen (1976) Specifications: A lineage (or closely related set of lineages) which occupies an adaptive zone minimally different from that of any other lineage in its range and which evolves separately from all lineages outside its range.

9. EVOLUTIONARY SPECIES

Synonyms: Unit of evolution, evolutionary group Related concepts: Evolutionary significant unit Principal authors: Simpson (1961); Wiley (1978); (1981) Specifications: A lineage (an ancestral-descendent sequence of populations) evolving separately from others and with its own unitary evolutionary role and tendencies (Simpson).

10. EVOLUTIONARY SIGNIFICANT UNIT

Synonyms: Biospecies (in part) and evolutionary species (in part) Principal authors: Waples (1991) Specifications: A population (or group of populations) that (1) is substantially reproductively isolated from other conspecific population units, and (2) represents an important component in the evolutionary legacy of the species.

11. GENEALOGICAL CONCORDANCE SPECIES

Synonyms: Biospecies (in part), cladospecies (in part), phylospecies (in part) Principal authors: Avise and Ball (1990) Specifications: Population subdivisions concordantly identified by multiple independent genetic traits constitute the population units worthy of recognition as phylogenetic taxa

12. GENIC SPECIES

Synonyms: none Related concepts: Genealogical concordance species, genetic species (in part), biospecies (in part), autapomorphic species (in part) Principal author: Wu (2001b; 2001a) Specifications: A species formed by the fixation of all isolating genetic traits in the common genome of the entire population.

13. GENETIC SPECIES

Synonyms: Gentes (sing. Gens) Related concepts: Biospecies, phenospecies, morphospecies, genomospecies Principal authors: Dobzhansky (1950); Mayr (1969); Simpson (1943) Specifications: Group of organisms that may inherit characters from each other, common gene pool, reproductive community that forms a genetic unit

14. GENOTYPIC CLUSTER

Synonyms: Polythetic species Related concepts: Agamospecies, biospecies, genetic species, Hennigian species, morphospecies, non-dimensional species, phenospecies, autapomorphic phylospecies, successional species, taxonomic species , genomospecies Principal author: Mallet (1995) Specifications: Clusters of monotypic or polytypic biological entities, identified using morphology or genetics, forming groups that have few or no intermediates when in contact.

15. HENNIGIAN SPECIES

Synonyms: Biospecies (in part), cladospecies (in part), phylospecies (in part), internodal species Principal authors: Hennig (1966; 1950); Meier and Willman (1997) Specifications: A tokogenetic community that arises when a stem species is dissolved into two new species and ends when it goes extinct or speciates.

16. INTERNODAL SPECIES

Synonyms: Cladospecies and Hennigian species (in part), phylospecies Principal author: Kornet (1993) Specifications: Organisms are conspecific in virtue of their common membership of a part of a genealogical network between two permanent splitting events or a splitting event and extinction.

17. LEAST INCLUSIVE TAXONOMIC UNIT (LITUS)

Synonyms: evolutionary group (in part), phylospecies Principal authors: Pleijel (Pleijel 1999; Pleijel and Rouse 2000) Specifications: A taxonomic group that is diagnosable in terms of its autapomorphies, but has no fixed rank or binomial.

18. MORPHOSPECIES

Synonyms: Classical species, Linnaean species. Related concepts: Linnean species, binoms, phenospecies, monothetic species, monotypes, types, Taxonomic species Principal authors: Aristotle and Linnaeus, and too many others to name, but including Owen, Agassiz, and recently, Cronquist (1978) Specifications: Species are the smallest groups that are consistently and persistently distinct, and distinguishable by ordinary means (Cronquist). Contrary to the received view, this was never anything more than a diagnostic account of species.

19. NON-DIMENSIONAL SPECIES

Synonyms: Folk taxonomical kinds (Atran 1990) Related concepts: Biospecies, genetic species, morphospecies, paleospecies, successional species, taxonomic species Principal authors: Mayr (1942; 1963) Specifications: Species delimitation in a non-dimensional system (a system without the dimensions of space and time, Mayr 1963)

20. NOTHOSPECIES

Synonyms: hybrid species, reticulate species Related concepts: Compilospecies, horizontal or lateral genetic transfer Principal author: Wagner (1983) Specifications: Species formed from the hybridization of two distinct parental species, often by polyploidy.

PHYLOSPECIES

Synonyms: Autapomorphic phylospecies, monophyletic phylospecies, minimal monophyletic units, monophyletic species, lineages Related concepts: Similar to internodal species cladospecies, composite species, least inclusive taxonomic units. Principal authors: Cracraft (1983); Eldredge and Cracraft (1980); Nelson and Platnick (1981); Rosen (1979) Specifications: The smallest unit appropriate for phylogenetic analysis, the smallest biological entities that are diagnosable and monophyletic, unit product of natural selection and descent. A geographically constrained group with one or more unique apomorphies (autapomorphies). There are two versions of this and they are not identical. One derives from Rosen and is what I call the Autapomorphic species concept. It is primarily a concept of diagnosis and tends to be favored by the tradition known as pattern cladism. The other is what I call the Phylogenetic Taxon species concept, and tends to be favored by process cladists.

21. PHYLOGENETIC TAXON SPECIES

See: Phylospecies Principal authors: Cracraft (1983); Eldredge and Cracraft (1980); Nixon and Wheeler(1990) Specifications: A species is the smallest diagnosable cluster of individual organisms within which there is a parental pattern of ancestry and descent (Cracraft); the least inclusive taxon recognized in a classification, into which organisms are grouped because of evidence of monophyly (usually, but not restricted to, the presence of synapomorphies), that is ranked as a species because it is the smallest 'important' lineage deemed worthy of formal recognition, where 'important' refers to the action of those processes that are dominant in producing and maintaining lineages in a particular case (Mishler and Brandon 1987).

22. PHENOSPECIES

Synonyms: Phena (sing. phenon) (Smith 1994), operational taxonomic unit (OTU) Related concepts: Biospecies, genetic concordance species, morphospecies, non-dimensional species, phylospecies (in part), phenospecies, successional species, taxonomic species, quasispecies, viral species, genomospecies (bacteria) Principal authors: Beckner (1959); Sokal and Sneath (1963) Specifications: A cluster of characters that statistically covary, a family resemblance concept in which possession of most characters is required for inclusion in a species, but not all. A class of organisms that share most of a set of characters.

23. RECOGNITION SPECIES

Synonyms: Specific mate recognition system (SMRS) Related concepts: Biospecies Principal author: Paterson (1985) Specifications: A species is that most inclusive population of individual, biparental organisms which share a common fertilization system

24. REPRODUCTIVE COMPETITION SPECIES

Synonyms: Hypermodern species concept , Biospecies (in part) Principal author: Ghiselin (1974) Specifications: The most extensive units in the natural economy such that reproductive competition occurs among their parts.

25. SUCCESSIONAL SPECIES

Synonyms: Paleospecies, evolutionary species (in part), chronospecies Principal authors: George (1956); Simpson (1961) Specifications: Arbitrary anagenetic stages in morphological forms, mainly in the paleontological record.

26. TAXONOMIC SPECIES

Synonyms: Cynical species concept (Kitcher 1984) Related concepts: Agamospecies, genealogical concordance species, morphospecies, phenospecies, phylospecies Principal author: Blackwelder (1967), but see Regan (1926) and Strickland et al. (1843) Specifications: Specimens considered by a taxonomist to be members of a kind on the evidence or on the assumption they are as alike as their offspring of hereditary relatives within a few generations. Whatever a competent taxonomist chooses to call a species.

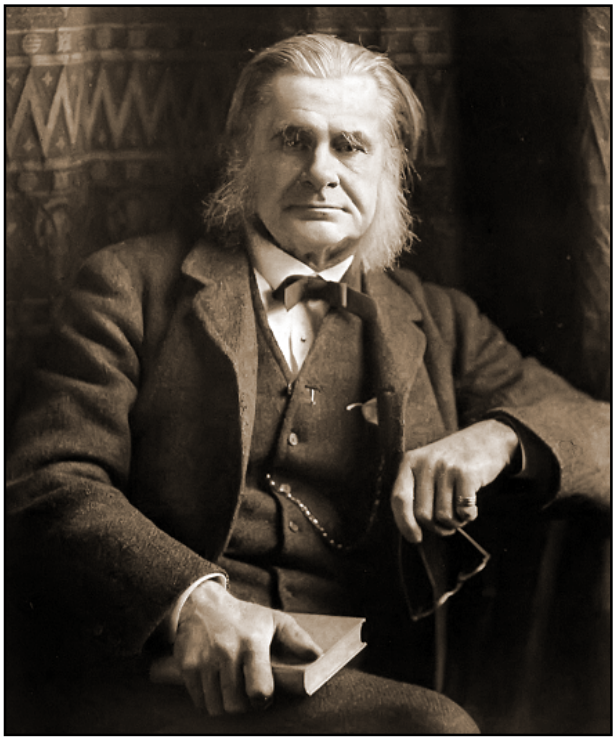
WALLACE, DARWIN AND THE SPIRITUALISM SCANDAL OF 1876

by Albert J. Klee, Ph.D.

(*Essays on Aquarium Hobby History*, November 22, 2014)

I became interested in this subject after reading a section called "Spiritualism and Evolution" in Tattersall and Névraumont's, book "Hoax" (see bibliography) because it involved of number of individuals I have written about previously in my two books. However the material was somewhat sketchy and I was looking for more detail and more information. Wikipedia was useless but I finally found two articles written by Richard Milner, an anthropologist and historian of science and a senior editor of Natural History Magazine at the American Museum of Natural History, New York City (see bibliography).

When it came to debating bishops, or lecturing on the new evolutionary biology, Charles Darwin preferred to send his "bulldog" and "publicist" Thomas Henry Huxley into the fray. Polemicist, surgeon ("too busy doing science" to ever practice medicine), zoologist, comparative anatomist, educator, and essayist, the bombastic Huxley enjoyed fighting for the new ideas. Huxley's protégé, in turn, became England's most influential biologist.



Thomas Henry Huxley (1825-1895).

Sir Edwin Ray Lankester (1847-1929).

His name, all but forgotten today, was Edwin Ray Lankester. He, too, was a zoologist, comparative anatomist, essayist, and educator—and for a decade (1898–1908) served as director of London's Natural History Museum.

For over 80 years, spiritualism enjoyed tremendous popularity in England, the U.S. and Europe. It attracted people with a wide spectrum of interests, but its major focus was on the possibility of communication with the dead. In the early 1870s Darwin's cousin and brother-in-law Hensleigh Wedgwood (his sister Emma married him in 1839) became a convert. Wedgwood (1803–1891) was a British etymologist, philologist, barrister and author of "A Dictionary of English Etymology." Wedgwood yearned to become a respected savant like Darwin, their cousin Francis Galton and Darwin's grandfather Erasmus, but a pair of swindlers, Charles Williams and Frank Herne, recognized that he was the most gullible of the clan. At their urg-

Hensleigh Wedgwood (1803-1891, Darwin's brother-in-law believed in Spiritualism.

ing, Wedgwood begged Darwin to come and see the self-playing accordions, levitating tables, automatic writing and glowing spirit hands at Williams's séances.

Darwin always managed to be too tired, too busy or too ill to attend but in January 1874, Darwin sent two close members of his circle to attend a séance with Williams. His friend Thomas H. Huxley was introduced as "Mr. Henry" (his middle name) and Darwin's son George, then 29 years old, went as well. Although bottles moved around and a guitar played by itself, the two concluded they had observed nothing but crude trickery. George, a budding astronomer, wrote that he was shocked to find his uncle Hensleigh's account of Williams's séances "so worthless." Later that year Darwin wrote to a newspaperman, urging him to expose Williams as "a scoundrel who has imposed on the public for so many years."

The following year Huxley's young laboratory assistant Edwin Ray Lankester decided to catch Williams and Herne in fraud—an act he knew would impress his heroes Darwin and Huxley. But after Huxley and George's visit, the medium became wary, avoiding anyone connected to Darwin's circle. Then, in April 1876, a tempting new target moved into Lankester's sights. A celebrated American psychic, "Dr." Henry Slade, had come to London "to prove the truth of communication with the dead." Slade was a trickster who plied his trade on both sides of the Atlantic. His specialty was slate writing, which involved a small chalkboard on which written messages from the Other Side would miraculously appear while it was hidden under a table. Having been caught out in New York scrawling messages with chalk held between his toes, as well as surreptitiously substituting boards,

Slade went to London in 1876 to try his luck. Unfortunately for him, some well-connected skeptics were lying in wait. Among them were Darwin, Huxley and Lankester. A highly practical man, Huxley actually had taught himself many of the

"Dr." Henry Slade (1835-1905), an American con man who plied his trade on both sides of the Atlantic.

Spiritualists' tricks. These included the curious ruse of snapping his toes inside his shoe to make rapping noises at varying volumes (he recommended rapping wearing thin socks and wide shoes).

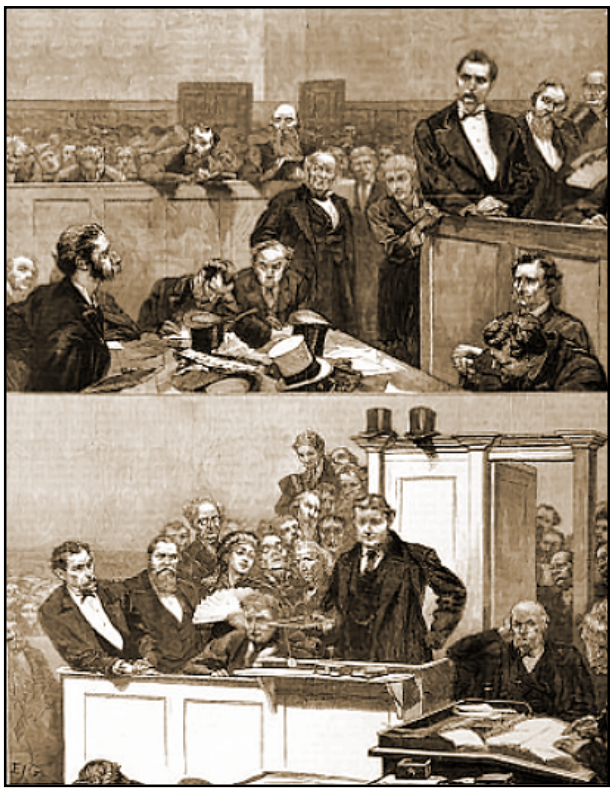
Lankester and his fellow medical student Horatio Donkin went to Slade's pretending to be believers. They paid the admission fee, asked questions of the spirits and received mysteriously written answers. Then, in the darkened room, Lankester suddenly snatched a slate out of Slade's hands, found the written answer to a question he had not yet asked, and proclaimed him "a scoundrel and an impostor."

The next day Slade and his partner, Geoffrey Simmonds, were in the hands of the police, charged with violating the Vagrancy Act, an old law intended to protect the public from traveling palm readers and sleight-of-hand artists. Throughout the fall of 1876, all London was abuzz over the Slade trial. The little courtroom was packed with Slade's supporters and detractors and 30 journalists, who spilled out into the street. The Times of London carried trial transcripts day after day.

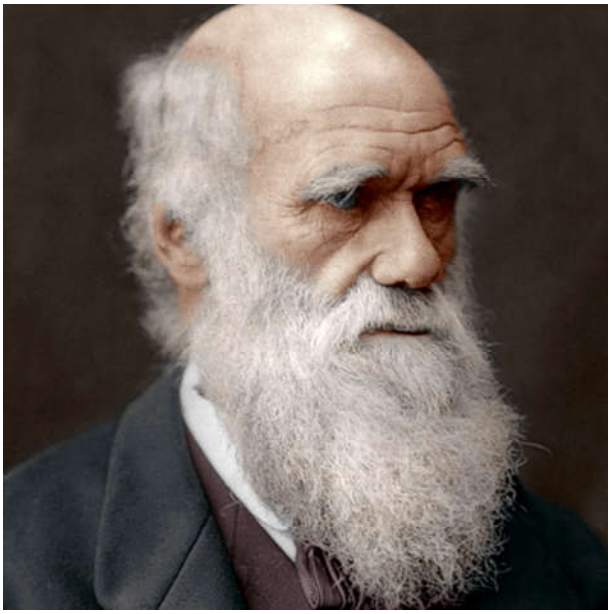
By hauling Slade into court as "a common rogue," Lankester would become the first scientist to prosecute a professional psychic for criminal fraud—an action Darwin thought long overdue. Although he was delighted at Lankester's attack on Slade, Darwin was distressed to learn that Alfred Russel Wallace, his friendly rival and co-discoverer of the theory of natural selection, was also a target.

The Slade trial was to become one of the strangest courtroom cases in Victorian England. Some saw it as a public arena where science could score a devastating triumph over superstition. For others, it was the declaration of war between professional purveyors of the "paranormal" and the fraternity of honest stage magicians. Arthur Conan Doyle, the zealous spiritualist whose fictional detective, Sherlock Holmes, was logic personified, characterized it as "the persecution [rather than prosecution] of Slade." But what made the trial unique was that the two greatest naturalists of the century ranged themselves on opposite sides. The "arch-materialist" Darwin gave aid and comfort to the prosecution, and his old friend Alford Lord Wallace, a sincere spiritualist, was to be the defense's star witness—making it one of the more bizarre and dramatic episodes in the history of science.

Wallace was respected as an author, zoologist, botanist, the discoverer of scores of new species, the first European to study apes in the wild and a pioneer in the study of the distribution of animals. But he constantly courted ruin by championing such radical causes as socialism, pacifism, land nationalization, wilderness conservation, women's rights and spiritualism. In addition to his classic volumes on zoogeography, natural selection, island life and the Malay Archipelago, he had written "Miracles and Modern Spiritualism," which lauded spirit-mediums. And he had just allowed a controversial paper on "thought transference" to be read at a meeting of the British Association for the Advancement of Science—touching off an uproar that led him to avoid scientific meetings for the rest of his life.



The trial of Henry Slade, the medium who was said to communicate with spirits by a slate board. Top sketch shows Mr G. Leis, counsel for the Prosecution and bottom image shows Professor E. Ray Lankester, giving evidence.



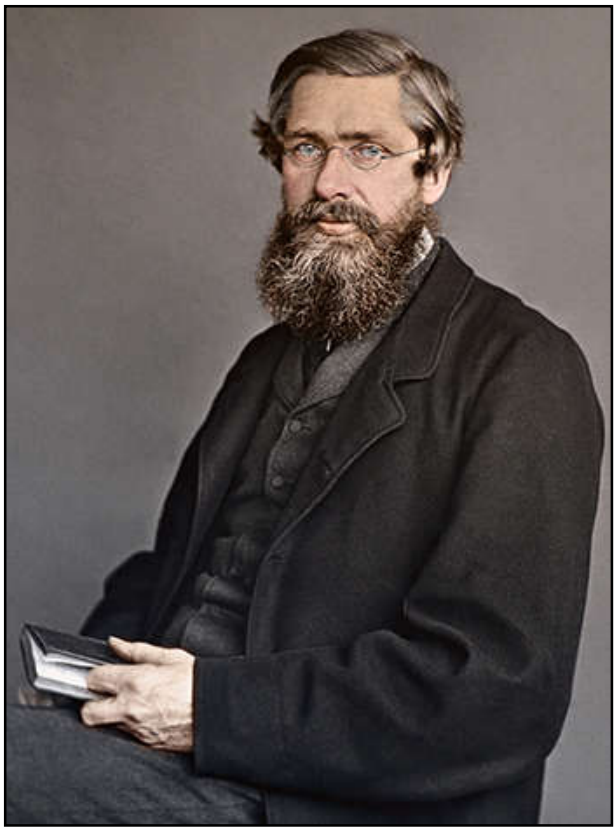
Charles Darwin (1809-1882).

Wallace wanted the best of both worlds. With insects or birds, he was even more rigorous than Darwin in applying the principle of natural selection, but he questioned its efficacy for humans. If early hominids required only a gorilla's intelligence to survive, Wallace asked, why had they evolved brains capable of devising language, composing symphonies and doing mathematics? Although our bodies had evolved by natural selection, he concluded, *Homo sapiens* has "something which he has not derived from his animal progenitors—a spiritual essence or nature… [that] can only find an explanation in the unseen universe of Spirit." Wallace's position did not stem from any conventional religious belief but from his long-standing interest in spiritualism: a melding of ancient Eastern beliefs with the Western desire to "secularize" the soul and prove its existence.

When Wallace published this view in 1869, Darwin wrote him: "I differ grievously from you; I can see no necessity for calling in an additional and proximate cause [a supernatural force] in regard to Man.... I hope you have not murdered too completely your own and my child"—meaning their theory of natural selection.

Darwin, whose beloved 10-year-old daughter Annie had died in 1851, had nothing but contempt for the "clever rogues" who preyed on grieving relatives. Yet he avoided saying so publicly—"On the Origin of Species" had stirred up enough controversies for a lifetime. Privately, he wrote Lankester an effusive letter of congratulations. Jailing Slade was a public benefit, he said, and insisted on contributing £10 to the costs of prosecution. (Under English law, the complainant paid court costs; £10 was a substantial sum, comparable to a month's wages for a workingman.)

