ESSAYS ON AQUARIUM HOBBY HISTORY

Written by Albert J. Klee, Ph.D.

Dedicated to the Aquarium Hobby Historical Society whose members understand that the history, innovations and ideas of aquarists throughout time is fundamental to our understanding of the life in the aquaria around us.

This book consists of essays written between 2003 and 2019 that appeared mostly in the Files section or posts of the *Aquarium Hobby Historical Society*. Three additional entries that are concerned with aquarium history are articles written between 2004 and 2007 that appeared in the *Buntbarsche Bulletin,* published by the American Cichlid Association.

You got a "C" in History? How hard could it be?

THE BIRTH OF THE AMERICAN KILLIFISH ASSOCIATION

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, March 26, 2011)

INTRODUCTION

Until the birth of the American Killifish Association in 1961, there never had been a successful national aquarium fish specialty organization in this country. In the early 1950s, Gene Wolfsheimer started the Aquarists Internationale, a global correspondence club of restricted membership that included a number of killifish fanciers of renown, such as Jorgen Scheel and Walter Bertholdt. But, because of its restrictions and being based upon the exchange of letters (although some of these letters were published in selected aquarium magazines), by no means could it be characterized as such an organization.

In 1957, Larry Konig and John Rutkowski offered a pair of their famous strain of show guppies to any aquarium society that would form a guppy group. This soon produced a flood of guppy organizations that reproduced faster than the guppies themselves, including one that described itself as being national in scope, the American Guppy Association (AGA), Konig has been its principal architect.

This organization dealt mainly with show rules, delta tail guppies, local guppy clubs, guppy shows and Konig's guppy columns that appeared in THE AQUARIUM magazine and THE AQUARIUM JOURNAL. In essence, however, it was not a true functioning, independent national association. Its structure was modeled after that of local aquarium societies and, because traveling any distance is both expensive and inconvenient, only those elected leaders of the group who lived close to each other were able to meet physically. However, if a subgroup meets on a regular basis, then the subgroup becomes a ruling clique, and the organization quickly becomes geographically restricted. This is what happened to the AGA and so, not being a truly national organization, it disappeared within a short time.

The 1950s also saw the establishment of umbrella organizations such as the International Federation of Aquarium Societies, the Northeast Council of Aquarium Societies and the Canadian Association of Aquarium clubs, but none of these were national aquarium fish specialty organizations.

In April, 1958 in a two-page article in THE AQUARIUM the Publications Editor, Alan M. Fletcher, announced the formation of the American Panchax Association (APA) and displayed a suggested logo. This was followed throughout the remainder of the year with letters of support for the idea, and invitations to anyone who wished to be members or who had any ideas about what the APA should be and do. The July 1958 issue contained an article by Aaron Dvoskin entitled "American Panchax Association," which went on to describe the association's purposes. Dvoskin and Gene Wolfsheimer were both mentioned as club officers and in November of that year it was announced that J. Edmond Harris, President of the Northeast Council of Aquarium Societies, had accepted the position of its Executive Secretary.

In the December 1959 issue of THE AQUARIUM in the "Editor's Letter" then written by Helen Simkatis, Simkatis announced the formation of a new section of the magazine called "The Panchax Exchange." The Exchange was a series of articles about killifishes, often ending with up "Available" or "Wanted" egg listings. This offer on the part of a national magazine was unequaled and exceedingly generous. I myself contributed an article to the exchange, as did many other well-known killifish aquarists, but like my friends

considered it as a vehicle for the publication of articles devoted to killifishes, nothing more. Had the APA existed in substance, other than just names in a magazine, I most likely would have joined. But, there was nothing to join. It was an organization in name only.

In "A Guest Editor's Letter" appearing in the January 1962 issue of THE AQUARIUM written by the acclaimed killifish hobbyist, Franz Werner, Franz wrote: **"Some years ago, I was active, in concert with a number of prominent and enthusiastic Panchax fanciers, in an attempt to form an association devoted to the keeping and propagation of the killies - Panchax then. The response to the initial call published in the April issue of 1958 of THE AQUARIUM magazine was beyond expectations. Unfortunately, circumstances caused all the preliminary work and effort to be in vain."** In other words, while efforts were made, a functioning organization never evolved or existed.

Co-founder of the American Killifish Association, Albert J. Klee.

THE FATEFUL TELEPHONE CALL

In June of 1961, the author's telephone rang: **"Hello! I'm Bob Criger. I'm interested in killifishes and wonder if we couldn't get together tonight for dinner?"** With this telephone call, in effect the American Killifish Association was born. Bob, who was visiting his home offices of the Armco Steel Corporation in Middletown, Ohio (some 20 miles from where I lived, projected such bright enthusiasm over the phone that I accepted the invitation and drove out to meet him.

Robert O. Criger turned out to be a tall, friendly, personable fellow, lately interested in killies. It turned out that his telephone call to me was triggered by a series of articles I had authored for the old AQUARIUM JOURNAL (see Klee, Albert J., "A Fresh Look at the Genus *Aphyosemion*," AQUARIUM JOURNAL, August, September, and October 1960). This particular series was one in which I had invested a great deal of time and effort for at that period, little information was available with regard to these fishes. Today, I look back at some of the inadequacies of that particular material with some misgiving. We have all learned much about killies since then!

In any event, Bob had read the series with interest and, knowing that I lived in the area, took a chance, located my telephone number and called me out of the proverbial "clear, blue sky." He was prepared with a list of killy topics for discussion that could have formed the basis for a good-sized book. These were tackled with enthusiasm, for in those days, finding persons who were devoted to killies wasn't that easy.

The conversation continued after dinner. We bemoaned the scarcity, not only of information about killies, but of the scarcity of the fishes themselves (today's killifish fanciers are really spoiled by the relatively easy access of these fishes). Sometime after midnight, Bob thought out aloud: "**Wouldn't it be great if we had some sort of club devoted solely to killies?"** At first

I was reluctant, knowing full well the work involved and that ventures of this sort usually wound up with but a few people carrying the main load, ultimately to fail because of general apathy. Further, the experience of the ill-fated "American Panchax Association" was not unknown to me. However, Bob was particularly interested in developing a professionally produced publication strictly for killies, and as he had had considerable publishing experience and access to processes and printers, his suggestion became persuasive. Then, too, the challenge of developing a really successful national aquarium organization was appealing and ultimately irresistible.

By our fifth highball, we mutually agreed to attempt the formation of a national killifish association. It was decided that Bob would handle publicity, membership and correspondence, and that he would simultaneously work out plans for a publication; to me fell the task of organization, planning, operations and By-laws. On this note we parted, Bob returning to Kansas City, his home at that time.

THE LETTER THAT SUMMARIZED IT ALL

After Bob left Middletown and returned home, he sent me the following letter:

June 22, 1961
Dear Al:

I have been doing a lot of thinking since seeing you last week...and a little work, too. You know more about these things than I do, but it's possible that what I am sending you might be the starting point of the International Killifish Society. Before I explain some of the things I thought about, I would like to say that I liked you very much and was very impressed with your frank and sincere manner. I feel that I am much the same as that...and like people who don't beat around the bush.

This I.K.S. idea has to work! I know it can be done if the information can be put out to the people. It is something that we have needed for a long time... and I hope you were sincere when you indicated that you would put all your efforts behind it.

I don't know whether or not you had a chance to write to Helen Simkatis... and it is quite possible that she has already told you that such a Society already exists — or that the possibilities of such a group are rather lukewarm. I hope no one is able to discourage you. I'd hate like hell to have to try to organize a thing like this on my own.
I hope you will look over the enclosed letter and questionnaire. Naturally they won't be absolutely correct, but as I said before, they might be a starting point for us. The letter is long — I know that — but it will take quite a bit of explaining, and I couldn't see any other way. We could send it out to anyone who inquired about the proposed Society through

Co-founder of the American Killifish Association, Robert O. Criger.

articles done in the various aquarium magazines. Of course, we would want to send it out immediately to those people we know are already avid killifish breeders. They'd form a nice nucleus from which to work...and I beleive (Sp?) each would want to join. (It's believe, isn't it?) It might not be such a good idea to send these things overseas written in English, but maybe you'll have a few ideas on this.

I am certainly not a rich man, but I would be willing to absorb some of the costs of getting this thing off the ground until we could get going. I can handle the printing in Kansas City...and will come up with enough letters, questionnaires, and return envelopes to take care of several hundred inquiries (or more, for that matter, if this thing should catch on). I will also handle the postage, and if we ever get any money, you can pay me back. I would also be willing to try my hand at getting out the publication, though my technical knowledge might embarrass us if it were thoroughly checked each time. I could also handle the compilation of news letter material and get it printed and distributed. I do not want to handle the organization's funds — you could simply send me a check when I send you some bills.

Charter Committee Member of the American Killifish, Association, John L. Gonzales.

There are, of course, some disadvantages in having the Society publication based in Kansas City, Missouri rather than New York or some-place like that. But if it is necessary, I'll do most anything to give this group a chance to get started. I want nothing in return other than new friendships and new killifishes.

I am sure you will be able to improve on the letter and questionnaire, so go head and tear it apart if you like, and send me a copy of what you come up with. I don't see any reason for fooling around too long with the idea. Let's get the letter started — let's make the contacts with as many publications as possible and give them the necessary information about the proposed group — let's get our printing done — and let's start mailing out letters and questionnaires to those we already know in the hobby.

I make it sound easy, huh?

Don't let me down, boy. I've got a printer already lined up and we can even have a four -color cover on the magazine if we can come up with the transparencies. If you wish to consider the possibility of having out-side advertising in the magazine, let me know what should be done along these lines. As far as the legal matters involved in a venture of this kind, maybe I can shove that off on you. I would make a lousy lawyer.

By the way, did you write to Bruce? I did, and if you didn't, he will probably be shocked as hell when he gets my letter. It probably sounded like I've known him all his life. Is he touchy?

The Sjoestedti I got in Cleveland are beautiful and I am getting them accustomed to my

tanks. I can't think of a reason in the world why the little boogers shouldn't spawn for me so I'm plowing ahead as if I didn't have good sense. Everyone I've talked to so far says they are nearly impossible to spawn. Maybe so. We'll see.

I'll be waiting breathlessly to hear from you, old friend, so get going with the old grey matter, and let's do something for the world of the killifishes.

Thanks again for driving up to Middletown to see me. The pleasure was definitely mine.

Your friend, Bob Criger.

The "International Killifish Society" mentioned in his letter was the name we came up with during our face-to-face meeting in Middletown. However, because of the way I decided to structure the organization, it was not feasible to make it a truly international organization so I settled on the name, "American Killifish Association" and this was the name I proposed to the Charter Committee. The enclosed letter that he mentioned was a draft of the announcement of the formation of the association that we planned to send to all the aquarium magazines, the final version of which I will show shortly.

In establishing any new organization, it is necessary to formulate both a short-term and a long-term plan. The short-term plan is the one that gets the organization going, and the long-term plan is the one that keeps it going. During that historic evening in the summer of 1961, Bob Criger and I formulated the following short-term plan. (1) We would start a three-month writing campaign to appear in as many aquarium publications as we could reach, describing the aims of the organization and the hobbyists who were supporting it. (2) We would describe the quarterly magazine we intended to publish, as well as our plans for a fish and egg exchange. (3) All those joining before January 1962 would be Charter members voting for the first Board of Trustees and the choice of fish for the Club emblem. They could also voice their opinions in a questionnaire we prepared that would help the Charter Committee in shaping the directions the organization would be taking in the future; they also could nominate persons for the first Board of Trustees that would convene in January 1962. In other words, we didn't just say, "Hey folks, would you like to join a killifish club?" Rather, a carefully considered campaign was conducted to show what the organization would look like and what it would do for those who joined. The lack of a short-term plan was, in my view, the main reason why the American Panchax Association failed to get off the ground.

THE CHARTER COMMITTEE

The role of the Charter Committee has not always been understood correctly. I had four reasons for forming this committee. First, we needed a cadre of aquarists well-known in killifish circles that would lend credibility to the proposed organization. Second, we needed a small staff to publicize the new association in and to recruit Charter Members from their respective geographical areas. Third, we needed a test group to experiment with the idea of conducting business via the mails, and to work out any of the bugs encountered before the first Board of Trustees took office. Fourth, since Bob and I were not the only ones with ideas, the proposed organization needed to garner as many as possible from this select committee of well-known killifish fanciers to get it off to a rolling start.

With Bob in Kansas City and I in Cincinnati, we already had a fair start of sorts on geographical dispersion. I then initiated a search for aquarists living in other areas who were interested in participating in and contributing to such a committee. My first invitation went to John Gonzales, then of Philadelphia. John was one of the real "old-timers" in the hobby. He was, for example, the first American aquarist to breed *Rasbora maculata*; a keener mind and superior breeder of kil-

lies could not be found. Due to a chronic back injury, John was forced to retire relatively early in life, but as he could not stand to be idle, he had decided to breed selected groups of fishes for the commercial market, i.e., those fishes requiring too much individual attention for commercial hatcheries to handle. Primary among the fishes he bred were killies.

In Chicago, we found two men with excellent qualifications. One was Charles Glut, an engineer who was gaining a reputation as an "innovator" in the killifish field. The other was George Maier, who possessed an enviable record of years of experience with aquarium fishes, particularly killies. At the time, George (who, with his wife, operated a fish store) was Advisory Editor of the now defunct TROPICALS magazine. George Maier, it might be mentioned was a man for all occasions. His technical craftsmanship was flawless and his warmth for people unsurpassed.

The next to be invited was Bruce Turner, of New York City. Bruce, then a student at Brooklyn University, lived, ate and breathed killifishes (he later was to become a professional ichthyologist specializing in killies). He corresponded with collectors and professionals all over the world, and could rattle off the musty references to killifishes in the literature of a hundred years ago with the same facility the more typical teenager rattled off baseball averages. The last member of the Charter Committee was Bernard Halverson, a chemical engineer who had attained a national reputation when he persuaded the Houston Aquarium Society to sponsor the sale of dwarf white worms, a fish food then relatively unknown in the hobby. These men provided at least some of the geographical diversity I thought to be critical.

Unfortunately, I had made a serious error that I have always regretted, i.e., selecting two of the five from the same area (Charles Glut and George Maier were both from Chicago). I did this because, at the time, they were extremely well-known in the killifish hobby in the east. A much better decision would have been to include an aquarist living on the West Coast, the logical choice being Gene Wolfsheimer. Unfortunately, by the time this situation was realized it was too late, since these five had already been asked and adding Gene would have brought the Charter Committee membership to an even number. Because of ties, an even number is not ideal for any committee.

In order for a committee of seven people dispersed about the country to operate without chaos, some system of corresponding had to be devised. Thus, the Charter Committee served as an experimental vehicle in which to work out the modus operandi that basically was to be used by future Boards of Trustees of the AKA. John Gonzales was instrumental in suggesting the technique that finally proved workable. Briefly, the chairman of the group sent his letter to the others about the first of the month; by the middle of the month the others sent their letters, with copies to all. The function of the chairman was to summarize the comments, formalize motions, assign motions a number and a place on the agenda, and to conduct and record the vote. Thus, regardless of where a participant resided, he shared the involvement in policy-making equally with the others in the group. The chairman had no greater powers than his peers. He was an equal among co -equals, but traditionally acted to minimize the discord that frequently plagues voluntary decision -making bodies and to expedite the flow of business. This approach served to eliminate the one-man-show responsible for the many prior failures of national organizations.

As might be expected, many of the individual members of the Charter Committee had particular interests in the structure of the Association. Bruce Turner and I, for example, had been seriously concerned over the loss of killifish species within the hobby over time. It was not uncommon for a newly imported species to be raised by a few aquarists and, within a few years - whether because of inbreeding or loss of interest or whatever - dis-

appear from the hobby. Therefore, Bruce and I proposed that we establish something we called "The Egg Bank." The idea was that, for each species thought to be in jeopardy, we would recruit a number of volunteers to maintain and breed that particular fish. However, a majority of the Charter Committee thought that this was unnecessary, their argument being that these species would be automatically kept up through the fish and egg exchanges that were to play an important future role in the Association. This, like the name of the organization, was a friendly disagreement, and since we could see their point, Bruce and I abandoned the idea.

Charles Glut devoted much time to setting up the fish and egg exchange, Bruce Turner applied himself mainly to the organization's acquisition of new species, George Maier cultivated crucial support from aquarists in the important Chicago area (George was responsible for recruiting more members to the AKA in its first year than any other person) and I occupied myself with the preparation of the bylaws. All of us, however, actively discussed and debated all aspects of the new organization.

Co-founder of the American Killifish Association, Robert O. Criger, in his fish room.

With regard to the fish and egg exchange, a dispute arose between Charles Glut and most of the rest of the committee (as Chairman of the Charter Committee I was obliged to remain neutral) over whether or not the AKA should set the asking prices. The general thought was that a free market system would be the most efficient and that prices should be unregulated. However, Charles strongly insisted that the AKA institute a price schedule, and woe to those who disagreed with him. As a result, John Gonzales in particular, and later Bob Criger, were the major recipients of some verbal abuse. Now John had been active in the aquarium hobby longer than any of us, having started keeping aquarium fishes in 1928, a year before I was born. He therefore was not about to take any nonsense and so a real donnybrook developed, albeit conducted through the mails.

The very nature of communicating via the written word allows one to express thoughts and feelings with an openness and frankness that is unusual in face-to-face or telephone conversations. The trouble is that, without the tone and expression of a voice, or signals given out by body language, the potential for misunderstanding is considerable. Nowadays, because of electronic communication, we have "Emoticons" (e.g., the "smiley face") that can be included in a written sentence to help clarify and express one's feelings. Unfortunately, we didn't have emoticons in those days, although we sure could have used them in this instance!

During this time, Bob Criger, acting as publicity liaison officer, contacted all of the national aquarium magazines with a view towards publishing news of the proposed organization and keeping aquarists informed of the progress of the Charter Committee. All agreed to cooperate with the single exception of the TROPICAL FISH HOBBYIST. Although the AQUARIUM JOURNAL, TROPICALS MAGAZINE, and THE AQUARIUM magazine published many progress reports and announcements

regarding the AKA none ever appeared in TFH. Bear in mind that by no means am I taking to task the present editorship of TFH; all this occurred 47 years ago and many editors have since come and gone. The following is an example of Bob's PR work, published in TROPICALS MAGAZINE, Fall Buyer's issue, 1961:

NEW GROUP BEING FORMED -
AMERICAN KILLIFISH ASSOCIATION
By Robert O. Criger

It was bound to happen sooner or later… and the sooner it happens the better, according to seven killifish fanciers from many parts of the country who recently got together and discussed the possibility of forming a society for persons interested in killifish (sometimes called Panchax). The men have tentatively selected a name for the group the American Killifish Association.

"The name might turn out to be something entirely different from that," said Bob Criger of Kansas City, Mo., who is handling the publicity for the group until a permanent publicity chairman is selected when elections are held for the organization. "We plan to send a questionnaire to anyone who will write for it," he said, "and let them help select a name if they don't like the one we have already chosen."

Criger also said that the questionnaire will give anyone interested a chance to express his views and ideas on mane other matters before the club is officially formed.

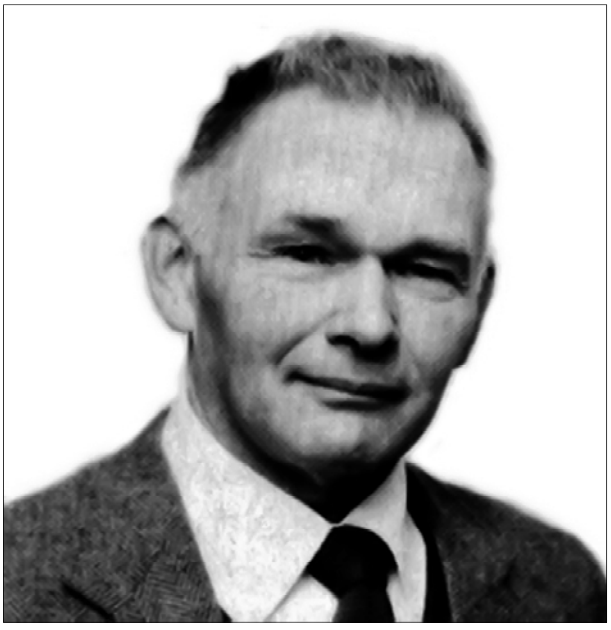
The most important ideas behind the organization, perhaps, are to increase the knowledge and skill of killifish hobbyists… to bring in many of the seldom seen species of killifish… and to distribute eggs of these species to the club members. It is the plan of the group to set up Egg Banks in the fish rooms of many of its members through-out the country to insure that once a new species is brought into America, it will always be available to members of the group.

The proposed group also plans to publish a quarterly magazine dealing exclusively with killifish, as well as a monthly newsletter through which members can buy, sell or exchange killifish and eggs. The magazine will contain articles written by advanced aquarists about killifishes and things pertaining to spawning and raising them.

The group plans to hold the membership open for the first 60 to 90 days so that all who wish to join as Charter Members may do so. Anyone joining after that will hold a regular membership.

An election for the Board of Directors and Committee Chairmen will be held after all Charter Members have joined.

Criger stressed that it was the feeling of those already interested that a large number



Charter Committee Member of the American Killifish Association, Bernard K. Halverson.

of members was not nearly as important as a "good, solid nucleus of dedicated killie fanciers." He also said, "We have even discussed having two types of memberships — one for beginners, whom we will help get started through the Egg Banks — and the other for the advanced hobbyists."

The other men who have joined their thoughts to the idea of forming an American Killifish Association are Albert Klee of Cincinnati, O.; Charles Glut and George Maier of Chicago; Bernard Halverson of Houston, Tex.; John Gonzales of Philadelphia, Pa.; and Bruce Turner of New York City. All are enthused about the idea and hope that once the American Killifish Association is formed and operating, overtures can be extended overseas regarding the possibility of forming an international group.

Complete details about the proposed group… and a questionnaire… can be obtained by writing to Robert O. Criger, 7405 East Gregory, Kansas City 33, Mo.

Compared to the egg bank controversy, a friendlier disagreement arose concerned with the naming of the new organization. The two main proposals advanced were: American Killifish Association, and American Panchax Association. The problem with "Panchax," however, was that it was based upon a scientific name long since abandoned by the profession, and one applied originally only to a very few killifishes. George Maier thought that it would be misinterpreted to mean a fish that killed others but then such fears could be applied to fishes such as "tiger" barbs, tricolor "sharks," etc. I pointed out in jest that pussycats are perfectly safe in the Catskills, and the Committee voted unanimously to adopt the AKA name.

It was a personal triumph for me when the Germans threw in the towel and abandoned their beloved, "Eierlegende Zahnkarpfen (egg-laying toothcarps)," calling their organization the Deutsche Killifisch Gemeinschaft. The French, of course, went their own way and called their organization, the Killi Club de France, but at least they got the term "Killi" in there! Since the history of the origin of the terms "Panchax" and "killifish" is a story unto itself, I present it separately in the article in this Compendium titled, "The Story of Panchax and "Killifish."

THE BY-LAWS

The by-laws of the AKA contained several novel features. A seven-man Board of Trustees was devised as the policy-making force for the Association. For continuity, three were elected in odd-numbered years, four in even-numbered years, and all served two-year terms (an early amendment to the bylaws stipulated that the Trustees had to take at least a one-year "vacation" before they could run again for office). Only members from the United States or Canada could vote or hold trusteeship office (foreigners were considered, of course, but the problems of conducting business via the mails among counties made it inadvisable).

Although Bob Criger and I had dealt with the short-term plans for the AKA, there remained the long-term problem, that of the extended survivability of a truly national association. This was resolved by the following two Articles in the by-laws. The first was an important clause read: **"...no more than two Trustees of the seven shall reside in the same State in the case of the United States, or in the same Province in the case of Canada."** With one clause then, the new organization avoided the old problem of regionalizing or concentrating power in any one particular area, an occurrence that killed many a prior national aquarium organization. Perhaps even more important was Article VII, **"Mode of Operations," which stated: "Insofar as it is applicable, the business of the Association shall be carried out by written correspondence."** Thus, in the AKA, anyone could run for the Board of Trustees and expect to participate equally with other Trustees if elected. It was no

longer necessary to be rich, retired, or both to fulfill one's obligations as a Trustee. One did not have to travel, say, from Alabama to California to vote at a national convention or in vis-à-vis committee. A $.06 stamp and a little time was all that was required. These by-laws were adopted unanimously by the Charter Committee.

All this occurred thirty years before a system was developed to simplify navigation on the Internet and another ten or so years before personal computers were common. The problems we faced in communicating in 1961, therefore, no longer exist today. I firmly believe that without these two provisions, the AKA would have been only one of many others, rather than the single, influential and international one it is today. As it turned out, the AKA's by-laws became the model for most of the specialty organizations that came after it. Indeed, shortly after the formation of the AKA I suggested to my good friend Richard Stratton, the founding fellow of the American Cichlid Association, that a national cichlid group be formed along the lines of our association, using its by-laws as a starting point. Although I had hoped that we were able to do this together, the launch of AQUARIUM ILLUSTRATED, where I was involved as its editor as well as one of its publishers, made it impossible.

Charter Committee Member of the American Killifish Association, George J. Maier.

Towards the end of 1961 Bob Criger, then acting as Secretary of the Charter Committee, asked all fourteen nominees running for the first Board of Trustees to prepare a resume consisting of no more than 50 words that would be placed on the ballot for our first election. Charles Glut objected, however, and insisted that he be allowed more. Bob, however, held his ground, the result being that Charles withdrew his nomination at the last moment. John Gonzales, who was in poor health at the time, was uncomfortable serving on a Board where such discord might erupt in the future, also withdrew his nomination at the last moment, although I tried hard to convince John to stay on the ballot. These actions could have caused us some difficulties, but there were a sufficient number of nominees so that all we had to do was to select the seven who garnered the highest number of votes.

THE ORGANIZATION BEGINS

At the beginning of 1962, prospective members had sent in $5.00 for their first year's dues and voted for seven Trustees and their choice of fish for the club emblem. Fourteen aquarists had been nominated for Trustee, based upon recommendations received by the Charter Committee and from interested aquarists during the latter part of 1961. In order that hobbyists would know who they were voting for, the bibliographic sketches noted above were prepared by the candidates, edited into a standard format by Bob Criger and distributed to the voters. Although Bob's PR announcement sent to the aquarium magazines had stated that Charter members would be able to vote on the final name for the organization, the Charter Committee decided that this would only delay getting the organization started and opted

not to have a vote on the name. If the membership objected, they could always change it later.

The top seven votes for the Board of Trustees were as follows:

Criger, Robert O.	**114**
Klee, Albert J.	**89**
Weitzman, Stanley H.	**86**
Adams, James N.	**85**
Maier, George J.	**80**
Haas, Richard	**79**
Seligmann, Edward B., Jr.	**63**

There was not enough time to remove the names of Charles Glut and John Gonzales from the ballot, both of whom requested that their names be removed, but if they had stayed on, Charles Glut would have nosed out (by two votes) John Gonzales, replacing Ed Seligmann as a Trustee. Following the AKA by-laws, the Board of Trustees elected their own officers and so I was elected as Chairman of the Board, with Bob Criger as its Secretary and Stan Weitzman as its Treasurer.

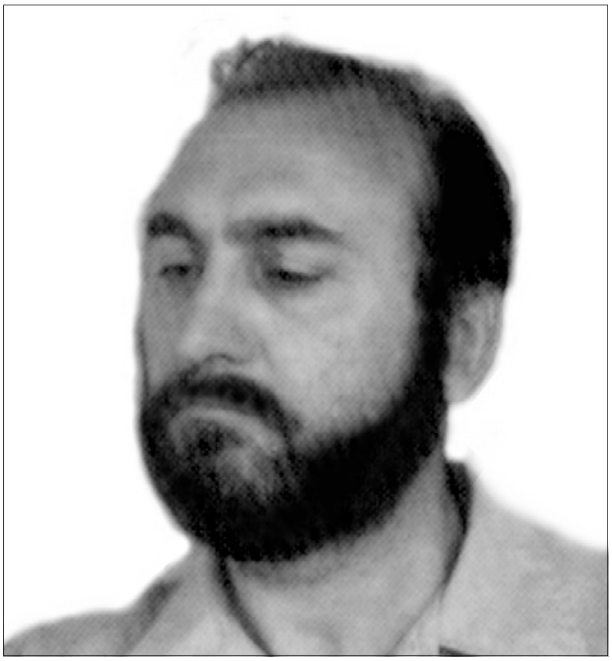
The top four votes for the AKA emblem were as follows (the names are those used at the time):

Aphyosemion gulare coeruleum (blue gularis)	**48**
Aphyosemion australe (lyretail)	**42**
Aphyosemion bivittatum	**18**
Nothobranchius rachovi	**16**

From the start, the AKA's publication program was a resounding success. KILLIE NOTES (a professionally produced offset publication) came first. This was a mixture of topical club news and technical material. It was later decided to separate the two functions, and when the Association had sufficient funds, the publication was discontinued with two new ones taking its place: the AKA NEWSLETTER and the JOURNAL OF THE AMERICAN KILLIFISH ASSOCIATION (JAKA). Because the AKA depends so heavily upon the exchange of fishes and eggs among its members, a booklet entitled "Killifish Exchanges" was published soon afterwards. A host of other specialized publications appeared, the most important of which included a beginner's guide and the KILLIFISH INDEX. In short, the publication activity of the AKA has been extraordinary — no other aquarium organization has ever matched it.

One of the most effective instruments for selling killifishes to the public and for recruiting new members proved to be the AKA's audio-visual (slide/tape) program. Sight and sound told the Association's story and the story of killifishes. It was loaned free of charge to responsible hobby organizations.

One of the really vital activities of the AKA was, and still is, its free (to members) egg and fish listings in its monthly newsletter. This enabled fanciers all over the world to obtain, exchange, and even sell many different species of killies. From a historical standpoint, two species of killies in particular spurred special interest in the hobby in the late 1950's and early 1960's. Indeed, they were partly responsible for the founding of the AKA in



Charter Committee Member of the American Killifish Association, Charles F. Glut.

that they created a general interest in the family. These species were *Aphyosemion filamentosum* (now *Fundulopanchax filamentosus*) and *Aphyosemion nigerianum* (now *Fundulopanchax gardneri nigerianus*), the former because it was a new, reasonably-sized and an easily-bred "bottom spawner" (bottom spawners being relatively rare at the time) and the latter because it was an easily -bred fish and a brightly-colored, exciting new "top-spawner" introduction. The AKA should really erect a monument to these two species! Another species important to the early AKA was the blue gularis. It was a natural "salesman" for the association.

Thus, there were two co-Founders of the AKA, Robert O. Criger and Albert J. Klee; seven Charter Committee Members, George J. Maier, Bernard K. Halverson, Bruce J. Turner, John L. Gonzales, Charles F. Glut, Robert O. Criger and Albert J. Klee; and 145 Charter Members, the last listed in the Appendix. The formation of the American Killifish Association was a labor of love for all who participated, and I for one wouldn't have missed it for anything!

An early American Killifish Association meeting in the NY-NJ area in the early 1960's. Left to Right: Peter Hall, Albert J. Klee (Co-founder), Bruce Turner (Charter Committee Member), Rosario LaCorte, Richard Blanc and John Gonzales (Charter Committee Member).

Appendix: Charter Members of the American Killifish Association (i.e., Members who joined prior to December 31, 1961).

THE FIRST ARTIFICIAL BREEDING OF FISH

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, March 8, 2014)

As I have previously documented, the luxurious and extravagant habits of imperial Rome involved the maintenance - but not the breeding - of fish in both saltwater and freshwater ponds. With the overthrow of that empire, its civilization and its industry, this practice was discontinued, and the art forgotten. But it was revived in the middle ages by the religious observances of the Catholic Church, which, by determining that fish and certain favorite species of water fowl were not *fleisch*, and accordingly not forbidden food at seasons of fasting and mortification, ingeniously contrived to reconcile the indulgence of the palate with the discipline of Lent.

To every favorably situated monastic establishment was attached a fishpond, which not only supplied the tables of the professed during the prescribed fasts, but often yielded a considerable revenue from the sale of fish to worldly penitents. The success of the monks led to the extension of this branch of industry, and large ponds were constructed by laymen, so that in the sixteenth century fishponds were an appurtenance of most great estates whether lay or ecclesiastical.

The following is a summary taken from a manuscript dated 1420, found by the Baron de Montgaudry while hunting among the musty archives of the Abbey of Reome. It is extracted from de Montgaudry's report of 1854, with my translation following.

"La pisciculture n'est pas chose nouvelle. Depuis plusieurs siècles, les moines s'en occupaient et savaient peupler les étangs et les cours d'eau de leurs domaines des espèces de poissons qui pouvaient y vivre et s'y multiplier. Dans le cours du quatorzième siècle, dom Pinchon, moine de l'abbaye de Réome, écrivait sa manière de procéder.

"Il avait des boîtes longues en bois, à fond de bois, grillées aux deux extrémités en grillages d'osier, ouvertes en haut et couvertes d'un grillage d'osier. Sur le fond de bois, il formait un lit de sable fin, et, imitant la truite qui creuse un peu le sable avant d'y déposer ses œufs, il préparait une légère profondeur dans la couche de sable pour déposer les œufs qu'il avait préalablement fait féconder. Il plaçait la boite dans un lieu où l'eau était faiblement courante et attendait l'éclosion, qui, à son dire, s'opérait après vingt jours rarement, et pour tous les œufs dans le mois à peu près."

"Fish farming is not a new thing. For several centuries, the monks knew of fish species that could live and multiply in cultivated ponds and streams within their areas. In the course of the fourteenth century, Dom Pinchon, a monk of the Abbey of Réome described his technique.

"He constructed long wooden boxes, both ends covered by a wicker mesh and open at the top but covered with a similar wicker mesh. On the wood bottom he formed a bed of sand and, imitating a trout digging a little sand before depositing her eggs, he prepared a shallow hollow in the layer of sand to place the eggs that had previously been fertilized. He placed the box in a place where the water was running gently and hatching could be expected, which, according to him, rarely took place after twenty days but with all the eggs hatching in a month or so."

How the reverend father obtained his spawn is unfortunately not recorded; but obtain them he did, and no doubt received the blessing of his confreres for the welcome additions to their larder.

I have supplied the original French from de Montgaudry's report of 1854 since there has been some controversy over whether Dom Pichon artificially inseminated his eggs. The following is taken from Jules Haime's 1873 paper on the history of fish culture in Europe:

"It appears, nevertheless, that toward the end of the middle ages new methods were sought for, which might serve to increase the production of fish; a monk of the abbey of Réome, near Montbara, named Dom Pichon, conceived the idea of artificially fecundating the eggs of trout by pressing out in turn the products of a male and female of this species into water, which he afterward agitated with his finger."

Haime provides the following footnote for the above:

"M. De Montgaudry explained the hatching-box of Dom Pinchon at one of the last sessions of the *Zoological Society of Acclimation*, and was kind enough to inform us also of the manner in which the monk of Réome effected the fecundation of the eggs."

However, the following is taken from James W. Milner's paper - in the same publication - on the progress of fish culture in the United States:

"The evidences advanced to prove a knowledge of the third method referred to, before the time of Jacobi, are not, so far, sufficiently definite, and the data produced by Baron de Montgaudry to show that Dom Pinchon was the inventor of the art, in so far as it involves artificial fecundation, are very unsatisfactory.

"The description he gives of the apparatus proves Dom Pinchon's process in caring for the eggs during the period of development to have been the original of the trough method. The manner of procuring of the eggs is not referred to; he merely explains how he prepared the bed of sand upon which to deposit the eggs which he had previously made fecund.

"The Baron based his statements upon the manuscript found at Réome, without quoting from it, and leaves his readers in ignorance as to whether the mode of obtaining the eggs is described in the original.

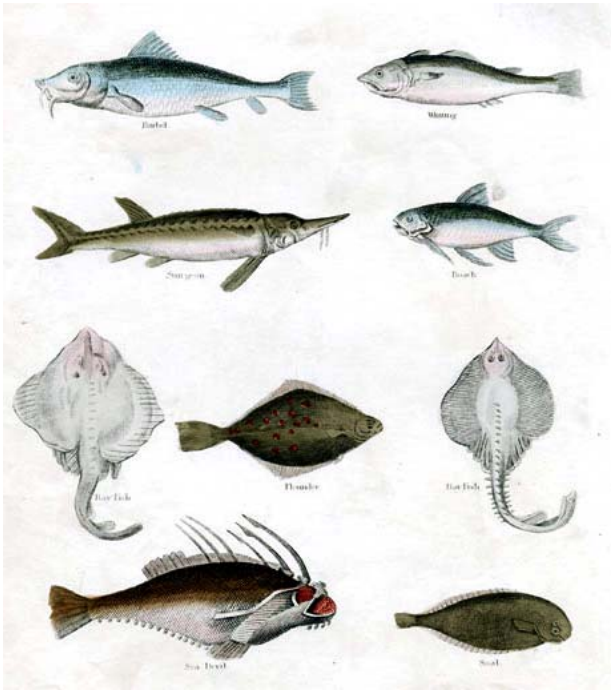
"In the absence of any publication of the manuscript the only data to support the claim are the statements made by Baron Montgaudry and the reference in a foot-note of Jules Haime's paper on pisciculture to the method employed for obtaining the eggs; this information on the subject afforded by Baron Montgaudry, and referred to in the foot-notes, was probably imparted in conversation, as there is no record of it in the papers published in the *Bulletin* or in the report of the *Procès-verbaux des séances* of the society from the time of Montgaudry's references to Dom Pinchon to the date of publication of Jules Haime's paper.

"The publication of the manuscript, if it is still in existence, would clear up the uncertainty and afford a definite record for the history of this important advance in the art of fish culture."

Although admittedly a bit cavalier about his references to Dom Pichon, Baron de Montgaudry's credentials are impeccable. He was the French Consul at Shanghai and Ning-po in 1855, and the grandnephew of Georges-Louis Leclerc, Comte de Buffon, 1707 –1788, the celebrated French naturalist, mathematician, cosmologist, and encyclopedic author. Serving as Consul, he sent back the first tofu seeds to the Society for Acclimatization in France, arriving under the name, "oil peas of China," (*Pois oléagineux de la Chine).* He was the President of the Société Centrale d'Apiculture, and Secretary and Member of the Board of Directors of the Société Zoologique d'Acclimatation. He rubbed elbows with Isidore Geoffroy-Saint-Hilaire, Baron de Rothschild and other notable French men of science of the day.

Because this information on how Pichon obtained his fertilized eggs was given to Haime orally, the piscicultural community generally recognizes Dom Pichon as the first to breed

fish but not the first to devise and use artificial insemination. Dom Pinchon is then, in all probability, the first inventor of artificial breeding. His work had, of course, had no influence on the progress of pisciculture, and is only interesting from a historical point of view. To aquarists, however, who obtain their fertilized eggs directly from their fish and breeding starts with them, the historical aspects are of somewhat greater interest.



Illustrations taken from Buffon's *Histoire naturelle, générale et particulière* (1749–1788, in 36 volumes. The bottom image shows sticklbacks spawning and nesting.

"Fish" versus "Fishes"

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Message 8453, May 17, 2009)

The origin of the word "fish" is Old English (fisc), Common Teutonic (fisco) and pre-Teutonic (pisko), the last-named which is cognate to the Latin "piscis." Early taxonomic ichthyologists started writing in Latin and since there is a clear division in that language for one fish and more than one fish (piscis for the singular and pisces for the plural), it was only natural that they used this singular/plural to differentiate between one species and a plurality of species even when they started writing in the vernacular. (It should also be mentioned that "fishes," with an apostrophe, also serves as the plural possessive of fish; e.g., "the fishes' scales were yellow," and, of course, "fishes" is the present-progressive verb (e.g., "he fishes in the river").

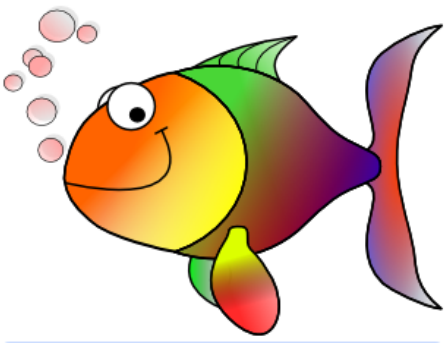
Over the years the rule in common parlance - excluding aquarists - has been to use "fish" for either a single fish or for a plurality of fish no matter whether the plurality involves more than one fish or more than one species of fish. In the early days of the aquarium hobby, however, the regular plural of fish ("fishes") was commonly used, such as "goldfishes." This, of course, has changed and that term is nowadays rarely used. Today, aquarists more often or not use the irregular plural ("fish"), e.g., "catfish" rather than "catfishes," even though reference is to more than one species. Although there is nothing to keep me from saying that I have a collection of fishes, I find it awkward and some of my friends find it a bit stuck-up for me to say anything other than that I keep a collection of fish. It often boils down to what one is comfortable in using. I would, for example, in writing about the ichthyofauna of that country, opt to use "The fishes of Guatemala" rather than "The fish of Guatemala," but my choice would be based on how it sounded, not on any grammatical "rules."

Although in biological contexts "fishes" (the "regular" plural) was used to denote more than one species, this usage is fast declining. In 2008, the Executive Secretary of the International Commission on Zoological Nomenclature, Dr. Ellinor Michel, described her background thusly: "My taxonomic specialty is primarily in malacology, but I have also worked on fish, crustaceans, sponges and bryozoans." It is interesting to note that whereas crustaceans, sponges and bryozoans are expressed here using the regular plural, Dr. Michel chose to use the irregular plural for fish (she has a long-standing interest in the role of behavior in evolution and ecology with regard to the cichlids of Lake Tanganyika). Dr. Michel is British and as an American ichthyologist friend shared with me, "Interestingly enough, I find British journal editors, in general, to be more comfortable than Americans with 'fish' as a collective plural. In fact, sometimes when I use 'fishes' as a collective plural, a British editor will try to change it to 'fish.'"

Grammar tends to lay down universal rules while usage lays down particular applications. Grammarians still disagree over whether fish as a plural is an irregular or regular form but in any case, grammarians ultimately must accede to those who speak the language. What many people tend to miss, however, is that usage is dictated by circumstance. The big struggle between grammar and usage is when a grammatically incorrect usage becomes standard or when a grammatically correct usage becomes non-standard. These are moments when most speakers use a term but most grammarians say is wrong. These instances create the great linguistic debates of history. A good example is "Woe is I" versus Woe is me." As Patricia T. O'Conner says in her book, "Woe is I," "Only a pedant would argue that Shakespeare should have written 'Woe is I' or 'Woe is unto me.'"

Following the rules of grammar strictly often makes you look pretentious. Following the rules of usage strictly often makes you look as if you're uneducated or even uncouth.* The answer is to find that middle ground, and with fish versus fishes, I find it by using my ear.

*Regarding "like" versus "as," the rule is that when the word is followed by a clause (i.e., a group of words with both a subject and a verb, as is the case above), "as" should be used; if no verb follows, use "like." However, the ground is shifting and "like" is rapidly gaining in usage on "as."



THE FOUR STAGES OF THE AQUARIUM HOBBY

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, November 18, 2005)

When did the aquarium hobby start? Who "invented" the aquarium? What do we mean when we say the "aquarium hobby" or, for that matter, the "aquarium"? These questions have presented difficulties for hobby historians precisely because there are no universally agreed-upon definitions. Trying to pin down a concise explanation of the meaning of a word or a term sometimes is - to paraphrase a remark of my grandmother's - akin to attempting to estimate the number of angels that can dance on the head of a pin. Even if we were to agree on these definitions (and bear in mind the line from Lewis Carroll's *Through the Looking-Glass and What Alice Found There*: **"When I use a word,"** Humpty Dumpty said, in rather a scornful tone, **"it means just what I choose it to mean—neither more nor less."**) there is no guarantee that this will take us any "forwarder" on our quest to elucidate the hobby. It also should be recognized that, in defining an object, the definition then limits the object, and this may have unforeseen consequences.

One way out of this dilemma is to avoid definitions and instead describe the major stages in the development of the aquarium hobby. The first stage clearly started when people began to keep fish for their ornamental and entertainment value in ponds and in indoor containers, e.g., goldfish by the Chinese a thousand years ago, and the piscina (from *piscis,* a fish, fish-pond, pool or basin – the term later took on different meanings) of the Romans. One can argue that these ponds and indoor containers were not aquariums in the technical sense since, although the owner of any respectable Roman villa could look down upon the animals in his fishpond, they could only be viewed from above through the opacity of rippled water. The same held for the indoor containers of the time since they, too, were opaque-sided. STAGE I of the aquarium hobby, therefore, is what I term **"The Top-Down Aquarium,"** exemplified by these ancient, opaque-sided, outdoor and indoor aquariums that were viewed from above, although obviously STAGE I aquaria are still common today. I use the term "aquarium" accurately here, as originally it was nothing more than a reservoir or large vessel holding water without any specification as to the uses to which that water was applied.

STAGE II is what I term **"Through a Glass Clearly,"** i.e., any container of glass or other

THE FOUR STAGES OF THE AQUARIUM HOBBY

STAGE I:
THE TOP-DOWN AQUARIUM
(circa 4000 BC)
Opaque-sided containers.

STAGE II:
THROUGH A GLASS CLEARLY
(late 1530's)
Glass jars: fish kept for ornamental or scientific study purposes.

STAGE III:
OCEAN AND LAKE IN GLASS
(mid 1800's)
Tanks frequently with flat glass sides; aquarium books; commercial aquarium fish and equipment suppliers; object to emulate a small portion of a natural habitat.

STAGE IV:
ASSOCIATION (circa 1900)
Aquarium societies; exhibitions; competitions; aquarium magazines.

Example of a STAGE I Aquarium, i.e., a goldfish pond.

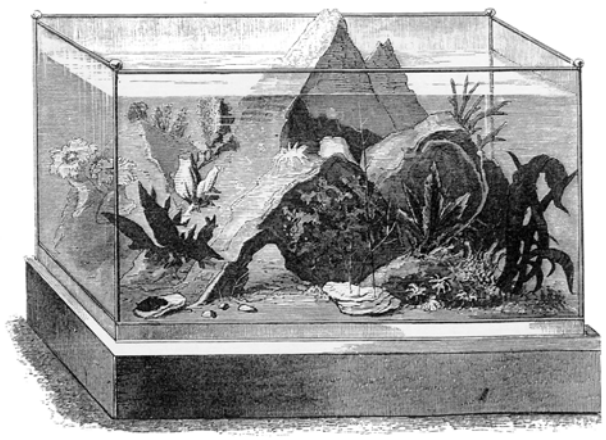
transparent medium that affords the viewing of a fish in the more direct, edge-on, eye-to-eye orientation. Since the Romans produced glass bottles and other glass containers, it might be supposed that they were used to house some of their fishes and thus were the first STAGE II aquarists. Not only is there is no evidence for this, it is highly unlikely since their fishes were rather large for such containers. The Romans, however, did maintain fish hatcheries and may have used glass jars to temporarily house the fertilized eggs of fishes destined to be introduced into waters where they were expected to reproduce and provide a source of food. Again, however, there is no evidence that they did so.

There has always been a great deal of speculation as to who was the first to keep a fish in a glass container. The Romans began to use glass for architectural purposes, with the discovery of clear glass (through the introduction of manganese oxide) in Alexandria around the First Century AD, although it was very expensive. Well-to-do Romans replaced one wall of their marble piscina with clear glass (albeit with poor optical qualities), arguably resulting in the very first aquarium in the sense that we define the term today. However, it was during the second half of the 15th Century that a material known as "Crystallo" was perfected in Venice. This was the beginning of the clear, almost transparent product we normally associate with the word "glass" today. Therefore, whether the Romans should be credited for the first glass-fronted aquarium is open to debate.

The first Stage II fish keeper of record was Jeanne Rondelet, who kept a fish alive in a glass of water for three years sometime in the late 1530's or early 1540's. In the mid to late 1700's, the keeping of fish in glass containers became fashionable in Great Britain and included such illustrious personages as Horace Walpole, the 4th Earl of Oxford.

What the aquarium craze of the mid 1850's in Britain did was to bring on STAGE III of the aquarium hobby, i.e., what I term **"The Ocean and Lake in Glass."** This stage is characterized by the following: (1) first, and most im-

The Stage II Aquarium. Cats and goldfish bowls are almost a cliché in the aquarium hobby.

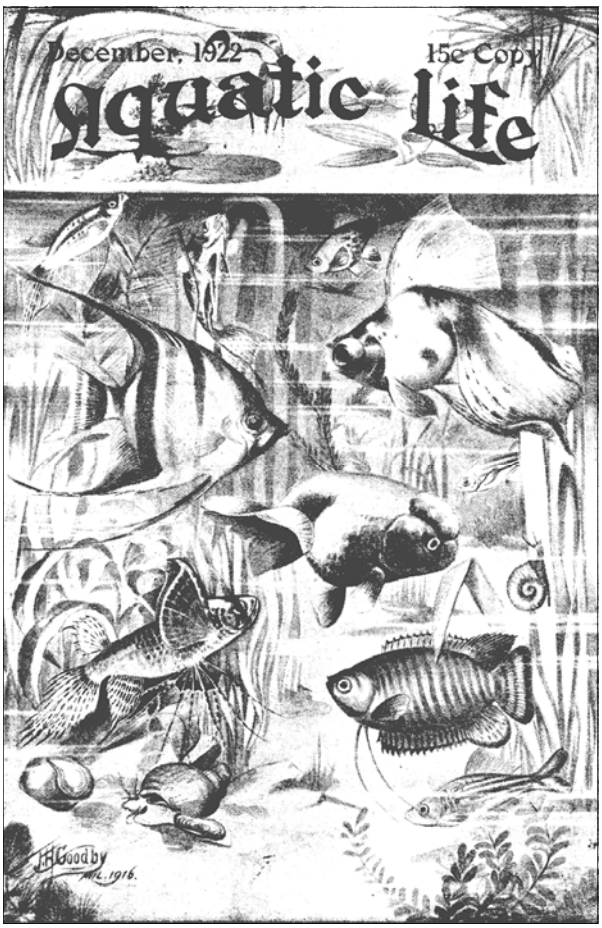


A Stage III Saltwater tank circa 1857.

portant, the interpretation of the aquarium as a mini-representation of a small portion of some natural aquatic environment - the marine aquaria of the day, for example, were frequently referred to as "parlour oceans," (2) an availability of books on the subject, and (3) the existence of commercial establishments supplying fish and equipment.

Towards the end of the 19th Century, improved printing, cheaper mails, and telephone service put people in quick touch with what was going on. It was the age of the periodical and in the aquarium hobby it started with the publication of Mulertt's THE AQUARIUM in the late 1870's and into the 1890's. Tropical fishes were being imported for the first time, starting with the Paradise Fish in 1876, and the others that followed shortly after the introduction of the Chanchito in 1895. In the 1890's, aquarium societies appeared on the scene as well as new authors such as Ernst Bade, Gregory Bateman, Charles Page, and Mark Samuel, ushering in the last stage of the aquarium hobby as we know it today, i.e., STAGE IV, **"Association,"** the notion of aquarium societies, exhibitions, and competitions, all strengthened by improved communication through the appearance for the first time of aquarium magazines, improvements in travel, and the changing nature of cities.

It should be noted that each successive Stage coexisted with previous ones and therefore one can find all four Stages today in various manifestations. Members of the Aquarium Hobby Historical Society are examples of Stage IV aquarists. Although it has been said that the aquarium hobby is the world's largest, since most present day fish keepers simply maintain their tanks for decorative purposes, a source of relaxation, a conversation piece, a learning tool, or teaching responsibility (especially for children), they more accurately may be characterized as Stage III aquarists.



AN EARLY STAGE IV AQUARIUM PUBLICATION.

The Perils of Aquarium History Research

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, September 17, 2012)

The attention of the members of the Aquarium Hobby Historical Society has been drawn to a posting that referred to a monograph that appeared on the Web site of McHenry County College, a two-year community college in Crystal Lake Illinois, written by Peter Ponzio[1] and titled, *Goldfish in America - the 1893 Columbian Exposition*.

In the monograph is a woodblock painting dated around 1700 A.D. that depicts two Japanese women examining a rectangular aquarium of spectacular size, clearly requiring relatively thick glass and exceptionally strong framing, especially considering the width of the framing. This resulted in a query asking whether the flat-sided glass tank pictured preceded anything of the sort found in Western Europe by over 100 years.

With regard to Japanese flat glass, Japan had been unable to support even a single glass-making facility until 1907, although the Meiji government (1868-1912) had tried to establish sheet glass manufacturing. The country had just emerged from 200 years of isolation, and in the last half of the 19th century Japanese businessmen scrambled

Aristocratic Lady of the Tokugawa Period by Hashimoto Shuen,[2] c. 1700 CE
Plate courtesy of *Kingyo*[3]

to compress centuries of technological progress into a few decades of growth. The glass-making field, however, remained open until Iwasaki founded Asahi Glass in 1907 with a factory in Kansai. Instead of merely importing technology from Belgium, then the world leader in flat glass production, he brought over Belgian glass blowers to get his company started properly. By 1909, these artisans had succeeded in producing Japan's first flat glass. In short, there was no Japanese flat glass in 1700.

Nonetheless, the tank pictured could have actually existed since the 1700 date is not particularly early for flat glass. Evidence has been found of glassmaking at the English settlement on Jamestown Island, Virginia and some glass windowpanes were made there after 1608. Flat glass was also, in theory, available in Japan via imports into Nagasaki and Hirado from at least 1616. However, I have gone through all of the illustrations I have come across on Japanese aquaria during the Tokugawa period and can find only two general types: globes and round or rectangular shallow bowls. An illustration (ink and color on silk) of the latter is shown below.

The Kyisai painting is interesting as it depicts an early form of “Discovery,” a method very popular in contemporary nature museums and public

Two Children Playing with Goldfish
Kawanabe Kyisai (1831–1889)4

aquaria where children have an opportunity to touch living creatures. The following are three additional paintings from the Tokugawa period.

An interesting earlier depiction is shown in the bottom image in the collection of the Boston Museum of Fine Arts where a child is playing with a shallow round container of goldfish while a couple is making love.

These shallow containers were later used in a Japanese traditional game started in the late Tokuga-

wa period, around 1810, called Kingyo sukui ("Kingyo" means goldfish and "sukui" means scooping). The game involves scooping up goldfish with a special scooper (sometimes bouncy balls or toys are substituted for the goldfish). The Japanese take this game seriously and they even hold a National Competition of Goldfish Scooping.

Each person plays individually. The basic rule is that the player scoops goldfish from a pool with a paper scooper called a "poi" and puts them into a bowl with the poi. This game requires care and speed as the poi can tear easily. The game is over when the poi is completely broken or incapable of scooping properly. Even if one part of the poi is

torn, the player can continue the game with the remaining part.

At ennichi or summer festival stalls, however, the game is not a competition. Participation typically costs around 100 yen (about $1.27) and players can take the scooped goldfish home in a special bag provided by the stall keeper. The game is unlimited, so players can scoop until their pois are completely broken. If they cannot scoop any goldfish, the stall keeper may be kind enough to give them one or two free goldfish. Each stall usually has its own rules. For example, there are some stalls where players can get a stronger poi if they pay more. Other stalls give players special presents if they scoop a lot. In some variations, medakas (*Oryzias latipes*) are used that are faster and harder to catch than goldfish. Usually, for every four goldfish, there is one medaka, so in ennichi, if you catch one, it counts as four goldfish.

Returning now to the question of whether the Japanese had the sort of aquarium shown in the Hashimoto Shuen painting depicting the Tokugawa Period, circa 1700. The Tokugawa period (also known as the Edo period) is a division of the history of Japan when it was ruled by the shoguns of the Tokugawa family, running from 1603 to 1868. The period was characterized by strict social orders, isolationist foreign policies, an increase in both environmental protection and the creation and popular enjoyment of arts and culture.

Hashimoto Shuen, better known to his contemporaries as Yoshu Chikanobu (1838-1912), was a military retainer of the Sakakibara clan of the Takada domain. After the collapse of the Tokugawa Shogunate, he joined the Shogitai and fought in the Battle of Ueno (1868). Following this, he joined the Tokugawa loyalists in Hakodate, Hokkaido, where he fought in the Battle of Hakodate (1868-1869) at the Goryokaku star fort and achieved fame for his bravery.

Following the Shogitai's surrender, his military career was over and in 1875, decided to try to make a living as an artist. He travelled to Tokyo where he found work as an illustrator for a newspaper. In addition, he produced nishiki-e artworks (literally “brocade picture” and refers to Japanese multi-colored woodblock printing). Chikanobu was known as a master of bijinga, images of beautiful women, and among his other work, illustrated women's pastimes as shown in his depiction of the goldfish aquarium from the 1893 Columbian Exposition.

There was a “goldfish boom” during the Genroku period (1688-1704) and later, during the Bunka and Bunsei eras (1804-30), where artists used them as a creative motif. Since Chikanobu was not alive in 1700, it is clear that this is no more than a woodblock painting depicting the artist's idea of what an aquarium looked like in those days. The depiction of an object in a painting does not mean that the object exists or ever existed; it is just an artist's conception.

It is fitting, therefore that I end with this quotation: “In God we trust, all others bring data.”[5]

NOTES

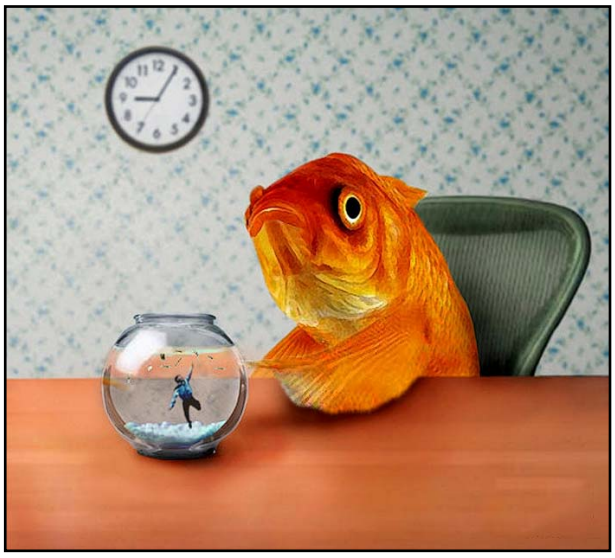
1. Peter Ponzio, a Humanities instructor at McHenry County College, is an American Goldfish Association certified goldfish judge, as well as being an Associated Koi Clubs of America certified koi judge. He has been raising and breeding goldfish for 45 years, and koi for 25 years. Ponzio has written three books on goldfish, and has written several hundred articles on goldfish and koi. He has judged over 50 goldfish and koi shows, and has given lectures on goldfish and koi throughout the U.S.

2. Also known as Hashimoto Chikanobu, Toyohara Chikanobu, Yoshu Chikanobu and
Yoshu Shuen.

3. Takaoka, Kazuya and Kuru, Sachiko; *Kingyo: The Artistry of Japanese Goldfish*. Tokyo: Kodansha International, 2003.

4. This and the images that follow (with the exception of the Artist Unknown image for which attribution is also unknown) are from the Boston Museum of Fine Arts.

5. This quote has been widely attributed on the Web to the American statistician, William Edwards Deming (1900-1993), but there is no evidence that he was its author. The quote is, in effect, anonymous.



UP AND DOWN THE BROOKS: AN ESSAY ON NATURE WRITING, 1860-1909

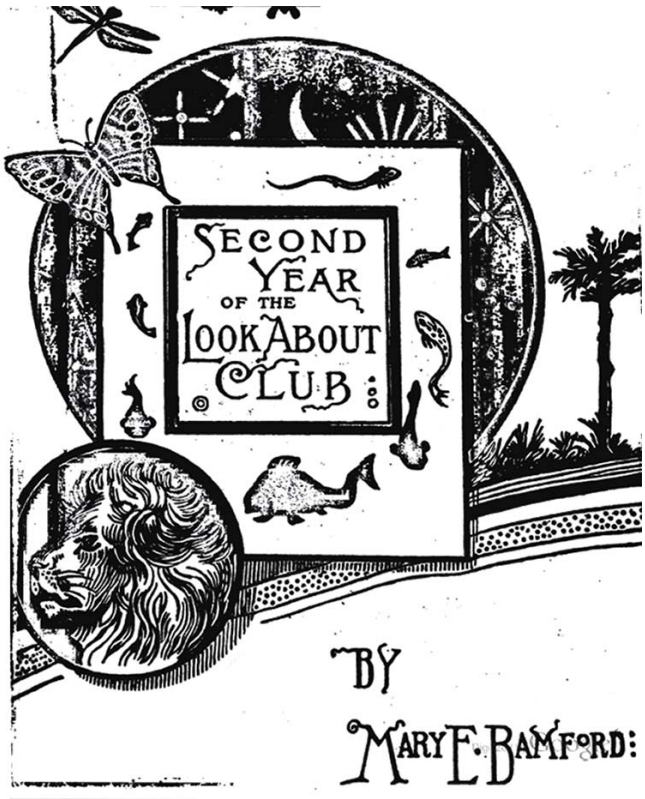
by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, March 25, 2009)

INTRODUCTION

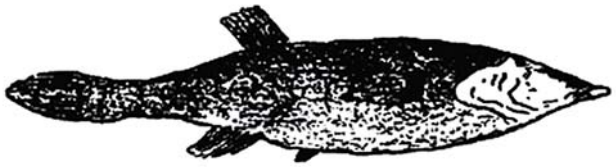
For those of you who are not familiar with the name Mary E. Bamford, she was born in 1857 (as Mary Ellen Bamford) in Healdsburg, California, the daughter of Dr. William and Cornelia Elizabeth (Rand) Bamford. Her father was a pioneer physician who traveled across the plains in the early 1850s. Her mother, a native of New Hampshire, went to California via long voyage (1854-1855) around Cape Horn.

Bamford graduated from the Oakland High School in California, and was an assistant in the Oakland Free Public Library for four years. Her father contributed to the *Western Lancet*, and her mother wrote a good deal for the *New York Independent*, *New York Observer* and other papers.



Bamford was the author of the twenty books listed in the Appendix. She also wrote a pamphlet, *Burma: The Work and the Workers*, published by the Woman's Baptist Foreign Missionary Society and did much writing for the *Youth's Companion* (Boston), Cook's publications (Chicago) and the publications of the different Baptist denominational boards. She also was secretary for North and Central California for the Woman's Baptist Foreign Missionary Society of the West, headquartered in Chicago. One of her passions, however, was for natural history, a good example being her *Second Year of the Look About Club*, published in 1889. Briefly, in this book a group of children unite to research and share stories, primarily about the birds, animals, and insects they discover near their home. An assortment of adult relatives offer guidance and participate in some activities. The following is an example taken from the book:

> "Now, it's papa's turn," said Al, and Mr. Perry called them all to come to the light and see a picture in a book he held. It was a picture of a blind fish.
>
> "Where do such fishes as that live, papa?" asked Blanche.
>
> "In Mammoth Cave," answered her father. "They are supposed to be found in all underground rivers flowing through the limestone region of the United States, and they have often been found in wells."
>
> "Are they blind all their lives?" asked Kittie.
>
> "People suppose so," said her father. "As far as people know, the baby fishes are blind as well as the bigger ones. Once in a while one is found that can see. But do you remember, Kittie, how quick to hear and



BLIND FISH

From Mary E. Bamford's, *Second Year of the Look About Club,* 1889.

touch anything some of those blind children were at the asylum?"

"Yes, indeed," said Kittie. "I couldn't have walked so fast with my eyes shut as that blind girl did."

"Well," said Mr. Perry, "that is the way with these blind fish. The sense of hearing and touch is so acute that they are very active. Mud-fishes live in the waters of Mammoth Cave, too, and these blind fish will rush after them and catch and eat them, although the mud-fishes have eyes."

"How do the blind fish catch them, then?" asked Al.

"Why, you see," said his father, "the blind fish have a very acute sense of touch, while the mud-fish is rather stupid in this respect, and so the mud-fish is always bumping against something in the dark, and that gives the blind fish a chance to catch up and capture the mud-fish."

This brings me now to another Bamford book written for children, but whose literary style was vastly different.

WRITING IN 1898 FOR "YOUNG PEOPLE"

One of the books I own and frequently re-read for my own delight is Bamford's *Up and Down the Brooks*, published in 1898 by Houghton, Mifflin as part of their Riverside Library for Young People. In a review of her book in the NEW YORK TIMES of November 9, 1898, one naturalist is quoted as: "She is so delighted herself that she makes you happy whenever she catches a pollywog. It is enough to make any one want to start out to catch one himself immediately."

Indeed, the prose is fun to read and entertaining, as the following example attests:

"Yet, when one possesses a caterpillar that desires to make a repast on spiny thistles, one is apt to have a slight bond of sympathy with that historic gentleman mentioned by Mother Goose:

'Simple Simon went to look
If plums grew on a thistle;
He pricked his fingers very much,
Which made poor Simon whistle.'"

A paragraph or so later, Bamford ups the ante on thistle poems with this classical reference:

"From this, the observant reader will perceive that I have never yet learned to grasp nettles firmly enough, a lesson inculcated in the old rhyme written by Aaron Hill in 1750 on that window in Scotland.

'Tender-handed stroke a Nettle,
And it stings you for your pains.
Grasp it like a man of mettle,
And it soft as silk remains.
Tis the same with common natures,
Use 'em kindly, they rebel;
But be rough as nutmeg-graters,
And the rogues obey you well.'"

However, I am always amazed at the abundance of classical references in the text. For example, on page 31 we read,

"Burton in his 'Anatomy of Melancholy' tells us that when Jupiter and Juno held their wedding-feast all the other divinities were invited and many noblemen besides, and among them came a Persian prince named Chrysalus, a very simple person, but gorgeously arrayed in golden attire. And the

> assembly, seeing him come with such pomp, were deceived, and rose up to give place to so noble a being. But Jupiter, seeing what a fantastic, idle fellow he was, turned him and his followers into butterflies, greatly to the astonishment of the guests, no doubt. If this be true, how comes it that Vanessa Antiopa wears black? Did Vanessa go to the wedding-feast wearing mourning?"

Re Vanessa Antiopa, Bamford is alluding to the Mourning Cloak butterfly (now known technically as *Nymphalis antiopa*), a specimen of which she came across while searching for a type of aquatic beetle that formed the subject of this chapter in the book.