As the trial got under way, the prosecutor announced that stage magician John Nevil Maskelyne was prepared to reproduce all the "alleged phenomena" that were observed at the séance. The judge, in turn, warned that performing magic slate tricks in court would prove nothing; the question was whether Lankester and Donkin had actually caught the defendants faking the alleged spirit writing. Both scientists turned out to be terrible witnesses; their observational skills, developed in anatomy and physiology labs, were useless in detecting fraud by professional cheats. As Huxley later noted, "In these investigations, the qualities of the detective are far more useful than those of the



Alfred Lord Wallace (1823-1913).

philosopher.... A man may be an excellent naturalist or chemist; and yet make a very poor detective."

Indeed, Lankester and Donkin apparently could not agree on anything much beyond their charge that Slade was an impostor. Did the medium use a thimble device for writing, or did he hold a pencil stub while his thumb was visible on the tabletop? Did he switch the blank slate for one that was previously written on? Was the table of ordinary construction, or did it have sliding bars and trick panels? The two could not establish when or how the writing had been done. Maskelyne's courtroom conjuring, in contrast, was perfect. In answer to a question about instant writing—and before the judge could stop him—he began scrubbing a blank slate with a wet sponge until writing appeared: "THE SPIRITS ARE HERE!" Then he wiped the slate clean and ran the sponge over it again.

Whenever the prosecutor could, he had Maskelyne slip in another slate trick until the judge finally barred them. The prosecutor then offered Slade two small slates joined by hinges and a hasp lock. Why not make writing appear inside the locked slates and convince the world? Slade replied he had been so pestered by such tests that Allie, his wife's spirit, had vowed never to write on a locked slate.

A chemist named Alexander Duffield was one of many witnesses for the prosecution. He said Slade had convinced him "that there could be established a sort of post office in connection with the 'other place.'" But now he had his doubts. Another witness testified that a few years earlier, in the U.S., someone had similarly snatched a slate from Slade in mid-séance and exposed him in fraud.

The high point of the trial was Wallace's appearance for the defense. His integrity and candor were known to all. When called, he said that he had witnessed the alleged phenomena but refused to speculate on whether the writings were caused by spirits. He considered Slade to be an honest gentleman, "as incapable of an imposture...as any earnest inquirer after truth in the department of Natural Science."

In his summation, Slade's lawyer argued that there was no real evidence against his client. No one had proved the table was rigged, and Maskelyne's demonstrations of how the trick *could* have been done were irrelevant. The writing's appearance before the corresponding question was asked proved nothing about its origin, and Lankester and Donkin could not agree on exactly what they had seen during the séance. Moreover, such an eminent scientist as Wallace should be considered at least as credible as young Lankester. The barrister concluded by invoking Galileo, remarking that innovative scientists who challenge the beliefs of their time are always vilified. His irony was not lost on the evolutionists.

John Nevil Maskelyne (1839 -1917) was an English stage magician and inventor of the pay toilet, along with other Victorian-era devices. His book "Sharps and Flats: A Complete Revelation of the Secrets of Cheating at Games of Chance and Skill" is considered a classic overview of card sharp practices. In 1914 he founded the Occult Committee, a group to "investigate claims to supernatural power and to expose fraud".

But nothing could save Slade. The judge said that he understood that spiritualism was "a kind of new religion" and did not wish to offend sincere believers. Still, the question before the court was whether Slade and Simmonds had fraudulently represented their own actions as paranormal phenomena. Concluding that he must decide "according to the well-known course of nature," the judge sentenced the defendant to three months' hard labor in the House of Corrections.

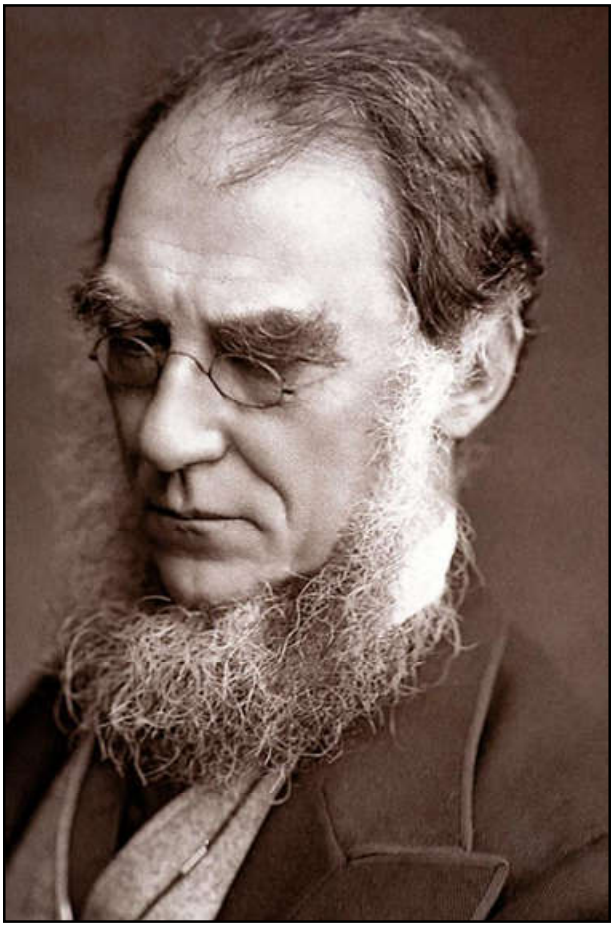
Slade, however, never served his sentence. On appeal, another judge ruled that the Vagrancy Act that prohibited palmistry was not applicable to claims of spirit writing. Slade and his partner fled England for Germany. Within a short time, Slade had convinced his landlord, a local conjurer, the chief of police and several prominent German scientists (including the physicist Johann Zöllner of the University of Leipzig) that he was in contact with spirits and various paranormal forces. When his act wore thin, he took to the road again. Eventually he wound up an alcoholic in a run-down New York boardinghouse, easy prey for tabloid editors who sent cub reporters to expose him one more time.

After the trial the controversy took a toll on participants other than Slade. In 1879 Darwin tried to drum up support for a government pension in recognition of Wallace's brilliant contributions to natural history. Wallace, he knew, had to earn his meager living by grading examination papers. But when Darwin wrote to his friend Joseph Hooker, director of Kew Gardens, the botanist refused to help. "Wallace has lost caste terribly," he replied nastily, "not only for his adhesion to Spiritualism, but by the fact of his having deliberately and against the whole voice of the committee" allowed the paper on mental telepathy at the scientific meetings. In addition, he thought the government "should in fairness be informed that the candidate is a public and leading Spiritualist!

Undaunted, Darwin replied that Wallace's beliefs were "not worse than the prevailing superstitions of the country"— meaning organized religion. Darwin and Huxley twisted a few more arms. Darwin personally wrote to Prime Minister William Gladstone, who passed the petition on to Queen Victoria. In the end, Wallace got his modest pension and was able to continue writing his articles and books; he died in 1913, at the age of 90.

In the years after the trial, Wedgwood and Darwin did not see much of each other. In 1878 a reporter for the journal *Light* had finally managed to unmask Charles Williams, the medium who had attempted to use Wedgwood to win over Darwin's family. When the journalist suddenly turned on the lights at a séance, Williams was found to be wearing a false black beard, phosphorescent rags and, as Darwin later put it, "dirty ghost-clothes."

"A *splendid* exposure," crowed Darwin when he read of it. But even then, his brother-in-law's faith remained unshaken; a few faked performances indicated only that the medium was having difficulty getting through to the other side and was under



Sir Joseph Hooker (1817-1911). Darwin tried to drum up support for a government pension for Wallace but Hooker declined because of Wallace's belief in Spirituality.

pressure not to disappoint his sitters. For Darwin, this was the last straw: "Hensleigh Wedgwood admits Williams is proved a rogue," he fumed, "but insists he has seen real ghosts [at Williams's séances]. Is this not a psychological curiosity?"

In 1880 Wedgwood sent Darwin a long handwritten manuscript: a spiritualist synthesis of science and religion. Would Darwin read it and perhaps suggest where it might be published? In a melancholy mood, Darwin sat down to reply to his cousin. He may have remembered the times Wedgwood had gone to bat for him many years before: he had helped persuade Darwin's uncle and father to let him go on the HMS *Beagle* expedition, and it was to his cousin that Darwin had once entrusted publication of his theory of natural selection.

"My dear Cousin," Darwin wrote, "It is indeed a long time since we met, and I suppose if we now did so we should not know one another; but your former image is perfectly clear to me." He refused even to read Hensleigh's paper, writing that "there have been too many such attempts to reconcile Genesis and science." The two cousins, who had once been so close, were now hopelessly estranged over the question of science and the supernatural.

That same year Lankester, now a professor of zoology, declined requests to continue ghostbusting. "The Spirit Medium," he wrote in an 1880 letter to the *Pall Mall Gazette*, "is a curious and unsavory specimen of natural history, and if you wish to study him, you must take him unawares…. I have done my share of the skunk-hunting; let others follow." As I have mentioned previously, he was later appointed director of the British Museum of Natural History.

Ironically, in 1912 Lankester, the nemesis of fakers was completely fooled by the Piltdown man hoax, one of the most notorious frauds in the history of evolutionary biology. For the next 40 years, scientists accepted the "ape-man" fragments, dug up about 25 miles from Darwin's home, as remains of the "missing link." Fired with enthusiasm for the Darwin-Wallace theory, Lankester and the younger generation of evolutionists uncritically embraced this fossil forgery.

Huxley, who died in 1895, knew full well that more than a few scientists were prone to develop their own irrationally held beliefs. While young, he had battled churchmen to establish the scientific approach to unraveling human origins but later quipped to an educator that "we or our sons shall live to see all the stupidity *in favor of science*"—a fitting prophecy of the Piltdown man. In *The Descent of Man*, Darwin himself had urged a skeptical approach to unconfirmed observations; he believed that accepting flimsy evidence is much more dangerous than adopting incorrect theories. "False facts are highly injurious to the progress of science, for they often long endure," he wrote. "But false views, if supported by some evidence, do little harm, as everyone takes a salutary pleasure in proving their falseness."

AQUARIUM ORNAMENTAL PLANT HISTORY

by Albert J. Klee, Ph.D.

(Essays on Aquarium Hobby History, April 8, 2022)

I have written much about the history of the aquarium, using as my definition of aquarium as any man-made container containing water with fish and/or plants. However, these writings mention very little about aquatic plants and so I plan to correct this in this essay. Discussions about aquatic plants in aquaria can involve many different aspects. In their historical context this is primarily food or religion but in this essay I am concerned with aquatic ornamental plants in the aquarium.

A.1 A BIT OF BOTANICAL NOMENCLATURE

Rules have been devised for the publication, validation and documentation of scientific names in order to ensure a unique name for every taxon. In defining taxonomic names for organisms, two primary sets of rules apply, depending on whether the species is zoological or botanical:

(1) International Code of Zoological Nomenclature (ICZN) and (2) The International Code of Nomenclature for Algae, Fungi and Plants, the latter being the set of rules and recommendations that govern the scientific naming of all organisms traditionally treated as algae, fungi or plants, whether fossil or non-fossil. Before 2011 it was called the International Code of Botanical Nomenclature (ICBN) and that is the abbreviation I will use in this essay.

Aquarists are more apt to be familiar with the ICZN rules than those of the ICBN. While there are many similarities between the two, there are some important differences. For instance:

According to the rules of ICZN, when a species is combined with a different genus, the name of the author of this new combination is not included in the scientific name. However, according to the rules of the ICBN the combination authors are included. For example:

(1) According to the ICBN the taxonomic name *Cucamis chysocomus* Shumacher, (1827) becomes *Rhaphiodiocystis chrysocoma* (Schumacher) C. Jeffrey (1962).

(2)According to the ICZN the taxonomic name *Bothynoproctiis portai* Straneo, 1941 becomes *Neotalis portai* (Straneo. 1941).

A tautonym is when the scientific name for a species is identical for both the genus and its specific names. While this is relatively common in zoology, in botany it is not allowed. For example, *Bison bison* is allowed in the ICZN but *Cabomba cabomba* would not be allowed in the ICBN.

The levels of classification hierarchy in the ICBN are rather specific: *kingdom, division* or *phylum, class, order, family, genus* and *species*. However, the levels of classification hierarchy in the ICZN do not go above the *superfamily*. Thus with regard to nomenclature, things are more complex than those in zoology. Because of this I will describe aquatic ornamentals mostly by their shapes and where they grow without their scientific nomenclature except for their Latin names.

A.2 ANGIOSPERMS

Angiosperms, also called flowering plants, are any of about 950,000 species of flowering plants, the largest and most diverse group within the kingdom Plantae. Angiosperms represent approximately ninety percent of all the known green plants now living. Aquatic plants are phylogenetically well dispersed across the angiosperms, but the fraction of aquatic species probably comprises less than two percent of the angiosperm species. Nevertheless, this two percent contains most of our aquatic aquarium plants. The term “angiosperm” is derived from the Greek words αγγειον (receptacle) and σπερμα (seed), and refers to those plants that produce their seeds enclosed within a fruit.

Angiosperms are classified in a single phylum: the Anthophyta. Modern angiosperms appear to be a monophyletic group, which means that they originate from a single ancestor. Figure 1 shows an angiosperm cladogram. A cladogram (from Greek clados "branch" and gramma "character")

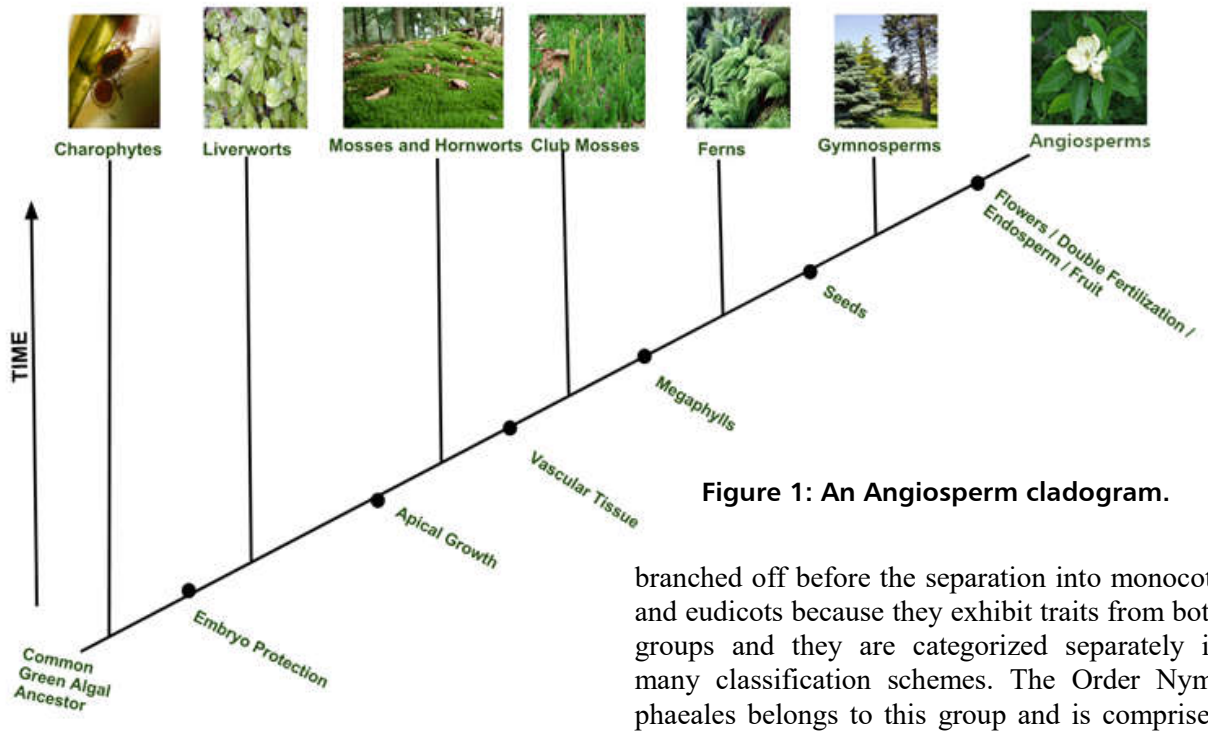

Figure 1: An Angiosperm cladogram.

is a diagram used in cladistics to show relations among organisms. A cladogram is not, however, an evolutionary tree because it does not show how ancestors are related to descendants, nor does it show how much they have changed, so many differing evolutionary trees can be consistent with the same cladogram. A cladogram uses lines that branch off in different directions ending at a clade, a group of organisms with a last common ancestor. Although traditionally such cladograms were generated largely on the basis of morphological characters, DNA and RNA sequencing data and computational phylogenetics, i.e., the application of computational algorithms, methods, and programs to phylogenetic analyses, are now very commonly used in the generation of cladograms.

Flowering plants are divided into two major groups; the monocots which include grasses and lilies, and the eudicots or dicots which form a polyphyletic group. Most common garden plants, shrubs and trees, and broad-leafed flowering plants such as magnolias, roses, geraniums, and hollyhocks are dicots. Basal angiosperms however are a group of plants that are believed to have branched off before the separation into monocots and eudicots because they exhibit traits from both groups and they are categorized separately in many classification schemes. The Order Nymphaeales belongs to this group and is comprised of the water lilies, lotus, cabomba and similar plants (Figure 2). All these species thrive in freshwater biomes (i.e., regions of the world with similar climate, e.g., weather, temperature, animals and plants, and have leaves that float on the water surface or grow underwater.

Water lilies are particularly prized by gardeners, and have graced ponds and pools for thousands of years. They live as rhizomatous aquatic herbs in temperate and tropical climates around the world. The family contains five genera with about 70 known species. During the initial growth period, the water lilies have strong roots while roots but will gradually thin themselves so that the plant

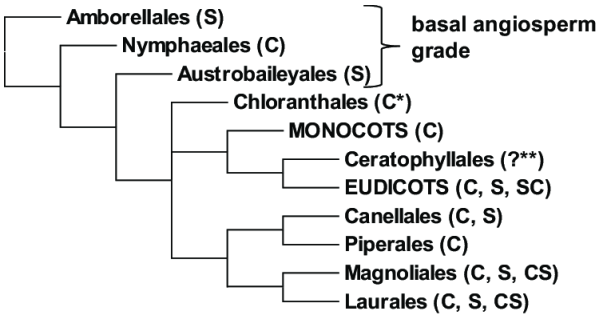

Figure 2: A simplified classification of the Dicots.

can easily absorb the nutrients from the soil. They save energy because they don't need to grow elaborate root structures or vascular tissues. Also, they don't need this additional support because the water keeps them afloat. Thus, water lilies don't need adaptations like strong woody stems and deep anchoring roots.

The angiosperm life cycle is dominated by the sporophyte stage (in plants and certain algae, this is the nonsexual phase in the alternation of generations—a phenomenon in which two distinct phases occur in the life history of the organism, each phase producing the other; the sexual phase is the gametophyte). Double fertilization is an event unique to angiosperms. One sperm in the pollen fertilizes the egg, forming a diploid zygote, while the other combines with the two polar nuclei, forming a triploid cell that develops into a food storage tissue called the endosperm.

An ancient Chinese fossil of a flower adds to the growing body of evidence that angiosperms originated underwater. An article by Ge Sun and his colleagues (Ge Sun *et al.*, 2002) provides the first fossil evidence to answer the question that has long puzzled scientists. It suggests that flowering plants evolved in parallel with non-flowering plants, rather than evolving from them.

"This is the first time we've got a completely reconstructed fossil plant which helps explain the evolution of flowering plants," comments Dr. Mark Clements of the Australian National Botanic Gardens in Canberra. Sun and his team analyzed recently discovered fossilized remains of a plant named *Archaefructus sinensis* and discovered that it lived at least 125 million years ago and was most likely an underwater plant. Farmers in China stumbled across the fossil and passed it onto the researchers.

Although it had no petals, said co-author Dr. David Dilcher (2010—present, Professor Emeritus , Department of Geology and Department of Biology, Indiana University), it had seeds enclosed in immature fruit, a trait separating flowering plants from all other seed plants. The researchers claim that the new fossil, together with fossil fragments of a related species *Archaefructus liaoningensis* discovered nearby four years ago, form the earliest known family of flowering plants, a now extinct sister group to other flowering plants.

Dr. Dilcher also studied *A. liaoningensis* but at the time was unable to locate where the plant fitted in the fossil record because of the fragmented nature of the fossils. However the *Archaefructus sinensis* fossil was so complete the researchers were able to construct the whole plant and then work out where it fitted into the evolutionary tree.

The plant was about 20 inches high, with long, thin, curving stems, which suggests it would have needed water for support, the researchers say. It probably stretched up to the surface, where its pollen and seed organs extending above the water. It is likely the seeds dispersed in the water and floated up along the shore and germinated in shallow water. Clements said that the new fossil material supports evidence from the morphology and genetics of living plants, such as the waterlily. "There's been a long-standing assumption that flowering plants came from non-flowering plants," he said. "We tend to think in linear terms but nature isn't necessarily like that." Thus, aquatic plants were among the earliest angiosperms (flowering plants). Fossil evidence places an early form of waterlily and the *Archaefructus sinensis* mentioned above at 125-115 million years BC.