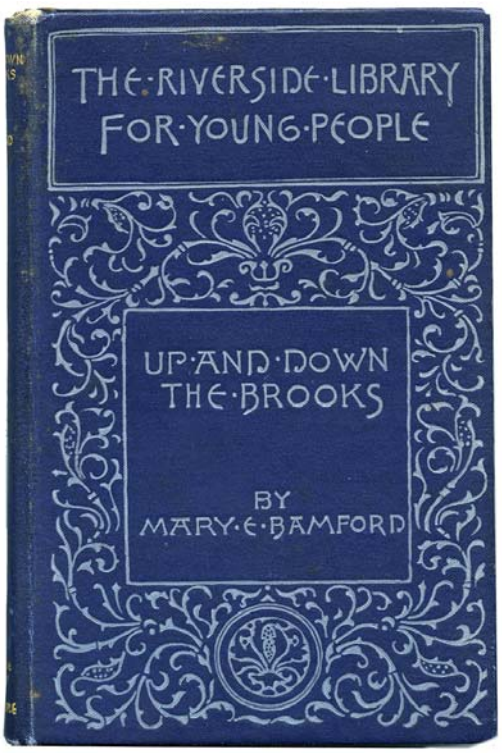
On page 94, while discussing the predatory whirligig, Bamford writes,

> "Perhaps when the child is older, and when she better understands the murderous character of many water-beetles, she will not be so ready to name herself after them. For the carnivorous water-beetles are as bloodthirsty as were the mob that Machiavelli tells us tore poor Ser Nuto to pieces. Says that chronicler: 'Ser Nuto being brought by the mob into the court, was suspended from the gallows by one foot; and those around having torn him to pieces, in little more than a moment nothing remained of him but the foot by which he had been tied.'"

And on page 125 in the course of describing the smaller aquatic life of ponds we read,

> "You sit down on a bank and think yourself alone. But there are many eyes on you. You hear a rustle, and behold a little white frog is hopping away from your feet. Aphides alight on your shoulder, and now would that a person might have as acute hearing as the mythic Heimdall had, he who lived in the fort at the end of the rainbow, and had so fine ears that he could hear 'the wool growing on the backs of sheep and the grass springing in the meadows.' For, if we had such ears we might hear many a bug and beetle and spider in this supposed-uninhabited nook saying to each other, 'Who is the giant who has come here and why has he come? This part of the world belongs to us. We are the Brookside Folk.'
>
> "And you reflect that the spiders and beetles and bugs really have more to substantiate their claims than had those Three Tailors" whom Carlyle mentions as addressing Parliament and the Universe, sublimely styling themselves, 'We, the People of England.'"

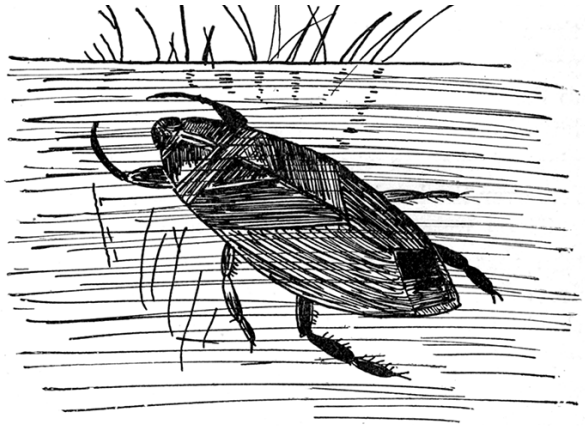
WOW! After quoting Machiavelli's 1525 *History of Florence* followed by one from Burton's 1850 *Anatomy of Melancholy*, on a single page we get references to Heimdall, a deity from Norse mythology, and Carlyle's 1875 *The Early Kings of Norway*. One might wonder how this kind of erudition was achieved in view of the fact that Bamford's formal education ended with her graduation from high school. However, in the 19th and even into the early 20th centuries, high



school was only for the children of the elite. In point of fact, in the 19th Century hardly anyone went to high school at all, let alone college. Throughout its career the Oakland High School has been an academic or cultural school; thus Bamford would have studied Latin and French, Geography (ancient, modern and physical), history (ancient, modern and United States), English (besides the usual reading, spelling, grammar and composition, it would have also included rhetoric, declamation and the history of literature), Mathematics (including arithmetic, algebra and geometry), and Natural Philosophy, the forerunner of what we would today call "science").

Be that as it may, one asks oneself the question, are these books in the Riverside Library really intended for "young people"? Bamford herself seems to have had had some misgivings about the ability of her audience to grasp the finer points of the language:

> "Still, there are drawbacks to one's felicity. I passed by a small house not long ago. A little scrap of a boy stood at the back gate, and, as I vanished down the road, these words were wafted to mine ears, 'There's the lady that catches fish.' I am consoled, however, by the appellation, 'lady.' Let all fish-women be hereafter known as 'fish-ladies.' To such a pass has come our English tongue."



Belostoma grandis.

From Mary E. Bamford's,
***Up and Down the Brooks,* 1898.**

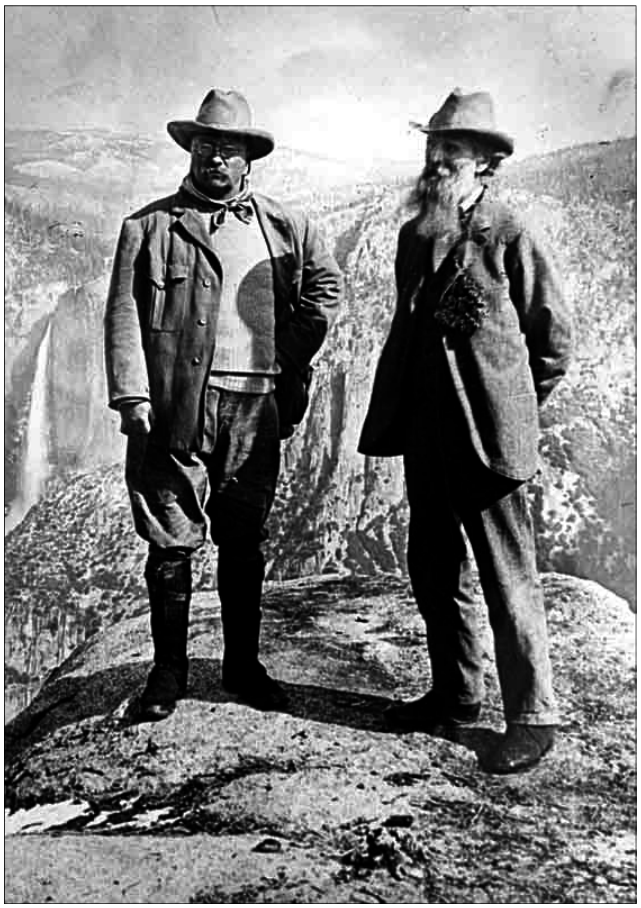
Perhaps a clue to the provenance to this kind of writing may be gleaned from this quote from the publishers:

> "The authors engaged are for the most part writers who already have won attention, but the publishers give a hospitable reception to all who may have something worth saying to the young, and the power to say it in good English and in an attractive manner. The books in this Library are intended particularly for young people, but they will not be written in what has been well called the *Childese* dialect. The publishers hope to have the active cooperation of parents, teachers, superintendents, and all who are interested in the formation of good taste in reading among young people."

In any event, I was determined to delve further into why Houghton would publish nature books for young people that included such scholarly references.

THE EMERGENCE OF AMERICAN NATURAL HISTORY WRITING, 1860-1909

John Burroughs and John Muir were the most prominent nature writers of this era. Muir led the fight to preserve wilderness with his *Century* articles about Yosemite, as well as with his founding of the Sierra Club. In the second half of the nineteenth century, however, John Burroughs was the most popular and significant nature essayist in America. During the Civil War, he was a close confidante of Walt Whitman and later one of the poet's most successful advocates. By the mid-1880s he was widely regarded as the pioneer of the recently emerged field of writing "treating nature in a half-scientific and half-poetical way." By the first decade of the new century, he had become a national celebrity—a friend of presidents and tycoons, an icon of teachers and schoolchildren, and the country's special ambassador to the natural world. Burroughs popularized the study of local nature with his many volumes of essays, and brought political and economic muscle into the conservation movement by befriending such influential figures as Theodore Roosevelt and Harvey Firestone. He represented not only the highest



LEFT: TEDDY ROOSEVELT; RIGHT: JOHN MUIR

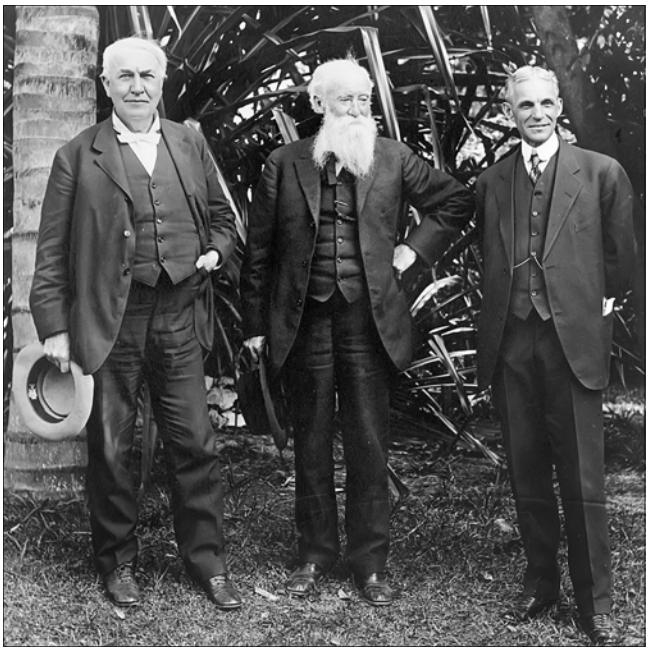
level of literary achievement, but also the simple, rural life that many middle-class Americans hoped to claim as their national heritage. Shortly after Burroughs's death in 1918 one writer offered a portrait of Burroughs as many Americans knew him in the final years of his life.

> "He smelled of wood smoke and wild berries. He was tanned with wind and sun and his hands were calloused by farm labor," writes Garland. "But when he took his pen in his fist he became the master of English which makes his pages a delight… In the door of an old barn, with a dry-goods box for a desk, he penned the most lucid, powerful, artistic prose—prose that has not been surpassed by any other nature writer in America."

Indeed, it was John Burroughs, not Henry David Thoreau, who was the instrumental figure in the genre's history before 1900. After Thoreau's death in 1862 his legacy seemed a subject hardly worth speculation. He was at the time more commonly identified as a social critic than as a natural historian, and at best he seemed a vaguely absurd devotee of Emerson and at worst, "a cold morbid misanthrope whose retreat to Walden was an attempt to disavow affiliation with humanity." Another claimed that he was merely an imitator who "treads in Emerson's tracks with legs painfully short." Only as Burroughs gained national prominence in the 1870s and 1880s did the importance of both Thoreau and nature writing become increasingly well defined.

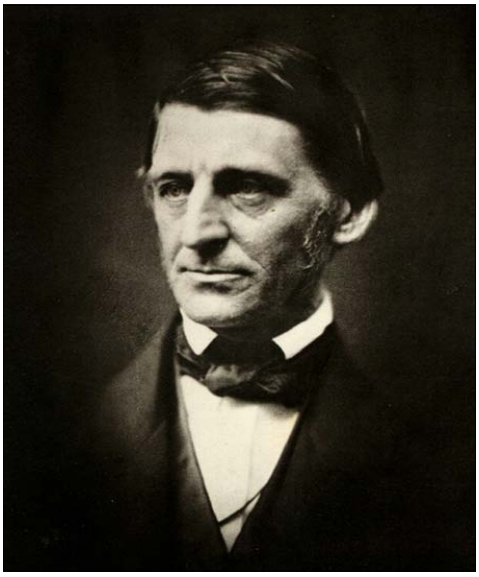
Burroughs's writings were shaped in part by Emerson early on. He first read Emerson in the spring of 1856 when he was nineteen years old and studying for a term at the Cooperstown Seminary in New York. At first he found Emerson's work difficult. Reading Emerson's *Essays* he observed was like "tasting green apples." Burroughs soon developed a taste for Emerson, however, and within the space of several months, read everything of Emerson's that he could find. The experience proved to be a watershed in his life and career. As he later noted, he read Emerson "in a sort of ecstasy. I got him in my blood, and he colored my whole intellectual outlook."

It is common wisdom that nature writing became an increasingly prominent feature in American literary



FROM LEFT TO RIGHT: THOMAS EDISON, JOHN BURROUGHS, HENRY FORD

LEFT: HENRY DAVID THOREAU



RIGHT: RALPH WALDO EMERSON

culture primarily because readers were concerned about the natural world. Overlooked, however, is that it emerged also through the efforts of several elite literary institutions whose influence strongly determined its form, its audience, and the cultural capital it represented.

Nature writing has played a more varied and significant role in American literary culture than is generally assumed. At the turn of the twentieth century, the genre participated in numerous and sometimes conflicting cultural discourses; not only the emergence of the conservation movement, but also the emergence of a decidedly middlebrow culture, the articulation of New England's regional identity, and the definition of a generally "American" identity that purported to speak for all parts of the expanding nation.

THE IMPORTANCE OF HOUGHTON, MIFFLIN AND COMPANY IN NATURE WRITING

Houghton, Mifflin and Co. packaged and promoted Burroughs's writing with great enthusiasm, and also made his work the foundation of an impressive collection of nature-related books. It is often overlooked that Houghton assembled and published nearly all of the important American writers now classified as "nature writers" before World War I. In the final decades of the nineteenth century, Houghton transformed what its editors referred to as "outdoor writing" from a miscellany of nature-related writing into a clearly defined tradition of essays centered on Burroughs and (eventually) Thoreau.

No wonder, then, that during these years the firm consistently named their "outdoor books" as one of their particular specialties. As the firm noted in its 1899 catalogue, the field of literature representing "the enthusiasm of lovers of nature" was now "largely occupied by Houghton, Mifflin and Company." Of course, the rhetoric of self-promotion should always be read with care. In this case, however, we can take the Houghton editors at their word. In the final decades of the nineteenth century—the years just before the term "nature writing" emerged and came to denote the tradition of literary essays that Burroughs had made popular—the field of environmental prose was indeed largely occupied by the Houghton firm. No other contemporary literary institution had as profound an influence on this particular field of writing.

Perhaps surprisingly, editors spoke of their natural histories intended for children in similar terms. Bamford's *Up and Down the Brooks* was commonly included in the outdoor book promotional materials of Houghton, as were several collections drawn from the work of Burroughs. Such works, according to house editors, needed to be lively, accurate, and accessible, never patronizing. Children's books failed, they often noted, when authors lacked respect for the imagination and intelligence of their young readers.

As with the work of Burroughs, editors emphasized that juvenile natural history needed above all to have elegant, graceful prose. One manuscript was dismissed by Houghton editor Horace Scudder noting that its sketches were "written with a good deal of vivacity, but in a careless style… a publisher dealing largely in such matter and not too particular about the literature might do fairly well with it." Similarly, in the *Atlantic* (owned by Houghton until 1908) Scudder questioned the underlying design of Julia McNair Wright's *Nature Readers* (a series published by D.C. Heath & Co. between 1888 and 1901) thusly:

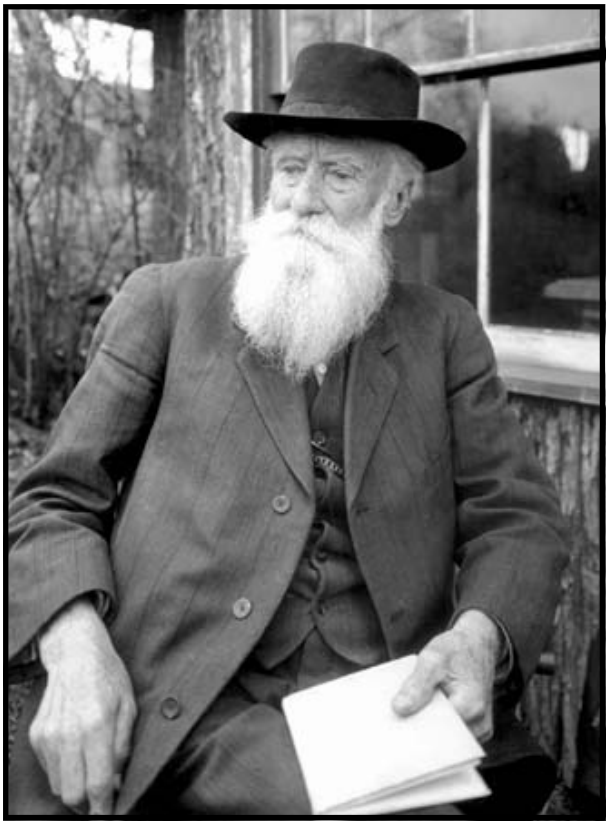
> "The plan of the books is to give beginners in reading an acquaintance with simple facts in nature. We have no criticism upon the facts in the book, but object to giving children reading matter instead of literature for reading. These books have no style whatever, and surely style is of the first importance."

When Bamford submitted her manuscript in 1888, Scudder reported that it was a "lively" work of outdoor writing for children—"accurate, readable, and… by far the best book of its kind yet produced in this country." Scudder, by the way, noted that the manuscript was only about 20,000 words long. If the book were larger, it would be "admirably adapted" to the Riverside Library for Young People (RLYP). Scudder thus recommended that Bamford triple the size of the manuscript and resubmit it, which she did.

After 1890, Houghton editors consistently considered these new criteria when reading nature manuscripts submitted for publication. Meanwhile, they began including works of outdoor writing in a number of general educational and juvenile series, making the genre an increasingly important part of the firm's more general mission to reform American schools (and schoolchildren) through literature.

According to an 1889 advertisement, the RLYP series was aimed specifically at "boys and girls who are laying the foundation of private libraries." Each title was illustrated, between 200 and 250 pages, and priced to be relatively inexpensive (seventy-five cents or about $15 in today's currency). Though the firm assured prospective buyers that "the books included in it are not ephemeral publications" and that the authors were of the highest rank, the series was something of a hodgepodge and ultimately, the Riverside Library for Young People had only limited success. While its selections of juvenile fiction and childhood memoirs such as Lucy Larcom's *A New England Girlhood, Outlined from Memory*, sold quite well, the average book sold between 100 and 200 copies per year. The collections by Burroughs fared slightly better than average, with sales between 200 and 250 per year. Still, the series is of particular importance because it helped set the standard for the books in the educational market that later formed an important part of Houghton's business.

Over the next several decades, the firm continued to advertise its connection to the nature writing tradition. Ironically, however, the years of nature writing's popular emergence also marked the rapid decline in Houghton's cultural authority. At the turn of the twentieth century the context in which Americans produced, sold, and used literary writing was wholly transformed, and in this time of flux the Houghton firm lost much of its



JOHN BURROUGHS

influence as a cultural trust. The changes in the national magazine market offer an instructive example: in the 1890s a host of new magazines emerged that were radically different from the "quality monthlies" in which Burroughs had established his career in the sixties and seventies.

The newer magazines— which included *Cosmopolitan*, *Ladies Home Journal*, *McClure's*, *Munsey's*, and *The Saturday Evening Post*—were loosely modeled on *Harper's*, the *Century*, and the *Atlantic*. However, these newer magazines conceived of themselves neither as repositories of permanent literature nor as the province of sophisticated readers. Rather, they actively sought a mass audience, to whom they delivered news, entertainment, and—of special importance—advertising. Indeed, advertising was these magazines' crucial function. *Cosmopolitan* and *Ladies Home Journal* were explicitly conceived as marketing instruments for large-scale manufacturers seeking to create and maintain a national market for their products. Within their pages, advertising shared space with articles, stories, and illustrations. And unlike, say, the *Atlantic*, these newer magazines were financed not through subscription fees but through advertising revenue.

EPILOGUE

I got my start in the aquarium hobby over 60 years ago by going up and down the brooks myself (and other bodies of water that supported fish life) when I was a teenager, collecting sticklebacks and breeding them as I did with *Cyprinodon* and *Fundulus*. This is an example, therefore, of how the aquarium hobby, spurring my interest in nature in general, has opened new vistas for me. I never would have become especially interested in Thoreau and Emerson nor would I have paid any attention to the name John Burroughs if I had not picked up a copy of Bamford's *Up and Down the Brooks*. A warning, however. If you decide to read her book and are interested in exploring her many classical references, be prepared to spend some serious reading time on the net!

ACKNOWLEDGEMENT

The historical material in this monograph was taken from Eric Christopher Lupfer's doctoral dissertation, *The Emergence of American Nature Writing, 1860-1909: John Burroughs, Henry David Thoreau, and Houghton, Mifflin and Company* (The University of Texas at Austin, May 2003).

The Aquarium Hobby's First Historian

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, October 7, 2012)

Edward Newman (1801- 1876) was an English entomologist, botanist and writer. Both his parents were keen naturalists, and he was further encouraged to take an interest in the natural world at his boarding school in Painswick, a village in Gloucestershire. He left school at sixteen to join his father's business in Guildford, in Surrey, moving to Deptford, a district of southeast London, in 1826 to take over a rope-making business. Here he met many of the leading entomologists of the day and became a founder member of the Entomological Club. In 1832 he was elected as editor of the club's journal, The Entomological Magazine, and the following year became a fellow of the Linnaean Society and one of the founder members of the Entomological Society of London.

In 1840 Newman published the first edition of "A History of British Ferns and Allied Plants." He became a partner in a firm of London printers, Luxford & Co., and a printer and publisher of books on natural history and science. He later became the natural history editor of The Field, editor of The Zoologist and editor of The Entomologist. His books included "Birds-nesting" (1861), "New Edition of Montagu's Ornithological Dictionary" (1866), "Illustrated Natural History of British Moths" (1869) and "Illustrated Natural History of British Butterflies" (1871). Newman's "Attempted division of British Insects into natural orders" in the Entomological Magazine in 1834 established many new families and is therefore an important work of scientific classification.

As an evangelical Quaker, he was deeply worried by the 1859 publication of Charles Darwin's On the Origin of Species, claiming that Darwin's theories were "not compatible with our notions of creation as delivered from the hands of a Creator."

Interestingly, Newman viewed the skeletons of Pterosaurs not as reptiles but as marsupial bats. This was based on earlier suggestions that some pterosaur fossils showed tufts of hair, which suggested they could not be typical cold blooded reptiles. As a result he published a reconstruction of pterosaurs as hairy animals in a 1843 edition of The Zoologist. This is, as far as is known, the first reconstruction of pterosaurs as hairy warm blooded creatures, which modern research suggests was actually the case. However, they are now thought to be highly evolved and warm blooded reptiles and not marsupial

M,DCCC.LXXIII.

bats. He argued, in this rather amusing article, that it was rather unlikely that his ideas were correct, since authorities like Georges Cuvier and William Buckland thought pterosaurs were reptiles, but, even so, it was still possible that the experts were wrong and he got it right!

In 1873, Newman embarked on a series of articles in The Zoologist that marked the first cohesive history of the aquarium hobby as it was known at the times. Although the books on the aquarium hobby published up to that time mentioned important developments in the history of the aquarium hobby, they were presented merely as facts without any attempt at analysis. The following is Newman's introduction to his theme:

"The Aquarium is an Institution, a great Institution, and in its present form a novel institution; but I venture to believe a lasting Institution: it has passed through two eras, and has entered on a third; the first, which endured for a decade, say from 1830 to 1840, was very humble, very instructive - almost wholly utilitarian; the second, which endured for two decades, say from 1840 to 1860, was literary, poetic and fashionable; and the third, upon which we have boldly and vigorously entered, may be styled commercial and ambitious: the first was the humble handmaid of Science; the second the servant of fashion; and the third the child of speculation. I need scarcely say the first decade had my entire and zealous sympathy; the second my amused attention; and the third my boundless admiration of the results obtained, without exciting much interest in its progress as a commercial venture."

Newman's history of the hobby primarily covers a period of about 30 years and this is quite detailed and contains information not previously found in aquarium histories, including my own since space would not accommodate such a level of detail. Newman deserves a place of honor with the other greats of his day, such as Warington, Ward, Gosse, Bowerbank and William Alford Lloyd. Indeed, his history contains a great deal of biographical information on the last-named not previously published. His section on aquarium aeration was extremely helpful to me personally when I wrote my monograph, "The Early History of Aquarium Aeration," and his discussions on the controversies of the day place the history of the aquarium hobby in greater perspective than was understood previously.

The following is his complete history, taken from "The Zoologist: A Popular Miscellany of Natural History," edited by Edward Newman, Second Series, Volume 8 (or thirty-First from the Commencement), John Van Voorst, 1, Paternoster Row, 1873. The text I have in hand is in PDF format and was digitized but not optical character recognized (OCR). *The Zoologist* numbered the pages consecutively so the text starts at page 3341, making it difficult to get to the three widely separated parts of his history or to do a search looking for a word or a name, so I took it upon myself to do the OCR.

All of the spelling and grammar of the day has been preserved in the process, often bringing smiles to my face when reading it. In order to make the reading easier I have, however, italicized scientific names when possible and broken up extremely lengthy paragraphs. In early times, long paragraphs were not unusual and Newman's history is a bit excessive on this point when he quotes these earlier authors. Where we would nowadays use periods to end a sentence, such authors often used colons. At one point I was trying to break up a paragraph of some fifty lines but was having trouble finding the end of a sentence. I finally tried using the search function in my editor to find a period and it did discover one, on line forty!

Short references such as "Zool. 796" refer to pages in *The Zoologist*. Except for the layout of the tanks in the Crystal Palace Aquarium, there are no illustrations in Newman's history. To break up the monotony of text only I have supplied illustrations typical of the period in question.

Newman starts with Era I, which he calls "Utilitarian:

ERA I. UTILITARIAN.

The birth of the aquarium is of such remote antiquity that we fail to ascertain the date with any certainty. The point at which, any vessel containing water and fishes becomes an aquarium is equally open to discussion. There is abundant reason to suppose that the Chinese and the Japanese had their fresh-water aquariums thousands of years before the Christian era; the Romans certainly had theirs; but in neither of these instances is there any evidence of their being considered, as now, a noteworthy institution; by the Romans they were established for economic purposes and nothing more. I do not know whether such vessels are again mentioned until 1665, when Mr. Pepys in his Diary, under date 28 May, 1665, as cited by Mr. Lloyd, observes, "Thence to see my Lady Pen, where my wife and I were shown a fine rarity; of fishes kept in a glass of water, that will live for ever—and finely marked they are, being foreign."

I consider this brief passage of infinite interest; were I in a severely critical mood I might object to the expression "live for ever," because I doubt whether any created being enjoys perpetuity of existence; but waiving this objection, I think the passage establishes the fact that fishes were kept in confinement at Lady Pen's in 1665; and that Mr. Pepys was informed that they had this extraordinary vitality. It is rather a notable fact that we know of no instances of fishes dying or being deteriorated by age: we never hear complaints of a sole, or a turbot, or a salmon, being old and hence objectionable: this can scarcely be asserted of our taurine or anserine, or even gallinaceous, food."

[I note with some amusement of Newman's reference here to "…taurine or anserine, or even gallinaceous, food," by which he meant beef, geese and chickens. Newman not only had an impressive command of the English language (and a good sense of humor), but by extension his readers also. AJK]

Coming down to later times, we find that in 1743 our countryman Baker distinctly represented specimens of *Hydra viridis* kept in water in an upright glass vessel.

"It appears from the works of Esper (the reference here is to Eugenius Johann Christoph Esper 1742–1810, a German entomologist), published continuously from 1771 to 1784, that that distinguished entomologist constantly kept aquatic insects in water: he has given us most interesting particulars concerning them, and seems to have been delighted in observing their longevity in confinement; he particularly mentions a male individual of *Dytiscus marginalis*, a carnivorous water beetle, that lived three years and six months in his aquarium; and James Francis Stephens many years subsequently, commenting on this seemingly extraordinary fact, attributes this prolonged life to enforced celibacy. Esper has left no record, so far as I am aware, of the plan or principle of his aquarium, and I believe only this single record of his success.

"Simultaneously with Esper, Gilbert White seems to have utilized the aquarium for observation: the first edition of his 'Natural History of Selborne,' printed in 1789, but written in 1781, has the following passage:—

"When I happen to visit a family where gold and silver fishes are kept in a glass bowl, I am always pleased with the occurrence, because it offers me an opportunity of observing the actions and propensities of those beings with whose lives we can be little acquainted in their natural State. Not long since I spent a fortnight at the house of a friend, where there was such a vivary, to which I paid no small attention, taking every care to remark what passed within its narrow limits." This great naturalist, for great he really was in his singular acuteness of observation and scrupulous truthfulness of narration, thus utilized an aquarium, although calling it by another name: his observations on the manner of death in fishes, on the structure of their eyes, and on their mode of progression, the pectorals being employed for gentle motion, and the caudal for "shooting along with inconceivable rapidity," show to what good purpose he devoted these opportunities of observing.

"I have met with no evidence of experiments or arrangements of the same kind until, in 1830, my esteemed and respected friend James Scott Bowerbank, then residing at No. 19, Critchell-place, New North-road, continuously and successfully utilized the aquarium in his researches into the "Circulation of the Blood in Insects." Of all investigators 1 ever knew, Dr. Bowerbank was the most enthusiastic, the most persevering, the most successful, and the most willing to impart his discoveries to others. I have always considered my introduction to Dr. Bowerbank one of the most fortunate events of my life, and the hours that I have spent under his tuition as the most delightful and most worthy of remembrance. Let us see what Dr. Bowerbank did with his aquarium. Cuvier's 'Règne Animal' was published in 1824, and contains the following paragraph translated from the French:

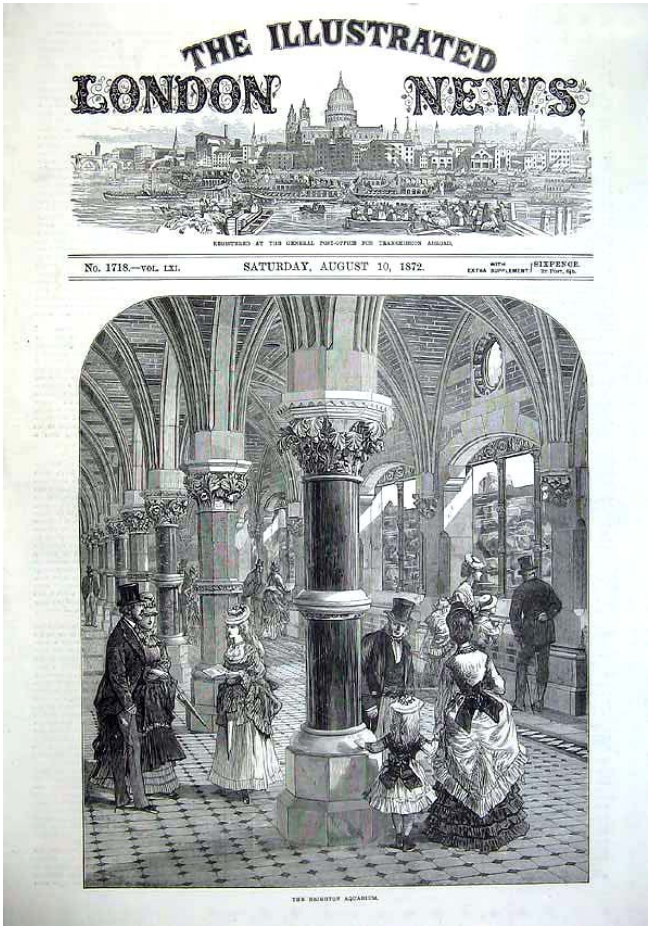
"In animals that have no circulation, in insects particularly, the parts are all bathed in the nutritive fluid; each of these parts draws from it what it requires, and if the production of a liquid be necessary, proper vessels floating in the fluid take up by their pores the constituent elements of that fluid."

No sooner had I read this than I expressed my dissent from such a doctrine; I felt certain that insects possessed a circulation. Whether influenced by a desire to bring Cuvier's dictum to the *experimentum crucis*, or from a simple and characteristic thirst for truth, Mr. Bowerbank went into the question heart and soul. Throughout the years 1831 and 1832 he worked hard at the important question whether or no insects possess a circulation: to this end he sallied forth on larva-hunting expeditions with the late Mr. Tully, the celebrated optician, with one of whose excellent instruments his microscopic researches were conducted.

'He [Mr. Tully] told me,' says Mr. Bowerbank, 'all about these larvae, and where to obtain them, and that they must be kept in the water to which they were accustomed; so we always adhered to that plan, for we found that if we brought them home in a very little water, and added a considerable quantity from the house-cistern, the water thus added generally killed nearly all of them; so I employed a man to take an earthen jar that would hold at least a gallon of the very water in which the larvae were found; this I poured into the glass prepared for it, putting in a little Conferva and a few water-snails, *Limnea peregra*, and the smaller species of *Planorbis*, in the water, and floating a little duck-weed on the surface: then the glass was placed in the sun, so as to assimilate the condition of the little captives as nearly as possible to what it had been when in the ponds on Hampstead Heath in which they had been hatched, and in which tile were found. Treated thus they continued alive and well, without change of water, and thus I was enabled to continue the observations for nearly two years."

Although in this passage the words "aquarium," "balance of life," and "compensating principle" do not occur, it is very evident that Mr. Bowerbank was aware of the use of vegetation in maintaining life-supporting properties in stagnant water, and the necessity also of imitating the natural conditions of the animals he desired to keep therein. To this hour none of us have advanced further with fresh water, and success only results from keeping these objects steadily in view. Mr. Bowerbank's paper was finished on the 1st of October, 1832, and was published at p. 239 of the *Entomological Magazine* for April, 1833. I need scarcely say that it placed the author at once at the head of all observers in this branch of Entomological Science. I regard it as the best, if not the first instance of thoroughly utilizing the compensation principle of the fresh-water aquarium: plants to evolve oxygen, animals to consume it.