Figure 3: Fossil of *Archaefructus liaoningensis*, one of the earliest known genera of flowering plants.

B. MACROPHYTES

Aquatic plants grow in wetlands, shallow lakes, rivers and streams. They are also referred to as hydrophytes or macrophytes to distinguish them from algae and other microphytes. They can be seen with the naked eye and include large algae, flowering plants and ferns.

Macrophytes are often classified according to their growth form: (a) submerged plants with roots, (b) floating plants with roots, (c) exclusive floating plants, and (d) emergent plants (Figure 4). Most macrophytes are attached to the water bottom with their roots in the sediment but some are free floating with their roots floating in the water beneath them. The macrophytes that have their roots in the sediment can be submerged, with all their parts under the water, or emergent, with some of their structures above the water. Some submerged macrophytes have leaves or flowers that come out of the water for only a short period of time. Emergent macrophytes are often in the transitional zone, the area along the shoreline between the land and the water.

This classification enables to transfer findings to general principles applicable to other species with a similar growth form (O'Hare 2015). The underground parts are used to anchor the plant in the soil to prevent uprooting (Sand-Jensen 1998) as well as for the uptake of nutrients from the soil. Plant parts rising above the water level can be used to produce flowers (O'Hare 2015) and the stems of emerged vegetation have often air channels to transport gases from the leaves to the submerged parts. The submerged leaves are often long and thin with a high surface to volume ratio, which increases light interception and gas exchange (Bloemendaal 1988). This specific shape also enables streamlining with high flow velocities (Sand-Jensen and Pedersen 2008; Schoelynck et al., 2013). Macrophytes growing in rivers developed two distinct strategies to cope with the hydrodynamic forces they encounter in rivers: avoidance versus tolerance strategy (Puijalon et al., 2011). The first strategy is characterized by a high flexibility of the plants which can bend with increasing flow velocities and as such maximally reduce the drag force they feel frim the flowing water. They also don't need to invest much energy in strength tissue (e.g. lignin). Plants with a tolerance strategy however, are mainly built of stiff and strong tissue with a high tensile force. Consequently they have less capacity to bend and therefore experience high drag forces (Coops and VanderVelde, 1996; Puijalon et al., 2011)

In lakes and rivers, macrophytes provide cover for fish, substrate for aquatic invertebrates, produce oxygen, and act as food for some fish and wildlife. Macrophytes are primary producers and are the basis of the food web for many other organisms. One of the most important plants of the world is rice (and an aquatic!) was domesticated in 4000 years BC, based on evidence in Thailand. The value of many aquatic plants as food cannot be underestimated but the subject here is their ornamental history.

Figure 4: A classification of macrophytes according to their growth form: (a) submerged plants with roots, (b) floating plants with roots, (c) exclusive floating plants and (d) emergent plants. (Figure from Schoelynck, 2011).

C.1 EARLY HISTORICAL REFERENCES TO ORNAMENTAL PLANTS

The question sometimes arises, are the waterlily and lotus the same? *Nelumbo nucifera*, also known as Indian lotus, sacred lotus or simply lotus, is one of two extant species of aquatic plants in the family Nelumbonaceae. It is sometimes colloquially called a waterlily, though this more often refers to members of the family Nymphaeaceae. The biggest difference between the waterlily (*Nymphaea* species) and lotus (*Nelumbo* species) is that the flowers and leaves of the waterlily grow on the surface of the water while the leaves and flowers of the lotus grow above water. The lotus also grows up to 6 feet tall, while the waterlily is only 8 inches tall. Also, the seedpod of *Nelumbo* is very distinctive. The waterlily has the typical center of most flowers, that is, the pistil and stamens are placed there. At the same time, the lotus has a ring of stamens surrounding the pistil at the summit of the ovary) in the middle of the flower that looks quite unusual and gives some decorative value.

The "lotus," most likely *Nymphaea caerulea* and *Nymphaea lotus*, appears in ancient Egyptian hieroglyphics as early as the First Dynasty (2950-2770 BC). Legends, myths, art and physical evidence bespeak its importance in ancient Egyptian culture and religion. How and when the lotus *Nelumbo nucifera* reached Egypt is not really known, but the Greek historian Herodotus wrote of its presence there in the fifth century BC.

The earliest planned gardens which included ponds were probably in Egypt, documented as early as 2800 BC. Decorative ponds and fountains were a major feature in gardens of the Middle Eastern civilizations of Mesopotamia, stimulated by the need for irrigation canals. The design tended to include four water features in the form of a cross, thought to stem from the four rivers of the Garden of Eden and the concept of "flowing to the four corners of the earth." The later Persian and Islamic empires greatly influenced garden design in such nations as Spain and India.

Hinduism had some of its roots in Mesopotamian civilizations as well as in the Indus, where the native lotus *Nelumbo nucifira* was and is today a major symbol in religion. Though its cultivation is not mentioned, we can surmise that it was featured in many gardens. Buddhism, which developed in part from Hinduism in India, also symbolized the lotus and made its way to China via the Silk Road.

Lotus seeds were found as a part of the Hemudu Culture in ancient China as long ago as 5000 BC and presumably were native to that region. Chinese poetry from the Zhou Dynasty (1122-256 BC) speaks of the lotus. The Imperial Gardens developed during the Han Dynasty (from 206 BC) in China are the first we can find noted for water features.

At about this same time, interest in plants was growing in Greece, though the Greeks were not known for ornamental gardens. The philosopher and botanist Theophrastus wrote "De Historia Plantarum" ("A History of Plants") and "De Causis Plantarum" ("About the Reasons of Vegetable Growth"). Though it's difficult to tell which plants he was writing about, he can be considered the first botanical taxonomist.

Roman gardens were largely utilitarian though the gardens of the affluent during the Roman Empire assimilated Islamic design, the use of fountains in particular. The collapse of the Roman Empire signaled a virtual end to ornamental gardening in Western Europe until the Islamic conquest of Spain in the eighth century. The pools and fountains of the Alhambra are major examples of that influence as is the Taj Mahal in India. In 552, Buddhism was introduced to Japan, en-

Figure 6: Theophrastus (c371-c287 BC).

hancing the incorporation of water and the lotus in Japanese garden design. Even earlier water was an important element. The lotus first appeared in the art and/or architecture of Japan in the seventh century.

From the eleventh to the thirteenth centuries, Crusaders brought back from the Middle East a desire to create ornamental gardens with water features. The Renaissance brought with it a resurgence of formal gardens in Europe, in Italy especially. Baroque gardens of the seventeenth century included Versailles.

C.2 THE GOLDEN AGE OF ORNAMENTAL AQUATIC PLANTS

The seventeen hundreds have been called the Golden Age of Botany, partly because wide exploration of exotic lands provided material for a growing group of scientists to study and partly because of Carl Linnaeus, whose "Species Plantarum" established the system of nomenclature and basis of taxonomy used today. In this book," Linnaeus named *Nymphaea alba* and *Nymphaea lotus*.

C.2.1 JOSEPH PAXTON

In the late eighteenth and early nineteenth centuries, a flurry of plant species was sent to Europe from around the world, heightening interest in waterlilies and ponds. News of the successful cultivation and flowering of *Victoria amazonica* by Joseph Paxton at Chatsworth in England in 1849 spread far and wide. Sir Joseph Paxton (1803-1865) was an English gardener, architect, engineer and Member of Parliament, best known for designing the Crystal Palace. In the early 1830's Paxton began experimenting with glass houses, which were to be the forerunners of green houses. He designed constructions with the exact angles to make optimal use of the morning and evening sun. In 1836, the first *Victoria amazonica*, a large waterlily was sent to England, but they would not grow and not flower so one seedling was sent to Paxton. Under his observation, his gardeners managed to grow the plant successfully and got it to flowering not much later. Since it continued growing, Paxton had to build another, much larger green house, later known as the Victoria Regia House. His experimentation resulted in a glass

Figure 7: Sir Joseph Paxton (1803-1865).

Figure 8: *Nymphaea hybr. Ortiesii* (*Ortgiesiano -rubra*) from Flore des serres et des jardins de l'Europe (Gand, L.van Houtte, 1852-1853).

house that later depicted a great inspiration for his famous Crystal Palace. His design was the first to make use of the invention of the cast plate glass method in 1848, which made it possible to cheaply produce large sheets of glass strong enough for construction.

This set the stage for the first waterlily hybrids to be made. The first generally accepted as a true hybrid was *N. 'Ortgiesiano-rubra'* by Eduard Ortgies at the Van Houtte nurseries in Belgium and the second was *N. 'Boucheana'* by Carl Bouché in Germany. Both of these were night blooming tropicals, created in 1852. William T. Baxter at Oxford Botanic Garden in England introduced a hybrid day blooming tropical, *N. 'Daubenyana'*, possibly as early as 1851, named for Dr. Charles Daubeny.

Figure 9: Eduard Ortgies (1829-1916).

Figure 10: Charles Antoine Lemaire (1800-1871).

C.2.2 CHARLES ANTOINE LEMAIRE

Charles Antoine Lemaire (1800-1871), was a French botanist and botanical author, noted for his publications on Cactaceae. It took an article by Lemaire about *Nymphaea devoniensis*, which appeared in the Belgian publication *Le Jardin Fleuriste* in 1854, to inspire a Frenchman to explore the potential of hybridizing waterlilies. Joseph Bory Latour-Marliac (1830-1911) was a

Figure 11: Joseph Bory Latour-Marliac (1830-1911).

French lawyer and horticulturalist noted for breeding waterlily hybrids. Latour-Marliac founded a waterlily nursery at Le Temple-sur-Lot in 1875. A display of his plants at the Exposition Universelle of 1889 in Paris attracted the attention of the painter Claude Monet who then obtained water lilies for his garden in Giverny from Latour-Marliac. Though much of the cultivation and study of aquatic plants was going on in England, Belgium and Germany, it was Latour-Marliac who, at the turn of the twentieth century, created hardy waterlily hybrids that set the standard for all who followed.

C.3 PONDS AND WATERLILIES IN AMERICA

Interest in ponds and waterlilies spread to America where Edmund Sturtevant, William Tricker and James Gurney led the way, and Henry S. Conard published his landmark monograph, The Waterlilies, in 1905. George Pring soon made Missouri Botanical Garden the aquatic Mecca of the United States and in the 1930's Martin E. Randig and Otto Beldt introduced their first waterlilies.

C.3.1 EDMUND STURTEVANT

Edmund Sturtevant established the first aquatics nursery in the United States in Bordentown, New Jersey, in 1876, with its first catalog published in 1881. Sturtevant developed a large collection of species and hybrid waterlilies from around the world and was, in many cases, the first to introduce them in America. His tropical night blooming hybrid *N. 'Sturtevantii'* was introduced in 1884 and is still in cultivation today. Sturtevant was fortunate in owning a sheltered millpond and so was able to get even quite tender plants to bloom in quantity. He received seeds of *Victoria amazonica* from Edward S. Rand Jr., in Para, Brazil. The flowers started out white but turned crimson over time. Sturtevant found that slashing the seeds improved the rate of germination.

C.3.2 WILLIAM TRICKER

Figure 12 Edmund D. Sturtevant (1842-1898).

Figure 13: Charles William Brett Tricker (1853-1916).

The firm of William Tricker is still very active today in Independence, Ohio, though it is no longer in family hands. The first William, whose complete name was Charles William Brett Tricker (1853-1916), was born into a gardener's family in England and became an apprentice at the Royal Botanic Gardens in Kew. When he immigrated to the United States, he initially worked for Henry Dreer in Philadelphia. He eventually established two aquatic nurseries of his own in New Jersey, the first one in 1892. Tricker's youngest son, Charles, took over the business in 1916 after William died.

William Tricker became prominent when he differentiated *Victoria cruziana* from *V. amazonica* in the early 1890s. In 1897, he published a book about the care and culture of water lilies: *The Water Garden.* Perry Slocum commented that he had learned how to raise water lilies from reading this comprehensive and authoritative book. Tricker is known for several excellent cultivars. One was *Nymphaea* 'Blue Beauty', a name chosen by the American Committee on Nomenclature because it was considered to be identical with Henry Conard's blue 'Pennsylvania', introduced at about the same time. Tricker had named his cultivar 'Pulcherrima'.

C.3.3 JAMES GURNEY

Born in Newport Pagnell, Buckinghamshire, England, October 12, 1831, James Gurney (1831-1920) learned gardening from his father, and as a young man received an appointment as a gardener at the Royal Botanic Garden, Kew. He was in charge of the aquatics section. The first *Victoria amazonica* at Kew was under his care and he was present when Queen Victoria, accompanied by, among other royals, the French president (later Napoleon III), went to view the first flowering.

Gurney was appointed to a Royal Commission going to Africa for botanical research Circumstances prevented him from leaving with the group which saved his life, as all of those who went died. Perhaps this is why he decided at age 36 to move to the United States, planning to settle in California. On the way there while staying in St. Louis, he heard that an epidemic was raging on the west coast and so elected to remain in St. Louis. He was short of funds and needed employment. The proprietor of his hotel suggested he see Henry Shaw, who was starting a garden outside the city.

Shaw was a businessman who had found great success in St. Louis. One of his many real estate acquisitions was a large tract of land southwest of the city where he built a country home. Shaw traveled widely and in 1851, he visited the Royal Botanic Gardens at Kew, the Crystal Palace and Chatsworth. He returned home determined to create a garden on his property equal to Kew. In 1859 he opened "Shaw's Garden" to the public. The same year, he made a will that would create the Missouri Botanical Garden (MBG) as a charitable trust upon his death.

In 1867 Shaw hired Gurney as his head gardener.

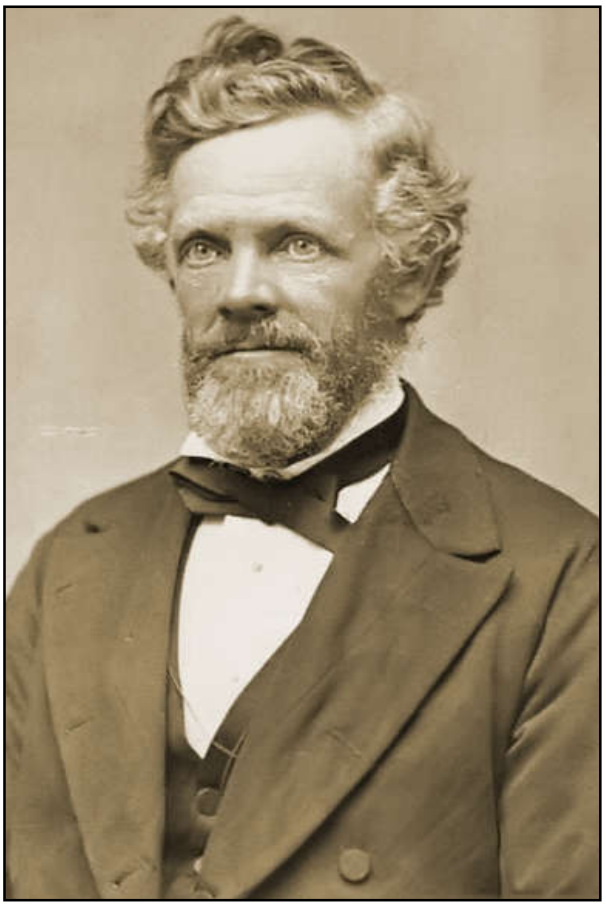

Figure 14: James Gurney (1831-1920).

Figure 15: Back in the early 20th century, working people were only free to go to the Park at night. This is why James Gurney concentrated on developing night flowering waterlilies. The Park was illuminated by bright arc lights atop tall poles.

It turned out they had been born only a few miles apart in England, possibly contributing to their lifelong friendship. Gurney was instrumental in the major changes made to the Garden in subsequent years. He was also responsible for the concepts and design of Shaw's other gift to the city of St. Louis, Tower Grove Park. The Park was first authorized by a state law passed in 1867, and came into existence in 1868, when Shaw conveyed the land, approximately 300 acres, to the city.

Gurney's idea of a park was that it be walled in with green, tall trees and shrubs, so that it would become a place of restfulness, solace and spirituality, without external distractions. He personally planted or helped to plant nearly every tree in Tower Grove Park, though Henry Shaw was deeply involved. Gurney became the Park's Superintendent when Shaw died in 1889, all the while retaining his position with the MBG and its *Shaw School of Botany* until 1903 when he began devoting full time to Tower Grove Park.

Aquatic plants, especially waterlilies, remained Gurney's first love. He was instrumental in making waterlilies an important feature of Tower Grove Park. He became well known as a specialist in their cultivation and hybridization. Working almost exclusively with tropical night bloomers, his earliest cultivar was *N. 'Frank Trelease'*, named for the son of then MBG Director William Trelease. The next were *N. 'Stella Gurney'* (a day blooming "star" lily named for his daughter-in-law), *'James Gurney, Junior'*, *'Rufus J. Lackland'* and *'D.R. Frances'*. A number of others were later described by B.C. Berry in the *MBG Bulletin*. These include *N. 'B.C. Berry'*, *'C.E. Hutchings'*, *'Emily Grant Hutchings'*, *'H.C. Haarstick'*, *'J.S. Walsh'*, and *'Tulipifera'*.

A Victoria was first grown in St. Louis by Gurney at the MBG in 1894, in a special heated pool. The next and subsequent years Victorias were also grown in a heated pool at Tower Grove Park which had better lighting for evening display. Attendance increased dramatically in those first years as residents flocked to see the massive water platters. On Gurney's death, a former student of his at the MBG, Professor A.T. Erwin, was quoted in the *MBG Bulletin*: "The job of head gardener often included about everything - time-

Figure 16: Henry S. Conard (1874 - 1971).

keeper, label writer, foreman, and what not. Careful, methodical, always on the job, courteous, and even-tempered even under trying conditions, the work of Mr. Gurney deserves an important place in the early day history of the Garden and Tower Grove Park, and the Garden pupils of his day remember his labors in their behalf with reverence and appreciation."

C.3.4 HENRY S. CONARD

Henry Shoemaker Conard (1874-1971) was a native of Pennsylvania who earned his B.S. and M.A. degrees at Haverford College and a Ph.D. at the University of Pennsylvania. As a Senior Harrison Fellow in Botany at the University of Pennsylvania, four years of study led to the publication of his landmark monograph on the genus *Nymphaea*, The Waterlilies, by The Carnegie Institution of Washington in 1905. In 1906 Conard joined the faculty of Grinnell College in Iowa as professor of botany. There he gained international recognition as an authority on mosses and waterlilies. He was honored by the *Botanical Society of America* on its 50th anniversary as a "taxonomist, morphologist, mycologist, ecologist, bryologist...and above all a beloved teacher." He retired to Florida in 1944, where he continued his research and publishing until his death in 1971 at age 97.

C.3.5 GEORGE PRING

George Henry (Harry) Pring (1885-1974), was an English-born horticulturist, plant collector and superintendent of Missouri Botanical Garden. Pring was an expert on orchids and an early and successful breeder of tropical waterlilies. He was born in Devon, but grew up near the Royal Botanic Gardens, Kew, where he began his horticultural training aged 14. At 19 years old he was permitted, thanks to his aptitude and enthusiasm, to join the two-year Kew training program at the Queen's School, although rules stipulated that students should be over 21. Completing the course, he joined Missouri Botanical Garden in 1906, where he remained employed for 63 years, shaping parts of the garden including its orchid collection and waterlily pools.

It was in the early part of the 20th century that MBG began research programs in tropical climes, seeking to catalogue the diverse species in Central and South America and beyond. George Pring was one of those sent to remote regions to amass dried specimens for the Missouri herbarium. His

Figure 17: The Mrs. George Pring lily, Introduced by the hybridizer of the Missouri Botanical Garden, George S. Pring and was awarded the silver medal in 1922 by the *Society of American Florists*.

Figure 18: *Nymphaea* 'Mr. Martin E. Randig' (Randig, 1939), a cultivar in the tropical day-blooming group of waterlilies, flowering in the Missouri Botanical Garden.

first plant collecting trip was made in 1923 to Colombia and Panama, where he established a tropical station for MBG. He returned with thousands of plants, including many living orchids, and met the orchid collector Charles Powell in the Panama Canal Zone. Powell later donated his impressive selection of plants to MBG. Over the course of Pring's career, a world-class orchid collection of more than 50,000 plants was amassed at Missouri, which hosted the first World Orchid Congress in 1954, chaired, of course, by Pring.

In 1907, Pring went home to see his family, meeting his future wife on the boat from America. He married Isabelle McAdie (known as Belle) three years later and together they had four children. Belle Pring also played a role at MBG, bringing in a team of volunteers to give public tours of Tower Grove House, home of the garden's founder, Henry Shaw.

As well as the fruits of his collecting trips, Pring left a legacy of fascinating hybrid water lilies. He first cross-pollinated water lilies in 1912 and went on to introduce a host of new cultivars. His creations, many of them firsts in the field, were so impressive that larger ponds had to be installed at MBG to showcase them. Pring wrote about horticulture for many popular publications and also hosted a radio show for gardeners. He collaborated on several gardening books and served as president of various plant societies, often giving lectures on horticultural topics. He was also a key consultant in the design of the lily pools at the Longwood Gardens of Pennsylvania.

C.3.5 MARTIN RANDIG

Martin E. Randig started his San Bernardino CA nursery in 1918 at 21 years of age. He specialized in growing water lilies and orchids. Starting with tropical waterlily species, (particularly color forms of Nymphaea capensis, var. zanzibariensis), he developed many hybrids which he exhibited in California state and county fairs in the 1930's. Randig consistently won first prize for the best collection of waterlilies. He won the gold certificate of merit for his display at the San Francisco's world fair, and Special recognition for new hybrids at the New York World Fair.

When the United States entered World War II, Randig put aside his hybridizing experiments to enter war work. All his tubers were covered with slightly moist sand and stored in sealed metal cans. After the war, he discovered that many of the cans had rusted, allowing mice to chew them open and eat the tubers. Nevertheless, he resumed his hybridizing starting with the few remaining tubers until after 12 years he had sufficient plants to introduce them to the public. He asked Ted Uber of Van Ness Water Gardens to utilize a separate page of his catalogue for the new waterlily introductions. Even after this momentous event, Randig continued his hybridizing and introduced new named varieties.

After his death, Mrs. Randig invited Ted Uber to select some waterlilies among the remaining stock that showed promise for subsequent introduction. This, Mr. Uber did, and after increasing the stock, introduced 5 more hybrids, one of which he named after Randig. The total number of named waterlily hybrids attributed to Martin Randig is 28.

The story of Ted Uber (1908-2007) is unusual. He was a master aluminum craftsman with a thriving business in metal objects for the house when the Korean War reduced the supply of aluminum for nonmilitary purposes to a trickle. In order to survive, Ted became a teacher in industrial arts at a local high school for a time. Things looked up when his cousin Edith Van Ness asked him to take over her water lily business in Upland, California. He accepted. The supply of aluminum subsequently returned to prewar levels, and he picked up his former work again, alternating between the two lines of business.

Randig consigned amazing new flowers to Van Ness, such as 'Afterglow' and 'Green Smoke'. Gardening reporters quickly found out about them and featured them in magazine articles. This boosted sales very effectively. About fifteen cultivars can be attributed to Randig. Uber's son William also bred water lilies of his own. His contribution to water gardening was gratefully acknowledged by Louella Uber in the March1987 Issue of The Water Garden Journal, Van Ness Water gardens Past, Present and Future "We owe much of our success to my friendship with Mr. Randig. His new introductions with their many shades and colors put Vans Ness Water Gardens on the Map." One of his lilies, 'Evelyn Randig," was not named for 10 years until the birth of his daughter Evelyn. Randig was inducted into the Hall of Fame in 1992 at the Houston Texas Symposium.

D.1 THE FLAT GLASS HISTORY OF AQUATIC ORNAMENTAL PLANTS

I have ended my chronical history of water lilies even though it overlaps the introduction of the aquatic ornamental plants that that came into vogue with the flat sided glass aquaria that appeared in the mid-eighteenth century. Prior to this, the aquarium was an in-ground container with its top near the surface of the water. This meant that submerged plants where all of their parts were under the water could not be observed; only emergent plants—which usually surrounded the border—or floating plants could be viewed from above. In other words, only the rooted submerged plants were favored in the glass-sided aquarium (although some floating plants were used for special purposes).

For example, the following plant genera are listed by Linnaeus as examples under "AQUARIUM PALUSTRA" (marsh ponds) in his *Hortus Upsaliensis, (Linnaeus, 1742)***:** *Acerus, Alisma, Butomus, Cyperus, Erigeron, Eriophora, Funcus, Iris, Phellandrium, Scheuchzeria, Scirpus, Shoenus, Sisymbrium, Sium, Sparganium, Triglochi*. Under "AQUARIUM FLUVIATILE" (river ponds) the following were listed: *Caricum, Hippuris, Hottonia, Myriophyllum, Potamogeton, Sagittaria* and *Utricularia*. Under "AQUARIUM LACUSTRA" (lake ponds) the following were listed: *Hydrocharis, Nuphar lutea* and *Nymphaea* alba. The Aquaria Palustra plants are definitely emergent plants as are some of the Aquaria Fluviatile plants such as *Sagittaria* which throw up summer stalks which develop long, oval leaves above the water. The Aquaria Lacustra plants are floating plants and include the waterlilies.

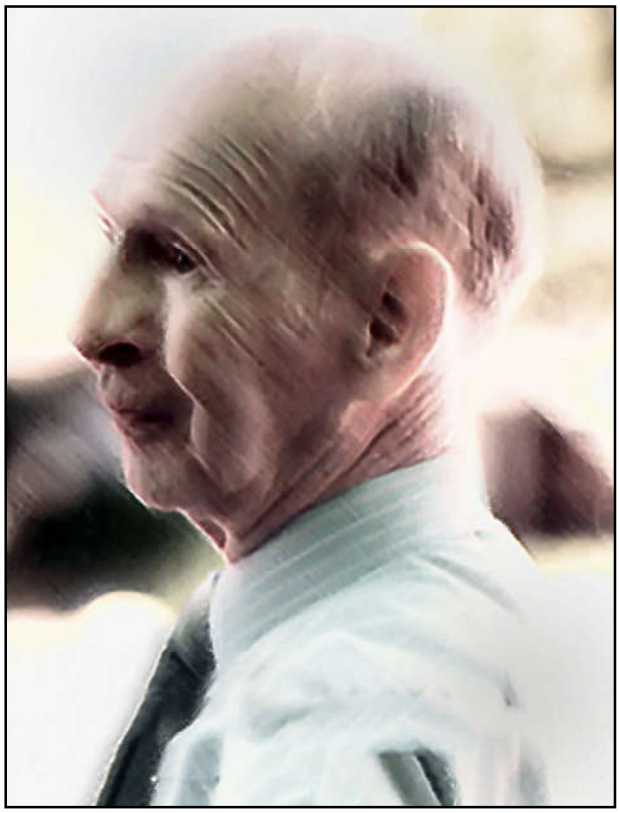

Figure 19: Theodore Uber (1908-2007).

John Claudius Loudon (1783—1843) was a Scottish botanist, garden designer and author. He was the first to use the term arboretum in writing to refer to a garden of plants, especially trees, collected for the purpose of scientific study. He was married to Jane, née Webb, a fellow horticulturalist and author of science-fiction, fantasy, horror and gothic stories. Loudon's *Encyclopaedia of Gardening* (Loudon, 1824) listed many more aquatic plants used by aquarists including *Aponogeton, Ceratophyllum, Crinum, Equisetum, Hippuris, Hottonia, Hydrocharis, Hydrocotyle, Lobelia, Nuphar, Sagittaria* and *Utricularia*.

Robert Warington FRS (1807-1867) was an English chemist considered the driving force behind the creation of the world's first enduring chemistry society, *The Chemical Society of London*, which later became the *Royal Society of Chemistry*. He who worked out that plants added to water in a container would give off enough oxygen to support animals, so long as their numbers do not grow too large. He published his findings in 1850 in the *Quarterly Journal of the Chemical Society of London* and his work is considered the origin of modern aquaria. Warington used *Vallisneria spiralis* in his experiments in 1850 and subsequent years.

D.2 HISTORY PROBLEMS

The problem with rooted, submerged aquatic aquarium plants—the type of most interest to aquarists—is that, as Table I shows, there are so many of them that tracing their history to determine the date they were introduced into the aquarium hobby and who imported them, would be both tedious and difficult, although where they were found geographically usually can be determined by examining their original scientific descriptions. The following two references were listed in the Wikipedia article from which the list was taken:

(1) The Plant List (TPL) is a working list of all known plant species produced by the botanical community in response to Target 1 of the 2002-2010 Global Strategy for Plant Conservation (GSPC). TPL has been static since 2013, but was used as the starting point for the taxonomic backbone of the *World Flora Online (WFO)*. Collaboration between the Royal Botanic Gardens, Kew and Missouri Botanical Garden enabled the creation of The Plant List by combining multiple checklist datasets held by these institutions and other collaborators.

Figure 20: The Plants List is composed of four groups: Flowering plants (Angiosperms), Conifers, cycads and allies (Gymnosperms), Ferns and fern allies (Pteridophytes) and Mosses and liverworts (Bryophytes).

COMMON AQUARIUM PLANT SPECIES CTD.

Aciotis acuminifolia
Acmella repens
Acorus calamus (Common sweet flag)
Acorus gramineus (Japanese sweet flag)
Aldrovanda vesiculosa
Alisma canaliculatum
Alisma gramineum
Alisma lanceolatum
Alisma nanum
Alisma orientale
Alisma plantago-aquatica
Alisma subcordatum
Alisma triviale
Alisma wahlenbergii
Alternanthera bettzickiana
Alternanthera philoxeroides
Alternanthera reineckii
Alternanthera sessilis
Ammania capitellata
Ammannia crassicaulis (Synonym Nesaea crassicaulis)
Ammania gracilis (Delicate ammania, red ammania)
Ammania latifolia
Ammannia pedicellata
Ammannia praetemissa
Ammania senegalensis
Anubias afzelii (Narrow-leafed anubias)
Anubias barteri var. barteri (Broadleaved anubias)
Anubias barteri var. angustifolia
Anubias barteri var. caladiifolia
Anubias barteri var. glabra
Anubias barteri var. nana (Dwarf anubias)
Anubias gigantea
Anubias gilletti
Anubias gracilis
Anubias hastifolia
Anubias heterophylla
Anubias pynaertii
Aponogeton appendiculatus
Aponogeton bernierianus
Aponogeton boivinianus
Aponogeton capuronii
Aponogeton crispus (Crinkled or Ruffled aponogeton)
Aponogeton decartyi
Aponogeton desertorum
Aponogeton dioecus
Aponogeton distachyos
Aponogeton elongatus
Aponogeton fenestralis
Aponogeton henkelianus
Aponogeton junceus
Aponogeton longiplumulosus
Aponogeton loriae
Aponogeton madagascariensis (Madagascar laceleaf, lace plant)
Aponogeton natans
Aponogeton rigidifolius
Aponogeton tenuispicatus
Aponogeton ulvaceus (Compact aponogeton)
Aponogeton undulatus
Armoracia aquatica
Arthraxon hispidus
Azolla caroliniana (water velvet, mosquito fern)
Azolla filiculoïdes (Azolla, moss fern)
Azolla pinnata
Bacopa amplexicaulis
Bacopa australis
Bacopa caroliniana (Lemon Bacopa, Water hyssop, Giant Bacopa)
Bacopa crenata
Bacopa innominata
Bacopa lanigera
Bacopa madagascarensis
Bacopa monnieri (Water hyssop, dwarf Bacopa, Baby Tears)
Bacopa myriophylloides
Bacopa rotundifolia (Round bacopa)
Bacopa salzmannii
Bacopa serpyllifolia
Baldellia ranunculoides
Barclaya longifolia (Orchid lily)
Barclaya motleyi
Berula erecta
Blyxa aubertii
Blyxa echinosperma
Blyxa japonica (Japanese rush)
Blyxa novoguineensis
Blyxa octandra
Bolbitis heteroclita (sometimes sold as B. asiatica)
Bolbitis heudelotii (African or Congo fern)
Bucephalandra gigantea
Bucephalandra motleyana
Bucephalandra catherineae
Cabomba aquatica (Yellow cabomba, giant cabomba)
Cabomba caroliniana (Green cabomba)
Cabomba furcata
Cabomba palaeformis
Cabomba piauhyensis (Red cabomba)
Caldesia parnassifolia
Calla palustris
Caltha palustris
Callitriche hamulata
Callitriche hermaphroditica
Callitriche palustris
Callitriche stagnalis
Callitriche terestris
Cardamine lyrata (Chinese ivy, Japanese cress)
Cardamine rotundifolia
Ceratophyllum demersum (hornwort)
Ceratophyllum submersum (tropical hornwort)
Ceratopteris cornuta
Ceratopteris pteridoides
Ceratopteris thalictroides (water sprite)
Cladophora aegagropila
Clinopodium brownei
Crassula aquatica
Crassula helmsii
Crinum calamistratum
Crinum natans (African onion plant)
Crinum purpurascens
Crinum thaianum (water onion)
Cryptocoryne affinis
Cryptocoryne alba
Cryptocoryne albida
Cryptocoryne aponogetifolia
Cryptocoryne auriculata
Cryptocoryne axelrodii
Cryptocoryne balansae
Cryptocoryne beckettii (Beckett's Cryptocoryne)
Cryptocoryne blassii
Cryptocoryne bogneri
Cryptocoryne bullosa
Cryptocoryne ciliata
Cryptocoryne cognata

COMMON AQUARIUM PLANT SPECIES CTD.

Cryptocoryne cordata (Giant cryptocoryne)
Cryptocoryne crispatula
Cryptocoryne cruddasiana
Cryptocoryne dewitii
Cryptocoryne diderici
Cryptocoryne elliptica
Cryptocoryne ferruginea
Cryptocoryne fusca
Cryptocoryne gasserii
Cryptocoryne grabowskii
Cryptocoryne gracilis
Cryptocoryne griffithii
Cryptocoryne hudoroi
Cryptocoryne keei
Cryptocoryne legroi
Cryptocoryne lingua
Cryptocoryne longicauda
Cryptocoryne lucens
Cryptocoryne lutea
Cryptocoryne minima
Cryptocoryne moehlmannii (Moehlmann's cryptocoryne)
Cryptocoryne nevillii
Cryptocoryne nurii
Cryptocoryne pallidinervia
Cryptocoryne parva (Tiny cryptocoryne)
Cryptocoryne petchii
Cryptocoryne pontederiifolia
Cryptocoryne purpurea
Cryptocoryne retrospiralis
Cryptocoryne schulzei
Cryptocoryne scrurillis
Cryptocoryne siamensis
Cryptocoryne spiralis
Cryptocoryne striolata
Cryptocoryne thwaitesii
Cryptocoryne tonkinensis
Cryptocoryne undulata (Undulate cryptocoryne)
Cryptocoryne usteriana
Cryptocoryne venemae
Cryptocoryne versteegii
Cryptocoryne walkeri
Cryptocoryne wendtii 'Tropica'
Cryptocoryne x willisii
Cryptocoryne zewaldiae
Cryptocoryne zonata
Cryptocoryne zukalii
Cuphea anagalloidea
Cyperus alternifolius
Cyperus helferi
Cyperus papyrus
Damasonium alisma
Didiplis diandra (Water hedge)
Diodia kuntzei
Diodia virginiana
Echinodorus africanus
Echinodorus amazonicus (Amazon sword)
Echinodorus andrieuxii
Echinodorus angustifolius
Echinodorus argentinensis
Echinodorus aschersonianus
Echinodorus barthii
Echinodorus berteroi
Echinodorus bleheri (Broadleaved amazon)
Echinodorus brevipedicellatus
Echinodorus cordifolius (Radicans sword, spade leaf sword)
Echinodorus fluitans
Echinodorus grandiflorus (Large- flowered amazon)
Echinodorus horemanii (Black-red amazon)
Echinodorus horizontalis
Echinodorus humilis
Echinodorus latifolius
Echinodorus longiscapus
Echinodorus macrophyllus (Large- leaved amazon sword)
Echinodorus martii
Echinodorus major (Ruffled amazon sword)
Echinodorus opacus (Opaque amazon sword)
Echinodorus osiris (Red amazon sword)
Echinodorus 'Ozelot'
Echinodorus palaefolius
Echinodorus paniculatus
Echinodorus parviflorus (Black amazon sword)
Echinodorus pelliscidus
Echinodorus quadricostatus (Dwarf sword)
Echinodorus radicans
Echinodorus rigidifolius
Echinodorus 'Rubin'
Echinodorus rubra
Echinodorus schlueteri
Echinodorus subalatus
Echinodorus tunicatus
Echinodorus uruguayensis (Uruguay amazon sword)
Egeria densa (Elodea, pondweed)
Egeria najas
Egleria fluctuans
Eichhornia azurea
Eichhornia crassipes (Water hyacinth)
Eichhornia diversifolia
Elatine gussonei
Elatine hydropiper
Elatine macropoda
Elatine triandra
Eleocharis acicularis (Hairgrass)
Eleocharis dulcis
Eleocharis minima
Eleocharis obtusa
Eleocharis parvula
Eleocharis vivipara
Elodea canadensis (Canadian pondweed)
Elodea granatensis
Elodea nuttallii
Elodea occidentalis
Equisetum spp.
Eriocaulon amanoanum
Eriocaulon cinereum
Eriocaulon depressum
Eriocaulon parkeri
Eusteralis stellata (Star rotala)
Fittonia argyroneura
Fontinalis antipyretica (Willow moss)
Glossadelphus zollingeri
Glossostigma diandrum
Glossostigma elatinoides
Gratiola amphiantha
Gratiola brevefolia
Gratiola viscidula
Gymnocoronis spilanthoides (Spadeleaf plant)
Helanthium bolivianum (Bolivian sword) (Synonym - Echinodorus bolivianus)
Helanthium tenellum (Pygmy chain sword) (Synonym - Echinodorus tenellus)
Helanthium zombiense
Hemianthus callitrichoides (Dwarf helzine)
Hemianthus micranthemoides (Pearlweed)
Heteranthera dubia

COMMON AQUARIUM PLANT SPECIES CTD.

Heteranthera reniformis
Heteranthera zosterifolia (Stargrass)
Hippuris vulgaris
Hottonia inflata
Hottonia palustris (Water violet)
Hydrilla verticillata
Hydrocharis morsus-ranae
Hydrocleys martii
Hydrocleys nymphoides
Hydrocotyle leucocephala (Brazilian pennywort)
Hydrocotyle sibthorpioides
Hydrocotyle tripartita
*Hydrocotyle verticillata (*Whorled umbrella plant)
Hydrocotyle vulgaris
Hydrothrix gardneri
Hydrotriche hottoniiflora
Hygrophila angustifolia
Hygrophila corymbosa 'crispa'
Hygrophila corymbosa 'glabra' (Broadlead giant stricta)
Hygrophila corymbosa 'gracilis'
Hygrophila corymbosa 'siamensis'
Hygrophila corymbosa 'strigosa'
Hygrophila difformis (Water wisteria)
Hygrophila guianensis
Hygrophila lacustris
Hygrophila lancea
Hygrophila natalis
Hygrophila polysperma (Dwarf hygrophilia)
Hygrophila salicifolia
Hygrophila stricta (Thai stricta, green stricta)
Hygroryza aristata
Hyptis lorentziana
Iris spp.
Isoetes lacustris (quillwort)
Isoetes malinverniana
Isoetes taiwanensis
Isoetes velata
Isolepis setracea
Jasarum steyermarkii
Juncus repens
Lagarosiphon cordofanus
Lagarosiphon madagascariensis
Lagarosiphon major (Elodea crispa)
Lagenandra dewitii
Lagenandra insignis
Lagenandra koenigii
Lagenandra lancifolia
Lagenandra meeboldii
Lagenandra nairii
Lagenandra ovata
Lagenandra thwaitesii
Lemna gibba
Lemna minor (Duckweed)
Lemna paucicostata
Lemna perpusilla
Lemna trisulca
Lilaeopsis brasiliensis
Lilaeopsis carolinensis
Lilaeopsis macloviana
Lilaeopsis mauritiana
Lilaeopsis novae-zelandiae (New Zealand grassplant)
Lilaeopsis ruthiana
Limnobium laevigatum (Amazon frogbit)
Limnobium spongia
Limnocharis flava
Limnophila aquatica (Giant ambulia)
Limnophila aromatica
Limnophila glabra
Limnophila heterophylla
Limnophila indica (Indian ambulia)
Limnophila sessiliflora (Dwarf ambulia)
Limnophyton fluitans
Lindernia crustacea F. Muell.
Lindernia dubia
Lindernia grandiflora
Lindernia parviflora
Lindernia rotundifolia
Littorella uniflora
Lobelia cardinalis (Cardinal flower, scarlet lobelia)
Lobelia dortmanna
Lomariopsis sp. (Süsswassertang)
Ludwigia alternifolia
Ludwigia arcuata
*Ludwigia glandulosa (*Glandular ludwigia, red star ludwigia)
Ludwigia helminthorrhiza
Ludwigia inclinata
Ludwigia inclinata var. verticellata 'Cuba'
Ludwigia mullertii
Ludwigia natans
Ludwigia sedioides
Ludwigia palustris
Ludwigia pulvinaris
Ludwigia repens (Creeping ludwigia, narrow-leaf ludwigia)
Luronium natans
Lycopodiella inundata (Lycopodium inundatum)
Lysimachia nummularia (creeping Jenny, moneywort)
Marsilea crenata
Marsilea drummondii
Marsilea hirsuta
Marsilea pubescens
Marsilea quadrifolia (water-clover)
Mayaca fluviatilis
Mayaca madida (Synonym Mayaca sellowiana)
Mayaca vandellii
Mentha aquatica
Micranthemum umbrosum (Helzine)
Microcarpaea minima
Microsorum pteropus (Java fern)
Monochoria vaginalis
Monosolenium tenerum (commercial name; plants sold under this name are actually a fern Lomariopsis sp.)
Murdannia keisak
Myriophyllum alterniflorum
Myriophyllum aquaticum (Brazilian milfoil, milfoil)
Myriophyllum elatinoides
Myriophyllum heterophyllum
Myriophyllum hippuroides (Green milfoil, water milfoil)
Myriophyllum mattogrossense
Myriophyllum proserpinacoides
Myriophyllum scabratum (Foxtail)
Myriophyllum spicatum
Myriophyllum tuberculatum (Red myriophyllum)
Myriophyllum ussuriense
Myriophyllum verticillatum
Myriophylumm oguraense
Najas graminea
Najas guadelupensis
Najas indica
Najas marina
Najas minor
Najas pectinata
Nechamandra alternifolia
Nelumbo nucifera
Neptunia oleracea
Nitella capillaris
Nitella flexilis

COMMON AQUARIUM PLANT SPECIES CTD.