In the same year Professor Daubeny read, at the Cambridge meeting of the British Association for the Advancement of Science, a paper communicating the result of researches he was then making on the subject of confining animals and plants together in water, in the course of which he established beyond dispute that it was the illuminating and not the heating powers of the sun's rays which caused the evolution of oxygen from plants. He then went on to say that the plants not only evolved oxygen but assimilated carbon from the poisonous carbonic-acid gas which results from the respiration of animals, decomposing it and rendering it harmless. Final-



THE ILLUSTRATED LONDON NEWS

No. 1718.—VOL. LXI. SATURDAY, AUGUST 10, 1872. SIXPENCE.

The Brighton Aquarium

ly, he asserted boldly 'that the influence of the vegetable might serve as a complete compensation for that of the animal kingdom.'

Thus he seems by inductive reasoning and possibly by seeing the successful results in many parlours in London, to have perceived as clearly, as he expressed happily, the theory and practice of the aquarium; but it must be recorded that while everyone else was succeeding to admiration, Dr. Daubeny utterly failed in reducing his theory to practice, and his establishment for exhibiting the compensatory process was totally unsuccessful.

Imitation is the inevitable tribute, the sweet-smelling incense, offered on the altar of obvious success. I will not presume to express a doubt of the originality of many of those who set up aquariums between 1830 and 1840, but I think that most of us were incited to the act by Mr. Bowerbank's successful example; Goring and Pritchard admit the fact; they even quote Mr. Bowerbank as the authority for their doings. I was a similar imitator of my friend: after seeing his captives, and watching the unspeakable grace and beauty of their movements, I caught at once at this new field of observation. In January, 1832, I commenced operations with a water-net made of cheese-cloth: the Woolwich Marshes and Wandsworth Common were the scenes of my exploits, and a large white basin my first aquarium: some of the results were published at p. 315 of the first volume of the *Entomological Magazine* in 1833, simultaneously with Mr. Bowerbank's.

I made my appearance as an aquarian, as I may truly say, hanging on by the skirts of my leader's coat. I soon became absorbed in the denizens of the white basin, and they were as speedily transferred to a more convenient receptacle, an upright glass jar, where they lived in health for a very considerable time, but the only observation published in 1833 was that "the carnivorous water-beetles, *Dytiscus, Colymbetes, Acilius, Hydroporus*, &c., in swimming moved their hind legs simultaneously, striking out with great vigour in the same way as a frog; whereas the herbivorous water-beetles, *Hydrous, Hydrophilus*, &c., moved their hind legs alternately, thus making weaker strokes and progressing in the water much more slowly." Professor Westwood, at pp. 97 and 123 of the first volume of his 'Modern Classification,' did me the honour to copy, endorse and adopt my observations. I might here introduce a multitude of jottings on the manners and customs of water-beetles in confinement, but I forbear.

In the years 1836, 1837 and 1838 my friend Mr. Edwards, a most accurate and painstaking observer, then residing at 17, High-street, Shoreditch, by means of his aquarium, made himself thoroughly acquainted with one of the most deeply interesting and unexpected facts ever discovered in the entire range of Natural History—I allude to the nidification of sticklebacks. It was not until fourteen years afterwards

that Mr. Warington, going over the same ground, observed the same facts, and recorded in the 'Zoologist' the wonderful results. In the course of his communication Mr. Warington incidentally observes, "Mr. Edwards, of Shoreditch, whose London garden-pond has afforded much interesting matter to many microscopists, informs me, in a note dated August 27,1852, that it is fourteen years since he first noticed the fact of the stickleback building a nest, guarding and defending the young ones." Mr. Gratton, Mr. Bowerbank, and I, as well as microscopists out of number, were in the habit of visiting Mr. Edwards, and took great interest in his aquarian researches.

I should, however, here record that Mr. Edwards's first aquarium was, as Mr. Warington has described it, a "London garden-pond"; in fact, it was a stuccoed basin through which a small stream of New River water was constantly flowing. This plan, perfectly successful as regards the health and vigour of his captives, was soon supplemented by the glass jar, so much more convenient for patient, continuous and accurate investigation. Mr. Edwards was a watchmaker, and his sticklebacks were kept in a delightful little parlour behind the shop. It was not until some years later that Mr. Gratton set up a similar stickleback observatory at 87, Shoreditch; and the late respected Matthew Marshall another, at his official residence in the Bank of England, so that I enjoyed abundant opportunities of watching the proceedings of these "wonderful fishes."

I mention Mr. Edwards as the first scientific man who observed the nesting of sticklebacks. I say "scientific," because I am aware that from time immemorial the boys hunting "stitlers," and bringing them home in a quadrate pickle-bottle suspended from a stick, were perfectly cognizant of a fact which seemed to have been unknown to naturalists: from them I had learned, long, long before, that there were "cock stitlers" and "hen stitlers," and that the former were also called "redbreasts," and were famous for their fighting propensities: often as I watched the exhibition of these propensities in the aquariums of Mr. Edwards, Mr. Gratton and Mr. Marshall, and often as my fingers itched to write an account of them, I always forbore, for the discovery was the property of these gentlemen, and not mine; and to them, and not to me, of right belonged the honour and glory that must result from making the revelation. Alas! these excellent men have passed away, have left no record of their doings except in the memories of their survivors.

Our stickleback doings at that early period not only engrossed the attention of the little company of aquarians who met at Mr. Bowerbank's hospitable mansion on a Monday evening, but attracted the notice of an outside public, to which they were the never-failing source of pleasantry: very refreshing was that incessant fusillade of small jokes to those who fired them, and very harmless to those who received them. Even the "inimitable" author of the 'Pickwick

Papers,' whom nothing amusing, or ludicrous, or note-worthy, or instructive, ever escaped, took the tide of this little mania on the flood, and rendered Hampstead Heath and its ponds and its sticklebacks immortal in his pages.

Mr. Pickwick is described as the author of a paper entitled "Speculations on the Source of Hampstead Ponds, with some Observations on the Theory of Tittlebats," and the Club of which he was the enlightened President sent forth that eminent man to make further researches. The author adds, "There sat the man who had traced to their source the mighty ponds of Hampstead, and agitated the world with his Theory of Tittlebats, as calm and unmoved as the deep waters of the one on a frosty day or a solitary specimen of the other in the inmost recesses of an earthen jar." This shows that the new fancy had taken so deep a hold on the public mind that it was worthy of good-humoured banter by a man who never fought with shadows.

It was not until the year 1842 that the nest-building talents of the stickleback were fully revealed to the world, and then it was another species of stickleback, *Gasterosteus spinachia*, through another medium of observation (the open sea), and another hand (that of R. Q. Couch) that held the pen (Zool. 796). Mr. Couch, like his predecessors, has passed away, but unlike them has left a trace of his handywork which will endure as long as Ichthyology is a science.

Again, Mr. Kinahan, addressing the Dublin Natural History Society, years afterwards, observes of *Gasterosteus leiurus*, "Concerning the manner in which this little fish preserves its spawn not the slightest notice, if I may judge from the silence of our latest authorities, has been taken by any naturalist." Alas! that it should have been so; yet numbers of us, I can positively assert, were as intimately acquainted with the facts which Mr. Kinahan recorded (Zool. 3526) as he could possibly have been.

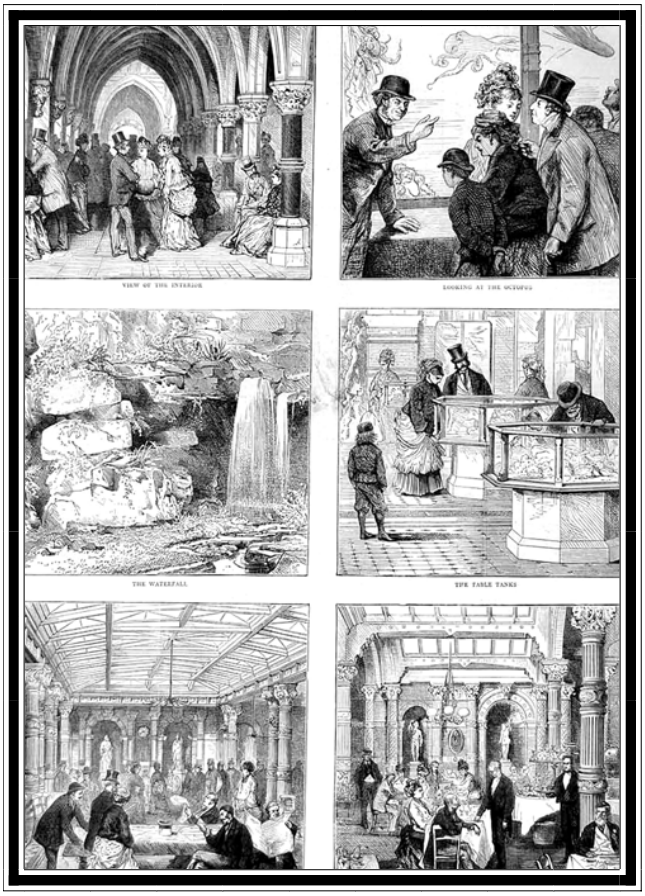
In 1851 Mr. Warington repeated these observations, and thus accomplished a task which Mr. Edwards was fully competent to have undertaken and completed twenty years previously. All honour to them both: these gentlemen, like Mr. Coach and Mr. Kinahan, and subsequently M. Conte of Paris, have given us abundant evidence that they observed accurately the facts which they have recorded so graphically. I trust that no confusion of dates will arise from my coupling the observations of 1838 with the records of 1851. It is really difficult to do otherwise, for a succession of observations were being carried on during the whole of the intervening period, although no contemporary record appears to have been made.

No one who has not witnessed, I may say who has not gloated over, the procreative and educational proceedings of the sticklebacks, can form any conception of their absorbing interest: no one who has not seen the "redbreast" in all his glory and pride of place, can possibly picture to himself the exceeding beauty of this little fish: it only endures while the cares of paternity are upon him: then, and then only, I might address to him the lines of Lord Byron's dedication of Childe Harold to Ianthe:

"Shall I vainly seek
To paint those charms which varied as they beamed?
To such as see thee not my words were weak,
To those who gaze on thee what language could they speak?
Oh, let that eye which, wild as the gazelle's,
Now brightly bold, now beautifully shy,
Wins as it wanders, dazzles where it dwells."

It may be a strange conceit to transfer this picture to a fish, and to a male rather than a female, but it is appropriate; the female is a nonentity, a being without attraction; a provision for the continuance of her kind, and nothing more; she fulfils her destination without love, without sentiment, without sensation, a perfect apathet: but with the male it is not so; his eye is more resplendent than the throat of a humming bird, and like that beautiful object varies with every change of position; it is now a burning sapphire, now a living emerald; his breast and belly are brilliant crimson thrown up by contrast with the delicate translucent green of his back; his entire body seems diaphanous, his eye alone retaining its solidity; the rest is glowing, aye, melting, with internal incandescence. Strange, but sad, this male Ianthe is possessed by a demon! Can he be jealous of his inornate mate? Jealous of the advent of other Ianthes? Yes, but he is only jealous of their meddling with his nursery: the loves of the fishes are wonderful, and man's sagacity cannot understand them.

But I am putting the cart before the horse: I have prepared a receptacle for this Ianthe, a lozenge-glass eight inches in diameter and twelve inches in height; two inches of loam cover the bottom, and perhaps an inch of very clean and very fine gravel covers the loam; a plant of *Valisneria spiralis* is rooted in the loam, and sends up its sword-like leaves and its corkscrew-like petioles to the surface of the water, each producing a single flower destined to float in company with innumerous green circular disks of duck-weed, and a dozen leaves of frog's-bit, each doing its best to take firm hold of the water with its roots; those of the duck-weed are simple threads; those of the frog's-bit generally tend downwards in an oblique direction, and are thickly fringed throughout with lateral fibres, making them look like minute bottle-brushes of rather unusual proportions; imagine small water-beetles treading the water in an orderly and business-like manner, and now and then rising to the surface like pigmy water-balloons, each with a bubble of air annexed to his posterior extremity.



The Brighton Aquarium

He is the manufacturer of his own gas: imagine half-a-dozen other water-beetles crawling deliberately, belly upwards, among the duck-weed, and add a few smaller living creatures floating, or walking, or darting in the water just as fancy or instinct guides them, and you will have a tolerably correct notion of the sort of aquarium in general use amongst as Bowerbankians, and into the depths of which we gazed with boundless and unwearyingly satisfaction. Next witness the arrival of a quadrate pickle-bottle, with a wet string twisted three or four times round its neck and once or twice across its wide mouth, this transverse portion of string serving as a handle by which to carry it: the boy who brings this recommends the contents as being "prime stitlers, all cocks." We take his word, and carefully pouring off the superfluous water, empty the living contents of the pickle-bottle into our aquarium.

Success is neither certain nor immediate: my feelings at Deptford, where all my manual acquaintance with the aquarium was gained, have many times been cut to the quick by finding the sticklebacks chevying one another for days and nights round and round the lozenge-glass, until they died apparently from sheer exhaustion; at first the amount of vital energy was excessive, far too great, but it was the old story, the sword wore out the scabbard; more frequently complete success was the result.

We will suppose a dozen of these little fishes turned into the upright aquarium I have described; an hour will scarcely elapse before one of the fiery redbreasts asserts himself master, selects a part of the establishment "for building purposes" and drives off all intruders: if a second redbreast should call his supremacy in question and contest the point, he must be removed at the risk of disarranging the establishment, but this disarrangement is of less importance than it appears: after stirring up the contents of the glass in a most violent manner in your determination to eject an objectionable tenant of any kind, they will settle down in half an hour and arrange themselves as prettily and as naturally as before you converted their dwelling-place into a miniature Maelstrom.

Leaving one redbreast master of the situation, he immediately commences building operations, but at first these operations do not seem to be conducted on any definite plan; and you begin to think the work is aimless and objectless: half a dozen nests will be begun and deserted; the structure is then pulled to pieces and the materials are carried elsewhere: what are these materials? little gravel-stones, roots of water-plants, hair-like Confervae spontaneously generated out of nothing, decaying leaves of *Valisneria*, and all manner of fragments, which we should characterize as rubbish: by-and-bye an event occurs, unseen and unnoticed, which concentrates all the attentions of the redbreast to one spot: this event is the deposition of spawn by a gravid female; I could never witness the operation, but have no doubt whatever that this event is the governing cause of future proceedings: a foundation, a circular wall or rim, is then constructed around the precious deposit, and this is increased, and improved, and consolidated, in the most wonderful manner, the builder being incessant in his labours; sometimes he will bite off a root of the duck-weed or frog's-bit, and will set it floating in the water.

He will then contemplate this fragment, remaining stationary at a little distance, and will hover like a kestrel over a mouse, supported by the incessant fan-like motion of his pectoral fins: should the fragment bear this rigid inspection he proceeds to utilize it; sometimes, however, the fragment does not meet with his entire approval, and then it is at once abandoned. Mr. Kinahan has observed that after a fragment has been thus abandoned by one fish no other will use it; they take hold of it, examine its capabilities, and invariably reject it; thus proving that these little creatures have some instinctive knowledge of its adaptability or otherwise to the purpose required ; the occupations of searching, finding, testing, examining, selecting and rejecting materials seems incessant; sometimes, however, it will be interrupted by the appearance of an intruder, who is immediately made an object of attack, seized, bitten, and compelled to retreat: the victor will chase him round the glass for a

few seconds, and then return and survey his building; he is ever suspicious that it may have suffered injury during ever so short an absence, and will hang in water, like a Syrphus in air, with his head pointed towards his nest, until he is assured that his nursery is intact.

This Syrphus-like suspension is well worth studying; the little fellow, although perfectly still at intervals, will often, with a kind of start, change his position, and take up a new one on the other side of the glass, but still with his nose pointing towards the object of attraction, "true as the needle to the pole," and there he will hang hovering, and winnowing the water with his fins, just as he had hung hovering before. After awhile, assured that his building is intact, he will resume his architectural labours. How often have I seen him, like a tailor- bird, carry some little plant-fibre, or perhaps a fragment of thread which I had dropped into the water for his especial use and benefit, and watched him pass the end through and through the walls of the nest, until it was adjusted to his mind; how often have

I seen him stop when his body was half-way through the nest, his head projecting on one side, and his tail on the other; how often have I wondered by what seemingly miraculous power he passed through the nest he had taken so much pains to construct—yes! pass through it in any direction, as though, like Pepper's ghost, the nest itself were an "airy nothing" which offered no resistance to his compact body, thews and sinews, muscles and spines. From time to time would he come forth, his eyes flashing fire, his breast glowing with rosy red, and if no disturbing element was near would contemplate his work with unmixed satisfaction; then he would go to work again.

The question when or how the eggs are deposited, whether before or after the building of the nest, is by no means finally ascertained. Something like a love chase occasionally takes place, proving that fishes are not altogether insensible to the tender passion, but such scenes are rarely witnessed, and only revealed to those who have an unlimited allotment of time and patience: I have seen a male seize a female by the small of the back, by which I mean that slender part of the body which succeeds the last dorsal fin and precedes the caudal fin; and sometimes also by the sharp spike or spine which we call the ventral fin, and having thus seized her he seems disposed to say by force, not by words, "come into my bower;" but these scenes are not understood: as I have already said, we know next to nothing of the loves of the fishes, and only imagine them by the results. As to the period required by the eggs in coming to maturity, we have evidence of a rather partial kind: "Mr. Gratton had a fine brood hatched in fourteen or fifteen days, the nest having been formed immediately after the introduction of the fish." This is the only record I possess.

These little fishes are wondrous creatures when they first assume the parental figure; they look

like spicules of silver or bright motes in sunshine, as they float in your aquarium: no one seeing them for the first time, and without the aid of a magnifier, could imagine them to be fishes: then as to number; we are accustomed to count the spawn of fishes by thousands and bund reds of thousands, but 1 think this is not the case with sticklebacks; I have taken some pains to ascertain, and have concluded that the average number of a brood does not exceed twenty: I have never counted more than fourteen. But I admit they may be more numerous: I have caught hundreds of these atomic fishes in my water-net, but then I know not how many broods composed the school.

One word more: in 1843 Mr. Frederick Holme, then at Oxford, published (Zool. 200) his account of keeping water-beetles in confinement: no description of the prison-house is attempted, but Mr. Holme speaks of it as a "glass": he says of his prisoners, "They speedily become familiarized to a certain extent, and will follow the finger round the glass in expectation of food." He continued his observations during summer and winter for a long period.

"When I kept a pair together," thus he continues, "I always found the male died first, and that his dead body bad generally been mutilated and pretty nearly devoured by his widow. The females were at all times much more voracious than the males. 1 generally fed them with raw beef, of which they sucked the juices, but in summer I sometimes supplied them with small aquatic insects, which they seized with their fore feet and tore to pieces with their mandibles, rejecting the elytra and other hard parts."

It will be seen from several expressions in his brief account that Mr. Holme's observations were continuous, extending over summer and winters; we also learn with pleasure that the widows of water-beetles are not utterly inconsolable. I wish here to invite attention to the fact that up to this period (1844), although the aquarium was thoroughly utilized, more so indeed than ever since, its name had not been mentioned.

ERA II. LITERARY, POETIC AND FASHIONABLE.

In this second era or campaign, as I may call it, Mr. (now become Dr.) Bowerbank resigned the command, which, like Alexander's, was divided amongst four of his generals, Warington, Gosse, Mitchell and Rymer Jones.

Mr. Robert Warington, of Apothecaries' Hall, not only devoted every spare moment of his life to experimenting on different forms of vessel, different arrangements of light, and different combinations of inhabitants, in order to ascertain the fittest, but he introduced a new element, substituting salt water for fresh, marine animals for fresh-water animals, sea-weeds for *Valisneria.* I was a constant visitor at Apothecaries' Hall, and

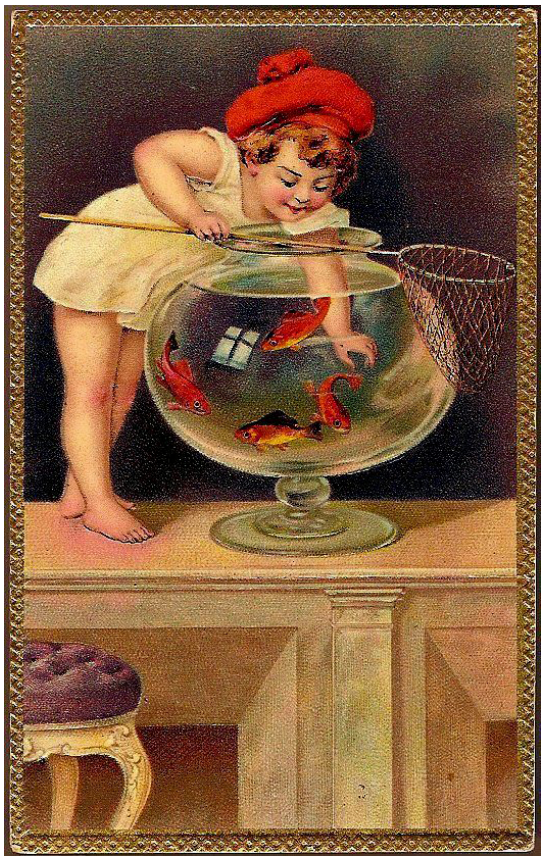
found Mr. Warington ever ready to exhibit and explain his experimental proceedings, for it must be admitted they were experimental; for unlike Mr. Bowerbank, who seems to have attained success at a single bound, Mr. Warington had to think out his plans, and as his was altogether new ground, or rather new water, he was subject to repeated failures and disappointments, but eventually he triumphed over them all.

At our delightful reunions at Mr. Bowerbank's, first at Critchell-place and afterwards at Highbury, the lamented David William Mitchell, then the energetic Secretary of the Zoological Society, who was ever on the alert for something to "draw," was a frequent visitor; the sticklebacks arrested and riveted his attention, and he was not long in taking a lesson from Mr. Bowerbank's book: every one urged it; and Mr. Mitchell listened with marked attention, and conceived the project of an aquarium in the Regent's Park. With Mr. Mitchell there was seldom much time lost between the conception and the execution of a plan. In this instance these followed each other with unparalleled rapidity; he commenced building forthwith, ordered his tanks, and stocked them with their appropriate inhabitants, availing himself of every observation previously made either by Mr. Bowerbank or Mr. Warington.

On Saturday, May 21st, 1853, as reported in the 'Athenaeum' of May 28th, there was opened at the Zoological Gardens in Regent's Park a building or room for the express purpose of exhibiting living marine animals. This building, I believe, received at the hands of the Council the title of "Marine Vivarium," but this inflated appellation soon became toned down by the visitors to the more modest and less assuming one of "Fish House," which it has borne from that time to the present. I extract from the 'Athenaeum' of Saturday, May 28, 1853, the following details, which will be interesting as a contemporaneous record of a notable event, and as inaugurating the second era in aquarian history. Moreover, it has the advantage of incorporating an account of the prior but more humble efforts, in the same direction, of Sir John Dalyell and Mr. Warington, and this saves me the otherwise necessary labour of describing the very important result of the indefatigable exertions of these distinguished aquarians.

"Fresh-water fish were tried first in these gardens. Perch, pike, roach, dace, eels, sticklebacks and minnows were all to be watched, and their domestic secrets and most retired proceedings to be brought to light. The grand experiment, however, of making a little ocean, a miniature sea, in which we might look on the habits of the creatures of the great deep had yet to be made. Sir John Dalyell, it was well known, had kept a sea anemone alive for twenty-eight years, and numerous other marine creatures for less periods; but then throughout these twenty-eight years every morning he had had sea-water brought to his house. It seemed almost impossible to bring up sufficient quantities for such a purpose into our inland towns. Gradually it became known that by aërating the salt water by means of filtering or agitation it became fitted for the support of animal life. Here then a chance of success to an object long desired seemed to present itself, and the enterprising Secretary of the Zoological Society determined to make a trial on a small scale. He began with sea anemones and some of the more hardy shell-fish, and succeeded most satisfactorily.

"While, however, this experiment was in progress a fact of much greater importance became known. It had been observed by vegetable physi-



ologists that plants purify a small quantity of water just as they purify the air,—that is, by taking up carbonic acid and giving out oxygen,—and here was the explanation of the fact of animals living for any length of time in a limited quantity of water, provided there were plants enough to take the carbonic acid which the animals threw off, and supply the oxygen which they needed. The question naturally arose, Why should not sea-weeds do the same for sea-water as fresh-water plants do for fresh water? Various dredgers and sea-shore naturalists had successfully had recourse to this plan; but we believe the merit of first having perfectly succeeded with an arrangement of the kind in London is due to Mr. Warington.

By arranging sea-plants and animals in a limited quantity of sea-water, he maintained the balance of animal and vegetable life that for several months they required neither fresh water nor any mechanical aëration. It is the adoption of this plan on a large scale that constitutes the novelty of the Vivarium now opened to the public in the Zoological Gardens. At the present moment there are in the glass house six large tanks of glass containing marine invertebrate animals and fish.

"These tanks have been arranged in something like zoological order. The first contains a variety of crustaceans, crabs, lobsters and shrimps. Here may be seen in living activity species of these creatures only to be caught by the dredge, and which have been only occasionally seen when cast up on our coasts or pinned down in our museums; several of the spider crabs—which are inhabitants of the deep sea—will attract more attention among these specimens. In the second tank is a collection of Echinodermata. A third tank contains a collection of sea anemones or animal flowers. The more common forms of these lowest members of the great family of polypes are scarcely unknown to the least curious visitors of oar sea-coasts, but it has fallen to the lot of few to see them to such advantage as they now may here.

"In variety of colour they almost vie with a bed of tulips, and they will enable the observer to understand something of the beauty which arrests the attention of the traveler in the South Seas, where these creatures and their allied forms abound. The naturalist will also find in this tank some of the less common of the species of the family Actiniadae which are found on the British coasts. In a fourth tank is a collection of the British Mollusca. Those who gather shells by the sea-shore will recognize many of their old acquaintances in this department, but no longer as uninhabited dwellings. Each contains its proper tenant. Several species of ascidian Mollusca are found here, whose rough membranaceous and ungainly exterior would hardly lead to the conclusion that they are allied to shell-fish at all, did not their interior inhabitant reveal the fact. In another tank a highly interesting group of Mollusca, the nudibranchiate, are to be seen.

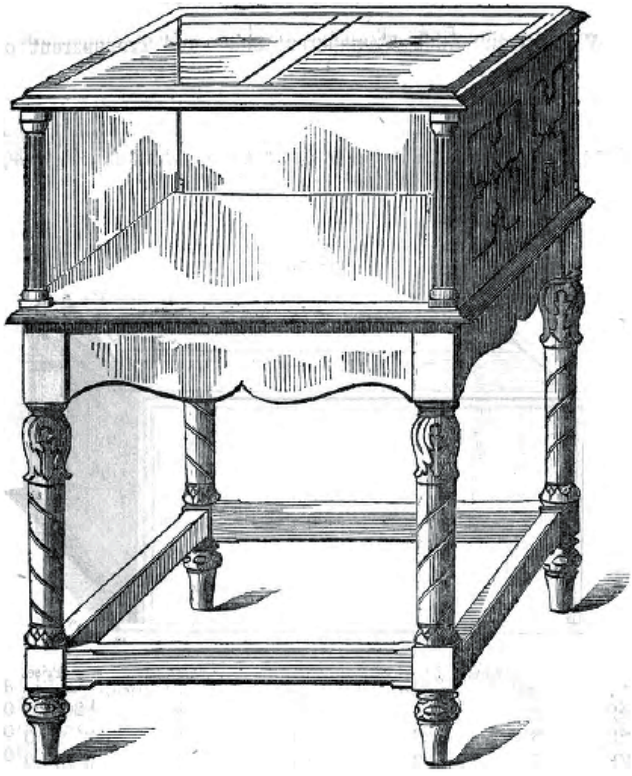
"These have no shells, and are remarkable for their delicate colouring, and for the curious forms assumed by their gills or breathing organs, which being placed outside of their bodies have got for them the name of naked-gilled. The species of this family belong to the genera *Doris* and *Eolis*. In the fourth tank are also contained some species of barnacles and sea-acorns (Cirripedia), which, with their hard molluscous-like shells, were once included under the Mollusca, but are now known to have an internal structure which allies them with the articulated tribes of animals: in this tank are some small species of sea-fish, including the blenny, the fifteen-spined stickleback, the wrasse and the father-lasher (*Cottus bubalis*). The Annelides are represented in several of the tanks by species of Aphrodite and the beautiful Sabellae.

"Many of the leaf-like and vegetable-looking objects at the bottom of the tanks are popularly called sea-weeds, and demand a microscope to make out clearly their animal nature. Nevertheless a sharp eye will detect a downiness on the surface of their bodies, which is the tentacle of the minute creatures that inhabit every portion of their structure, and are the representatives in our seas of those mighty workers, the coral animals of the southern ocean. The present collection is, we believe, only an earnest of future development. Some marine creatures, such as the jelly fishes, are not at present represented, but before the summer is over a collection of these fragile forms will undoubtedly find a place in the Marine Vivarium of the Society."

The aquarium immediately became a fashion, a rage, an infatuation, which, now that we are sobered down and are able to regard a stickleback with equanimity and a sea anemone without any sensible increase in the rapidity of pulsation, it seems difficult to realise. The press lent its powerful aid to this result. A judicious publisher is not he who invents, but he who avails himself of an invention: a man who embarks his capital in a 'Principia' or a 'Paradise Lost' will be esteemed a man of discernment by future generations, but will not be remunerated by the present. The successful journalist follows, while he is supposed to lead, public opinion; he deludes even himself with this gratifying but shallow fallacy.

It was not until the parlour-pond had thoroughly established itself as a fashion that the press detected in it a source of profit. Book-makers and book-publishers then saw their opportunity, and were not slow to embrace it: the press teemed with aquariums. My friend Mr. Van Voorst took the lead in this movement, and amid the surging wave of aquarian literature, original and imitative; his volumes are still the best and most likely to endure. I will give the titles and dates of those aquarian volumes which appear to possess inherent excellence, interspersing those of a few tracts which, although of minor importance, assisted greatly in fanning into flame the fire that had already been kindled.

1850. "On the Adjustment of the Relation between the Animal and Vegetable Kingdoms, by which the Vital Functions of both are Permanently Maintained." By Robert Warington.



An aquarium and stand in Lloyd's Catalogue.

('*Zoologist*' for 1850, p. 2868.)

1852. "Observations on the Natural History of the Water Snail and Fish kept in a confined and limited portion of Water." By Robert Warington. ('*Zoologist*' for 1852, p. 3638.)

1853. "On Preserving the Balance between the Animal and Vegetable Organisms in Sea Water." By Robert Warington. Read at the Hull Meeting of the British Association. (Printed in the 'Annals and Magazine of Natural History' for November, 1853, and at p. 4118 of the '*Zoologist*' for 1858.)

1853. "Aqua-vivarium." An article by Dr. Edwin Lankester. (Printed in the Natural History Division of the '*English Encyclopedia*')

1853. "A Naturalist's Rambles on the Devonshire Coast." By Philip Henry Gosse. 452 pp. letter-press and 28 plates, most of them coloured.

1853. "The Aquarium; an Unveiling of the Wonders of the Deep Sea." By Philip Henry Gosse. 278 pp. letter-press, 6 coloured plates, and 6 engravings on wood.

1856. "Tenby; a Sea-side Holiday." By Philip Henry Gosse. 400 pp. letter-press and 23 plates, most of them coloured.

1858. "The Aquarian Naturalist; a Manual for the Sea-side." By Thomas Rymer Jones. 524 pp. letter-press and 8 coloured plates.

1860. "Actinologia Britannica; a History of the British Sea Anemones and Corals." By Philip Henry Gosse. 362 pp. letter-press and 11 plates, 10 of them coloured.

These delightful works abounded with lucid descriptions, pleasing pictures, poetic quotations, and graphic accounts of the doings of aquatic animals as first seen by the assistance of the aquarium: nothing can exceed the beauty of some of the word-painting by Philip Henry Gosse; and as for Thomas Rymer Jones, he is overflowing with poetry: no less than one hundred and sixty-two quotations, or as I may call them "snatches of song," are scattered through his "pleasant pages." He seems to have been so led away by his subject that he could not resist the impulse to break forth into melody.

A complete change had now taken place in the element as well as in the style of treating of it, the water employed for the experiments during the first era being almost invariably fresh, during the second period almost entirely salt: the object during the first era was almost entirely confined to the habits of the living tenants of the aquarium; during the second period, the fashion, admeasurements, size, materials, structure and ornamentation entered largely into aquarian literature; indeed these matters, utterly ignored by Bowerbank and his followers, became of paramount importance. Mr. Gosse says:—

"The tank is 2 feet long, 1-1/2 foot wide, 1-1/2 foot deep; the sides and the ends of 3/16th plate-glass; the bottom of slate, the corners of beech wood, turned into pillars, each surmounted by a knob, and united by a frame top going all round. The glass is set in grooves in the slate and wood, and fastened with white-lead putty."—'Aquarium,' p. 101.