Nitella gracilis
Nomaphila siamensis
Nuphar advenum
Nuphar japonica (Spatterdock)
Nuphar lutea (Yellow water-lily)
Nuphar pumilum
Nuphar sagittifolium
Nymphaea alba
Nymphaea lotus (Tiger lotus)
Nymphaea lotus var. rubra
Nymphaea micrantha
Nymphaea pubescens
Nymphaea pygmea
Nymphaea stellata (Red and blue water lily)
Nymphaea zenkeri 'Red' (Red tiger lotus)
Nymphoides aquatica (Banana plant)
Nymphoides humboldtiana
Nymphoides indica
Nymphoides peltata
Oenanthe javanica
Oenanthe aquatica
Oldenlandia salzmannii (Synonym Hedyotis salzmannii)
Orontium aquaticum
Ottelia alismoides
Ottelia mesenterum
Ottelia ulvifolia
Penthorum sedoides
Persicaria hydropiperoides
Persicaria praetermissa
Pilularia americana
Pilularia globulifera
Pistia stratiotes (Water lettuce)
Phyllanthus fluitans
Physostegia purpurea
Pogostemon helferi
Pogostemon stellatus
Pontederia cordata
Potamogeton coloratus
Potamogeton crispus
Potamogeton densus
Potamogeton filiformis
Potamogeton gayi
Potamogeton gramineus
Potamogeton lucens
Potamogeton malaianus
Potamogeton natans
Potamogeton perfoliatus
Proserpinaca palustris
Ranunculus aquatilis
Ranunculus limosella
Regnellidium diphyllum
Riccia fluitans (Crystalwort)
Ricciocarpos natans
Rorippa aquatica
Rotala indica
Rotala macrandra (Giant red rotala)
Rotala mexicana
Rotala ramosior
Rotala rotundifolia (Dwarf rotala)
Rotala pusilla
Rotala wallichii (Whorly rotala)
Ruppia maritima
Sagittaria chapmani
Sagittaria eatonii
Sagittaria filiformis
Sagittaria graminea
Sagittaria guyanensis
Sagittaria isoëtiformis
Sagittaria latifolia
Sagittaria microfila
Sagittaria montevidensis
Sagittaria natans
Sagittaria papillosa
Sagittaria platyphylla (giant sagittaria)
Sagittaria pusilla (dwarf sagittaria)
Sagittaria sagittifolia
Sagittaria subulata (needle sagittaria, floating arrowhead)
Salvinia auriculata
Salvinia cucullata
Salvinia minima
Salvinia natans (water spangles)
Salvinia oblongifolia
Salvinia rotundifolia
Samolus valerandi (Water cabbage)
Saururus cernuus (Lizard's tail)
Selaginella sp.
Sium floridanum
Sium latifolium
Shinnersia rivularis (Mexican oak leaf)
Spiranthes romanzoffiana
Spirodela polyrhiza
Staurogyne repens
Staurogyne stolonifera
Stratiotes aloides
Stuckenia vaginata
Subularia aquatica
Syngonanthus caulescens
Synnema triflorum (out of date synonym)
Taxiphyllum barbieri (Java moss)
Tonina fluviatilis
Trapa natans (Water chestnut)
Triglochin maritima
Triglochin palustris
Triglochin striata
Trithuria austinensis
Trithuria austinensis
Trithuria australis
Trithuria inconspicua
Typha angustifolia
Typha latifolia
Utricularia bifida
Utricularia gibba
Utricularia graminifolia
Utricularia minor
Utricularia vulgaris
Vallisneria americana (Dwarf vallisneria)
Vallisneria asiatica
Vallisneria asiatica var. biwaensis (Corkscrew vallisneria)
Vallisneria gigantea (Giant vallisneria)
Vallisneria neotropicalis
Vallisneria rubra
Vallisneria spiralis (Straight vallisneria)
Vallisneria tortifolia (Twisted vallisneria, dwarf vallisneria)
Vallisneria tortissima
Vesicularia montagnei (Christmas moss, Xmas moss)
Veronica americana
Wolffia arrhiza
Wolffia microscopica
Wolffiella floridana
Zannichellia palustris

(2) Peter Hiscock's, "Encyclopedia of Aquarium Plants," (Hiscock, 2003). Peter Hiscock trained at Sparsholt College in Hampshire, one of the United Kingdom's leading schools for aquatic studies and has published widely on fish behavior and aquarium keeping.

The Plants List is composed of four groups: Flowering plants (Angiosperms), Conifers, cycads and allies (Gymnosperms), Ferns and fern allies (Pteridophytes) and Mosses and liverworts (Bryophytes). I'll deal here with the Angiosperms as they contain most of aquatic plants used by aquarists.
The status of the 951,140 species names for the Angiosperms recorded in The Plant List, are as follows:

Accepted	304,419	32.0%
Synonym	430,346	45.2%
Unassessed	216,132	22.7%
Unplaced	243	~0.0%

Unassessed names are those for which there is no evidence within any of the contributing data sources that the status of this name had been evaluated by the data owners. None had recorded that it was either 'accepted' or a 'synonym.' None had recorded that they had attempted such an evaluation.

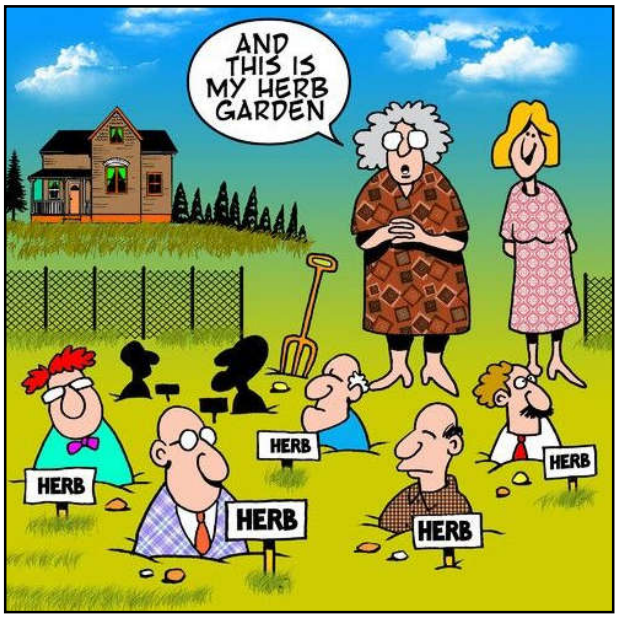
Unplaced names are those for which the data source supplying that record indicated positively that the data owners had sought to resolve its status and not been able to come to a conclusion so as to place it either in synonymy or as the accepted name of a new species. This is often the case if the name has insufficient description and no herbarium specimens are known or where one or more nomenclatural acts are required to provide the accepted name for which the unplaced name would be a synonym. Thus, unresolved names are those to which it is not yet possible to assign a Status of either 'Accepted' or 'Synonym.' The status above indicates that there is much confusion about botanical names and the taxonomy of most plant genera is not final. The scientific names listed in the table may therefore be at odds with other sources.

One of the problems with Hiscock's, Encyclopedia of Aquarium Plants is that most of the pictures in his Plant Profiles section are of emergent plants grown above water, macrophytes that are not of much interest to aquarists. Nonetheless, this is the best book on aquarium plants that I have ever seen and I recommend it highly.

E. CONCLUSIONS

Biologists have worked with the Linnaean system of naming of species for over two centuries. The deficiencies of this system to the modern user are that (a) Latin, a classical language, is the basis; (b) irregular and illogical names have entered into the picture because of the gradual evolution of rules; (c) the abundance of synonyms and homonyms which have arisen from work in independent systematic fields; and (d) the interjection of illogical or erroneous names by previous workers (in good faith) which must now stand unless invalidated for rigorous taxonomic reasons (not for reasons of nomenclature). Whilst such irregularities are accommodated by the professional taxonomist and serious amateur, they can be discouraging to the lay user. Many ordinary people choose not to use scientific naming at all, preferring popular names which carry little or no systematic meaning.

Problems in nomenclature do exist for the plant taxonomist even if they are not as severe as those facing the zoologist. In one limited area of his work, however, that dealing with ornamental



plants, the botanist cannot keep such problems to himself. Gardeners cultivating ornamental plants have to use scientific names. As they out-number the taxonomists concerned with naming, they stimulate pressure for the maintenance of acceptable and for the abandonment of ungainly names. Unfortu-nately, if an awkward name is 'correct' according to the International Code of Botanical Nomenclature, there is little hope of getting rid of it. The Code merely recommends that such names should not be created. If they are, then they have to be recognized.

Recently, for instance, a name has been published for a cactus species, the epithet being the name of the Aztec god of the sun and of war, a distinctly unpleasant deity. Admittedly, "Huitzilopochtli" is an imaginative name, but it is clearly unsuitable for speech, plant labels or in catalogues. Cactus enthusiasts will, I think, continue to use the collector's serial number (i.e., a unique identifier assigned to a plant to uniquely identify it) given on its first introduction. Again, many awkward names are derived from personal names rather than from a characteristic of the plant, which latter could be of real help to the user. As the user has to accept names which conform to the rules but ignore the spirit of the Code it is the more important that when changes are made the facts should be ascertained correctly and the Code applied properly. Unfortunately, I doubt that this will come to pass any time in the near future.

RESEARCH AND AQUARIUM HOBBY HISTORY: CARL LINNAEUS

by Albert J. Klee, Ph.D.

(*Essays on Aquarium Hobby History*, July 1, 2022)

Some people believe that Linnaeus was the first to name plants and animals, at least in any comprehensive manner. A much greater number have the idea that he: (1) invented binomial names, i.e., two-word, names (genus and species); (2) was the first to completely classify plants and animals; (3) started the practice of creating names for all groups by compounding words from Latin and Greek roots and affixes; and (4) created an hierarchy of classification (kingdom, class, order, genus, species) and formulated names for all of these groups and (5) created pseudoscientific ideas about human biological diversity.

Actually, none of these are true; yet, his reputation was such that it is sometimes impossible to trace the actual application of ancient names because lexicographers simply quote him as an authority. It is also difficult or impossible to trace the development of plant and animal names in reference books and even biological dictionaries and encyclopedias because they start with his classification and nomenclature and discuss the development as if his treatment were the beginning. Before I start to examine these beliefs in detail, the following biographies are presented since they are relevant to this examination.

ARISTOTLE

In his *Historia Animalium* (History of Animals), Aristotle (384 BC-322 BC) was the first to attempt to classify all animal life. He grouped the types of creatures according to their similarities such as animals with blood and animals without blood, animals that live on water and animals that live on land. Aristotle's view of life was hierarchical. He assumed that creatures could be grouped in order from lowest to highest, with the human species being the highest. Subsequent commentators on Aristotle interpreted this as a "ladder of nature" (*scala naturae*) or a "Great Chain of Being," but these were not Aristotle's terms. His system of classification was not evolu-

Carl Linnaeus (1707–1778), later Carl von Linné.

Aristotle (384 BC-322).

tionary, and the various species on the ladder had no specific genetic relationship to each other. Aristotle regarded the essence of species as fixed and unchanging, and this view persisted for the next two thousand years.

His other innovation, however, *was* binomial definition. "Binomial" means "two names," and according to Aristotle's system each kind of organism could be defined by the two names of its "genus and "difference." The word "genus" comes from the Greek root for "birth," and among its meanings are "family" and "race." Aristotle's notion of definition was to place every object in a family and then to differentiate it from the other members of that family by some unique characteristic. He defined humans, for example, as the "rational animal." This is binomial nomenclature and according to Aristotelian thought, defines the essence of what it is to be human, as opposed to such what he thought were pseudo-definitions such as "featherless biped." But what Aristotle did *not* do was to methodically use binomial definition in his system of biological classification. This innovation had to await the development of modern science after the Renaissance.

Aristotle's influence was profound and long-lasting. Much of his work has not survived to the present day, so that we don't know the details of his study of plants, but his student Theophrastus (372-287 BC) continued it, becoming known as the "father of botany" is believed to have planted the first botanical garden on the grounds of Aristotle's Lyceum. Most of the text of his two botanical works, *De Historia Plantarum (On Plants)* and *De Causis Plantarum (*The Causes of Plants) still exists, although only in Latin translations. The first describes the anatomy of plants and classifies them into trees, shrubs, herbaceous perennials and herbs. The second work discusses their propagation and growth and served in part as a practical guide to farmers and gardeners. However, he introduced no new principles of classification. After Aristotle, there was little innovation in the fields of the biological sciences until the 16th century AD.

ANDREA CESALPINO

Andrea Cesalpino (Latin, Andreas Caesalpinus, 1519-1603) was an Italian physician, philosopher, and botanist who sought a philosophical and theoretical approach to plant classification based on unified and coherent principles rather than on alphabetical sequences or medicinal properties. He helped establish botany as an independent science.

Cesalpino succeeded his teacher, Luca Ghini, as professor of medicine and director of the botanical gardens at the University of Pisa. From 1592 he served as physician to Pope Clement VIII and taught at Sapienza University in Rome. His work on the anatomy and physiology of the cardiovascular system anticipated the work of William Harvey. Vol. XVI (1583) of his "*De plantis libri* (The Books of Plants)," is considered the first textbook of botany and is widely considered his most important work. He published a total of 16 books of which the first consisted of 14 chapters where he presented his principles of botany.

Andrea Cesalpino (1519-1603).

Cesalpino covered the nutrition of plants, structures of the flower, fruit, and seed and used his knowledge of Aristotle's thoughts on biological classification and Theophrastus's criteria for plant classification.

The remaining 15 books described and classified more than 1,500 plants. The basis for his classification system was philosophy. Consequently, in his botanical research he went beyond the individual description of plants and sought to find the general out of the individual, the important out of the senses and the physical. He strove to classify plants on the basis of natural conditions and, through Aristotelian philosophical deductions, came to the conclusion that only the fructification (the act of forming or producing fruit) organs were suitable for the construction of the most natural system.

This led him to highly unnatural groups. Nonetheless, he was the first scientist to establish an ordered system of plants, which he divided into 5 classifications: (1) the group of arbores (trees); (2) the group of frutices (shrubs); (3) the group of suffrutices (shrub herbs, i.e., a perennial plant woody only at the base); (4) the group of tlerhae (herbs) and (5) the group of seedless plants, to which he counted fungi, ferns, mosses and algae, among others. His innovation in basing his system of classifying plants on the basis of the structure of their fruits and seeds influenced subsequent scientists, including Linnaeus.

While his classification system anticipated Linnaeus' system of binomial nomenclature, Cesalpino retained the false classic divisions of woody and herbaceous plants and the belief that plants are not sexual. Although he profoundly influenced later botanists such as Linnaeus, he cannot be given credit for inventing biological nomenclature.

Unfortunately for Cesalpino, his major work did not receive the attention it deserved. It is said that even for contemporaries, the work was hard to read with its dense prose which relied heavily on Aristotelian principles relating to the soul of plants but left much only implied and not fully stated. Also, there were no illustrations or tables to explain Cesalpino's system. It's important to note that Cesalpino's book has no illustrations. He wrote that he didn't think they were necessary because he was less interested in differentiating among species that in illustrating ways in which they were alike.

GASPARD BAUHIN

Gaspard Bauhin (1560-1624), also called Casper Bauhin, was a Swiss physician, anatomist, and botanist. A student of the Italian anatomist Fabricius ab Aquapendente at the University of Padua, Italy, he spent most of his career at the University of Basel where he was appointed professor of Greek (1582), anatomy, botany (1588), and medicine (1614). One of the first to describe (1588) the ileocecal (Bauhin's) valve, located between the large and small intestines, Bauhin wrote the *Theatrum anatomicum* (1605; *Microcosmographia, A Description of the Body of Man*), considered the finest comprehensive anatomy text to that time. In this work he replaced the

Gaspard Bauhin (1560-1624).

ambiguous practice of numbering muscles, vessels, and nerves with a system that named parts according to their most salient features.

Bauhin's 1623 *Pinax theatri botanici* (Illustrated exposition of plants) described thousands of plants and classified them in a manner that draws comparisons to the later binomial nomenclature of Linnaeus. It is a landmark of botanical history, describing some 6,000 species and classifying them. Refining the principles of systematic botanical classification developed by Andrea Cesalpino, Bauhin was first to clearly delineate botanical species and groups of species, or genera, utilizing the concept of natural relationships, or "affinities," as criteria for his classifications. His 1623 *Pinax theatri botanica* was the most celebrated of the early attempts to name and catalog all known kinds of plants. He listed and described briefly about 6,000 species, while introducing the practice of naming plants by their genus and species (binomial nomenclature), a system that found wide application by the botanists John Ray and later Linnaeus.

The classification system was not particularly innovative, using traditional groups such as "trees, "shrubs" and "herbs," and other characteristics such as utilization, grouping spices into the Aromata, for instance. He did correctly group grasses, legumes and several others. His most important contribution is in the description of genera and species. He introduced many names of genera that were later adopted by Linnaeus, and remain in use. For species he carefully pruned the descriptions down to as few words as possible; in many cases a single word sufficed as description, thus giving the appearance of a two-part name. However, the single-word description was still a description intended to be diagnostic, not an arbitrarily-chosen name (in the Linnaean system, many species names honor individuals, for instance). Nonetheless, he was thus the first scientist to use binomial nomenclature in classification of species.

During this same time period, his brother Johann worked on his pioneering book *Historia plantarum universalis* ("General History of Plants") which was published after Gaspard's death. Although unfinished, it captured all the knowledge of botany that was known at the time including Gaspard's unique naming convention. It was Gaspard Bauhin, therefore, who introduced the practice of naming plants by their genus and species (binomial nomenclature), a system that found wide application by the botanists John Ray and Linnaeus. However, the idea of the binomial species name did not catch on at that time. It was Linnaeus who reintroduced usage of binomials for species names and popularized it. However, he did credit Bauhin with originating this system. Linnaeus also honored the Bauhin brothers in the genus name *Bauhinia*.

JOHN RAY

John Ray (1627-1705) was a Christian English naturalist widely regarded as one of the earliest of the English parson-naturalists. Until 1670, he wrote his name as John Wray. From then on, he used "Ray" after "having ascertained that such had been the practice of his family before him."

Bauhin Pinax, 1623, page 291showing binomial examples of the genus *Tithymalus*.

He published important works on botany, zoology, and natural theology.

One of the most eminent naturalists of his time, John Ray (1627-1705) was also an influential philosopher and theologian. Ray is often referred to as the father of natural history in Britain. He was born in the village of Black Notley, Essex, England. His father was a blacksmith, and his mother was known as a healer and herbalist; perhaps it was from her that Ray gained his love of nature, and especially of plants. Entering Cambridge University in 1644, Ray rapidly became expert in languages, mathematics and natural science; he became a Fellow in 1649, a Lecturer in 1651, and a junior Dean in 1658. In 1660 he was ordained a priest in the Anglican Church.

Soon after, for political reasons, he left Cambridge. Between 1660 and 1671 he made many trips throughout England and one trip to Europe, to collect plants, animals, and rocks. He also did experimental work in embryology and plant physiology; among other things, he proved that the wood of a living tree conducts water. His researches received so much renown that Ray was inducted into the newly-formed Royal Society of London, one of the world's first scientific societies, in 1667.

His classification of plants in his *Historia Plantarum*, was an important step towards modern taxonomy. Ray rejected the system of dichotomous division by which species were classified according to a preconceived, either/or type system, and instead classified plants according to similarities and differences that emerged from observation. He was among the first to attempt a biological definition for the concept of species, as “as a group of morphologically similar organisms arising from a common ancestor.”

Another significant contribution to taxonomy was his division of plants into those with two seedling leaves (dicotyledons) or only one

(monocotyledons), a division used in taxonomy today.

Ray's classification of plants in his *Historia Plantarum* was an important step towards modern taxonomy. In these volumes he delineated 18,600 plants, giving information on structure, physiology, distribution and habits. The main divisions of classification recognized today were laid out on the basis of a natural system. He did almost as much for animals.

He remarked, in particular, that classification must proceed upwards, beginning with the description of species, to proceed then with the comparisons upon which the species may be grouped into genera, the genera into families, and so on. This was a basic upside down revolution in respect to Cesalpino's where he classified plants according to their fruits and seeds, rather than alphabetically or by medicinal properties, in which Aristotle's logic was applied by dividing the whole of the plant kingdom into progressively smaller subgroups, down to the individual species.