Mr. Warington, after experimenting unsuccessfully for some years, gave instruction for the making of a small tank as a more permanent reservoir, with certain improved modifications as regards form and the admission of light. He writes thus:—

"From the experience I had obtained in my experiments with the fresh-water tank, I was induced to modify slightly the construction of the vessel; thus at the back or part towards the light the framing was filled with slate, in the same way as the ends and bottom; for I had found that the glass originally employed very soon became covered with a confervoid growth which had an unpleasing appearance to the eye, and in consequence of which I have been obliged to paint the glass on the exterior to prevent the growth from increasing to too great an extent. It was almost an unnatural mode of illumination, as all the light should pass through the surface of the water.

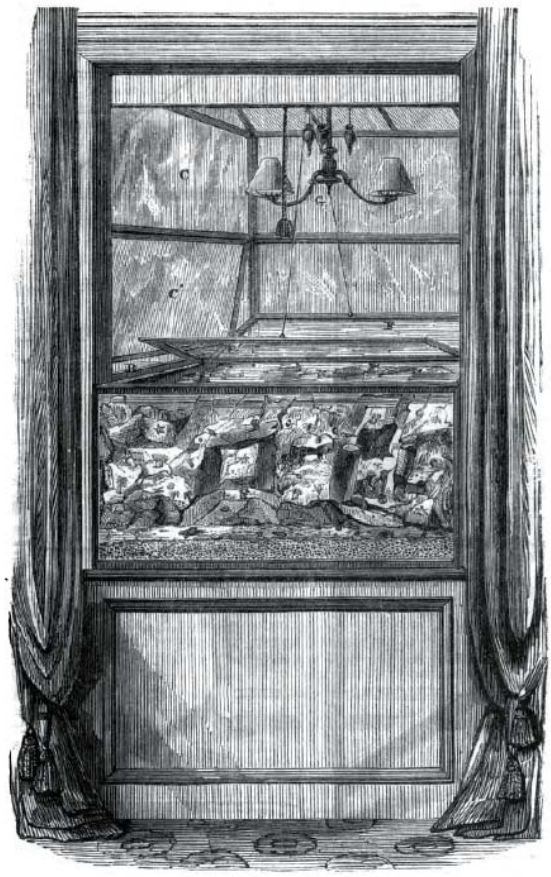
The front towards the room and the observer was constructed of plate-glass, the whole being set in a stout frame-work of zinc and cemented with what is known under the name of Scott's cement, and which I have found to answer for the purpose most admirably. Within the tank were arranged several large pieces of rockwork thrown into an arched form, and other fragments were cemented against the slate at the back and ends, and at parts along the water-line, so that the creatures could hide themselves at pleasure; a short beach of pebbles was also constructed in order that shallow water could be resorted to if desired; the whole tank was covered with a light glass shade to keep out the dust and retard evaporation." —'*Zoologist*' 4119.

Professor Rymer Jones, modestly referring to Mr. Warington and Mr. Gosse as his authorities, recapitulates Mr. Warington's instruction, and points out its advantages:—

"First, that it allows of a most extended view of the whole interior of the aquarium.
"Secondly, that it enables the occupants to resort to any depth they may desire, or even to ascend the sloping back and emerge from the water.
"Thirdly, it admits of a much larger surface being exposed to the action of light; and
"Fourthly, the sloping top allows the water which condenses on the glass to trickle off and return to the aquarium without first resting on the zinc or iron frame-work. It need hardly be suggested that the sloping back is to be covered with light rockwork extending to a short distance above the water line."— '*The Aquarian Naturalist*,' p. 6.

Each of these various instructions, insisting on the exclusive use of putty, white lead, red lead, Scott's cement, &c., were severally regarded as embodying the perfection of human wisdom until the next adviser suggested an improvement; but notwithstanding this wide divergence on minor points, it is an important fact that all aquarian authorities seem to have deliberately considered and tested, and then uniformly rejected and condemned, all attempts at aëration or circulation.

Dr. Lankester avers that circulation is only needed as "precautionary" until the vegetation is quite established. Mr. Warington says, "With the sea-water obtained in January, 1852, I have been working without cessation up to the present time, agitating and aërating when it became foul during unsuccessful experiments on the sea-



The interior of a window sill aquarium.

weeds, but since then it has rarely been disturbed," and then he emphatically adds, and I think it desirable to express his decision by italics:—*"It must be decidedly understood that no agitation or so-called aëration is required when the balance of animal and vegetable life is properly established."* This sentiment, perhaps somewhat less decidedly expressed, runs through all the aquarian books of this era: I wish, indeed, to show beyond the possibility of doubt, that the system of aëration and circulation belong to the third era, but it were of no avail to supplement the fiat of the leader with the milder enunciations of the followers; it is like adding wine and water to wine.

It must not, however, be supposed for a single instant that the aquarian literature of the era is restricted to dry and useless advices or mistaken prohibitions: such a conclusion would be decidedly erroneous, utterly opposed to fact, and Mr. Gosse's work especially abounds in truthful descriptions of aquatic life which might fairly challenge a comparison with anything that has ever been written on the "manners and customs" of the World of Animals. I will make but one extract in proof of this, a long one indeed, but I cannot divide it without destroying its value, and as for making an abstract or abridgment, it is quite out of the question. The author's ideas might possibly be conveyed in an abstract, but the life, the soul of the passage would be wanting if I robbed it of the author's phraseology.

"The Sepiola **[Note: This is a genus of bobtail squid]**. —My notions of the Cephalopoda, derived from figures of the various species in books, were anything but agreeable. I thought of them as hideous, repulsive, fierce, atrocious creatures, hated and feared whenever seen. But an acquaintance with the pretty *Sepiola vulgaris* has not a little modified these ideas; and its beauty, sprightliness, and curious habits have made it quite a favorite pet among the denizens of my Aquarium. I take it in considerable numbers in this Bay, by means of the keer-drag already described, which rakes the bottom. It is a little creature, rarely exceeding an inch in length; though the extensibility of the arms somewhat varies its dimensions.

When we turn out two or three from the net into a pail of sea water, they are at first restless and active. They shoot hither and thither, as if by a direct effort of will, but in reality by the impulse of rapid and forcible jets of water directed towards various points from the mouth of the flexible funnel situated beneath the body. After a few moments they suspend themselves in midwater, hovering for many seconds in the same spot, scarcely moving a hair's breadth either way, but waving their large circular swimming-fins rapidly and regularly up and down, just like the wings of an insect.

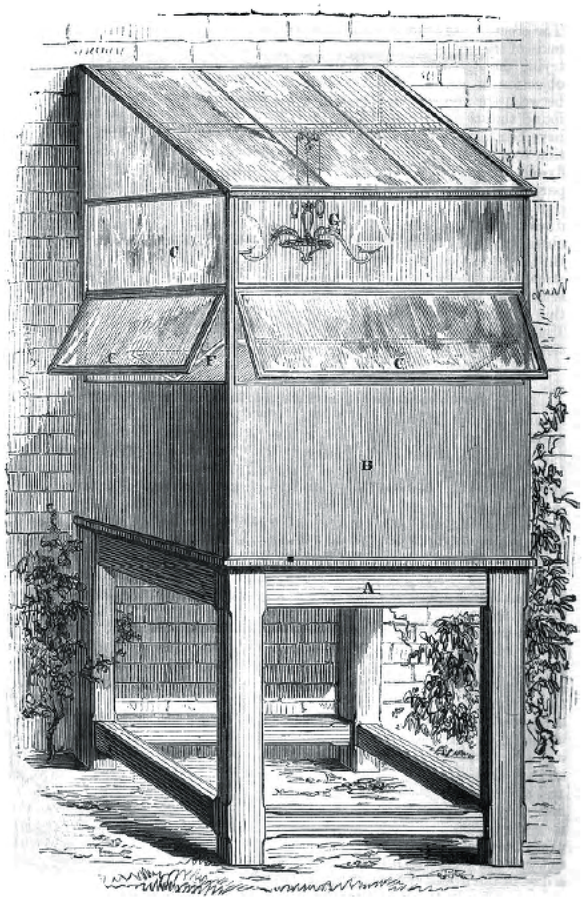
"Indeed, the resemblance of the little Cephalopod, in these circumstances, to a brown moth hovering over a flower, is most close and striking, and cannot fail to suggest an interesting comparison. The body is held in a horizontal

position, the large protuberant eyes gazing on either side; and the arms, grouped together into a thick bundle, hang freely downwards. If you essay to count these organs you find only eight; and even if you are aware that one of the characters of the genus is to have ten, of which two are much longer than the rest, you may search for these latter a long time in vain.

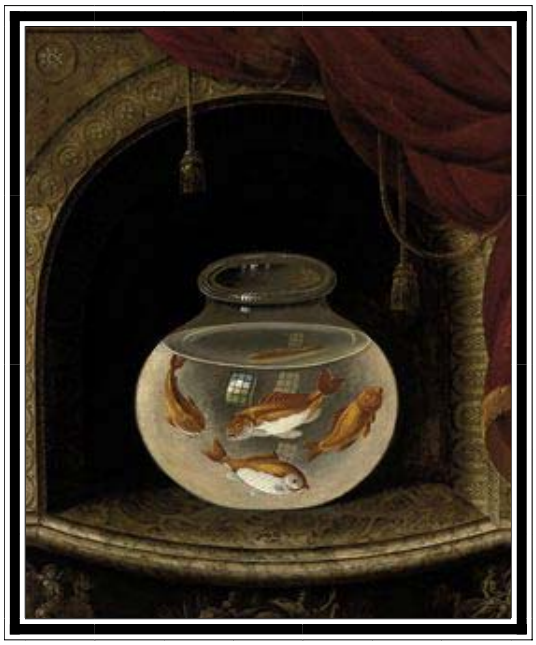
Of course I mean during the life and the health of the animal, when its impatience of being handled presents obstacles to a very accurate investigation; you may then turn it over and over with a stick, and look at the bundle of arms from above and below in turn, now grouped together, and now thrown all abroad in anger at being teased; still you can make out but eight. It was not until after many trials that I at length caught a peep at the missing organs—the pair of long arms—and discovered that it is the animal's habit to carry them closely coiled up into little balls, and packed down upon the mouth at the bottom of the oral cavity. If we manage to insert the point of a pin in the coil, and stretch out the spiral filament, the little creature impatiently snatches it away and in a twinkling rolls it up again.

"A zealous votary of the circular system would seize on this analogy with the spirally folded tongue of a moth, and triumphantly adduce it as additional proof that the Cephalopoda represent, in the Mollusca circle, the Lepidoptera among insects. While thus hovering motionless in the water, the Sepiola presents a fair opportunity for observing its curious transitions of colour, which are great and sudden. We can scarcely assign any hue proper to it. Now it is nearly white or pellucid, with a faint band of brown specks along the back, through which the internal viscera glisten like silver. In an instant the specks become spots, that come and go, and change their dimensions and their forms, and appear and disappear momentarily. The whole body,—arms, fins, and all,—the parts which before appeared free, display the spots which, when looked at attentively, are seen to play about in the most singular manner, having the appearance of a coloured fluid, injected with constantly varying force into cavities in the substance of the skin, of ever-changing dimensions.

"Now the spots become rings, like the markings of a panther's skin; and as the little creature moves slightly, either side beneath the fin is seen to glow with metallic lustre, like that of gold leaf seen through horn. Again the rings unite and coalesce, and form a beautiful netted pattern of brown, which colour increasing leaves the interspaces a series of white spots on the rich dark ground. These and other phases are every instant interchanging and passing suddenly and momentarily into each other with the utmost irregularity. But here is a change! One is hovering in quiescence, his colour pale, almost white; one of his fellows shoots along just over him; with the quickness of thought, the alarmed creature turns from white to a uniform deep brown, the



The exterior of the window sill aquarium.



rich full colour suffusing the skin in a second, like a blush on a young maidens face. The hue is very beautiful; it is the fine, deep, sienna-tint of tortoise-shell; a substance which, indeed, the mingling clouds of brown and pellucid horn closely resemble in the intermediate phases of colour.

“Hitherto we have seen the Sepiola only in the pail of water into which it was turned out of the net. After a little while it drops upon the bottom, and crouching up remains motionless; if you rouse it, it will again swim for a few minutes, but presently seeks some corner, into which it thrusts its rear, and huddles up as before. This is all that you will see of its habits under such circumstances; for in all probability the morning will reveal your protégé a lump of white jelly, dead and stiff, with uncoiled arms, on the naked floor of his prison. But introduce him while in health into an Aquarium, where living sea-plants are perpetually revivifying the water, and where the bottom, varied with sand, gravel, and pieces of rock, imitates the natural floor of the sea, and you will soon see other particulars in the economy of our little friend, which will, I doubt not, charm you as much as they have pleased me.

“The Sepiola is a burrower; and very cleverly and ingeniously does it perform a task which we might at first suppose a somewhat awkward one— the insertion of its round corpulent body into the sand or gravel. Watch it as it approaches the bottom, after a season of hovering play such as I have described. It drops down to within an inch of the sand, then hangs suspended, as if surveying the ground for a suitable bed. Presently it selects a spot; the first indication of its choice being that a hollow about the size of a silver fourpence is forcibly blown out of the sand immediately beneath the group of pendant arms. Into the cavity so made the little animal drops; at that instant the sand is blown out on all sides from beneath the body backward, and the abdomen is thrust down ward before second series the cloud of sand which has been blown up settles, but which presently falls around and upon the body.

“Another forcible puff in front, one on each side, and another behind, follow in quick succession, the fine sand displaced at each blast settling round the animal, as it thrusts itself into the hollow thus more and more deepened. I was not at first quite sure by what agency these blowing, so admirably effective and suited to the purpose, were performed. The jet in front I readily attributed to the action of the fleshy funnel projecting from beneath the mantle on the breast; but 1 did not see how this could blow a stream directly backwards. I therefore put one of my pets into a vessel with glass sides, which was furnished with the requisite sand and water.

“I at once saw that the funnel was indeed the organ employed, and the only one, in every case; and perceived its beautiful adaptation for the work it had to do, in its extreme flexibility. This organ is very protrusile, and being perfectly flexible, its orifice can be, and is, at will pointed in any direction, so as to blow the jet of water forward, backward, or to either side at pleasure. It frequently occurs, of course, that small stones are mingled with the sand, or the animal may find it convenient to burrow in the loose gravel. In either case the arms come to the aid of the funnel, the sucking disks with which they are

furnished being made to adhere to the stones, which are dragged out and thrown aside.

"You may suppose this to be a clumsy expedient, but you would think differently if you saw it; the rapidity with which the arms are thrust under, and drawn out, bearing pieces of stone of comparatively large size, and the graceful ease with which they are then thrown forward, discharging and dropping the burden, impress the mind with admiration of the beautiful fitness of the organization for the requirement. This use of the funnel, and of the sucking arms, so different from their normal purposes, affords additional examples of that Divine economy in creation, which, when a new formation is ordained, does not always form new and special organs for the necessity, but adapts some already employed in other service for the new work; while still both the one and the other function are fulfilled with such perfection as shows that every emergency was foreseen and provided for in the mighty plan, and that it was not for want of resources that distinct actions are performed by the same instrumentality.

"We admire the skill of the artisan who can effect different operations with the same tool, especially when we see that each kind of work is of faultless excellence. The ordinary employment of the sucking arms is no doubt the same as in other Cephalopoda, the capture and retention of prey. Of this I saw an instance in the case of one of my Sepiolae which had seized a shrimp (Crangon trispinotus), a sand-burrower like itself, and was, when I saw it, holding it firmly against the horny jaws, which were devouring it. The discharge of ink through the funnel I have also witnessed, though this is far from being a frequent action with this species.
"One of them that had been for a day or two in an Aquarium, and was evidently at home there, I put into another vessel. No other animal was present, but the strangeness of the new abode evidently frightened it; it darted about in manifest alarm and excitement, and presently shot forth from its funnel a cloud of inky fluid to a distance of several inches; another and another discharge succeeded in rapid sequence, and it was not for some time that the animal recovered its equanimity. It did not appear to me that this fluid could be of much service to the little creature in the way of concealment; for although the matter was tolerably copious, and densely black, it did not diffuse itself in the water, but remained in masses, and when moved with a stick was drawn into slimy strings."

Here ends the second era in the history of the aquarium, and although we are indebted so greatly to the leaders of this period for their patient research and indomitable perseverance, it cannot truthfully be denied that a large share of these qualities was wasted on useless instructions about selecting and cultivating sea-weeds; in cruel and mistaken advice to keep the captives without food; and in denouncing the very principle, that of aëration and circulation, by which alone the aquarium can become permanent.

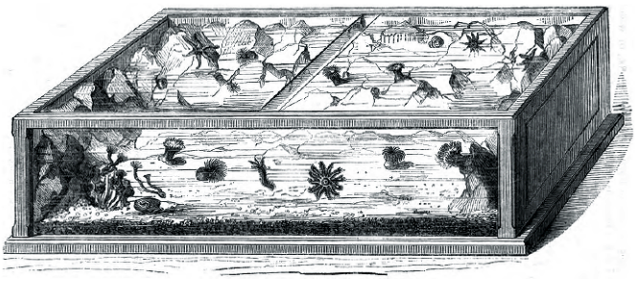
ERA III. COMMERCIAL AND AMBITIOUS.

From the preceding pages it must, I think, be evident that nearly all the conclusions at which we arrived during the First and Second Eras require careful reconsideration. I cannot say that what has been termed the balance of nature—so much water, so much air, so many animals, so many plants—is altogether a mistake; but I do without hesitation say that we made too much a rule-of-three sum of the affair, and that the formula we were in the habit of laying down was framed under the idea that by the aid of experience we could define what laws ought to govern Nature, rather than leave Nature entirely unfettered, and humbly ask her to show us how she governs herself; for, as a sea-cave in full flower with anemones is far more beautiful than anything we can achieve by our own management, so are the concomitant conditions which have produced that result infinitely more subtle than any arrangements we have in our power to devise.

As for sea-weeds in a state of nature, I deny none of the properties which have been attributed to them, but I maintain that in our clumsy attempts to introduce sea-weeds into our fictitious seas, we frustrate rather than promote the object we have in view; and it is not a little curious that when Nature was actually sowing broadcast her Algae and Confervae in our aquariums we deliberately laid our unwise heads together for the express purpose of defeating her beneficent intentions.

We wrote instructions how to get rid of the green growth that was such a nuisance in our otherwise successful aquariums: it is as though a man writing on breeding poultry were to recommend the destruction of all the chickens. Nature should be her own marine gardener. There should be a bottom and sides to an aquarium—this seems an absolute necessity, whether that aquarium be an ocean or a tank; and Nature, unassisted and uninvited, will clothe the bottom and sides with a drapery of vegetation wherever the light can penetrate. The seeds of sea-weeds are ever floating in the water, and ever ready to find anchorage where they meet with a stable surface. So universal is this sporadical growth of aquatic vegetation, that I believe it impossible for a stone to be immersed in water under the influence of light, without attracting the seeds of aquatic plants, and these will assuredly vegetate on its surface; and it is also a most indubitable fact—a fact that loses none of its importance by frequent repetition—that this humble vegetation emits, in a powerful light, a series of ascending bubbles of oxygen.

But there is another necessity, a necessity which aquarians of the first and second eras, as we have seen, not merely refused to acknowledge, but took the utmost pains to condemn. I think it probable that every naturalist who trusts himself on the ocean, even for a dozen hours, and from



A marine aquarium pictured in Lloyd's Catalogue.

the deck of a steamer snuffs the invigorating breeze as it passes over the agitated surface of the water, will after a while admit that some other principle is at work beside the maintenance of an exact balance between the breathings of sea-weeds and the breathings of sea anemones or fishes; and will perhaps also admit that motion is such a principle.

It has been asserted by voyagers over and over again that the sea itself becomes foul during a long calm, and that its life-supporting powers seem absolutely to have departed; fishes and pelagic crabs die by myriads and float on the surface, and, together with dead sea-birds and detached sea-weeds, constitute a putrid, fetid, fever-generating scum, more dreadful, more fatal to man, than when the great deep is in its wildest and stormiest moods. The introduction of sea-bang, sea-lettuce, sea-endive, sea-whistle, sloke, dulse or carrigeen will not remedy this. Whatever quantity of these life-restoratives be cast upon the waters, they will do harm rather than good; they will float on the surface, decay, and add to the seething and putrefying mass.

A more powerful agent is required, and Nature kindly supplies it. A breeze springs up; a change comes o'er the spirit of the scene; motion sets in, and all is restored. We read that in a space of time incredibly short, the water resumes its life-sustaining power, and every trace of impurity has vanished as by a miracle. These narratives must, I think, convincingly establish to those who read them, the fact that there is no necessity for changing the water. When the life-sustaining power of the sea has been exhausted, Nature herself restores it, and the restoring element is motion. She has no power to change the water; the same sea must be used again and again; the same water must be encompassed by the same land. However clearly the theory of change in relative position may have been established—however manifest it may be that the ocean now rolls over what was once dry land, and that what is now dry land was once covered by the sea—still there is nothing new, nothing added, nothing subtracted; the same materials remain, fluid and solid, and will remain for ever. Motion continually exposes a fresh surface to the atmosphere, and this contact of air and water, called aëration, is in continual operation.

"The great want felt," says Mr. Lloyd," was constant motion like that of Nature, by which the water may be continually turned over and over, presenting successive and multitudinous surfaces to the surrounding atmosphere, and may by contact with it incessantly absorb large quantities of oxygen necessary for the sufficiently rapid decomposition of organic matter given off by the animals."—'Handbook,' p. 18.

Twenty years before this the absolute necessity for motion and aëration was, I believe, first pointed out by Mr. E. W. H. Holdsworth, in his 'Handbook to the Fish House in the Gardens of the Zoological Society of London.' This excellent little pamphlet is not only useful as a companion to the aquarium, but is a philosophical exponent of the only principles and arrangements on which marine aquariums can be established so as to become permanently successful. Mr. Holdsworth has shown himself perfectly acquainted with his subject, and thoroughly competent to explain it to others. The 'Handbook' is now so exceedingly rare that I need make no apology for the rather long quotation given below.

"The main difficulties at present met with in the satisfactory maintenance of the aquarium are unquestionably due to our ordinary inability to imitate that most important condition of the

sea—its continual motion. The advantages derived from that movement are incalculably great to its inhabitants; so much so as to mask, in a great measure, the principle of compensation on which plants and animals are largely dependent for the supply of the gases necessary for their respiration. In a small tank the presence of decaying animal or vegetable matter, even in inconsiderable quantities, is often sufficient to destroy the purity of the water, and so to cause the death of the animals in it; for the poisonous gas, carburetted hydrogen, arising from putrefaction, is there confined within a small space, and the stagnant condition of the water prevents its rapid combination with the oxygen, which, uniting with the hydrogen, produces water, and with the carbon results in carbonic acid.

"But, in the sea, any dead matter not consumed by crabs or other scavengers is distributed in every direction as fast as it becomes decomposed and assumes the gaseous form, and a supply of pure water immediately takes its place, so that the plants and animals in the neighbourhood are not exposed to any hurtful influence arising from it, as is the case when the decaying matter gives off its deleterious gases in the motionless water of the aquarium. In large establishments this movement of the water may be produced without much difficulty by the aid of gutta-percha pipes and a small reservoir or supply tank from which the water may flow into the aquarium and the waste be pumped back to continue the circulation; for it is not necessary that the water should be renewed. *Any loss that may take place by evaporation should be made good by the addition of pure fresh water; but the great bulk of the sea-water will last for years if it is kept well aërated; indeed, there is no reason for its ever being unfit for use.*

"The salts held in solution retain their properties for an indefinite time, as far as is known; and as the pure water is all that is lost by evaporation, that alone requires replenishing in order to preserve the proper specific gravity or density of the whole. In small tanks the water may be temporarily agitated by the use of a convenient kind of force-pump, adopted by Mr. W. A. Lloyd; but unless there is a special supply tank placed on a higher level than the aquarium, so as to ensure a continuous stream, the movement of the water cannot be easily maintained. Prawns and fishes are also useful, to a certain extent, in causing a motion of the water, but they have too little power to produce anything like the continued washing of the sea which the Actiniae are accustomed to; for it will be remembered that these animals, being attached, are exposed to the recoil of the water from the resistance of the rock as well as to the influence of the tidal current; and this double motion of the water produces the wash which gives such a life- like appearance to everything growing within its reach. Animals subjected to this peculiar movement of the sea display vigour almost unknown in the usually quiet waters of the aquarium.

"The Actiniae attach themselves firmly in sheltered crevices and expand their flower-like disks to the ever-changing water around them, every wave brings a fresh supply of food within their reach, and their bodies are kept clean by the motion of the water. Fishes, and other swimming animals, also seem to enjoy the continual strug-

gle necessary to prevent their being carried away by the stream, and thus all their vital powers being called into action, everything presents the appearance of health and animation. Such are the results we must endeavour to produce in the aquarium, and we can only do so effectually by imitating, as far as possible, the means employed by Nature. In cases where it is inconvenient or difficult to establish a constant change of water, as in small tanks, great advantage may be derived by occasionally drawing off the water, and in this manner placing the animals in the condition to which they are accustomed when the tide is out. Of course this treatment is only applicable to those animals and plants naturally living between tide-marks; for, except in the case of some of the blennies, and a few other small fishes, this exposure to the atmosphere is unsuited to the habits of free-swimming animals.

"The appearance of the Actiniae, and other soft-bodied creatures, when left thus exposed, is often so unlike their condition, when immersed, as to give rise to the suspicion of their being in an unnatural state; but experience tells us that these animals thrive best when subjected to this periodical exposure, and they show renewed vigour on the subsequent rising of tube artificial tide. A great advantage is also gained by returning the water in a small stream to its place in the tank; by this means the whole of it undergoes purification in its passage through the air, and becomes better fitted to support life. We need only take a glance at the rocks at low water to satisfy ourselves that periodical exposure to the atmosphere is almost one of the necessary conditions of life with many species of marine animals.

"Some of the sea anemones are found so high up in the range of tide that they must necessarily be out of the water for at least six hours of the twelve occupied by its ebb and flow; and if we go lower down and look under the large boulders, and into the dark crevices of the rocks, we shall find a multitude of creatures, and many of them of the most delicate structure, which, for an hour or two in every tide, are quite out of reach of the water. Marine animals can bear this exposure better than the inhabitants of fresh water; the salts held in solution in sea-water retain a moist atmosphere around the bodies of the various animals which have been bathed with it, and evaporation consequently does not take place very rapidly, so that we need not fear imitating Nature even in what, at first sight, appears to be a hazardous proceeding."— 'Handbook to the Fish House,' p. 10.

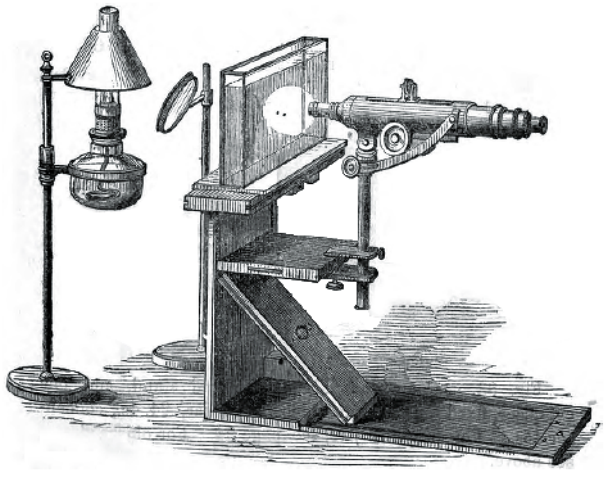
Here we have the principle of the salt-water aquarium clearly explained; and I have, as in one or two previous instances, italicised a passage to which I wish particularly to invite attention. Nothing can be more truthful than the entire extract, and it is difficult to conceive anything more neatly expressed than the sentence I have printed in italics; Mr. Holdsworth's method of returning the water into the aquarium is perhaps somewhat superseded by the more energetic operation of the steam-engine, but the idea is the same, and is perfectly in accordance with present practice.

I believe it was during the year following the successful opening at Regent's Park, that the late Dr. Robert Ball introduced a novel mode of aëration at Dublin: this is spoken of as "a method of keeping the sea-water in occasional motion by passing bubbles of air through it from a pair of bellows worked by visitors." I cannot find at this moment any categorical description of the experiment, or any statement of its success or otherwise; but it is due to the memory of this enthusiastic and kind-hearted naturalist, with whom I had the honour to be personally acquainted, to preserve the record of an ingenious invention.

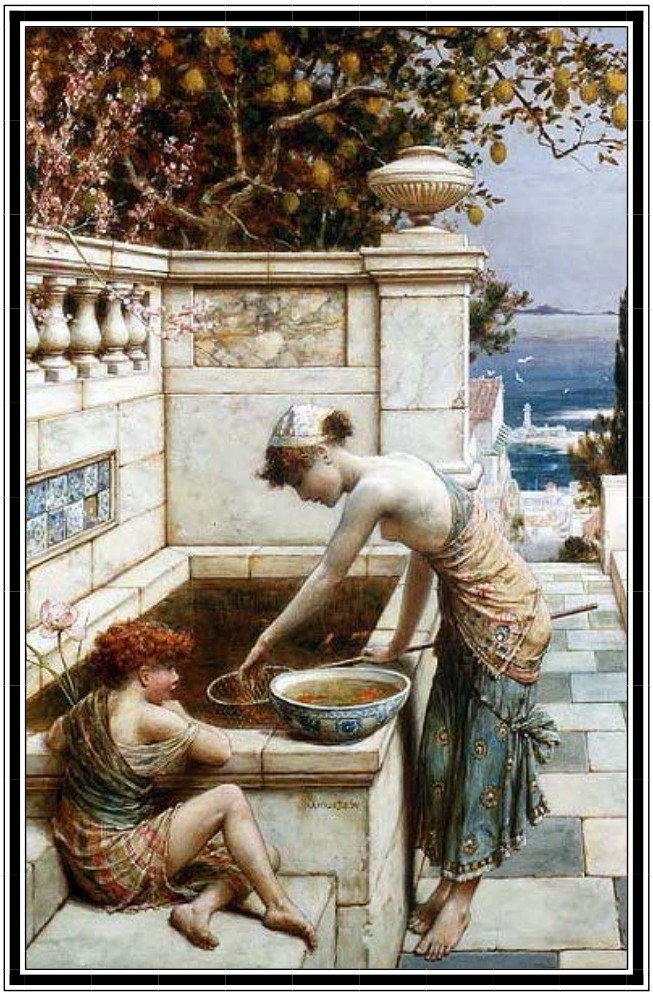
Again, two years subsequently, in 1856, the Baron Cloquet, whose ingenuity is well known to all the savans who took part in establishing the Jardin d'Acclimatation at Paris, revived the use of bellows for the purpose of aëration. His instrument had a gutta-percha pipe fitted to its nozzle, and at the extremity of this a leaden tube, which extended to the bottom of the aquarium; the aperture of the tube was covered with wire-gauze, which pulverized in the most complete manner the air forced through it by the bellows; the emission of the air at the bottom of the aquarium would doubtless partially effect the desired object, but not so thoroughly as Mr. Lloyd's; for on his plan, presently to be described, the air comes in contact with the water, both in its rapid descent and its deliberate ascent, whereas in the baron's method it could only do this in its ascent.

Still subsequently, M. Milne-Edwards the younger, son of the great naturalist of that name, invented an apparatus for aërating an aquarium, the peculiar advantage of which was said to be that it required neither manual labour nor any attention; it is described as working "automatically," thus reminding one of that grand desideratum in mechanics, perpetual motion: its figure was that of our old hour-glass, consisting of two chambers connected by what may be called a narrow waist. The upper chamber was full of water, the lower full of air; the water descended by its own gravity from the upper chamber into the lower, expelling the air and driving it into the water of the aquarium, which thus became saturated with air: the operation of emptying the upper chamber took a long time on account of its large size and the smallness of the waist; but when once this was accomplished the entire apparatus swung and reversed itself, in which operation it closed one valve and opened another, and the chamber which now contained water being uppermost, the same result took place as before: without seeing the machine I am unable to understand this, so I feel my inability to explain it to others: we all know that under any circumstances the heavy or water-filled chamber would, like a modest gentleman, evince an invincible repugnance to take the uppermost place.

In 1859 Mr. George Hurwood, of Ipswich, contrived an arrangement whereby the pressure of a stream of fresh water, such as exists in the pipes of water-works in towns, or such as can be got from a high cistern already existing in a dwelling-house, may be employed to compress air, which compressed air in turn forces a current of sea-water into an aquarium. This arrangement was adopted by Mr. Lloyd in the Jardin d'Acclimatation, and was eminently successful: it has continued in operation for thirteen years.



A microscope for viewing small marine creatures in a large glass cell (Lloyd's Catalogue).



The necessity of aëration and motion having been generally admitted, after their introduction in the Zoological Gardens in Regent's Park, other aquariums, more or less fully adopting the principle, were established in the Surrey Zoological Gardens in London, in the Zoological Gardens in Dublin, in Belfast, Galway, Edinburgh, Scarborough, Weymouth, Vienna, and the Crystal Palace; the last named, under the management of Mr. Bartlett, the present invaluable Superintendent of the Zoological Gardens: this was remarkable for the ugliness of its exterior and the extreme beauty and temporary success of its internal arrangement. Others were established in America, and those at Boston and New York became somewhat celebrated—a result, at the latter city, probably due in great measure to the matchless advertising talent of Mr. Barnum. Mr. Lloyd, however, tells us that all these exhibited two faults: the stock of animals was invariably excessive in number, and the animals themselves excessive in size, faults which carried their own punishment, for from this very excess the creatures dwindled and died.