He was the first to give a biological definition of the term species. In his 1686 *Historia Plantarum he wrote:*

No surer criterion for determining species has occurred to me than the distinguishing features that perpetuate themselves in propagation from seed. Thus, no matter what variations occur in the individuals or the species, if they spring from the seed of one and the same plant, they are accidental variations and not such as to distinguish a species…Animals likewise that differ specifically preserve their distinct species permanently; one species never springs from the seed of another nor vice versa.

JOSEPH PITTON DE TOURNEFORT

Joseph Pitton de Tournefort (1656-1708) was a pioneer in systematic botany, whose system of plant classification represented a major advance in his day and remains, in some respects, valid to the present time. His interest in botany began early, but only after the death of his father, who was forcing him toward the priesthood, was he able to drop theology and study botany. He became a physician to support himself but continued his botanical studies. In 1688 he received an appointment as professor at the Jardin des Plantes in Paris, a position he held until his death. He collected many plant species on scientific expeditions to the Pyrenees, Asia Minor, and Greece and acquired a wide reputation for his botanical works, particularly the beautifully illustrated 1694 *Éléments de botanique* (Botanical Elements).

Tournefort placed primary emphasis on the classification of genera, basing his classification entirely upon the structure of the flower and fruit. He excelled in observation and description, and

Joseph Pitton de Tournefort (1656-1708).

some of his generic descriptions are still acceptable. He was less innovative in theory, however, for he denied the sexuality of plants, and the classifications that he put forward above the level of the genus were often artificial. As the first to make a clear definition of the concept of genus for plants he provided a major step in the development of the binomial nomenclature.

HISTORY OF BINOMIAL NAMES FOR PLANTS

Stearn (1957) pointed out that binomial names for plants may be found in ancient Greek, Latin, German and English long before they were used by Linnaeus. Furthermore, as I have pointed out, Gaspard Bauhin in 1623 published a review of all known plants, about 6,000 species, using a system of classification based upon genus and species, essentially the binomial system. This has been traced back to the ancients, as it is an attribute of the human mind to group like things, and then distinguish them from each other. This can frequently be done with only two words. As pointed out in my short biography of John Ray, in his "*Historia Generalis Plantarum*" he described 18,600 plants, giving information on their structure, physiology, distribution and habits. The main divisions of his classification recognized today were laid out on the basis of a natural system and he did this almost as much for animals.

The insect generic names of Linnaeus were largely (91%) Latin and Greek words adopted almost without change, and some of the compounding from roots and affixes can be traced back as far as Sophocles in the 5th Century B.C. (Montgomery, 1973). Linnaeus named seven orders of insects, Aptera, Diptera, Coleoptera, Hemiptera, Lepidoptera, Neuroptera and Hymenoptera. These names are elegant expressions of the wing characters and it would seem that he did a fine job in formulating them. However, three, Aptera, Diptera and Coleoptera, were used by Aristotle and Hymenoptera appears in the writing of Strabo (Liddell et al., 1940).

LINNAEUS AND PLANT NAMES

Linnaeus' first knowledge of the names of plants and their classification came from the works of Tournefort. Tournefort was notable as the first to make a clear definition of the concept of genus for plants. Most likely for this reason Linnaeus was inclined to use Tournefort's names, attributing to him many which had been in use for a long time, some since antiquity.

Linnaeus said that Latin and Greek names were the best and a great proportion of his names, especially those of animals, are just that. This was shown for insects (Montgomery, 1973) and the same appears to be true for other animals, especially mammals and birds, although no exact percentages have been calculated. As his knowledge of plants was much greater than that of animals, his need for names for plant genera was correspondingly greater and this is why this essay is concerned more with botany than zoology (although John Ray also was important in the field of ichthyology).

In addition to the adoption of the names of others and the compounding of some from roots and affixes, Linnaeus turned to patronymics. A patronymic, or patronym, is generally formed by add-

ing a prefix or suffix to a name. Thus, a few centuries ago, the male patronymic of Patrick was Fitzpatrick ("Patrick's son") that of Peter was Peterson or Petersen, that of Donald was MacDonald or McDonald, and that of Hernando was Hernández.

Today, of course, each of these is an ordinary family name, or surname. (In Russia, both a patronymic and a surname are still used; in the name Peter Ilyich Tchaikovsky, for example, Ilyich is a patronymic meaning "son of Ilya.") Linnaeus named plant genera for his father-in-law, most of his former teachers, many of his students, famous botanists and a host of others. No patronymic has been detected among his names for animals.

Linnaeus had no idea of selecting a name on the basis of priority. He merely wanted what he considered the best name. If he found none that satisfied him he selected new ones; his selections were seldom, if ever, without reason. He rejected names with more than 12 letters, those ending in -oidea, obviously double names, etc. It has been those following him who made him the "second Adam" by decreeing through the Codes of Nomenclature that whatever name Linnaeus used would be the name of the plant or animal.

Such features of nomenclature were not formulated for over 100 years; the exact dates for such "beginnings" came even later. The Kew Index (Jackson, 1895) cites papers of Linnaeus from 1735 to 1753 for the origin of his generic names. Gray's Manual (Gray, 1890) cites the older authors rather than Linnaeus for the names which he adopted from them. The citation of authors for these names of Linnaeus has led to the dual system of credit in citing authors in botanical work, Linnaeus and the author from whom he took the name for Linnean genera, and the author of the species name plus the name of the authority who placed it in the genus to which it is assigned for species. This double citation is not followed in zoology.

Linnaeus wrote in Latin because that was the universal language of the universities of his time. His use of it, however, was far from classical, and he virtually created a new language, taxonomic Latin—descriptions in a telegraphic style, almost entirely without verbs, employing only a few nouns and depending chiefly on adjectives. He did retain one feature, gender, which has little intrinsic value to nomenclature, and which is one of the most troublesome problems in nomenclature to the average American biology student today. As gender is an essential property of both Latin and his native Swedish, the thought that it might not be necessary could never occur to Linnaeus.

CRITICISMS OF LINNAEUS

His contemporaries charged Linnaeus with two particular faults (Blunt, 1971). Haller, the Swiss naturalist, accused him of trying to be a second Adam and name all plants and animals; and Dillenius, Professor of Botany at Oxford, objected to his system of classification and his use of the Greek names of Theophrastus and Dioscorides. Dillenius noted that the day might come when the plants to which the ancients applied these names would be identified and if the names were used for other plants the confusion would be great. A later botanist, J. van Sachs, observed that Linnaeus "was content to know all his species exactly by name and never made a single important discovery throwing light on the nature of the vegetable or animal kingdom" (Stearn, 1957).

Linnaeus increased his knowledge greatly between 1735 and 1758/59. Although he was interested primarily in botany he listed only genera of

Linnaeus' house at the Uppsala Gardens.

plants in 1735. However, he had a most elegant chart, snowing classes, orders, genera and species of animals. A close examination reveals that his actual classification of animals was considerably less impressive than the treatment would indicate. Species names were quite variable in form—one word which was sometimes the same as the genus name, or two words one of which was frequently, but not always the same as the genus name. The development of a true binary nomenclature in his publications came much later, reaching completeness only in 1753 for plants (Linnaeus, 1753) and 1758 for animals (Linnaeus, 1758). Although folk names tend to be single words, or binomials to distinguish related species as pointed out above, rarely trinomials, names had become much longer as the knowledge of plants and animals grew. The naming followed the rule of Aristotle for defining or distinguishing anything—place it in its lowest possible group (genus) and differentiate it from other members of that group (differentia, or specific name).

This practice of naming a species—genus plus differentia—had been more or less the practice since antiquity. With the increase in the number of species known, the "species names" necessarily became longer. These were the "species names" referred to by Linnaeus when he first formulated his rules of classification. He expressed the opinion that they should not exceed 12 words in length! Heller (1964) suggested that the adoption of a two-word name by Linnaeus was not a direct development from the frequent use of such names in the past. It was adapted from the type of citation he used for literature in his publications almost from the beginning. Many of the "trivial names" (so-called since the differentia were still referred to as the true specific names) of plants were selected from some feature of the specific discussion—a word from the differentia, i.e., one referring to habitat, locus (country), etc. Others were obtained from various other sources.

Frequently the names of genera placed in synonymy by Linnaeus were used for trivial names — Tulipifera of Catesby became a species of Liriodendron, Blatteria of Bauhin one of Verbascum, and Chamaedrys Bauhin (in which several species had been placed) and Bonatota Micheli both were made species of Veronica. The common American corn was named Mays by Tournefort, but suppressed by Linnaeus in favor of Zea, and used as the trivial name.

The specific names chosen by Linnaeus for animals were more varied than those for plants. For mammals there were frequently enough classical names for both genus and all of the species. The Latin name Felis was selected for the genus of "cats," another, catus, for one species, and most of the other species had Latin or Greek names which he used, i.e., leo, tigris, pardus and lynx. Only 465 different names were used for the 544 species of birds listed in 1758, as some names were used several times. Some were classical names of mythological characters, others names of other birds and animals. Most appear to be adjectives, indicating country or region as orientalis, lapponica, canadensis, habitat as montana, sylvatica, alpina, color as alba, chloris, fuscus, anatomical features as cristus (used 11 times), curvirostra, etc. In the Insecta, names of all the types previously mentioned were used, sometimes after some method, but usually indiscriminately mixed.

Heller (1945) published an excellent analysis of the use of mythological names in the genus Papilio. Names of individuals of groups such as "Trojan and Greek horsemen," the nymphs, the graces, the muses, the Argonauts, etc., were used for species of the systematic groups of the genus. However, the animal names of Linnaeus have been studied far less than his plant names and many interesting areas probably remain to be explored.

An interior room of Linnaeus' house.

PLUSES AND MINUSES

Linnaeus, in an autobiographical sketch begun in early life and frequently updated and written in the third person, declared (Blunt, 1971):

No one before him had pursued his profession with greater zeal and had more hearers; made more observations in natural history; had fuller insight into the three kingdoms of nature; been a greater botanist or zoologist; so well described the natural history of his own country—its flora, fauna and topography; written more books, more correctly, more methodically, from his own experience; so completely reformed a whole science and inaugurated a new era; sent out his disciples to so many parts of the world; written his name on more plants and insects, indeed on the whole of Nature; become more famous the whole world over; listed so many animals—and yes, as many as all the others put together; been a member of more scientific societies.

In view of these divergent criticisms and assessments of Linnaeus, one may well ask the true character and value of his contribution to biology. While he did not contribute any new discoveries, or even invent any nomenclatural schemes, his compilation and organization of all known species of plants and animals, neatly arranged in a system of categories, instituted a major epoch in the history of biology. The introduction of a uniform scheme of names for known biological units enabled the proper integration of the vast numbers of new plants and animals which were discovered during the century following his work. This era of systematic growth dominated biology until the appearance of Darwin's theory of evolution. The systematic arrangement of living things probably made the discovery of evolution inevitable, although nothing could have been further from the idea and beliefs of Linnaeus.

THE WOKE GENERATION AND LINNAEUS

The Gustavus Adolphus College (Minnesota) Board of Trustees made the decision to remove the name "Linnaeus" from its campus arboretum. The 125-acre greenspace located on the southwest corner of the Saint Peter campus was renamed "The Arboretum at Gustavus Adolphus College."

In recent years, Linnaeus' writings on human taxonomy have come under scrutiny as an example of scientific racism based on his classification and description of human varieties in his seminal work, *Systema Naturae*. Board Chair Scott Anderson stated:

I'd like to publicly thank the students, faculty, and staff who encouraged the College to reexamine the name of the arboretum and the broad cross-section of our community who engaged in intentional, deliberate, and thorough reflection over the last several months," Anderson said. "The Board of Trustees has made the decision to remove Linnaeus' name from the arboretum. Moving forward, Gustavus will embrace the educational opportunity to tell a more complete history of Carl Linnaeus, examining not only his contributions to science but also the problematic elements of his work.

Enlightenment thinkers inherited a very hierarchical view of the natural world from the Middle Ages and the Renaissance: a 'Great chain of beings' arranged in a series of gradients or steps, with God at the very top, man underneath, and down through animals and vegetables to inorganic minerals at the bottom. Linnaeus' taxonomic work partly upset this linear hierarchy of more or less 'perfect' natural beings. The alignment of races with four continents, for example, put them all on the same level as 'natural' varieties. But the idea of a graded scale of nature also survived in the linear arrangement of human varieties. Linnaeus' classification of man was certainly viewed by contemporaries in a hierarchical manner, and carried on being used in such a way through the following decades. Thus Linnaeus' hierarchy, with black people at the very bottom, associated with negative moral and physical attributes, stuck.

Linnaeus was not the only naturalist writing about the human species in the eighteenth century. In

fact, he wrote comparatively less on the subject than his contemporaries, such as the Comte de Buffon and Maupertuis in France, or the German physician Johan Friedrich Blumenbach, all of whom would influence later writers such as Immanuel Kant and Charles Darwin.

Linnaeus unfortunately used his nomenclature to classify humans by "variety," ascribing inherently positive traits to lighter-skinned Europeans and negative traits to darker-skinned Africans and Asians, thereby laying a pseudoscientific foundation for racism that persists today. Linnaeus's classification of humankind according to skin color (Linnaeus, 1735) is often taken as the starting point of the anthropological study of race (Sloan, 1995). Right next to the genus *Homo* and its definition—"*Nosce te ipsum" (*Know thyself) —he presents human diversity in the following, apparently straightforward way as part of the animal kingdom:

Europaeus albescens
Americanus rubescens
Asiaticus fuscus
Africanus nigriculus

In literal translation, Europeans are said to be "whitish," Americans "reddish," Asians "tawny" and Africans "blackish. The terms are rather vague and broadly applicable, and hence indicate that Linnaeus did not mean to draw sharp distinctions. And indeed, in a discussion of the difference between species and varieties in *Critica botanica* (1737), we find the following statement about the variation of traits in humans (Linnaeus 1738, 153):

God created one man only, dictates Scripture to us, yet if the slightest trait [difference] was enough, there would easily stick out thousands of different species of man: they display, namely, white, red, black and grey hair; white, rosy, tawny and black faces; straight, stubby, crooked, flattened, and aquiline noses; among them we find giants and pygmies, fat and skinny people, erect, humpy, brittle, and lame people etc. etc. But who with a sane mind would be so frivolous as to call these distinct species?

Linnaeus classified people into different races just as he divided other living creatures into groups. But he based that classification on geography – Asian, European etc. – and not on skin color. Linnaeus did have stereotypical ideas, such as that Africans were more volatile, but he did not make that a hierarchical judgement. On the contrary, he was more inclined to find the culture of the French court inferior to that of the Scandinavian Sami Laplanders, for example. The former led an incestuous and decadent life, according to him, while the Sami were still uncorrupted.

While it is true, as many scholars argue, that Linnaeus did not promote the idea of distinct human species, unfortunately his concepts of human classification helped pave the way for pseudoscientific ideas about human biological diversity—the consequences of which are still felt today.

However, Johann Blumenbach, a German physician, naturalist, physiologist, and anthropologist. considered to be a main founder of zoology and anthropology as comparative, scientific disci-

Johann Friedrich Blumenbach (1752-1840).

plines, laid out the scientific template for contemporary race categories in his "On the Natural Varieties of Mankind." Blumenbach strongly opposed slavery and believed in the potential equality of all people. Nevertheless, he mapped a hierarchical pyramid of five human types, placing "Caucasians" at the top because he believed a skull found in the Caucasus Mountains was the "most beautiful form of the skull, from which...the others diverge." This model was widely embraced, and Blumenbach inadvertently paved the way for scientific claims about white superiority.

THE DRAGON MURDER CASE, A DETECTIVE STORY FOR AQUARISTS

by Albert J. Klee, Ph.D.

(*Essays on Aquarium Hobby History*, January 14, 2023)

My mother was extremely fond of reading mystery books and as a young boy I followed her lead avidly. Although I have never counted them, I have probably read well over a thousand or so mystery books in my lifetime. When I was in OCS (Officer Candidate School) in the 1950's I attended a required a speed-reading course where I increased my reading speed by an order of magnitude. As an example, I was trained to look at the paragraphs or even the complete pages in a book as opposed to the habit of reading a single line used by most people. As a result I could read the average mystery in 20 minutes and still maintain all its details. In any event, of the American authors I liked best, the Philo Vance Mysteries led the way.

A. WILLARD HUNTINGTON WRIGHT

Although this essay is not intended as an autobiography, a brief summary of his life is helpful in understanding his mystery books, one of which is of historical interest to those interested in aquarium hobby history. Willard Huntington Wright, (born Oct. 15, 1888, Charlottesville, Va., and died April 11, 1939, New York, N.Y.), was an American critic, editor, and author of a series of best-selling detective novels featuring the brilliant but arrogant sleuth Philo Vance. Wright was educated at St. Vincent and Pomona colleges in California, at Harvard University, and in Munich and Paris. Pursuing a career as a writer,

Wright became literary editor of the *Los Angeles Times* in 1907 and in 1912 moved to New York to become editor of *Town Topics* and *The Smart Set*, where he remained with the latter until 1914. With H.L. Mencken and George Jean Nathan he published a book of travel essays called Europe after 8:15 (1914). He also wrote the poetry collection Songs of Youth (1913), the novel The Man of Promise (1916), and several critical works on art and philosophy, including Modern Painting (1915) and What Nietzsche Taught (1915). Wright also edited the anthology The Great Detective Stories (1927) and wrote the essays "Twenty Rules for Writing Detective Stories," which appeared in the *American Magazine* (1928), and "I Used to Be a Highbrow but Look at Me Now" (1929).

Well into the fall of 1917, indifferent to those who were listening closely, Willard continued to speak loudly and disdainfully about the President, the Allies, and the informant- mentality that was pervasive even in New York. Again like Oscar Wilde, Willard was to pay a large price for overlooking certain hard, crass social realities. One individual who was paying particular attention to Willard's politics was Genevieve Matthews, the freelance stenographer he sometimes employed when he found himself behind in his work for his paper, the Mail. An efficient secretary, Miss Matthews was also a vigilant patriot. At first, his secretary's humorless ideas about German evil and

Willard Huntington Wright in 1907, about 19 years old.

British saintliness tickled Willard. When she would come for an afternoon session of dictation in his apartment, he would be apt to take a break at the piano, selecting a German Lied and singing softly in the all-but- forbidden language of the Kaiser.

Genevieve Matthews was easily goaded, apparently, and none too subtle. When Willard was out of the room or left the building on an errand, she would use her break from typing Willard's copy to rifle his desk and files for the incriminating evidence of espionage she was sure she would find. Visions of heroism and delight at seeing the Mail's most notorious writer in jail got the better of her. Earnest and unimaginative, Genevieve Matthews was a woman of her time, caught up in the fervor of the Allied cause.

When he became alert to his secretary's eagerness to prove his treachery, Willard decided not to dismiss her but to play along. It was just the kind of situation that appealed to him. He took to leaving odd papers on his desk to see if they had been moved in his absence. They often were. One day in early October Willard pushed the game further and dictated to Matthews a bizarre, cryptic letter hinting at clandestine meetings with unnamed persons on the Mail, the implications being that they were in touch with German agents in the United States. At this point Willard's "amateur spy-hunter" needed nothing more definitive and, once her employer's back was turned, darted from the apartment out into the street with the letter in hand.

What followed should have been the stuff of mildly humorous recollection in later years—the material for a silly anecdote Willard might have told as an old man. Matthews took refuge in a drugstore phone booth on the corner of Lexington Avenue and 63rd Street, clutching the document while she tried to reach the Secret Service. Willard, exasperated, cornered her in the phone booth. A small crowd gathered to see what the commotion was all about, and at the cries of "German spy" someone got the police. Willard was escorted back to his rooms by two Secret Service men. By the time he was able to explain the truth of the matter, enough of a row had taken place to alert the city newsrooms. A headline in the next morning's Times read: **Writer and Secretary in German Spy Mix-Up**. The Sun was less benign: **Editor Is Accused by Woman as a Spy**.

The editors of the Mail were horrified. It was the last kind of publicity the Mail wanted. That week Willard was curtly informed that his services were no longer needed at the paper. Protestations of innocence got him nowhere, and he was told to leave the building. Living as he did from paycheck to paycheck, without any savings to fall back on, Willard very quickly found himself in desperate straits. He referred the episode as "that comedy," but each day brought him new evidence that his joke had been a grotesque miscalculation. Professional and social acquaintances shunned him, interviews with editors at other papers were impossible to get, and even many of his old friends kept a safe distance. For that matter, not everyone in New York was convinced, in the light of Willard's writings about Germany and

Wright's photo in 1913, considerably retouched by him to appear older than his real age of twenty years.

Nietzsche, that he wasn't in the pay of the Wilhelmstrasse. The resulting scandal, though, cost him his career in journalism, and he spent several years mooching off friends and doing drugs, before deciding to write mysteries.

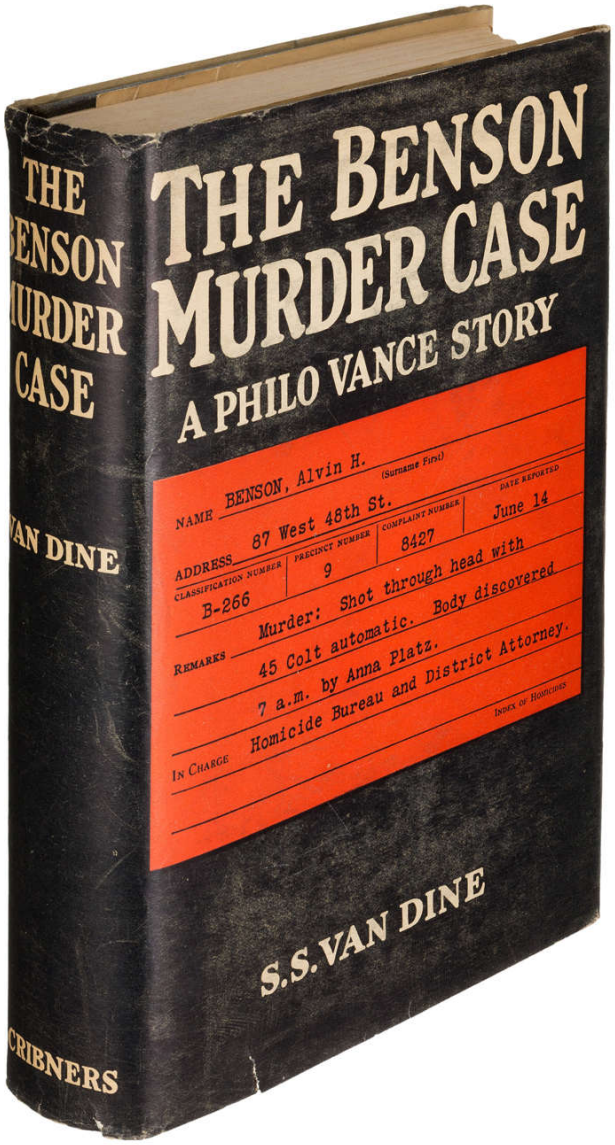
Although Wright continued writing as a minor cultural critic and journalist until 1923, he became ill from overwork. He was confined to bed because of a heart ailment for more than two years. To occupy him, his doctor suggested light reading, such as detective fiction. For someone who had once written, "There are few punishments too severe for a popular novel writer," it sounded like a dubious proposition, but to Wright's surprise, he found mystery novels challenging and entertaining and in frustration, he began collecting thousands of volumes of crime and detection.

In 1926, all this work paid off with the publication of his first S.S. Van Dine novel, "The Benson Murder Case," that had everyone even remotely interested in detective fiction wondering who S.S. Van Dine was. (Wright was outed as being the author after publication in 1928 of his The Greene Murder Case). His aristocratic amateur sleuth, Philo Vance (who shared a love of aesthetics like Wright), was so popular that Wright became wealthy for the first time in his life. Mysteries featuring his detective Philo Vance, *The Benson Murder* Case, *The Canary Murder Case* and *The Bishop Murder Case* among others, sold more than a million copies by the end of the decade, and dominated book sales dur-ing the first rough months of the Great Depression.

Even by the standards of the Jazz Age, Wright lived an outsized life but by the late 1930s, he was a broken, desperate man consumed by the fear of failure that had shadowed him all his life. The fashions of detective fic-tion had changed—Wright deplored the "all booze and erections style" of his competitor Dashiell Hammett—and he was reduced to writing novelizations of his failed screenplays in order to get by.

B. S.S. VAN DINE

Regarding the name he chose, of the "S.S.," Van Dine commented that the steamship abbreviation would be easy for readers (and booksellers) to remember; of the "Van Dine," that it was an old family name on his mother's side. The first point is true, but the second is not. There are no Van Dines to be found in the family tree. At another time Van Dine remarked that he selected the "Dine" with some ironic thought to his years of living on less food the he cared to, and there is probably more seriousness than not in that bit of humor. It is also the case that "S.S." was the common abbreviation for the Smart Set—echoes of Van Dine's happiest days—and that Van Dine



was very close to Van Dyck, Ruben's peer, with all the associations with painting, aristocratic living and accomplishments that the Van Dyck name reverberates.

Note that Van Dine had a title formula, The "¥" Case," where "¥" was a six letter name for the book. The Gracie Allen Murder Case (1938) was the only one to break the title formula, and The Winter Murder Case (1939) was a novella that Van Dine intended to expand into his twelfth full-length book, a project cut short by his death. Both had actually begun as treatments for Hollywood vehicles, the first for radio comedienne Gracie Allen (George Burns' other half) and the second for ice skater-turned-movie-star Sonja Henie. Wright later novelized the scripts, inadvertently pioneering the concept of the movie tie-in. Both books were poorly received.

What interests me here are his novels (and one in particular). The following are the twelve he wrote using the name "S.S. Van Dine."

1. The Benson Murder Case (1926)
2. The Canary Murder Case (1927)
3. The Greene Murder Case (1928)
4. The Bishop Murder Case (1929)
5. The Scarab Murder Case (1930)
6. The Kennel Murder Case (1933)
7. The Dragon Murder Case (1933)
8. The Casino Murder Case (1934)
9. The Garden Murder Case (1936)
10. The Kidnap Murder Case (1936)
11. The Gracie Allen Murder Case (1938)
12. The Winter Murder Case (1939)

The Philo Vance novels were particularly well suited for films, where the more unpleasantly affected aspects of the main character could be toned down and the complex plots given more prominence. One of these films, The Kennel Murder Case, has been called a masterpiece by renowned film historian, William K. Everson. In fact, in a very interesting chapter of his 1972 survey of screen sleuths, "The Detective in Film ," he grouped Kennel Murder amongst the best of the genre, with Green for Danger (a 1946 British thriller film, based on the 1944 detective novel of the same name by Christianna Brand) and The Maltese Falcon (a 1941 American film noir directed and scripted by John Huston in his directorial debut, based on the 1930 novel of the same name by Dashiell Hammett), and in this I agree.

1. The Canary Murder Case (1929) with William Powell
2. The Greene Murder Case (1929) with William Powell
3. The Bishop Murder Case (1929) with Basil Rathbone
4. The Benson Murder Case (1930) with William Powell
5. The Kennel Murder Case (1933) with William Powell
6. The Dragon Murder Case (1934) with Warren William
7. The Casino Murder Case (1935) with Paul Lukas
8. The Garden Murder Case (1936) with Edmund Lowe
9. The Scarab Murder Case (1936) with Wilfrid Hyde-White (a lost film)
10. Night of Mystery (1937) (based on The Greene Murder Case) with Grant Richards
11. The Gracie Allen Murder Case (1939) with Warren William as Philo Vance, billed below Gracie Allen
12. Calling Philo Vance (1940), a remake of The Kennel Murder Case with an altered setting with James Stephenson

C. PHILO VANCE

One innovation of Wright's was to also give the name S.S. Van Dine to the first-person narrator of the books, a trick that would later be used in a similar way by Ellery Queen. Even the name Philo Vance was a pseudonym. The real detective, we are told, has only permitted publication of his solutions to "impossible crimes" on the condition of anonymity. The following is taken from his first novel, The Benson Murder Case and is the first time Van Dine himself was used as a first-person narrator of his books:

If you will refer to the municipal statistics of the City of New York, you will find that the number of unsolved major crimes during the four years that John F.-X. Markham was District Attorney, was far smaller than under any of his predecessors' administrations. Markham projected the District Attorney's office into all manner of criminal investigations; and, as a result, many abstruse crimes on which the Police had hopelessly gone aground, were eventually disposed of. But although he was personally credited with the many important indictments and subsequent convictions that he secured, the truth is that he was only an instrument in many of his most famous cases. The man who actually solved them and supplied the evidence for their prosecution, was in no way connected with the city's administration, and never once came into the public eye. At that time I happened to be both legal advisor and personal friend of this other man; and it was thus that the strange and amazing facts of the situation became known to me. But not until recently have I been at liberty to make them public. Even now I am not permitted to divulge the man's name, and, for that reason, I have chosen, arbitrarily, to refer to him throughout these *ex-officio* reports as Philo Vance.

Whatever his true name, the wealthy dilettante lived in a posh two-floor apartment on East 38th Street in Manhattan. When not hobnobbing with his personal lawyer Van Dine, whom he calls "Van," or helping New York District Attorney John F.X. Markham, and the bluff, boneheaded Sergeant Heath of the homicide department keep their jobs, Vance spends his time studying art and aesthetics. Educated in Europe, he still carries the mannered speech of an upper-class Englishman, habitually referring to his colleagues as "old thing" or "old dear," and punctuating nearly every other sentence with "don't y'know." Latin spills from Vance's mouth in almost every page, the following example being taken from The Benson Murder case:

"No, Van old dear," he explained languidly. "I am not becoming sentimental or even human, as that word is erroneously used to-day. I cannot say with Terence, '*Homo sum, humani nihil a me alienum puto*', because I regard most things that are human as decidedly alien to myself."

Vance does not translate his Latin or explain who Terence was, leaving the average reader wondering what Vance meant (it can be translated as "I

**From the Benson Murder case:
Left Philo Vance (Dick Powell),
Right Sgt. Heath (Eugene Pallette).**

am human, and I think that nothing of that which is human is alien to me" from his play *Heauton Timorumenos* written in 163 B.C. by Terence, i.e. Publius Terentius Afer, a dramatist of the Roman Republic. Another example from the Benson Murder case combines some French with a goodly dose of Latin, all sans translation:

Rousseau wrote, La patience est amère mais son fruit est doux. But peerhps your legal taste runs to Latin. Superanda amnis fortuna ferendo est, quoth Virgil. And Horace also spoke on the subject. Durum! said he, sed levius fit patiencia—.

(The French means "Patience is bitter, but its fruit is sweet"; the quote from Virgil is "Every misfortune is to be subdued by patience" and from Horace the full saying is "Durum! sed levius fit patiencia quicquid corrigere est nefas" or "It is Hard! But that which we are not permitted to correct is made lighter by patience.") The monocle-wearing Vance is remarkably indolent and frequently yawns his way through conversations. In truth, about the only thing that saves him from total insufferability is a droll sense of humor. This air of condescension is not surprising since Vance appears to be an authority on every subject on the face of the earth, knowledge that he shares with his associates at every opportunity. In solving crimes, however, he puts more stock in understanding a suspect's personal psychology than he does in picking up tangible clues. "When material facts and psychological facts conflict, the material facts are wrong," he blithely tells Markham:

Basil Rathbone played Philo Vance in The Bishop Murder Case.

"I say, Markham," he drawled; "it has always been a source of amazement to me how easily you investigators of crime are misled by what you call clues. You find a footprint, or a parked automobile, or a monogrammed handkerchief, and then dash off on a wild chase with your eternal *Ecce signum*! 'Pon my word, it's as if you chaps were all under the spell of shillin' shockers. Won't you ever learn that crimes can't be solved by deductions based merely on material clues and circumst'ntial evidence?"

I think Markham was as much surprised as I at this sudden criticism; yet we both knew Vance well enough to realize that, despite his placid and almost flippant tone, there was a serious purpose behind his words.

"Would you advocate ignoring all the tangible evidence of a crime?" asked Markham, a bit patronizingly. "Most emphatically," Vance declared calmly. "It's not only worthless but dangerous. The great trouble with you chaps, d' ye see, is that you approach every crime with a fixed and unshakable assumption that the criminal is either half-witted or a colossal bungler. I say, has it never by any chance occurred to you that if a detective could see a clue, the criminal would also have seen it, and would either have concealed it or disguised it, if he had not wanted it found? And have you never paused to consider that anyone clever enough to plan and execute a successful crime these days, is, *ipso facto*, clever enough to manufacture whatever clues suit his purpose? Your detective seems wholly unwilling to admit that the surface appearance of a crime may be delib'rately deceptive, or that the clues may have been planted for the def'nite purpose of misleading him.

D. VAN DINE'S HUMOR

Since the early novels were stiff reading for

Eugene Pallette as Sgt Earnest Heath in The Dragon Murder Case.

some, some humor was provided, especially in the movie versions, by the characters of Sgt. Heath of the Homicide Bureau (played by Eugene Pallette) and Dr. Emanual Doremus, the coroner's physician (played by Etienne Girardot). Eugene William Pallette was an American actor who worked in both the silent and sound eras, performing in more than 240 productions between 1913 and 1946. After an early career as a slender leading man, he became a stout character actor. Physically, he was often called roly-poly, though we'll go with the more respectful heavyset. No actor was more immediately recognizable by his voice than Eugene Pallette. It is variously described as gravelly, sounding like a bullfrog or a foghorn, and several octaves below this, that or the other. He appeared as the detective, Ernest Heath, in five different Philo Vance movies, more than any actor who played Vance himself.

Of Anglo/French parentage, birdlike comic actor Etienne Girardot was an established theatrical favorite long before the turn of the century. He was an actor, known for his portrayal of the crotchety New York City Coroner's physician in The Kennel Murder Case, The Garden Murder Case and The Dragon Murder Case. The following are some quotes from the Philo Vance movies:

Vance to Doremus: How about a warm cup of embalming fluid?
Doremus: Never mind the levity.

Doremus to Markham and Vance [to the butler who's showing him in]: I don't need an usher to lead me to a corpse.

Dr. Doremus: Evening, Mr. Markham. Evening, Mr. Vance.
Heath [sarcastically]: What! No kiss for me, honey?
Dr. Doremus: Ah!

Vance [as Doremus takes a sandwich out of his bag]: My dear doctor, what is that?
Doremus: My dinner.
Markham: You're not going to eat in here?
Doremus: Why not? For fourteen years you've called me from my soup to look at some dissipated cadaver. From now on, I'll eat with some corpse.

Heath: Don't forget, Doc, Christmas dinner at the morgue.

Etienne Girardot as as Dr. Emanual Doremus in The Dragon Murder Case.

Doremus [Deadpan]: I hope to see you there.

Doremus to Markham [angered that there is no body]: I can't perform an autopsy on a theory! I'm a coroner, not a philosopher!

Doremus to Heath [arriving at the crime scene]: Well, where's the body?
Heath: I'm afraid there ain't any, Doc.
Doremus: [annoyed]: You called me away from my breakfast for nothing?
Heath: Well, at least you got a sniff at it. That's more than we've had.

Doremus: Well, where was the body when you phoned?
Heath: We thought it was in the pool.
Doremus: [annoyed]: I don't want thoughts; I want bodies, and when there aren't any bodies, I want to be left alone!

Doremus: Ernest, it's clear that you don't know much about women. Now I'll tell you, women are, generally speaking...
Heath: You certainly said it! They ARE generally speaking!

Doremus: [leaving the scene, thoroughly annoyed that the body was not dead]: Now I'm going to get some breakfast [turning for one last word]... and, Heath, don't you call me out here again unless you've got a corpse. I'm here as a coroner, not as a doctor!
Heath: [shouting after him sarcastically]: Why don't you learn to carry a hard-boiled egg in your pocket?

Doremus: [Heath has been called to the phone], If it's my wife, tell her I've gone.
Heath: That'll please her! Now you take my wife...

Heath: You keep her. I can't use her!

Punctuated with frequent footnotes and elaborate diagrams, the Philo Vance novels were well-crafted puzzlers that captivated readers. The first two novels, 1926's The Benson Murder Case (which was trumpeted by Scribner's with the ad line, "At Last—A Detective Story for the Intelligent!") and 1927's The Canary Murder Case, were based on real crimes: the 1920 unsolved murder of stockbroker Joseph Elwell and the 1923 killing of Dorothy King (also known as the "Broadway Butterfly). Benson sold well, but it was Canary that launched the Philo Vance phenomenon, selling 60,000 copies in its first month and making Willard Wright a wealthy man.

E. CLAIRE DE LISLE, DOGS AND FISH

In the spring of 1929, at a party aboard an ocean liner docked in New York Harbor, Wright had met an attractive, well-dressed young woman who worked as an illustrator for a local paper and seemed to know something about art. She was several years Wright's junior and had the appealing name of Claire de Lisle. Wright later told the

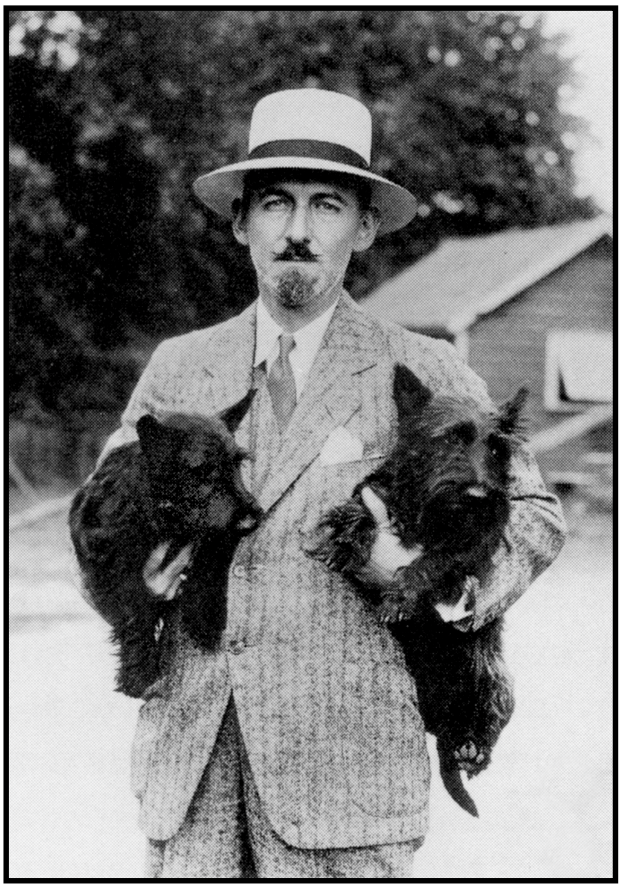
Willard Wright with his second wife, Claire de Lisle1930.

story, undoubtedly fictitious, of overhearing her in conversation with another woman disparaging the trashy novels of S. S. Van Dine. Agreeing with her vehemently, he introduced himself and asked for a date. It was a perfect match from the start, and Claire became that rare presence in Willard's life—a woman he wanted to see more than a few times, whom he regarded as congenial as well as sexually desirable. She had some of the qualities that made the first Claire interesting to him, like her worldliness, charm, and eagerness for experience, all of which was tempered by a greater gentleness and reserve.

This was an opportunity for Willard to be the unquestionably dominant one—the rich older man instead of the "kept" boyfriend—but dominant in relation to a strong, confident woman who had already made her way in the world, unlike his wife, Katharine. For S. S. Van Dine, the self-created detective writer, there was also something intriguing about Claire's smaller efforts to construct a name and an identity for herself in New York. She had been born Eleanor Rulapaugh in Philadelphia and, with an equally adventurous girlfriend, had taken herself to Europe after high school to study art. In Paris in the early Twenties she was a student of Cubist painter Andre Lhote and a fairly typical young American expatriate intent on having a good time. Back in New York, she landed her newspaper job, forgot about painting and cultivated a full social life, and devised her own professional name.

With her, he was able to relax and forget the strange frustrations of his position. His new mistress, the only woman in his life in 1929 and 1930 who hadn't known Willard as an aspiring critic and editor, was content with her lover as he was—and more than content to help him spend the money that was pouring in. She wore clothes well, enjoyed dining out, was a sparkling conversationalist ("a quick study" was a friend's comment), and when Willard wasn't in one of his truculent moods while driving himself to meet a manuscript deadline, she knew how to be the On October 24th, 1930, Wright's the divorce decree from his first wife, Katherine, was finalized. A disastrous marriage of twenty-three years and three months, during which time Willard and Katharine had lived together for no more than six years, was over. Three days after the divorce became final, exhausted by the anxiety but relieved at the outcome, Willard and Claire de Lisle left Manhattan to be married without publicity in Hoboken, New Jersey.

Wright had a warm feeling for dogs, but his transient urban life never seemed suited to the owning of one. Now, in contrast to so many of the problems that money couldn't rectify, Wright's desire for a pet was given full rein. But it wasn't only a pet Wright wanted; he wanted the best dog, or dogs, that a man of his means could find or breed. Through the spring and summer of 1930 Wright intensively, maniacally, investigated dog breeds and bloodlines. He had decided on Scottish terriers—they were, he felt, the most loyal, tenacious, inquisitive, and forthright dogs in his experience—and was determined to know every-



Willard Wright with his Scottish Terriers at the S.S. Van Dine Kennels in New Jersey, 1932.

thing there was to know about them before embarking on his quest for the perfect dogs. By the end of the summer he had added to his growing library more than two hundred books about canine care, breeding conditions, lineage, and professional showing, he had talked to all of the breeders, trainers, owners, and authorities he could find, and subscribed to every periodical on the subject that existed.