William Alford Lloyd, the projector of the Crystal Palace Aquarium, and now the Superintendent, and the author of the 'Official Handbook,' was born on the 8th of August, 1828, at No. 6, Bush-lane, Cannon-street, in the City of London, the site now occupied by the premises of Messrs. Barron, Squire and Co., wholesale druggists. He was a weak and sickly child, and at five years of age was sent into Wales for the invigoration of his body and improvement of his mind: he was put to a hedge-school at Llwynlleia, in Merionethshire: the spot thus honoured is equidistant from three villages rejoicing in names which I am totally unable to pronounce, and therefore gladly take refuge in letter-press: these villages are Bettwsygwerfilgoch, Cerrigydruidion and Llanfihangel—names a familiarity with which, Mr. Lloyd tells us, in his pleasant autobiography, largely assisted his speedy acquisition of the German language in after years. Would that they had the same effect on me! Mr. Lloyd's "school days" might possibly have furnished matter for a narrative as interesting as those of Tom Brown, but he has only given us a very small installment of such a narrative, and I believe even that would have been withheld had it not been for the accidental finding a crab, a circumstance that incidentally leads us to an introduction to his school and schoolmaster in the year 1833.

"I smuggled the crab into the school-room," says Mr. Lloyd, "in order to get the schoolmaster, Humphrey, the learned man of the place, to tell me all about it. He was a little thin old man, with a yellow, shrunken face, yellow teeth, and yellow finger-nails, was dressed in a black velvet coat, waistcoat, and knee-breeches, with black stockings and huge shoes. He knew no English; and at intervals throughout the day smoked very coarse tobacco from a short black pipe in the school-room, which was also the dissenting chapel of the place. There were no writing-desks

or tables of any kind, but the scholars knelt on the rubble-floor, and used as desks the deal forms on which the congregation sat on Sundays. Humphrey's scholastic fees were all paid in kind: some of the lads brought com, or oatmeal, or flour, or wool, or bacon, and I remember once trying to carry on my head my payment, a big square lump of coal; but it was too heavy, and another boy kindly let me carry his payment of a lump of butter, and he, being stronger, conveyed my coal. Cheese was a luxury known only to the rich: money was seldom seen in the form of coin, and farthings never. I did not take my crab to school as a matter of payment, nor yet for play or idle curiosity, but truly to learn something about it from the only person whom I thought could give me help, and his reply was, 'Ah, William Bach! only learned men in London can give information on such things,' and he smoked his pipe vigorously, and gave me permission to put the crab away during school-time in the chapel pulpit, to be out of the reach of the boys."

In 1837 Mr. Lloyd returned to London, and visited the Zoological Gardens, which proved a constant source of amusement and interest to him whenever he obtained a holiday: this continued for many years, during which his reading and learning, equally sources of instruction and amusement, seemed incessant and most miscellaneous.

In 1838 he obtained the exalted post of errand boy at Messrs. Pontifex and Wood, engineers, of Shoe-lane, and stayed in this place for three years. Unlike any other errand boys whom I have known, his constant study was to acquire a knowledge of the various mechanical contrivances and combinations which he saw around him. We next find him apprenticed to Messrs. Remnant and Edmonds, the bookbinders, in Lovell's-court: but he was far less assiduous in gaining a knowledge of that branch of trade. He was out of his time in 1847, and then, and before, seems to have found opportunity for a most extensive and varied course of reading, and just such reading—deeply instructive reading—as a lad usually pronounces to be "slow" and "dry"; however, he now had reading to his heart's content. The first book he ever bought with his own money was, in 1840, Craik's 'Pursuit of Knowledge under Difficulties.' "No written or spoken words," says Mr. Lloyd, 'can express the avid-

ity with which I read Craik's book over and over again, or can tell the encouragement I gained from it." At the same time he met with a memoir of John Hunter, and was absorbed in admiration of the great anatomist.

"By my reading I was constantly, as it were, brought into contact with him, and learned how he kept at Brompton many living animals in a small menagerie, observing their habits and forms when alive, and dissecting their bodies when dead, and doing so amidst many difficulties. Reaumur and Hüber were two other naturalists of whom I read with mentally wondering eyes." But at this time Mr. Lloyd got involved in figures, and the works of Thomas Simpson and James Ferguson, mathematicians, engrossed a principal share of his time, and, stranger still, Augustus de Morgan's 'Elements of Arithmetic'; thus his attention was diverted for a time from facts to figures; from truths to the expression of truths.

In 1851 he obtained a place in Old-street, at Mr. W. Browns second-hand book shop, and here, of course, he had an opportunity of indulging his taste for books, and of making his store of knowledge still more extensive: from the 'Penny Magazine,' that great source of miscellaneous knowledge, he learned a little of everything.

The 18th of November, 1852, was a public holiday, the funeral of the Duke of Wellington: this memorable day Mr. Lloyd spent in the Zoological Gardens, and here he met with an incident that gave an aquarian tendency to the whole course of his future life.

"On arriving there, near the side entrance, was a building I had never seen before, and which had risen since my last visit—a conservatory-looking glass erection of not large dimensions, standing on a low wall. The door was fastened, and I could see no one inside, and on my asking of a passing attendant what the place was for, he said it was a 'Fish House,' though Borne people called it an 'Aquarium' and that it was destined to contain fish and other such things, even sea-fishes and lobsters, and that it was intended to be opened in the following spring. He added his disbelief in its success and an expression of his sense of the impropriety of its introduction into a zoological garden.

"I went back to the 'fish house,' and passed round to its rear, and there to my great astonishment, I saw through the glass side of the tank containing perfectly clear water, and wonder of wonders, a living pike! I wish I could write what I then felt; I wish I could now feel as I then felt, but such freshness of wonder comes to one not more than half-a-dozen times in a life. I could not get away from the place—it was at the extreme north-east corner of the building, and the tank has been for years converted into a marine one—but I went to it again, and remained there till it began to grow dusk, and it was time to get home. During the last eighteen years in London and Hamburg I have never been without a pet jack in an aquarium."

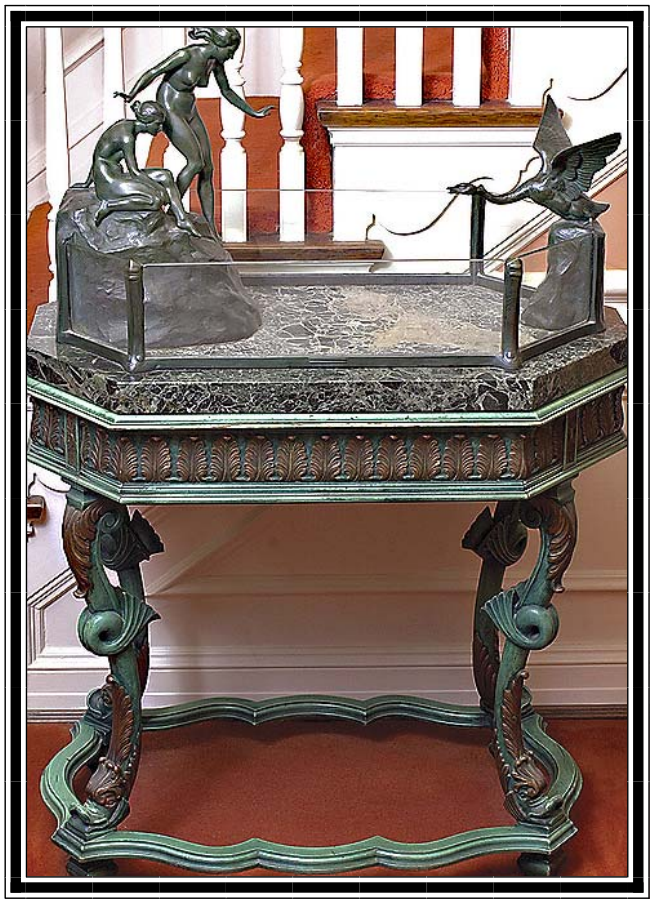
This seems to have been Mr. Lloyd's first introduction to fresh-water captives. I will now intro-

duce both him and my readers to the denizens of the sea: he says that although now (1873) in the Crystal Palace, with all possible means and appliances at his command, he can look back on a time, twenty years ago, when his pence and halfpence had to be laid out with rigid economy, and I am thus introduced to one of the most interesting passages in his life—the search for sea anemones in the streets of London! He had already set up small aquariums in wide-mouthed glass bottles filled with artificial sea-water, but these miniature establishments were without living inhabitants: his *modus operandi* for supplying this want is thus described:—

"I used to sally forth at dead of night, where heaps of oyster-shells were thrown by day from street oyster-stalls, in Smithfield and St. John's-street, and bring them home. The oysters devoured in such poor neighbourhoods are not the genteel little smooth 'natives' eaten at luncheon-bars, but big, rough commoners with bold foliations on the upper shell, and deeply ribbed on the lower one; and in and below these hiding-places I could find many little sea anemones of several species, some hopelessly smashed, but others quite perfect, having been protected by the strong projections of the oyster-shell and unharmed by rain or other fresh water. The species I found thus were *Actinoloba Dianthus, Sagartia viduata, S. Troglodytes, B. Bellis, S. elegans*, and, but very seldom, *Actinia Mesembiyanthemum*.

"All these I used to pick off the shells with never-wearying patience and care, and drop them into the fictitious sea-water and transfer them to my bottle, to which they adhered and made themselves happy. I used to feed them with little morsels of oyster-flesh which I found adhering to the inside of the shells, and when the water would become offensive from the effects of the food, because the quantity of fluid was too small to hold enough oxygen in solution to decompose the dead animal matter fast enough, I poured the water from the little bottles into a great earthenware foot-pan covered with a sheet of glass to keep out dust, and standing in a dark corner of the room. The foot-pan was so very large in comparison with my small bottles that the emptying of them periodically into the pan did not interfere with the water in the latter, so that from it I immediately refilled the bottles, one at a time on successive days. The water in the foot-pan on the floor thus effectually counteracted all tendency at going wrong in the bottles on the window-sill above."

Two years after this, namely, in 1854, Mr. Lloyd sent me two short papers for the '*Zoologist*,' which show that his love for sea things continued in all its force. These exhibit beyond all question the deep, and I may almost say, the devout attention, with which he studied Nature at this period: his "Note on the Habits of *Limnea stagnalis*" (Zool. 4248) is a master-piece of descriptive writing. Of course I was anxious to know such a man, and in March, 1855, I found him located at 164, St. John-street-road, in Company with poverty and sea anemones, sacrificing



all worldly considerations to a love of Science. Other papers soon followed, entitled severally "Occurrence of *Edwardsia vestita* in Britain" (Zool. 5180) and "Note on a Sea Cucumber in Confinement" (Zool. 5181).

These exhibit in an especial degree three great qualifications of a naturalist—1st, the knowledge which leads to the instant selection of what is peculiarly worthy of observation; 2ndly, the faculty of observing systematically, or in the words of De la Beche, the knowledge "how to observe"; and 3rdly, the power of defining the observations: these qualities Mr. Lloyd possessed and possesses in an eminent degree. I have never forgotten, and hope never to forget, that first visit to the great aquarian and the appearance of his little aquariums; glass bottles or cylindrical vessels, some on the table, some on the window-sill, some in the dark, some in the light,—all contributing to his already large stock of knowledge, all revealing secrets previously hidden.

In 1856 he removed to Portland-road, and embarked in business; as a matter of course, the aquarium business,—and almost also as a matter of course, unsuccessfully; he was not cut out for business on his own account; he had no skill in buying and selling; but his reputation as an aquarian was established, and in 1859 he was summoned to Paris, and undertook the management of the aquarium in the Jardin d'Acclimatation.

In 1862 I find Mr. Lloyd again in London, exhibiting an aquarium, worked by compressed air, at the International of 1862, and accompanying the exhibition by the publication of a very clear and compendious account of the principle and construction of aquariums in general and of the Exhibition aquarium in particular.
While thus occupied he was visited by Dr. H. A. Meyer, who was desirous of establishing an aquarium at Hamburg, and this finally led to an arrangement with Baron Merck for Mr. Lloyd's removal to that city and the construction of an aquarium in the Zoological Gardens there, under his sole superintendence: this was opened in the spring of 1864, and soon became eminently popular as well as successful in a pecuniary point of view; the names of the late Dr. Meyer, Professor Mobius, Chief-Justice Schwartz, and the late Baron Ernst von Merck must always be associated with that of Mr. Lloyd in this admirably managed establishment. The sea-water is circulated partly by a water-pressure engine set

in motion by the town water-works, which drive a pair of water-pumps (instead of compressing air as was done in Paris), and partly by a steam engine which drives two other pumps.

"The great pecuniary success of the Hamburg Aquarium caused other aquariums to be erected in various parts of the Continent, namely, in Hanover and at Boulogne-sur-Mer, in 1866; in the Boulevard Montmartre in Paris, in 1867; in the Reserved Park of the Paris International Exhibition, in the same year, in two places; twice at Havre in 1867 and 1869; in the Zoological Gardens at Brussels, in 1868; in the Flora Gardens at Boulogne, in 1869; and in Berlin, in 1869."—' Official Handbook; p. 20.

I do not mention these dozen aquariums as under Mr. Lloyd's superintendence, but as called into existence by his successful management at Hamburg and elsewhere. In 1870 he returned to London, at the summons of the "Crystal Palace Aquarium Company," and there he is located at present, and I trust bids fair to become a fixture. And here it is indispensable that I mention that since the Crystal Palace Aquarium was opened two others (at Copenhagen and Brighton) have been completed; five more (at Vienna, Manchester, Southport, San Francisco and Naples) have been commenced; and still three others (at Frankfort, Birkenhead and Rothesay) are partially erected.

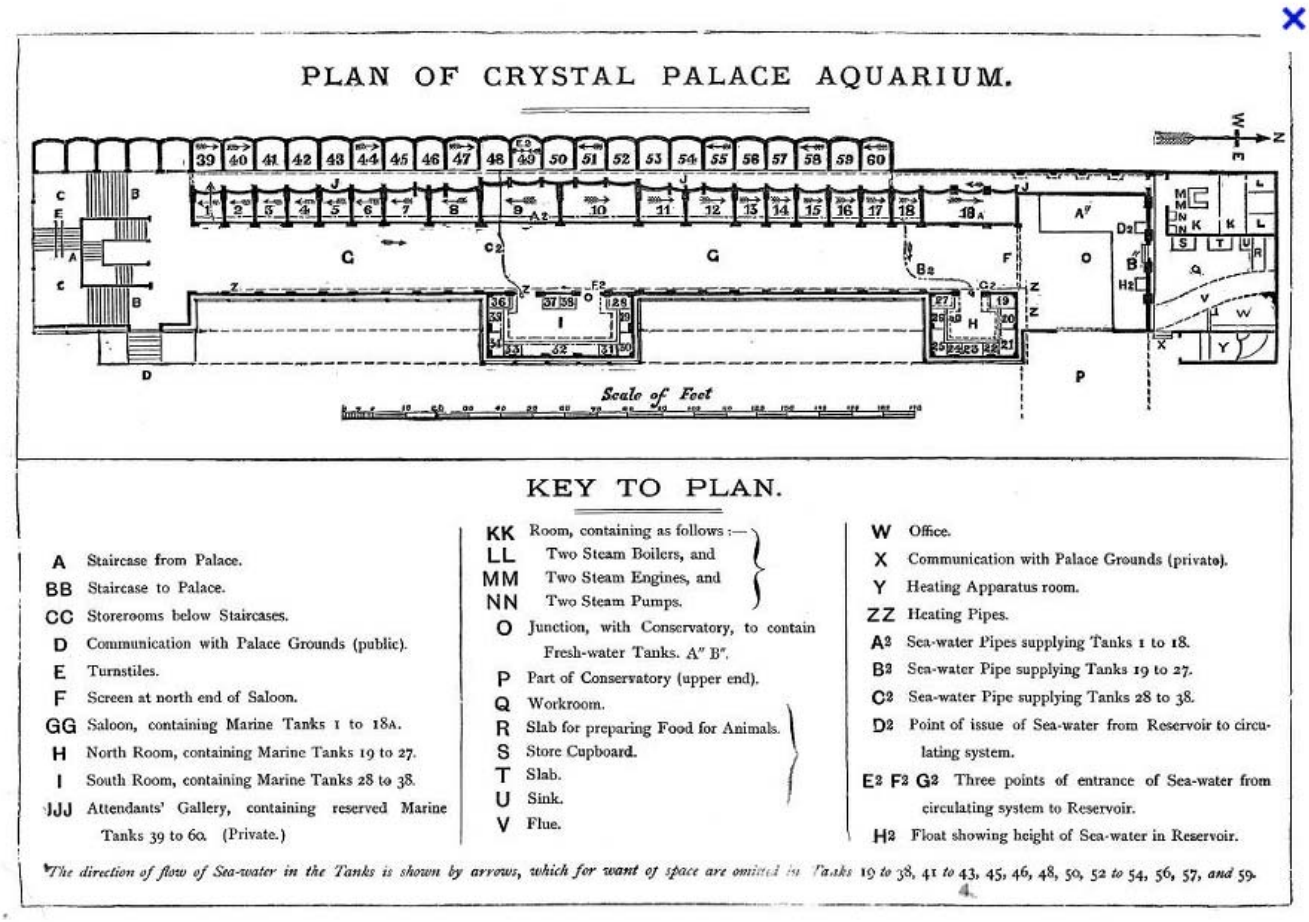
We will now enter the Crystal Palace Aquarium, Guide-book in hand, or rather 'Zoologist' in hand, for I am indebted to the courtesy of the Crystal Palace Company for the use of their stereotype plan of the aquarium, which explains the details. I fear I have been a long time in reaching this point, but I hope I have spent that time pleasantly and advantageously; and thus between fear and hope, the two great ingredients of human life, I also enter a restricted passage, which is not without its dangers:

"Contra, jussa monent Heleni, Scyllam atque
Charybdim ♣
Intra utramque viam, leti disorimine parvo,
Ni teneant cursus."
Aentid, book iii. line 684.

The prosy style is my Scylla, the florid my Charybdis; I will try to steer between them.

The plan of the aquarium is shown by the plate: in round numbers, it is 400 feet long and 70 feet broad. It is only one story high, and this ground-plan exhibits everything that requires explanation, except a reservoir, which is under ground, and contains 100,000 gallons of sea-water, kept in the dark. On the subject of keeping a very large proportion of the water in the dark a great deal has been said by Mr. E. Edwards, formerly of Menai and now of Chester, Mr. Warington, of London, and Mr. Lloyd. Various contrivances have been tried for keeping a portion of the water of aquariums thus in the dark, on the plea that but little light can penetrate the ocean, a fact strongly supported by the fact that the deep-sea animals are frequently without eyes, or at least without eyes that we are accustomed to consider as such, thus showing that vision is neither required nor possessed at great depths below the surface: on this subject I cannot forbear to quote Mr. Warington.

"When the rays of light strike the glassy surface of the water, the greater part of them are reflected, and those which penetrate are refracted and twisted in various directions by currents of



the water; and when the depths are considerable it would be few rays that would penetrate to the bottom; but let the surface become ruffled by the passing wind, and it is little light that can be transmitted; and when the same disturbing cause lashes into waves and foam, not a ray can pass, and all below must be dark as night"—Zool. 6702.

The great bulk of water in the ocean being then in its "dark unfathomed caves," the plan of keeping it dark in an aquarium is obviously little more than a direct obedience to the teachings of Nature, and there is little necessity for explaining the principles which require, or the circumstances which accompany, profound darkness. Sea-water constantly exposed to light is apt to become opaque and of a greenish brown colour—a very serious evil in a public aquarium. The darkened tank extends under the floor of the aquarium from end to end (i.e. beneath G, G, F, &. C, in the plan) and also under the compartments marked 9 and 10. It is no part of Mr. Lloyd's design to change or renew this vast bulk of water, but it will become necessary to add from time to time a portion of distilled fresh water to compensate for the waste which must inevitably result from evaporation, leakage of pipes, or breakage of glass, this last being a calamity to which all such establishments are unfortunately subject.

Keeping the plan still in hand, the compartments or pigeon-holes, representing tanks, are numbered 39 to 60, 1 to 18 a, 38 to 28, and 27 to 19, are also filled with water, and contain altogether no less than 20,000 gallons, in which the living objects of the aquarium constantly reside, and all of which are lighted from above, nineteen of them having in addition one side (that fronting the area, G G) of plate-glass, by which means additional light can penetrate the water and illu-

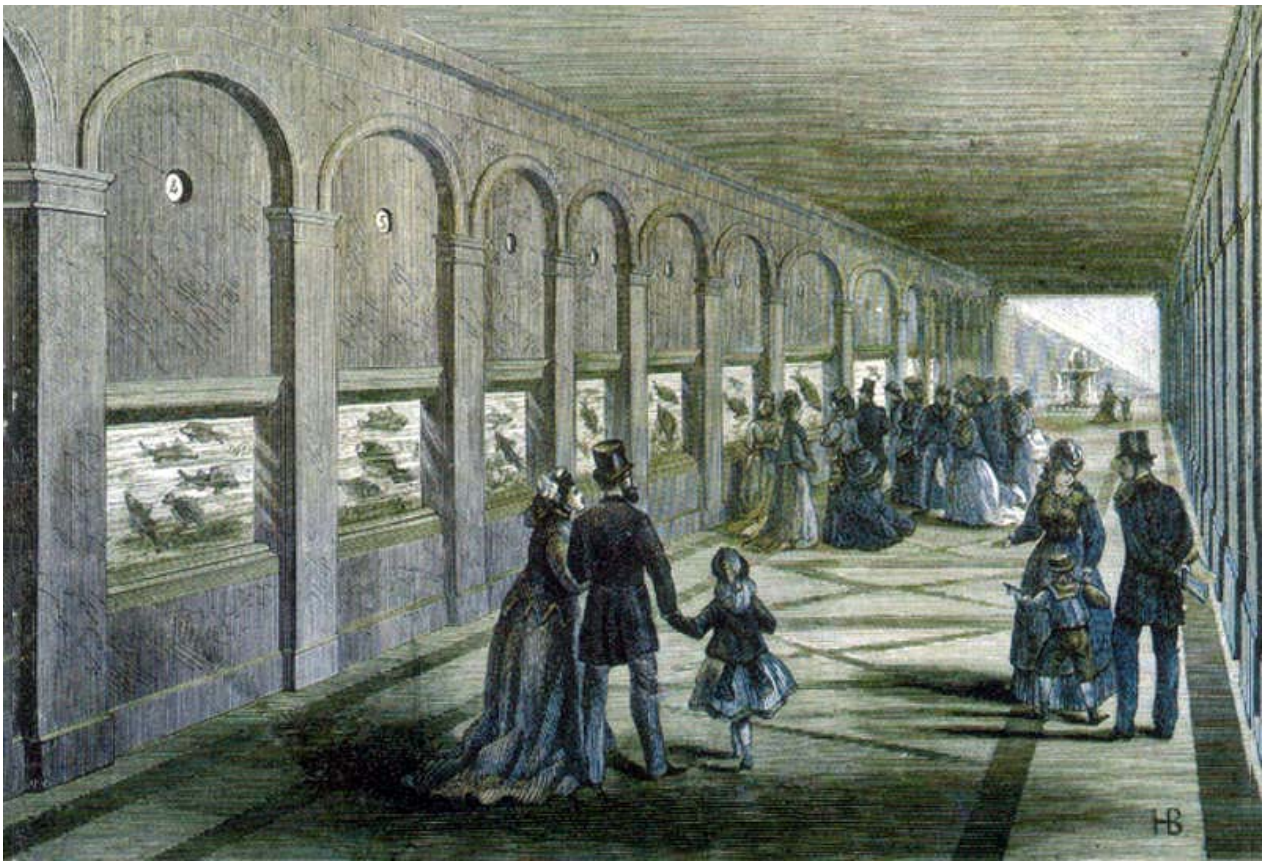
minate the objects living therein. Thus the entire quantity of water is 120,000 gallons, of which five-sixths is in the dark and one-sixth in the light. This large quantity of water is kept in constant circulation; a steam engine of three-horse power (M) and one of Forbes' patent vulcanite pumps (N) work day and night to raise water from the dark reservoir (G G F) and discharge it into the light reservoirs 9 and 10, at the rate of from 5000 to 7000 gallons per hour.

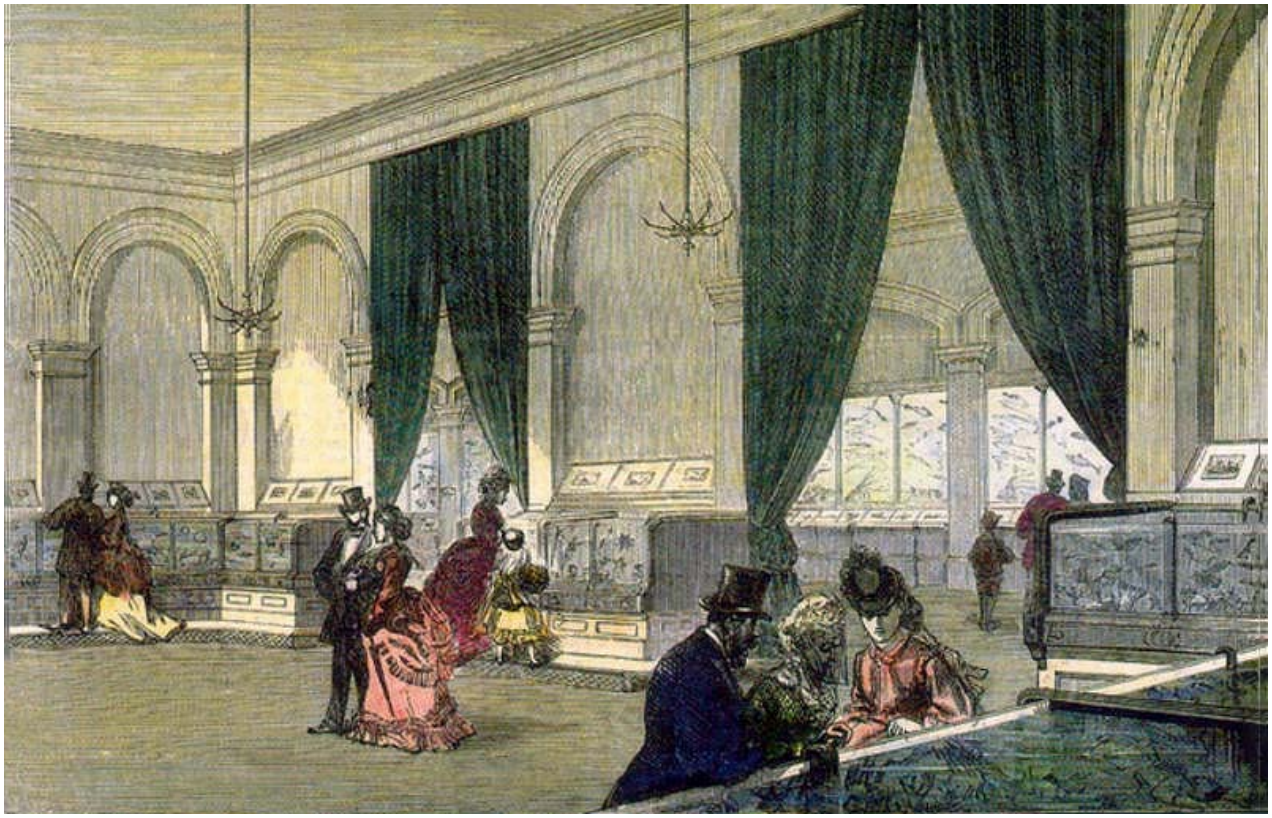
This engine and pump are necessarily in duplicate, because if either should break down through any unforeseen casualty, the motion of the water would be arrested and the lives of the prisoners jeopardized; indeed, so dependent are these on this sea-like movement of the water, that the stoppage of a pump for a single hour has produced visible effects on their health and spirits. These pumps and engines necessitate the employment of three engine-men, and these relieve each other every eight hours, so that one is always on duty. The exigencies of the animals also necessitate the employment of three other attendants, and I can bear my willing testimony to the great intelligence and unvarying civility of those now employed.

The pumped-up water flows, as I have said, into tanks 9 and 10, half into each; the stream pumped into tank 10 passes to the right, — an aperture having been purposely left in each party wall, as these divisions might be called, — into No. 11, thence into No. 12, and so on until it reaches No. 18 A; here it passes beneath the corridor or pathway (J J J), called the "Attendant's Gallery" in the "Key to Plan," and flows into tank 60; thence it turns to the left, through an earthenware pipe, into tank 59, and so on through tanks 58, 57, 56, 55, 54, 53, 52, 51 and 50, into tank 49, where it falls through a cylinder into the dark tank below. A second stream, also pumped up from below, falls into tank 9, and thence passes to the left into tank 8, and thence into tanks 7, 6, 5, 4, 3, 2 and l, whence it crosses under the corridor (J) into tank 39, and then turning to the right through tanks 40,41,42, 43, 44, 45, 46, 47 and 48, finally plunges into the cylinder in tank 49, and there, uniting with the stream I have traced from the right band, returns to the great abyss below, thence again to be pumped up, when its turn shall arrive, into tanks 9 and 10, and pursue the same course as before. The arrows in the plan show the direction which the stream is continually taking. The animals in the tanks numbered 1 to 18 A are intended to be viewed laterally from the saloon (G G F). I have already explained that the sides of these tanks facing the saloon are of plate-glass, and therefore the animals can be seen as perfectly as if you were in the sea in a transparent diving-bell: the other row of tanks 39 to 60, is intended for reserves, not open to public inspection: this reserve is very necessary, as casualties by death must of necessity occur now and then: all these forty tanks are on the left or west side of the saloon which is entirely devoted to the public.

On the east of the saloon are two apartments (H and I) containing respectively nine and eleven tanks; the whole of these tanks, numbered 19 to 38 inclusive, are very shallow, open at the top, and of a convenient height for viewing the animals vertically, or dorsally, for that is a better term, since we look down on their backs. The water is here circulated much in the manner I have described in those on the west side of the saloon, but the stream is smaller and less rapid: it passes under the floor of the saloon in both instances, into apartment H by means of an invisible pipe B 2, and into apartment I by means of an invisible pipe C 2. The flow of the water after being pumped into tanks 9 and 10 is caused simply by gravitation, there being a fall of from three to six inches from tank to tank; thus in tanks 9 and 10 the water stands at a height of six feet, while in tanks 1 and 18 A it is only three feet.

Yet this constant flow Mr. Lloyd considers still insufficient for the supply of oxygen to all the inmates; he has therefore arranged a number of small pipes, one for each tank, with a nipple nearly touching the surface of the water, and through each of these water is forced in a small but powerful stream: in its short passage be-





Scenes from The Crystal Palace Aquarium.

tween the nipple and the surface of the water each of these streams entangles and incorporates a great quantity of air, so tab myriads of bubbles of air are driven with great force, but in a state of subdivision so fine as to resemble steam or falling sand, almost or quite to the bottom of each tank, whence they return and reascend to the surface with a gentle and deliberate movement strangely contrasting with the violence of the descent. This forcing in of the air corresponds as nearly as possible with what takes place in the ocean when lashed into foam by the violence of the winds; the waves tumbling tumultuously one over another entangle and carry with them by their proverbial violence a vast quantity of air, which, after being dashed downwards, again rises to the surface, having discharged its office of communicating purity to the water and life-supporting breath to its inhabitants.

It appears from a paragraph at page 9 of Mr. Lloyd's 'Handbook,' that he places more reliance on the effects of vegetation than his admirable arrangements for aëration and circulation, just described and explained, would have led us to suppose; nevertheless "if all the necessary vegetation of the Crystal Palace Aquarium could be gathered together, it would, when deprived of water, probably not weigh one ounce": these are Mr. Lloyd's own words; but the passage to which I desire to invite attention is the following:—

"Towards the close of the [last] Century, namely in 1790, the late Sir John Graham Dalyell began to keep living marine animals for observation, in his house in Edinburgh; and continued this practice till his death, about 1850; but he changed the sea-water two or three times a week, though some of the animals lived for eight or ten years; and one sea anemone (*Actinia Mesembryanthiemum*), taken by him from the sea in August, 1828, is still alive and well. But Sir John knew nothing of employing plants to evolve oxygen, and therefore to preserve a balance of life with unchanged water, though Dr. Joseph Priestley (1733—1804), the discoverer of oxygen gas, and the first observer of the fact that that gas is emitted by plants under the influence of light, and therefore the earliest enunciator of the main principle on which the maintenance of aquariums depends, had published this discovery and observations. Ingenhousz also had shown that plants evolved this gas. Therefore if Dalyell knew this, he did not apply the principle."—'Handbook,' p. 9.

However, I have a widely different object in introducing this notice of Sir John's aquariums and their success. Mr. Lloyd, who never leaves a stone unturned if there be a chance of finding a particle of information beneath it, obtained access to Sir John's quartos ("Rare and Remarkable Animals of Scotland," By Sir John Graham Dalyell, Bart. 2 vols. 4to, 1847-48, and "The Powers of the Creator displayed in the Creation," Same author, 3 vols. 4to, 1851-58.), with a view of ascertaining his practice, his experience, and his views, at a period when this now engrossing subject was almost totally ignored; but in doing so he found explanations that required explaining. Miss Dalyell, a sister of the Baronet, was then still living in Edinburgh, and, although at the advanced age of nearly a hundred years, was in full possession of her faculties and her memory: he therefore conceived the idea of framing a series of questions on those points which appeared obscure, and of respectfully soliciting information. It was indeed a bold step, but a successful one.