Early in the next year Wright was in the market for his own kennels and full-time trainer outside the city, which he eventually found across the Hudson in Haworth, New Jersey. With his new wife, Claire, he began traveling the length of the northeast coast from New England to Washington, D.C., to enter his Scottish terriers in all of the prestigious area dog shows. For Heather Reveller, his great champion, he reportedly paid $2,000. Before he retired from showing and breeding terriers, Wright saw his dogs claim all of the top prizes in the American competitions, and he came to esteem those honors as highly as his modern paintings and his Chinese ceramics. By mid-September, 1931 Wright and Claire entered not only a new home in New York but a whole style of living that they could never have imagined for themselves only a few years earlier.

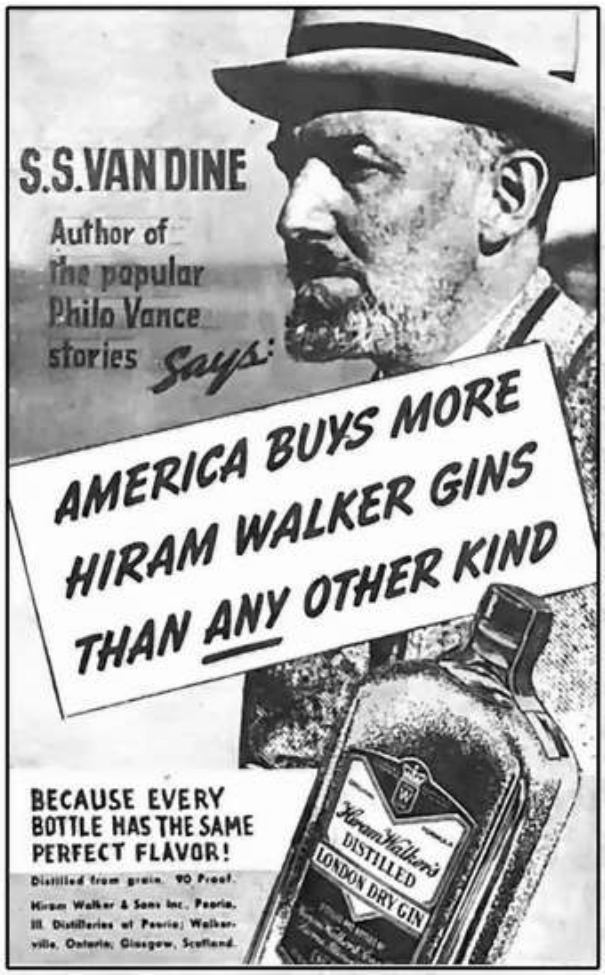
The two-floor penthouse at 241 Central Park West on the corner of 84th Street overlooked a splendid stretch of the park. From the balcony of this late-Twenties building with a vaguely Art Deco flair to it, Wright could see the Metropolitan Museum on Fifth Avenue and, to the south, the skyline of midtown. The rooms were large and accommodated quarters for the servants the Wrights now employed principally a cook and but -ler. Wright installed floor-to-ceiling bookcases, gratified his taste for expensive Chinese ceramics, and eventually purchased a black-jack table and roulette wheel for the amusement of his guests inclined to gambling.

For getting around town and out to New Jersey to the ten-acre Van Dine Kennels, Wright and Claire now had their own car and chauffeur. In all, it was the life of a successful industrialist or Wall Street tycoon that Wright had decided to cultivate.

F. THE BEGINNING OF THE END

But by the end of 1931, Wright had commenced the practice of spending almost every-thing he made on a given book or screenplay and, most danger-ously, of dipping into the advances Scribner's would give for the next Van Dine novel. His restaurant and clothing bills alone were astronomical, and his home might have been more appriate as a showplace for a great capitalist than a popular writer who never knew how much his income might fluctuate from one year to the next, but Wright was determined he wouldn't succumb to the virtues of prudence and economy.

Within a few months, his exaggerated level of comfort proved too much even for Willard to sustain. Spending money like mad throughout the first half of the year, he was angrily and reluctant-



Van Dine's opulent life style forced him during the Great Depression to take minor jobs, such as touting this brand of gin.

ly looking to make cutbacks by June. The Wrights, therefore, were forced to cut back on their entertaining for a time and put the New Jersey kennels on the market. The original scheme to make money by breeding the finest terriers in the country hadn't brought in the anticipated buyers, not in the third horrendous year of economic catastrophe, and it seemed wisest to let go of the property and the full-time manager and keep just a few of the best dogs. Then, too, Willard had already achieved his dream of showmanship and was ready to move on to another hobby, another obsession, tropical fish.

With regard to The Dragon Murder Case, the New York Times noted, "The piscatorial side of this book, at least, is authentic. The author is on the Board of Governors of the Aquarium Society of New York, and has won many prizes with his fish." Actually, the new hobby of exotic fish was at first more Claire's than Willard's. In 1932 one newspaper account reported: "Some of them (i.e., referring to *Betta splendens*) belonged to Mrs. S. S. Van Dyne (Mrs. W. H. Wright), who won the cup in the novice class for the best young fish raised by an exhibitor." Note that The Times got Van Dine's name wrong, pretty careless of the reporter for such a prodigious newspaper. In any event, it was also a good deal less costly in the beginning than dog breeding, though it eventually consumed thousands of dollars anyway, as did every pastime the Wrights enjoyed. There was space in the study for the sixty-eight aquaria, built

Male Bettas fighting, taken from the 1934 Dragon Murder Case movie.

The Dragon Murder Case movie: Left Sgt. Earnest Heath (Eugene Pallette), Middle Philo Vance (Warren Williams) and Right, District Attorney John F.X. Markham.

to hold more than a thousand exotic fish that the room even-tually contained. Its justification for Willard (if one was needed) was that, just as their dog phase proved to be the inspiration behind the Van Dine novel *The Kennel Murder Case,* the passion for fish gave rise to the book that followed.

G. THE DRAGON MURDER CASE

Tropical fish were not as yet popular in Southern California where the movie was filmed. Pet stores did not stock Bettas as there was no demand. At one time Wright had turned his sun-parlor into an aquarium and devoted several years to breeding Bettas. He succeeded in producing cornflower blue, deep maroon and even black specimens; and he won several awards with them at the exhibitions of the New York Aquarium Society at the Museum of Natural History. They were therefore called for in the script as one of the film's most important sets was a solarium filled with fish tanks, including Bettas or "fighting fish" as they were called then. To obtain the necessary tanks and fish, an advanced collector located in the San Fernando Valley agreed to have his collection rented. The appearance of tropical fish in "The Dragon Murder Case" was the spark that boosted tropical fish sales nationwide and when Philip Vance says he has bred tropical fish, he is actually echoing the experience of Willard Wright.

The Dragon Murder Case showcases Vance at his most supremely irritating. The book is set at a mansion owned by Rudolph Stamm—a well-known aquarist—in the northern reaches of Manhattan, complete with a picturesque pool. Into that pool dives Sanford Montague—the fiancé of Stamm's sister—never to be seen again. Fools (and as usual, they are thick on the ground in Van Dines' mysteries) rush to blame the supernatural. They note that the pool is known as "The Dragon Pool," home to a monster known to the Lenape Indians. Philo's not so sure: He is (of course) an expert on both dragons and the Lenape Indians, with a sort of sideline expertise in pools and fish.

It would be tempting to sympathize with Ogden Nash's claim that "Philo Vance needs a kick in the pance." Philo may be a know-it-all, but apparently he comes by it honestly. By the time you reach the end of Dragon, you will almost certainly want to aim your boot at Vance's posterior, but you will have had a swell time getting there. Still, Philo Vance is an objectionable character. He continues to flaunt his Oxford accent, to lift his eyebrows whimsically, and to speak disagreeably when he tries to be humorous. Yet as always the book presents a good puzzle, and that, according to a New York Times review, Mr. Vance and his tens of thousands of readers, is what murder mystery books are for."

H. RUDOLPH STAMM AND HIS FISH

The following is a comment by Sgt. Heath to Markham where Vance offered some information about Stamm.

"I don't like those fish!" he blurted. "Fish?" repeated Markham in astonishment. "What fish?" Heath hesitated and contemplated the end of his cigar sheepishly. "I think I can answer that question, Markham," Vance put in. "Rudolph Stamm is one of the foremost aquarists in America. He has a most amazin' collection of tropical fish—strange and little-known varieties which he has succeeded in breeding. It's been his hobby for twenty years, and he is constantly going on expeditions to the Amazon, Siam, India, the Paraguay basin, Brazil and Bermuda. He has also made trips to China and has scoured the Orinoco. Only a year or so ago the papers were full of his trip from Liberia to the Congo. . . ." "They're queer-looking things," Heath supplemented. "Some of 'em look like sea-monsters that haven't grown up." "Their shapes and their colorings are very beautiful, however," commented Vance with a faint smile.

The following is a comment made by Trainor, Stamm's butler, to Vance. He makes a mistake in the name of the scat that amuses Vance.

"Oh, yes, sir. I am very fond of the fish, sir. And I'm something of an authority on the subject—if I do say so myself. In fact, I disagree with the master quite frequently on the care of some of his rarer varieties. Without his knowing it I have made chemical tests of the water, for acidity and alkalinity—if you know what I mean, sir. And I took it upon myself to increase the alkalinity of the water in the tanks in which the Scatophagies argus are kept. Since then, sir, the master has had much better luck with them." "I myself am partial to brackish water for the Scatophagus," Vance commented, with an amused smile.

This last quote occurs when Stamm is showing Vance his aquaria and equipment. It is a lengthy bit but it shows that Van Dine knew what he was

The Dragon Murder Case movie showing an aquarium with a discus.

The Dragon Murder Case movie : Left to right: Markham, Vance and Dr. Doremus

talking about when it came to tropical fish.

Stamm led the way across the library and into the first aquarium. This room was even larger than the library, and had an enormous skylight as well as a row of high windows along both walls to the east and west. Beyond, through a second archway was still another aquarium, similar to the first; and beyond that was the terrarium with windows on three sides. The aquarium in which we stood was lined with fish tanks of all sizes, reaching to the base of the high windows; and half-way between the walls, running the entire length of the room, were two double rows of additional tanks, set on a long metal rack. There were more than a hundred such tanks in the room, ranging in capacity from five to one hundred gallons.

Stamm, beginning at the tank nearest the door, on the left, led us about the room commenting on his living treasures. He pointed out the various types of *Platypœcilus maculatus—pulcher*, *ruber*, *auratus*, *sanguineus*, and *niger*; various *Xiphophorus hellerii* (the Mexican Swordtail) and the Red Helleri (a cross between the Swordtail and the Red Platy); *Mollienisia latipinna*, with their dotted mother-of-pearl sides; and Black Mollies, perfectly line-bred to enhance their original black mottled coloring. His collection of the genus *Barbus* was extensive: he had beautiful specimens of the opalescent red-finned *oligolepis*; the rosy *conchonius*; the *lateristriga*, with its chameleonlike golden, black and carmine coloring; the black-banded *pentazona*; the silvery *ticto*; and many others.

After these came the species of the genus *Rasbora*, especially *heteromorpha* and *tœniata*; and still further were beautiful specimens of the Characinidæ, particularly of the subfamily Tetragonopterinæ—the Yellow, Red, Glass, Bronze, and Flag Tetras, and the *Hemigrammus ocellifer*, or Head and Tail Light fish. In a series of tanks down the centre of the room Stamm pointed with pride to his specimens of the Cichlidæ—*Cichlasoma facetum*, *severum*, *nigrofasciatum*, *festivum* (the Flag Cichlid), *urophthalmus*, *aureum*, and so on. He also showed us several specimens of that enigmatical *Symphysodon discus*, about which so little is known, either as to its sex distinction or its habits. "I'm working on this species," Stamm said, proudly indicating the blue-green brassy specimens. "They are closely related to the *Pterophyllum* and are the only one of their genus. I'll surprise the oldtime aquarists yet."

"Have you succeeded in breeding any of the *Pterophyllum*?" Vance asked with interest. Stamm chuckled. "I was one of the first aq-

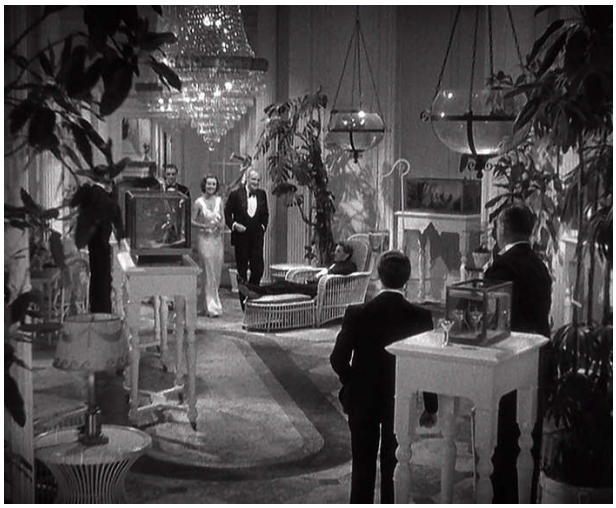
The Dragon Murder Case movie showing one of the larger aquariums.

The Dragon Murder Case movie showing a tank of Tilapia.

uarists in the country to find out that secret. . . . Look here." He pointed to an enormous tank of at least one hundred gallons. "That's the explanation. Plenty of swimming space, with heavy-stemmed Sagittaria for the eggs, and a good warm temperature." (There were many beautiful specimens in the tank, some of them twelve inches from dorsal to anal fin.) He moved along the west wall, talking proudly and fluently of his fish, with the enthusiasm of a fanatic. Before we had completed the circuit he had shown us specimens of the *Æquidens portalegrensis* (the Blue Acara); tiny transparent glass fish (*Ambassis lala*); many species of *Panchax*, especially *lineatus* and the rare Nigerian species, *grahami*; a pair of pike-like *Belonesox belizanus*; the usual *Danio malabaricus*; such mouthbreeders as *Haplochromis multicolor*, *Astatotilapia moffati*, *Tilapia heudeloti*, and *Etroplus maculatus*; labyrinthine fishes, such as *Osphromenus*, *Macropodus*, *Anabas*, and *Ctenopoma*; and hundreds of *Lebistes reticulatus*.

"Still," said Vance, "despite their commonness, there aren't many fish among the tropicals more beautiful than the Guppies." Stamm snorted and moved on toward the room beyond. "In here are the fish that really count," he said. This second aquarium was similar to the one we had just quitted and contained quite as many tanks, but they were arranged differently. "Here, for instance," said Stamm, standing before a tank at the right, "is the *Monodactylus argenteus*." "Brakish water, of course," Vance remarked. "Oh, yes." Stamm shot him a curious look. "Many of the tanks in this room are really marine aquaria, and, of course, I use brakish water also for my *Toxotes jaculator*—the Shooting Fish—and the *Mugil oligolepis*." Vance leaned over the tank that Stamm had indicated. "The *Mugil oligolepis* resembles the Barb, but it has two dorsals instead of one," he observed.

"Quite right." Stamm again looked at him curiously. "You've spent some time with fish yourself, haven't you?" "Oh, I've dabbled a bit," returned Vance, moving on. "Here are some of my best," Stamm said, going to a series of tanks in the middle of the room. And he pointed out to us some *Colossoma nigripinnis*, *Mylossoma duriventris*, and *Metynnis roosevelti*. "How do you manage to keep these rare Characins in such apparently good condition?" Vance asked. "Ah, that's my secret," returned Stamm with a shrewd smile. "High temperatures, of course, and large tanks and live food . . . and other things," he added enigmatically, turning to another series of tanks along the west wall.



The Dragon Murder Case movie: The solarium containing the aquariums. Note the hanging aquariums

"But here are a few fish about which even less is known."

He put his hands in his pockets and regarded the tanks with satisfaction. "These are the Hatchet Fishes: the *Gasteropelecus sternicla*, the *Carnegiella strigata*, and the *Thoracocharax securis*. The so-called experts will tell you that the breeding habits of these species are not known, and that they cannot be bred in aquaria. Tommy-rot! I've done it successfully." He moved further down the room. "Here's an interesting one." He tapped on the front wall of a particularly attractive tank. "The Blow Fish—*Tetrodon cucutia*. Watch this." He took one of the fish out of the water in a small net, and it inflated itself into the shape of a ball. "Curious idea," Stamm commented, "—blowing oneself up to keep from being swallowed." Stamm grinned. "I never thought of that," he chuckled.

"And right next door here," he went on, "is the *Pantodon buchholzi*. Just look at those large transparent pectoral fins. I brought these Butterfly Fish with me from West Africa. . . . And here are some beauties—the *Scatophagus*." He pointed to two tanks containing fairly large hexagonal fish—one tank of the spotted *argus* and the other of the striped *rubrifrons*. "And just here," Stamm continued, moving along the wall, "are a couple of *Luciocephalus pulcher*." Vance looked at this fish closely and inquiringly. "I've heard of them," he commented. "They are related to the Anabantidæ, I believe. But I didn't know any one was versed in their habits and care." "No one but me," Stamm boasted. "And I might add that they are not bubble-nest breeders, as many believe, but viviparous—live-bearers." "Astonishin'," Vance murmured.

Stamm directed our attention to a series of small individual tanks on the shelf above. "Piranhas," he said. "A rare species. And savage devils:—take a squint at those wicked teeth. I believe these are the first ever to come to the United States alive. Brought them back myself from Brazil—in separate cans, of course: they'd kill each other if they were put together. Damned cannibals—the *Serrasalmus*. I had a couple that were nearly twenty inches long,—not the *spilopleura*: they rarely grow over a foot in length. . . . And here," he went on, moving away, "is a nice collection of Sea-horses—the *Hippocampus punctulatus*. Better than those in the New York Aquarium. . . ." Stamm moved a little further on. "Here's an interesting fish—pugnacious and dangerous. The *Gymnotus carapo*. Have to be kept separately. Known as the 'Electric Eel'—*Electrophorus electricus*. But that's all wrong, really. Though they have eel-like bodies, they are not eels at all, but related to the Characinidæ. These are only about eight inches long, but they grow to three feet."

Vance looked at the queer specimens closely: they were vicious looking and repulsive. "I have heard," he remarked, "that they are actually capable of electrocuting a man by a moment'ry contact." Stamm pursed his lips. "So they say, so they say."

At this point Tatum and Mrs. McAdam came into the room. "How about a little battle?" Tatum asked of Stamm with a smirk. "Teeny

Dragon Murder Case movie: Some of Stamm's guests watching male bettas fight. Other guests thought it was cruel.

and I are bored." Stamm hesitated. "I've wasted eight of my biggest Bettas on you now. . . . Oh, all right." He went to a wide niche in the east wall, where there were numerous quart tanks each containing one Siamese Fighting Fish. From the ceiling hung a globe of water, on three slender chains, at a height of about five feet from the floor. He took up a small round Brussels net and transferred two veil-tail fish—a beautiful blue-green and a purple one—to the suspended globe. The two fish appeared to look at each other cautiously before attacking. Then, with brilliantly heightened color and with fins and tails twitching and spreading furiously, they rushed about. Coming close together and nearly parallel, they slowly rose, side by side, to the surface. Soon they seemed to relax, and sank to the bottom of the globe. These preliminary manœuvres continued for a few minutes. Then, with lightning swiftness, the fight was on.

They dashed at each other viciously, ripping off scales, mutilating each other's tails and fins, and tearing bloody bits from the sides. Tatum was offering odds on the purple Betta, but no one paid any attention to him. The blue-green one fastened on the other's gill with a terrific grip, hanging on until he was compelled to rise to the surface for air. The other then attached himself savagely to his antagonist's mouth and relinquished his hold only when forced to go up for air himself. It was a terrible, but beautiful, sight.

Vance looked toward Tatum. "You enjoy this sort of thing?" he asked. "Too tame," Tatum complained, with an unpleasant laugh. "I prefer cock-fighting myself; but when there's nothing else to do. . . ." Leland had entered the room without our hearing him. He stood just behind Vance. "I think it is a brutal sport," he said, his smoldering eyes on Tatum. "It is beastly." The purple Betta was now at the bottom of the globe, mutilated and almost entirely stripped of its scales; and the other was attacking it to give the *coup de grâce*. Leland quickly picked up a small net and, reaching into the globe, removed the wounded loser and placed him in a small tank of Mercuro-chrome water. Then he went back to the library.

The Dragon Murder Case movie: Vance and Markham behind one of the tanks.

It is interesting to note that in the discussions by aquarists of The Dragon Murder Case, aquarists were more interested in the movie version that the book is was based upon. This is understandable because for the first time, aquarists were able to view the tanks and live fish of the early 1930s.

I. ADDENDUM

All the novels by S.S. Van Dine are available for free on-line in PDF format. Just enter the name of the case and look for the hits that offer downloadable copies. With regard to the movies, Amazon has "The Philo Vance Murder Case Collection" that contains the following DVDs: The Bishop Murder Case, The Kennel Murder Case, The Dragon Murder Case, The Casino Murder Case, The Garden Murder Case and Calling Philo Vance.

Amazon also has a collection called "The Philo Vance Lost films Collection" that contains the following DVDs: The Canary Murder Case, The Greene Murder Case, The Benson Murder Case, The Kennel Murder Case and The Gracie Allen Murder Case.

Finally, for those interested in an exhaustive biography of Willard Wright, I recommend the book (296 pages) "Alias S.S. Van Dine" by John Loughery, Charles Scribner's Sons, 1992.