To these questions Miss Dalyell most obligingly sent the following categorical replies, which cannot fail to be read with the deepest interest. My sincere thanks are due to Mr. Lloyd for having, unsolicited and unreservedly, placed these letters in my hands for the express purpose of illustrating this notice of his 'Handbook.' Miss Dalyell's replies evince a wonderful retention of faculties to extreme old age, but also prove what an observant and intelligent interest she must have taken, during very many years, in her brother's scientific pursuits.

LETTER I.
Miss E. Dalyell to Mr. W. A. Lloyd.
8, St. Colme Street, 2 January, 1800.

Sir,—In answer to your enquiries regarding the way Sir John Graham Dalyell kept his marine animals, I will certainly give you all the information I possibly can, by in the first place telling you the vessels containing them were all made of the very finest, clearest glass, wide at the top, just the same width as at the bottom: they were invariably round, and all sizes, some short, some long, some wider, some not so wide.

I cannot remember ever seeing more than one fine specimen in one glass; no marine plant whatever was in the water where the animals dwelt. Sir John fed them himself; what he gave them I do not exactly know, but raw mussel I know was one thing: he kept many of his subjects eight and ten years alive. He was most particular in giving them sea-water always out of the sea, when it was flowing: he changed the water every morning, often twice a day, if he perceived the smallest fragment amongst it, wiping and washing the glasses very clean. He got sea-water always twice a week, and sometimes three times; it was carried in an earthenware jar holding about three or four gallons of water: a person was specially employed for the purpose.

Sir John's subjects were always kept on a shelf under the window of his study; it was situated in the north out-look; whether they were put there for any purpose I don't know, but I think it was just to put them anywhere out of the way; sometimes he had a fire in his study and sometimes none. He understood nothing of Marine Botany; his chief aim was water fresh from the sea, when it was flowing and full of animalculae, and particularly clean vessels. If I can give you any more information upon the subject I will be happy to do it.

I remain your obedient Servant.
E. DALYELL.

LETTER H.
Miss E. Dalyell to Mr. W. A. Lloyd.
8, St Colme Street, 4 February, 1860.

Sir,—Your letter of the l8th of January reached me, but it being a difficult task for me to perform furnishing you with dates, I am sorry to say I am unable to perform it further than to mention, the first aquatic subject I found was dated in the year 1790, and as a curiosity I desired it to be engraved upon one of the copper-plates. It is the river worm which forms into a little fly. As you have the work, you will observe a little fly and beside it a black little worm; the worm ought to have been of the most brilliant scarlet colour. I know as to the Hydra tuba, Sir John was busily engaged about experimenting upon it in the years 1800 and 1808. This is all the information I can give you. I know very well once every subject was dated, but where these dates are now I cannot tell.

I am, Sir,
Your obedient Servant.
E. Dalyell.

Here then I conclude my observations on aquariums and arrangements for their maintenance. I have in reserve sundry notes as to their inhabitants, which are perhaps rather more in my way. I confess to feeling a greater interest in living beings than in the mechanical arrangements for their benefit. Still I shall do my best to explain should explanation be required at my hands, and shall only be too happy to receive questions that I can answer.

I should also like to add that although I have mentioned only one 'Handbook,' it is because I knew of only one when I commenced this notice. Since then I have received a second, the 'Official Guide Book to the Brighton Aquarium,' by W. Saville Kent, F.L.S., F.Z.S. It is a pleasant and readable account of that magnificent building, and I hope to return to it again and again. In the mean time I would impress on the compilers of these books the value of simplicity. They themselves luxuriate, aye revel, in technicalities and what is called the language of Science; but they must not on this account hope to inspire the general public with the same refined taste. Visitors to these aquariums are for the most part, like myself, "out for a holiday." On such occasions we do not absolutely abjure the idea of receiving instruction from books, but neither are we disposed to expend much labour in the pursuit of knowledge.

EDWARD NEWMAN.

Aquarists of The New York Aquarium, 1896-1941

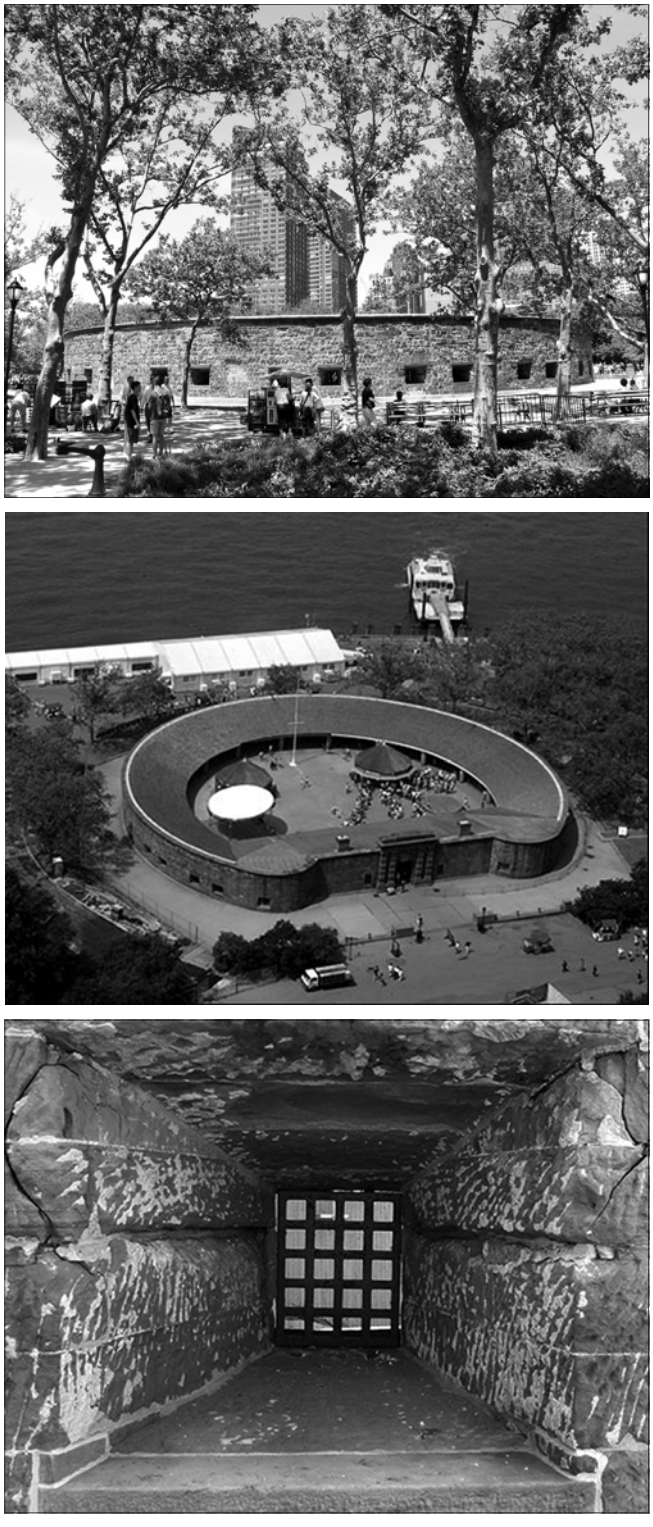
By Albert J. Klee, Ph.D.
(Aquarium Hobby Historical Society, August 24, 2008)

INTRODUCTION

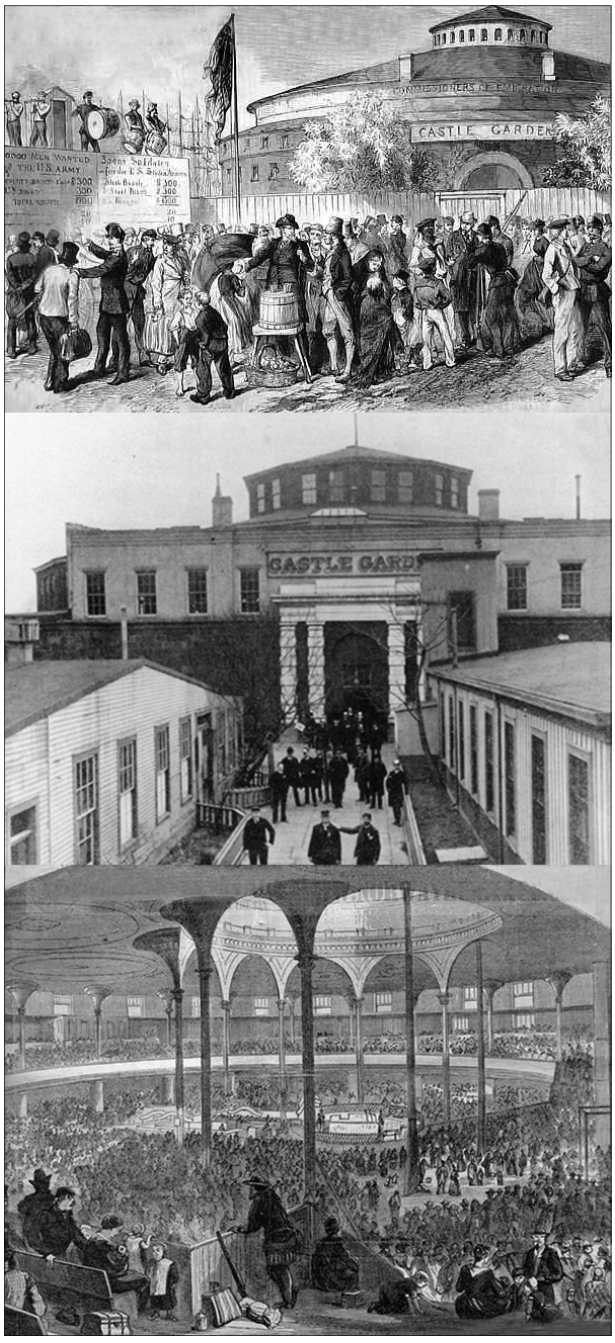
Meaningful aquarium hobby history is not so much a matter of dates and priorities as it is of people - who they were and what they did - and in this monograph I have tried to help the reader to understand a bit of the past, uncover the previously unknown, identify the relationships that the past has to the present, provide a historical perspective, and to record and evaluate the accomplishments of individuals and institutions. This, of course, is a formidable task, but I hope I have, even if only in some small way, achieved some of these goals.

The cutoff date chosen in the title is 1941, the year the Aquarium temporarily closed until it could move into its present quarters, but this is not necessarily the stopping point for the discussion of the individual aquarists selected. As I have indicated, most of them went on to further enhance their eminence within the aquarium fraternity. Since these aquarists worked for whomever was the Director of the Aquarium at the time, I have spent some time discussing most of these administrators even though one of them (Charles H. Townsend) was not an aquarist in the hobby sense. He was, however, important in the historical developments during this time period.

The relationship between the history of public aquariums and the aquarium hobby is not always clear. Both deal with fishes, but the comparison usually stops there since only a small part of the aggregate of fishes kept is identical and the equipment, although more or less based on the same principles, is hardly the same. However, there is one aspect of the public aquarium that is of historical interest in this regard, viz., aquarists who have in their younger, formative days worked in public aquaria and whose names are either well-known or whose work has meaningful significance to the aquarium hobby. This, then, is the substance of this monograph on the aquarists of the New York Aquarium.



Castle Clinton after its restoration in 1975.

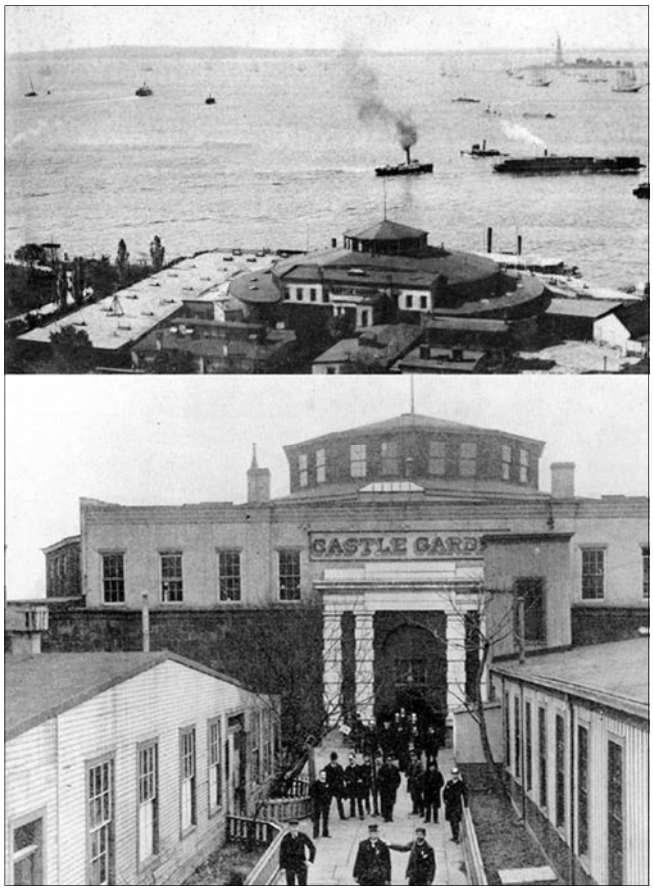


Castle Garden, site, exterior, and interior.

PRELUDE TO THE AQUARIUM

With war looming in the 1790s, Congress authorized an ambitious harbor defense construction program to protect the Atlantic seaports. As a consequence, more than a dozen forts were built to defend New York Harbor at the time of the War of 1812. The West (sometimes known as the Southwest) Battery was constructed on the rocks off the tip of Manhattan Island between 1808 and 1811. It was intended to complement the three-tiered East Battery (still existing and now known as Castle Williams) on Governors Island.

The fort was a single-tiered, open-casemated masonry structure (a casemate is the chamber behind the openings where the 30 guns were placed) of Newark sandstone, nearly circular in plan with a diameter of 205 feet and walls fifteen feet deep. It was originally designed to be built quite close to the land in only 15 or 20 feet of water, but city regulations required that it be placed 200 feet from shore where the water was 35 feet deep. An artificial island was made just to support it, a remarkable engineering feat for its time. Because subsequent



Castle Garden as an immigrant landing depot. Numerous auxiliary buildings were constructed around the site to facilitate the handling of the immigrants.

land filling expanded Battery Park, today it is located on Manhattan Island.

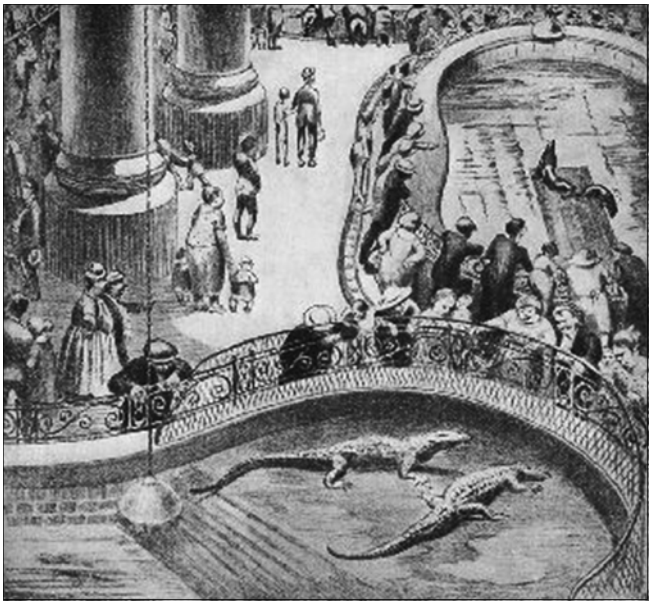
Although fully armed, these forts never had occasion to fire upon an enemy. In 1815 the fort was renamed Castle Clinton in honor of DeWitt Clinton, Mayor and later Governor of New York. The army vacated the fort in 1821 and the structure was deeded to New York City in 1823. In the summer of 1824, a new restaurant and entertainment center opened at the site. In the 19th century, such places were called "gardens" (Madison Square Garden, for example, still exists) and the Castle, which could accommodate up to 6,000 persons and even 10,000 in a pinch, became known as "Castle Garden."

It served in turn as a promenade, beer garden/ restaurant, exhibition hall, opera house, and theater. Designed as an open-air structure it was eventually roofed over in the 1840's to accommodate these uses and served as such until 1854. Important events included the triumphal return of the Marquis de Lafayette to America in 1824 and the debut of opera diva Jenny Lind in 1850, brought to America by P. T. Barnum. Many new inventions were demonstrated there to amazed audiences, including the telegraph, Colt revolving rifles, steam powdered fire engines, and underwater electronic explosives.

On August 3, 1855 Castle Garden, now leased to New York State, opened as an immigrant landing depot, the nation's first such entity. In 1890, the Federal Government took over control of immigration processing, subsequently opening the larger and more isolated Ellis Island facility for that purpose in 1892. Most of the immigration records burned in a pier fire during the transition to Ellis Island, but it is generally accepted that over 8 million immigrants (and perhaps as many as 12 million) were processed through Castle Garden.

THE ESTABLISHMENT OF THE NEW YORK AQUARIUM

Renovation of this ancient structure started in 1893 and continued to 1895, reopening as the New York City Aquarium on December 10, 1896. As I have described in my book, *The Toy Fish, A History of the*



Exterior and interior images of the Aquarium at the turn of the Century. At this time the exterior had not been altered from its Castle Garden days.

In its earliest days the Aquarium collected local fishes by seining the lakes in the Bronx Zoo.

Aquarium Hobby in America – The First One-Hundred Years (Finley Aquatic Books, 2003), Hugo Mulertt played a significant role in its establishment. Partly through Mulertt's influence, its first director was the respected ichthyologist, Dr. Tarleton Hoffman Bean, who oversaw its reorganization and rebuilding after a disastrous start. Under Boss Tweed's rule at Tammany Hall, the Aquarium was devoted less to the exhibition of fish than to the exhibition of the incompetents who were supposed to care for them. For many years workmen tinkered about the place, erecting tanks for fish, only to see the tanks burst when the water was let in. The public could not be admitted to the building and the place was a monument of useless expense. To add insult to injury, the floor pools and exhibition tanks had been lined with white tile and the general impression was that of a dim and dingy bathroom.

In February of 1894 there had been a complaint about the tiling of the Aquarium floor. The contractor maintained that the work was done according to specifications and if it was not satisfactory the specifications were to blame. In any case, the work had to be done over again. In April, Harvey T. Woodman, who was in charge of getting the Aquarium ready for its opening, presented a rosy picture before the Park Commissioners. He reported that the aeration system "was the most perfect in the world," and believed that he could keep in the aquarium species of the herring family, which had heretofore proved almost impossible before. Woodman estimated that the opening would be about July 4th. This was not to be, however. In August it was found that the tanks were leaking. The Edgewood Company, who had constructed the tanks, accused Woodman of using inferior aquarium cement. Park Commissioner Bell took the part of the Company and told Woodman that, if he had tested the tanks several weeks ago the trouble could have been averted.

Fortunately, a reform Mayor, William L. Strong, was elected in 1895 and placed the Aquarium under the control of a director who knew what keeping fishes was all about, i.e., Tarleton H. Bean (more about Bean can be found in my book, *The History of Ichthyology*, Finley Aquatic Books, 2004). The Aquarium finally opened on December 10, 1896 under Bean's Directorship. At the time the Aquarium had 78 species of fishes but in 1897 Bean made a detailed report of the fishes received at the Aquarium between 1895 and 1897. During this time there had been a total of 165 fishes of which 125 were marine species, the rest being freshwater forms. The marine species were supplied mainly by John B. DeNyse, a veteran fisherman, and his sons.

In 1896 the beauty of the big marine aquariums was greatly increased by the crystal clearness of the water. How this came about was due to a natural system of filtration, the water passing into a well in the cellar of the aquarium. The discovery of this perennial supply of water was made quite by accident. When Bean learned that there was a standing pool of water in one of the cellars of the building on the inshore side, he examined the pool with a hope he did not dare to express for fear it might be unfounded. One of the city engine companies came to his assistance with the intent to pump the cellar dry. Two 2-1/2 pipes were put down, and for twenty-five minutes a five-inch stream of water was pumped from the cellar without decreasing it. "We can't get the water out for you,

Interior of the Aquarium, 1904.

Dr. Bean," said the man in charge. "Well, I should be sorry if you could," said Bean, divulging his hope at last. The water filtered in through about 200 feet of gravel and rock fill under the building and had the same saline qualities of the water outside in the bay but was much purer. Bean had a seventeen-foot well sunk, doubling the quantity of water needed for the tanks. One great advantage in the well water was that it was some 20° warmer than the water of the bay. By this means the fifteen sharks which had been taken into the aquarium were able to be kept alive during the winter, something that had not been possible before.

THE FIRST TANK MEN

Bean hired two excellent men as Assistant Superintendents to care for the exhibits, Washington I. DeNyse (one of John DeNyse's sons) for the marine aquaria and Leonard B. Spencer for the freshwater aquaria. Stories about these two men and happenings at the Aquarium frequently appeared in the local newspapers. Indeed, Spencer acquired a reputation of being a "fish doctor," and the Aquarium was touted as having "The Only Fish Hospital in the World." He conceived the idea of doctoring fish and performing surgical operations on them as well. The following is a quote from the NEW YORK TIMES of August 21, 1904:

"New York has the only fish hospital in the world. It has its surgeons and its physicians, its wards and its operating tables. All diseases that the members of the finny tribe are heirs to are scientifically and successfully treated, and thorough investigation and research are made into some of the unknown diseases with which the piscatorial family is afflicted. This remarkable hospital is located just back of the big glass tanks arranged in a circular form in the Aquarium at the Battery. It was started as an experiment some time ago, but has developed into a regular institution that is one of the most important adjuncts of the Aquarium. In fact, it has much to do with the success of this admirable exhibition of fish that has been collected from all parts of the glebe. On entering the big building one is at once impressed with the activity and healthfulness of the fish that seem intent on

This is the original wooden framework of the Aquarium building. The timbers were later concealed by a ceiling and plaster-encases columns.

Leonard B. Spencer

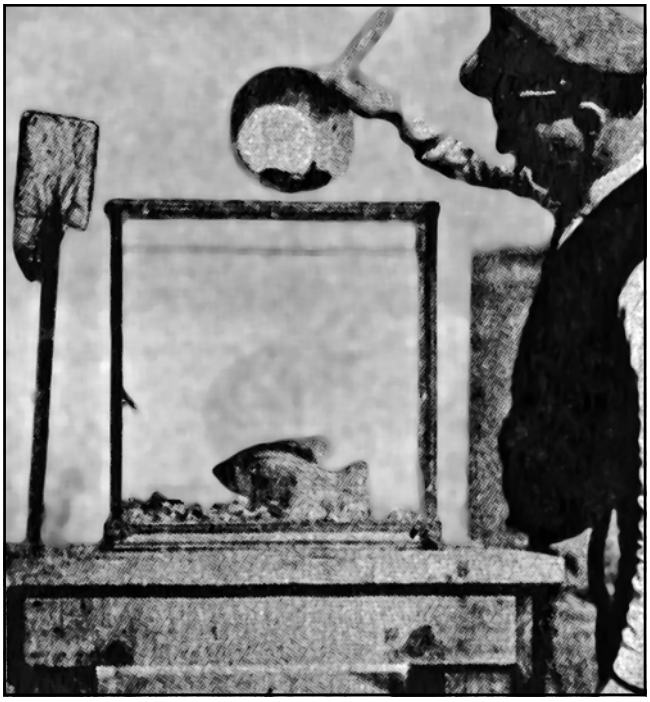
displaying their charms and accomplishments. This is all the more noteworthy from the fact that fish taken away from their native streams, lakes and ocean are inclined to become ill and consequently sluggish. But not so with the inhabitants of the Aquarium. Their physical condition is carefully looked after, and the slightest indisposition is promptly attended to."

Spencer was also a pioneer in the photography of fishes predating even William T. Innes and Charles M. Breder, Jr. who followed Robert W. Shufeldt's early successes in this area. The following is taken from a 1903 newspaper story about how fishes were photographed in the Aquarium:

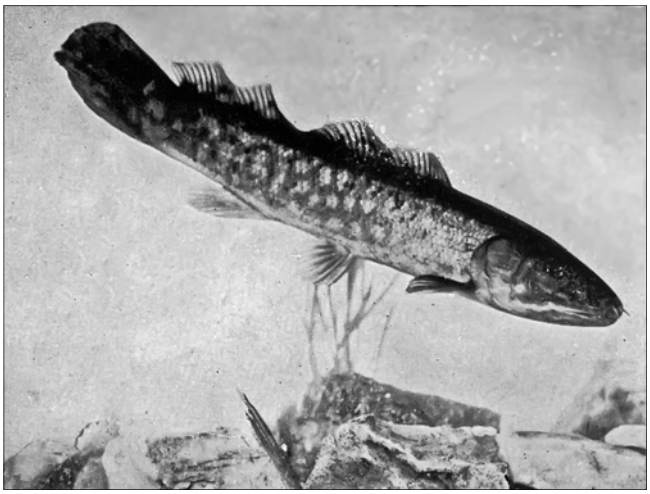
"But it is not always the amateurs who are fooled. Quite recently a reporter on one of the illustrated dailies came here, accompanied by a staff photographer, and asked permission to make some pictures to illustrate a story. Of course, permission was granted, and, although warned as to the fruitlessness of his undertaking, the photographer proceeded with his work and departed confident that he had several good views, but I was by no means surprised when shortly afterward a messenger from the paper dashed in and inquired if I could not loan it some photographs.

"Now, when we wish photographs, we remove the fish from the exhibition tanks to an aquarium specially constructed for photographing purposes (Note: Spencer indicated here with a motion a group of long and extremely narrow aquariums resting on a table in the laboratory), and even under such conditions the results are often disappointing, success only being assured under the strongest light, and when the object is completely at rest.

"One of our greatest difficulties heretofore has been our inability to photograph the living fish in their natural surroundings, for just so sure as we introduce sea-weed, foliage, rocks, or shells into the photographing tank, behind



The narrow, portable aquarium used in 1903 to photograph fishes at the New York Aquarium. Its size was 18 x 18 x 3 inches.



One of Spencer's pictures - the Bowfin, Amia calva.

these objects the fish would anchor, and they acted generally as if they knew exactly what was taking place or had personal objections to sitting for their portraits. To overcome this contrariness on the part of the fish, I am having built an aquarium fitted with an inner glass slide, in the rear of which can be placed the 'properties' characteristic of the subject. Thus equipped, we will be better prepared to carry on the educational work which is now being done in our laboratory."

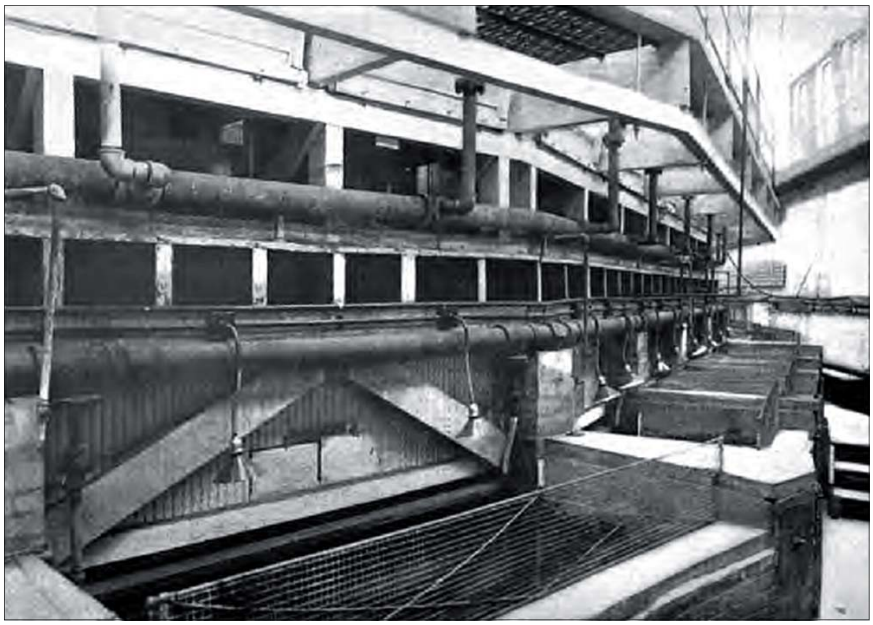
In an article that appeared in the NEW YORK TIMES for August 12, 1910 under the title "Raiders of the Aquarium, Wharf Rats Are Depopulating Tanks," Spencer discussed an odd problem that had developed in the Aquarium. The "Night Raiders" in the story alluded to a previous one that reported on some townsmen who, during the night, had cut down various advertising signs in Palisade, New Jersey:

"'I was just reading about the Night Raiders,' said Leonard Spencer, in charge of the salt water fish at the Aquarium, laying aside his paper. 'We have night raiders right here in the Aquarium, and much trouble they have caused us. The raiders in this case are hardened specimens of the wharf rat. They are fond of a fish diet, and they know how to catch fish.'

"Mr. Spencer led the way behind the scenes where one could look down into the exhibition tanks.

"'Do you see that goldfish tank?' he continued. 'Well, we had to put that wire screen over the top to protect the fish from the rats. In times past we used to lose three or four fish in a night. In the morning the attendants would find on the broad stone ledge about the tank evidence of the night visitors and parts of fish.

"'The rats catch the small fish, which swim near the surface. We keep on hand a tank full of killies, which we use to feed the large fish. They are great favorites with the rats, and the only way we can keep them from being killed each night in large numbers is to put the outlet pipe half way down in the tank, so that the water will not rise near the top.



A view of the Service Gallery of the old Aquarium, 1904.

One of the exhibition tanks, 1919.

> "'I have never seen a rat fishing, but from the evidence they have left behind and from what I know of the rat I know how it is done. They lie down on the ledge surrounding a tank and wait for a victim to float near: then out goes a paw, and quick as a wink the fish is gaffed. Once in a while the rat catches a tartar, and it is the rat, and not the fish, that is caught.'
>
> "Mr. Spencer gave a demonstration of his meaning. Approaching a tank in which were a number of vicious-looking sturgeon, he put one finger down to within an inch of the water. One of the fish watched the finger for a second, and then like a flash he sprang at it. Mr. Spencer jerked his hand up, but only just in time. Being a student of nature, Mr. Spencer argues from this fact that rats reason and that they have learned by experience where the tanks of easy victims stand."

Bean served at the Aquarium with notable distinction from 1895-1898, when political changes led to his resignation. Unfortunately, all the good work he did at the Aquarium was promptly undone in the days of the Van Wyck regime. Robert Van Wyck was the first mayor of Greater New York following the consolidation of the five boroughs in 1898. He became involved in probably more scandals than any mayor in the city's history, having been selected by the leaders of Tammany Hall as a man who would do little to interfere with their running of the city. In 1898 Van Wyck gave Bean's job to "Captain Jim" Jones, a politician whose interest in fish was mainly confined to shore dinners. Fortunately, both DeNyse and Spencer stayed on in their jobs.

CHARLES HASKINS TOWNSEND

In 1901 anti-Tammany forces elected a reformer, Republican Seth Low, to become mayor and in 1902 the New York Zoological Society took over the administration of the facility at the city's request, electing Charles Haskins Townsend as its Director.

Townsend was born at Parnassus, Pennsylvania, September 29, 1859. His parents had intended to prepare him for the ministry, but at an early age he became interested in natural history. At the age of twenty he joined Ward's Natural History Establishment in Rochester New York where he met William T. Hornaday who was later (in 1896) to become the first Director of the New York Zoological Garden (i.e., the Bronx Zoo). Three years later Townsend spent some time at the Academy of Natural Sciences in Philadelphia. In 1883, he first met Professor Spencer Fullerton Baird who offered him a position in the U.S. Fish Commission, and within a month shipped him off to the salmon hatchery on the McCloud River in northern California where he began the career in fishery work that was destined to occupy his attention for the remaining sixty years of his life.

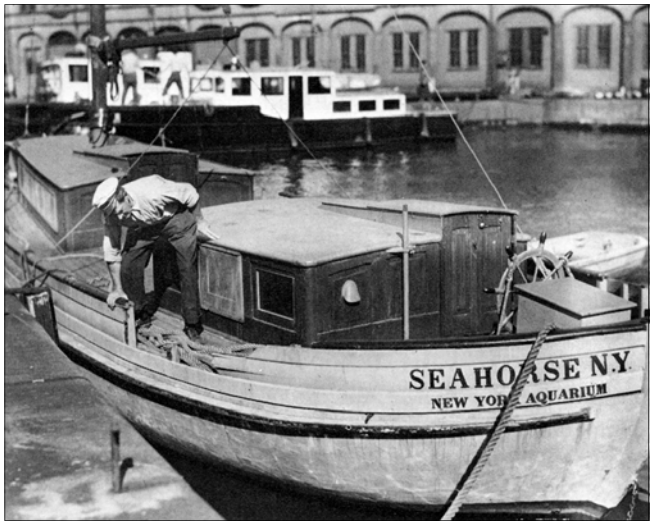
In 1885, he was detailed to the Revenue Cutter *Corwin* on a voyage to Kotzebue Sound, Alaska, and the following year he made a cruise on the Fish Commission Steamer *Albatross* to the Bahamas. In 1887, he collected on the Segovia River in Honduras, and in the autumn of that year accompanied the *Albatross* through the Straits of Magellan to the Pacific where it stopped for 11 days at the Galapagos Islands.

Charles Haskins Townsend (1859-1944)

While he was serving as Naturalist on the *Albatross* during the decade from 1886 to 1896, most of his time was spent in the North Pacific, surveying the fishery grounds along the northwest coast and in the Bering Sea and mapping the fur-seal rookeries on the Pribilof Islands. He also took part in the Bering Sea patrol, charted part of the Aleutian region, and sounded the route for the Hawaiian cable. He was a member of the Fur Seal Commission in 1896-1897 and, after serving five years as Chief of the Division of Fisheries of the Fish Commission, was detailed as Fishery Expert in 1902 to the Russo-American Arbitration Commission at The Hague. (As we shall see, the fur seal commission and the Hague arbitration assignments came back to haunt him some years later.) 1902 also was the same year he was appointed Director of the New York Aquarium. In the years that followed the collections increased considerably and the Aquarium attracted hundreds of thousands of visitors each year. In 1909, Washington and Jefferson College in Washington, Pennsylvania awarded him an honorary Ph.D.

When Townsend took over, the physical plant of the Aquarium was in dire straights. At the time of new-moon tides, the sea water rose so high in the boiler and pump rooms that the stokers had to wear hip boots while shoveling wet coal into the furnace from half-submerged wheelbarrows. Sometimes the pumps were flooded and the fires extinguished, so that there was no heat or circulating water until the tide fell. Four days' coal was all the Aquarium had room to store, and when the Commissioner of Parks ordered the unsightly coal shed removed, the margin dropped to two days. In the winter of 1917 the building had to be closed to visitors for several days and the living collections would probably have been lost had it not been for twenty-five tons' emergency supply of coal long hidden in an underground pipe conduit.

In 1921 the executive committee of the New York Zoological Society decided that conditions at the Aquarium really were intolerable, that the city was not going to act, and that after nineteen years perhaps the Society owed something to its foster child. It voted $75,000 for new pump and boiler rooms and larger exhibition tanks as "a gift from the Society to the City of New York." Then, as promptly as if all along it had been waiting for such a gesture, the city voted $86,000 for the enlargement of the second story, modifications along the front of the building,



The Aquarium's collecting wellboat, the Seahorse, was launched in 1920.

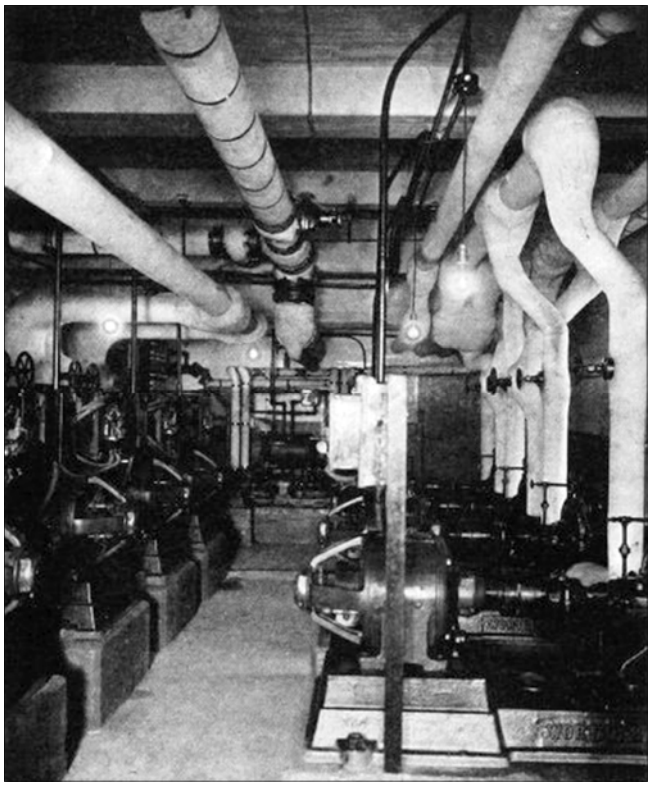
and the addition of a third story. (To my mind, however, the additions did not enhance the overall appearance of the structure. To counter-paraphrase Elizabeth Bennet in Jane Austin's *Pride and* Prejudice, '…natural beauty had been… counteracted by an awkward taste.'")

The Society's money was expended promptly and the director's annual report for 1921 was a proud showcase for photographs of the new pump rooms and boiler room. The city's part of the work proceeded more spasmodically; it was not until 1926 that the second and third floors were finished, the second given over to water distribution tanks and shops and the third to offices, a library, and a laboratory. Now the collections could be expanded by about a fifth, and the new offices allowed Townsend and his small staff to move back into the Aquarium from the basement room in Pearl Street which they had occupied while reconstruction was going on.

Townsend had little instinct to compile, document, and release his thoughts in writing. He produced no books except the *Aquarium Guidebook* in 1919, a rewritten edition in 1937, and a small (91 pages) booklet on *The Public Aquarium: Its Construction, Equipment and Management*, published by the U.S. Bureau of Fisheries in 1922 (and reprinted in 1928). He did, however, produce a steady flow of observational papers in the early years. In the Zoological Society's Annual Reports he published "Notes on the Manatee" in 1903, "Notes on Certain Pinnipeds" in 1904, "The Cultivation of Fishes in Natural and Artificial Ponds" in 1906, "Pollution of Streams - an Appeal to Anglers" in 1907, and in 1908 "Observations on Instantaneous Changes in Color Among Tropical Fishes," the first of four papers he devoted to these interesting transformations as he had seen them in the Aquarium's tanks. During World War II the Navy made use of the four-color maps he had prepared showing where whale catches had been concentrated, to give submarine commanders an indication where their sonar was most likely to be confused by whales instead of detecting enemy submarines. Townsend's publications, about 100 titles in all, were mainly devoted to fisheries, fur seals, whaling and oceanography, but he also published several papers on birds.

Exterior views of the Aquarium after the 1920's renovations.

Apart from Townsend's own limited writings, scientific work at the Aquarium was slow in getting started, even though the Society's Executive



The new pump room, 1921.

Committee had directed him when he took over his duties to make the Aquarium a center for scientific studies. The one exception was practical work on fish pathology. In 1915 the Society appointed Dr. George A. MacCallum of the College of Physicians and Surgeons of Columbia University as pathologist to the Aquarium, and in the next three years he produced five papers on trematodes and nematodes found in the collection of fishes. They were considered so important that the Society established a special journal for their publication.

However, nothing more at the time could be done at the Aquarium; there was no proper laboratory or other facility for scientific work until the third story of the building was completed in 1926. For that matter, it is doubtful whether Townsend was greatly interested in the kind of scientific work that required a laboratory. Several of his associates in the 1920s and 1930s have recalled his attitude in almost identical terms. Dr. Charles M. Breder, Jr., who succeeded Townsend as acting director in 1937, commented:

> "Dr. Townsend considered himself a 'naturalist' and indeed he was just that in the full old-fashioned sense. He became annoyed whenever anyone who worked with live animals was referred to as a biologist, or even more so if the word used was 'scientist.'
>
> He would pull himself to his full height and declare, 'We are naturalists! Naturalists describe and only scientists explain.' Frequently he would add for my particular benefit, 'That means you, too, Breder.' I still cannot quite explain that bit."

By the mid-1930's Dr. Townsend was at last beginning to think about retirement. His quirks - and they were many, of a kind perhaps more common in his day than today - had ripened and provided much innocent amusement for his staff. Among other things, he was a "string saver," with all the hoarding tricks that phrase implies. Breder wrote of him:

> "From his office windows he could see floating trash in the harbor. When something caught his fancy, often some large timber, he would send some of the boys out in the redoubtable Seahorse to 'rescue' it. This would go into the 'attic,' a capacious annular space that surrounded the skylight over the large center pool in the public area. Usually it took four or five men with a block and fall to get it up there. It usually was very heavy because of being waterlogged."

Building inspectors did not look with favor on the storing of heavy junk over a public area and periodically ordered it removed, to Townsend's great distress.

Townsend normally wrote his replies to correspondents on the back of their original letters, and much of the time he wrote standing up. He had two desks, one a normal office desk and the other an old-fashioned bookkeeper's desk intended to be worked at from a high stool. Dr. Breder commented on it:

> "The only place I can recall seeing such a piece is in one of the illustrations accompanying Dickens's *Christmas Carol* showing Bob Cratchit at his daily stint. He once told me he could not sit long in his standard swivel desk chair because of what he called his 'bone ache.' This he claimed he got from staying too long in the Pribilof Islands on the fur seal project."

However, there may have been another reason why he preferred standing to sitting. When Breder inherited the office, he found that the desk chair's seat was so sprung that the occupant sat on the ironwork beneath. It had been that way for years, but Townsend was not a man to discard a chair simply because it was broken.

Townsend was devoted to the sea and to ships, and it was a common belief among the men working at the Aquarium that anyone could get a job if he could splice a rope. He was disappointed because Breder did not know how to put in an eye splice, and Breder finally had one of the men teach him how to do it, just so his handicap would not bother the director so much!

Townsend retired in 1937, having served the Zoological Society for thirty-five years. Under the severest handicaps of an ancient and inappropriate building and always inadequate financial support, the Aquarium during his time became one of the showplaces of New York.

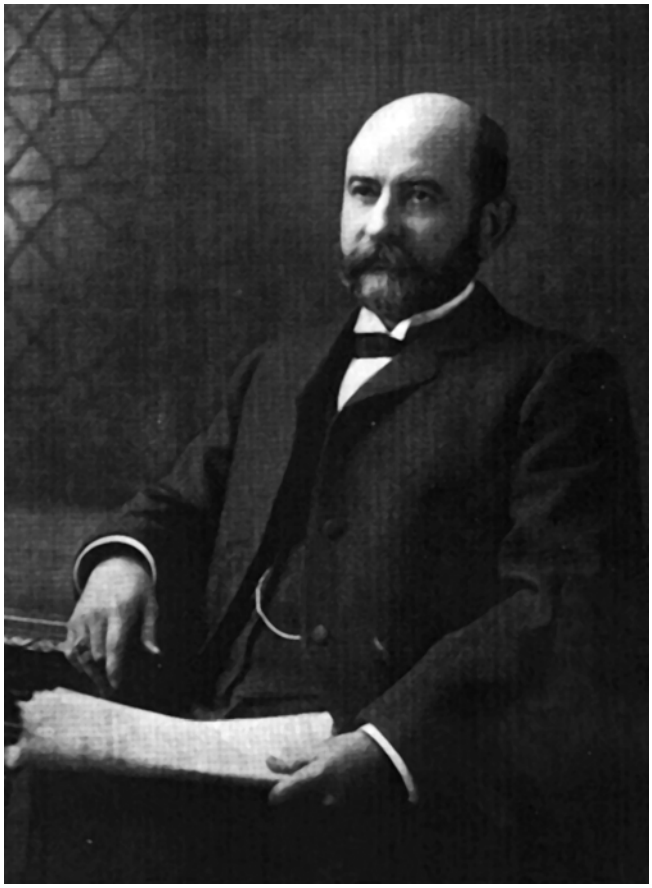
THE TOWNSEND-HORNADAY CONTROVERSY

It is ironic that Hornaday had proposed Townsend for the Aquarium job. On April 7, 1902, he wrote to Henry Fairfield Osborn, the President of the Society:

> "If you are still looking for a man to be Superintendent of the Aquarium, let me mention and strongly recommend my old friend C. H. Townsend. He is capable, vigorous, experienced, knows administrative work thoroughly, and is as fine a man personally as could be found in a years search. No man in Washington has a cleaner record."

A few years later, however, Hornaday looked upon his "old friend" as one of his worst enemies.

The Hornaday/Townsend clash was of epic proportions. At its center were the fur seals of the Pribilof Islands in Alaska, which were in a bad way around 1910. Pelagic, or ocean, sealing indiscriminately killed females and males of any age, and on land the motherless pups starved to death. International treaties put an end to pelagic sealing, but the harvesting of surplus males on land continued. Hornaday was determined to have a five-year moratorium declared on land sealing and allied with him - and even more violently aggressive and outspoken, if that is possible - was Henry Wood Elliott. Besides being best known as the savior of Alaska's fur seals, Elliott was also one of the finest watercolorists to work in the Territory. Elliott first visited Alaska in 1867 with the Western Union Telegraph Survey. Later he was the official artist for



William Temple Hornaday (1854-1937)

Henry Wood Elliot (1846-1930)

the U.S. Geological Survey expedition to the western United States. He came north again in 1872 as U.S. Treasury Agent supervising the Alaska Commercial Company's management of the fur seal industry in the Pribilof Islands. Elliott traveled more extensively in Alaska than any other late nineteenth-century artist.

Hornaday, Elliott, and their allies took on the United States government head-on but reserved some of their bitterest attacks for the advisory board of the Fur Seal Service on which Townsend was a member. Both sides agreed that pelagic sealing was bad, but harvesting the surplus of non-breeding age males on land was another matter. When Townsend was in governmental service he had spent years in the Pribilofs, making censuses and examining the logbooks of sealers to determine what and how many seals they had taken; Hornaday had never been in Alaska. Townsend and his fellow zoologists on the advisory board believed it would be safe, even beneficial, to the land herds to remove the young males and minimize the fighting for possession of the females, which often led to trampling, injury, and death of the pups. The board saw no reason why the United States government should not have the revenue that controlled killing would permit.

The jockeying and name-calling by Hornaday and Elliott, the Hornaday-produced pamphlet appeals to save the fur seals, the letters to Senators, the Secretary of State, and even to President Taft, were unremitting. Not that Hornaday attacked Townsend by name - as he did some members of the advisory board - but the "Barren Work of the 'Experts' of the 'Advisory Board'" (a heading in one pamphlet that was never circulated) left no doubt about his feelings for his fellow director in the service of the Zoological Society.

Even Osborn and Madison Grant (a lawyer by profession, Grant was Chairman of the Society's Executive Committee) got caught up in the fray, with Osborn publicly differing with "my friend Dr. Hornaday." Tensions reached a point at which the society decided it was time to call a halt. A peace agreement was declared, both directors were ordered to cease firing, and Hornaday's pamphlet entitled "The Last Fight for the Persecuted Fur Seal: New Light on an Amazing Situation" was withheld from circulation after it had been printed and was ready for distribution to the United States Senate.

Townsend's stint as an arbiter for the State Department at The Hague just before becoming director of the Aquarium also turned out to be a problem for him and an embarrassment to the Zoological Society. The dispute, between Russia and the United States, concerned a sealing vessel, the *James Hamilton Lewis*, which had been seized by Russia in her territorial waters and for which the United States asked $50,000 compensation. Townsend's role in the dispute was a minor one; he was to be called upon merely to testify about general sealing activities of the time and to provide statistics when needed. In the end, the award was made to the United States, and Townsend probably looked upon it as just another minor chore for the government.

However, in 1911 a House of Representatives committee under the chairmanship of John H. Rothermel of Pennsylvania began holding hearings to investigate the fur seal industry of Alaska where the policy of permitting killing on land under lease to a commercial company was under debate. The nationality of the owners of the *James Hamilton*

Lewis and their relation to a commercial company engaged in Alaskan sealing became one line of questioning thrown at Townsend, and Henry W. Elliott was permitted to put a series of highly irrelevant and somewhat unfair questions to him through the chairman of the House committee. Elliott was free with such comments as "Liar!" and "He dare not tell what he knows to the Committee with Elliott's eye on him." However, it is hard to see how Townsend could have answered some of the questions since they were entirely outside his frame of reference at The Hague. Elliott's excesses here are a stain on his otherwise exemplary career as a conservationist.

The charges that Townsend had been party to presenting a fraudulent claim against Russia and that he received compensation for his testimony at The Hague out of the award were widely publicized in a majority report of the Rothermel Committee. A minority report of three of the seven members completely exonerated him (politics played a greater part here than conservation; the three were Democrats, the majority four were Republicans). The Society's executive committee thereupon asked William White Niles as its counsel to make an independent investigation. On the basis of the Niles report, it was "the unanimous opinion of this Executive Committee that the honesty and integrity of Dr. Charles H. Townsend have not been impugned in any way" and that "the attack on him is unjustifiable, malicious and untruthful."

Hornaday, Elliott and their allies, however, did win the battle to save the fur seals. Some time after his retirement Hornaday wrote a fifteen page memorandum, the following being an excerpt:

> "We won! All three of our original demands; but the cost to me in old friendships forever broken up was great, and even today is painful to contemplate. I have many ex-friends who never will forgive me for having started that fur-seal salvage campaign, nor for having been successful in gaining the ends desired."

Townsend's bitterness toward Hornaday survived and years later when a member of his staff happened to be reading one of Hornaday's books and inadvertently left it lying on his desk, he angrily ordered it out of the building. "Never let me see you looking at a thing like that again!"

EARLY STAFF ASSIGNMENTS AT THE AQUARIUM

In 1904, the Aquarium staff assignments were as follows:

Charles Haskins Townsend, Director
Leonard B. Spencer, Asst. In charge of fresh-water collections
Washington I. DeNyse, Asst. In charge of marine collections

Spencer and DeNyse were two of the few who survived from the Tarleton H. Bean Directorship and Townsend came to rely greatly on these competent men. (Spencer, who had been connected with the Aquarium in the capacity of Aquarist since May 1,

Henry Fairfield Osborn (1857-1935)

Madison Grant (1865-1937)

1894, died in 1910, at the age of 73 years, and DeNyse died in 1921.)

LOUIS L. MOWBRAY

In 1916, the Aquarium staff assignments were as follows:

Charles Haskins Townsend, Director

Washington I. DeNyse, Assistant
Louis L. Mowbray, Assistant
Ida M. Mellen, Secretary
George A. MacCallum, Pathologist

I have previously mentioned Dr. George A. MacCallum's appointment in 1915. Of the two newcomers, Mowbray and Mellen, we'll take a look at Louis L. Mowbray first.

Louis Mowbray (1878-1952) was a Bermudian appointed in 1912 to be the first Director of the South Boston Aquarium. As Jerry Ryan points out in his book, *The Forgotten Aquariums of Boston* (Finley Aquatic Books, 2002), Mowbray took his responsibilities very seriously and had dreams of making the South Boston Aquarium a first class institution and a model for scientific research. In January of 1914 Mowbray was allotted $1,500, the equivalent of about $22,000 in today's currency, to purchase fishes in Philadelphia. A month later he was fired for "inefficiency and conduct injurious to the discipline of the Park Department."

Reading between the lines, Mowbray either spent the funds without Park Department approval or else the Department was dissatisfied with how, or the manner in which, the funds were spent. Mowbray did not dispute the injurious conduct charge but demanded that the accusation of "inefficiency" be struck from his record as unfounded and misleading. The Park Department complied with his request

Mowbray went from Boston in 1914 to assume the position of Assistant Aquarist at the Aquarium. He left New York in 1921 to oversee the construction of the Miami Beach Aquarium and was its director until it was sold in 1924. After another short stay (1925) in New York, this time as Chief Aquarist, he returned to his native Bermuda and went on to become one of the most famous and respected ichthyologists of his time. He served as curator of the Bermuda Aquarium until his death in 1952. Mowbray is credited with the discovery and capture of several species of rare fish, and his obituary notice in the NEW YORK TIMES notes his success in sending live eels in bottles from Florida to Denmark via parcel post; they arrived in good health!

It is interesting to note that in 1914, Mowbray and John T. Nichols described a new angelfish from Key West, naming it *Angelichthys townsendi* (BULLETIN OF THE AMERICAN MUSEUM OF NATURAL HISTORY, vol.33, art. 37, 1914). Unfortunately, *Angelichthys townsendi* turned out to be a naturally occurring hybrid between the queen angelfish (*Holacanthus ciliaris*) and the blue angelfish (*Holacanthus bermudensis*). It is thus a junior synonym and therefore the name is invalid.

IDA MAY MELLEN

Ida May Mellen was born on January 9, 1877 in Manhattanville, an area of New York City now a part of West Harlem, to parents Andrew Jackson Mellen and Mary Davis (Sprague) Mellen whose roots respectively were in New Hampshire and Massachusetts. Her mother was usually referred to in the family as "May," hence the origin of Ida's middle name. She had two older brothers, Frank, and Fred, 12 and 7 years her senior, respectively. Unfortunately, her father died when she was but three years old, leaving her and her brothers to be raised by her mother who was only 41 years old at the time. They relocated to Brooklyn, which was not a part of New York City at the time. Her older brother, Frank, took on a job as a clerk with the American District Telegraph Company (he later became President of the Flatbush District Telegraph Company of Brooklyn) but the family was well provided for by her relations. Ida, therefore, was raised in a middle-class environment, so schooling and summer vacations typical of this economic status were not a problem.

She graduated from the Lockwood Academy in Brooklyn, a highly respected private college preparatory school, in 1893 at the age of 16. Mellen at first considered a career in teaching and enrolled in the Normal Kindergarten Training school in Brockton, Massachusetts in 1895 but evidently changed her mind. After a bout with pneumonia in 1898 she entered Browne's Business College and Academy of English situated at 246 Fulton Street in Brooklyn. Established in 1860, it was one of the leading and most distinctive institutions of its kind. She graduated in 1900 and, at various times from 1901 to 1916, she was a free-lance law reporter (i.e., a.k.a. shorthand reporter or court reporter recording testimony, etc.) in the city until 1916 when she joined the New York Aquarium as its Secretary and stenographer.

She did, however take advantage of three additional educational opportunities during the 1901-1916 period. In 1902 she received a diploma from the Young Woman's Christian Association's Nurses Training School in Brooklyn as an Attendant Nurse (in later years she also obtained credentials as a Red Cross Nurse). These were trained attendants that came into the house and cared for convalescents, chronic cases or invalidism and minor illnesses where the cost would be less and the service as satisfactory as that of the professional nurse. Women of social standing frequently took this course, which lasted 11 weeks and consisted of lectures and probationary work in a hospital. Then, during 1908-1910, she was a student in zoology at the Marine Biological Laboratory, Woods Hole, and Massachusetts. Founded in 1888, the Marine Biological Laboratory was unusual for its time in that it encouraged the enrollment of women students of science on an equal basis with men. In these early years, approximately one-third of the classes in advanced scientific studies were composed of women who came from many areas of the country. Individual women as well as women's social and educational groups had been instrumental in raising approximately half of the funds required for the

Ida May Mellen (1877-1970)

College women collecting marine specimens at Woods Hole, site of the famed Marine Biology Laboratory attended by Ida Mellen from 1908-1910.

establishment of the Laboratory. Finally, in 1912, she was a summer student at the Eugenics Research Association, Cold Spring Harbor, N.Y.

Mellen quickly became more than just the Secretary of the Aquarium, and it wasn't long before she became Aquarist, working for Mowbray. She wrote a number of monographs and articles on aquatic animals and aquariums including:

1917 - "Care of salamanders and frogs in captivity," N.Y. Zoological Society, New York Aquarium; INFORMATION CIRCULAR No. 4.
1918 - "Salt Water Aquaria at Home, AQUATIC LIFE, Vol. III, No. 5, January 1918.
1918 - "The Common Snails -Their Relation to Balanced Aquaria," SCIENTIFIC AMERICAN SUPPLEMENT, Sept. 21, 1918.
1919 - " Prehensile-Tailed Pipefishes," N. Y. ZOOLOGICAL SOC. BULLETIN, November, 1919.
1922 - "The Effects of Captivity on A Sex Character," SCIENCE MAGAZINE, November 17.
1923 - "Whitefishes Reared in the New York Aquarium," ZOOLOGICA, 2(17).
1924 - "Tyrian Purple from Sea Shells," BULLETIN NEW YORK ZOOLOGICAL SOCIETY, Vol. 27, No. 2, p. 23, March 1924.
1925 - "A Table of Information Regarding the Large Aquariums of the World," in *Twenty-Ninth Annual Report, New York Zoological Society*, N.Y.Z.S.
1926 - "New Medicines for Sick Fishes," ZOOLOGICAL SOCIETY BULLETIN, 29.
1926 - "The Goldfish Puzzle," AMERICAN SPEECH, v.2, No. 1, pp. 62-64, October
1927 - "The Natural and Artificial Foods of Fishes," AMERICAN FISHERIES SOCIETY TRANSACTIONS, Vol. 57, Issue 1.
1927 - "Plea for the Turtles, NATURE MAGAZINE, Vol. 9, February.
1928 - "The Treatment of Fish Diseases," ZOOPATHOLOGICA, vol. 11, no. 1, April.
1928 - "Aquarium English," AMERICAN SPEECH, v.3, No. 6, pp. 460-463, August.
1930 - "Can A Catfish Count?" SCIENCE MAGAZINE, June 6 (published in 1930 but written while she was still at the Aquarium).

She even found the time in 1925 to study psychoanalysis under the renowned physician, Dr. Gregory Stragnell, editor of the NEW YORK MEDICAL JOURNAL. In 1927 she presented the paper, "Limulus," read at the New York Academy of Medicine and in the same year published two books: *Fishes in the Home* (New York Zoological Society) and *Young Folks' Book of Fishes* (Dodd, Mead & Co.). The following year she toured Europe to study the operations of public aquariums. During all this time Mellen gave many lectures and lantern slide programs on the Aquarium, its operation, and its fishes.

Townsend wrote a number of *Guide to the New York Aquarium* booklets, the annual reports of the Aquarium, *The Public Aquarium* (published by the Bureau of Fisheries in 1928), and also was editor and wrote much of the ZOOLOGICAL SOCIETY BULLETIN. Townsend, however, had a great deal of difficulty with his writing. In 1905, Hornaday complained to

Madison Grant that Townsend's *Annual Report* copy needed two day's hard work – paragraphing was bad, capitalization was erratic – and suggested that it be sent back to the Aquarium's director to be rewritten. Mellen was a godsend to Townsend since she corrected and re-wrote much of Townsend's work after her arrival at the Aquarium.

Ida Mellen was a pioneer in aquatic-animal therapy. In 1928 she received national fame as "the Fish Doctor" and was covered in a number of newspapers around the country. An Ohio newspaper ran the following short feature:

> "DOCTOR' REMEDIES FISH ILLS
>
> "Doctor' Ida Mellen, of the New York aquarium, is believed to be the only woman in the world who is a physician and surgeon to fish. She has found they are heir to much the same ills as humans - they even have nervous prostration. Thirty-eight distinct fish diseases have been discovered and remedies have been found for 35 of them."

The caption to one of the drawings of her that accompanied the article read, "Only woman in the world to practice the profession of physician and surgeon to fishes."

If this were not enough, from 1922 to 1938 she presented a series of radio talks on keeping fishes and marine biology. In 1925, for example, she gave a series of radio talks on New York City Station WEAF on the following subjects "The New York Aquarium and its denizens," "Goldfishes and the care of fishes in captivity," "Carps and sea horses," "Fishes that make noises and some that can live out of the water," "Eels and flounders," "Pike, pickerel and muskellunge and how to tell them apart," "Pacific salmon : fishes that bring forth their young alive and those that build nests and defend their young," "Gars and mudfish," "How much does a fish know?" "Sharks," "Poisonous and dangerous fishes and fishes of the deep sea," "Disappearing sturgeon, depleted by over-fishing, and sardines and herrings that no amount of fishing can exterminate," "What do fishes eat?" "What is the fastest fish in the sea?" and "Why is a fish?" A concluding talk was in answer to the common question, "Is a whale a fish?" This was followed in 1926 with twelve talks, this time on Station WJZ, and in 1927 with a series of seventeen talks on Station WNYC. Most of these talks involved fishes, but she also discussed whales, porpoises, sea birds, seals, sea cows, alligators and turtles.

CHARLES M. BREDER, JR.

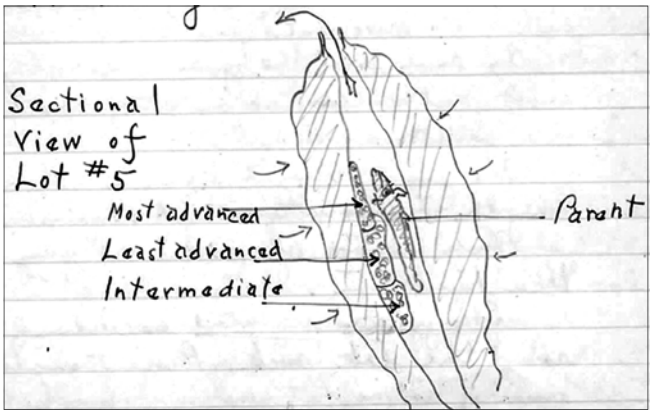
In 1921, the Aquarium staff assignments were as follows:

Charles Haskins Townsend, Director
Robert J. Lanier, Assistant
Charles M. Breder, Jr., Aquarist
Ida M. Mellen, Secretary

The Annual Report of the New York Zoological Society for this year included the following notation:

> "Mr. C. M. Breder, Jr., scientific assistant, U.S. Bureau of Fisheries, was appointed

Charles Marcus Breder, Jr. (1897-1983)



Breder's sketch of the blenny and its eggs found inside a yellow sponge mentioned in the text.

> aquarists on April 1, to fill a vacancy caused by the death of the late W. I. DeNyse, who had been in the service of the Aquarium since its inception. Mr. Breder contributed two papers to *Zoologica* (Scientific Contributions of the New York Zoological Society): The life History of the Puffer (*Spheroides maculatus*), and Hermaphroditim in the Croaker (*Micropogon undulatus*), both being illustrated with drawings by the writer."

For much of the following information I am grateful to Dr. James W. Atz, who worked for Dr. Breder for many years.

Charles Marcus Breder, Jr. was born in Jersey City, New Jersey, on June 25, 1897 and he grew up in nearby Newark. Before finishing high school, Breder had established a pattern of investigative activity to which he would follow the rest of his life: the observation of animals and plants, either in nature or a laboratory setting, followed by a published description of what he had observed and what were his thoughts on the subject. He frequently made use of apparatus that he had constructed himself, and his articles were often illustrated by his own drawings and photographs.

His earliest publication, which was written when he was 18, concerned the photography of local birds with the aid of a long-distance, electromagnetic shutter-tripper he had built for his seven-dollar, second-hand, 4 x 5 Eastman plate camera. (I have described his equipment and technique for the photographing of aquarium fish in The Toy Fish, *loc. cit.*) By the time he was 21 he had published 15 popular articles and notes, more than half of them on home aquaria, mostly in AQUATIC LIFE.

Breder was truly a self-made biologist. He once was reported to have said that everything he knew about biology and ichthyology at the time he got his first job he had learned at the Newark Public Library. In fact, Breder was a 22 year old youth with a high school education when he was hired as a scientific assistant by the U.S. Bureau of Fisheries. (His doctorate was an honorary one that was awarded to him in 1938 by the University of Newark, now the Newark campus of Rutgers University.)

Although his short period of employment with the Bureau of Fisheries was professionally successful (17 scientific publications resulted from it), he wanted to be freer to pursue his own interests and was happy to accept the position in 1921 of Aquarist at the New York Aquarium. However, in spite of its large collection of fishes and ambitious plans for a new laboratory, things did not turn out as expected. As I have previously mentioned, Townsend had a sharply ambivalent view of scientific research in a public aquarium, and for the next 16 years, he and Breder skirmished intermittently over the number and kinds of investigations Breder wanted to carry out.

However, Breder took advantage of the many opportunities to make worthwhile observations that were presented by the Aquarium's diverse fish population, and also conducted successful experiments despite its limited facilities. Moreover, he arranged to spend significant periods of time in the field: three months on the Rio Chucunaque in eastern Panama in 1924; two months on the Dry Tortugas in 1929; two months in the Bahamas, especially Andros, in 1930, 1932, and 1933; one and one-half months aboard the Atlantis in the Sargasso Sea and Caribbean in 1934; several months on the Florida west coast 1938 through 1942; one month in San Luis Potosi, Mexico in 1940; and one month in the Gulf of Guayaquil in 1942.

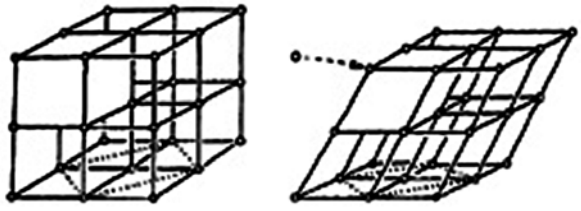
A particularly noteworthy accomplishment of Breder's research program at the Aquarium was the development of a simple method of controlling the progressive acidification of seawater that occurs in all closed circulations of aquariums without ready access to the unpolluted ocean. Subsequent studies have shown this procedure, the periodic addition of sodium bicarbonate, to be the only practical way of keeping recirculated seawater alkaline enough for delicate captive marine animals. When Townsend retired on November 1, 1937, Breder was appointed Acting Director, and 27 months later, Director. At the end of 1943, Breder left the Aquarium to become chairman of the department of fishes at the American Museum of Natural History.

If Breder had any quirks it was his reluctance for administrative positions. Early in his career he fulfilled his share of administrative chores, but as time went on he became less willing to do so. Although not indifferent to peer-recognition, he wanted no part of any of the public activities that so often came with it. In 1925, for example, the New York Academy of Sciences awarded him the A. Cressy Morrison Prize for his pioneering and penetrating analysis of fish locomotion, and during 1939–45 he served as Secretary and as President of the Academy's Section on Biology and as a member of its council. When, however, it became apparent that he was on the way to becoming the President of that prestigious organization, Breder resigned from it. Conversely, he served as President of American Society of Ichthyologists and Herpetologist in 1932, but thereafter attended less than half a dozen of its annual meetings. In 1941 he reluctantly became an adjunct professor in the Graduate School of Arts and Science of New York University, and through the years he taught a successful course in ichthyology and sponsored a small number of doctoral candidates (one of his students was Eugenie Clark).

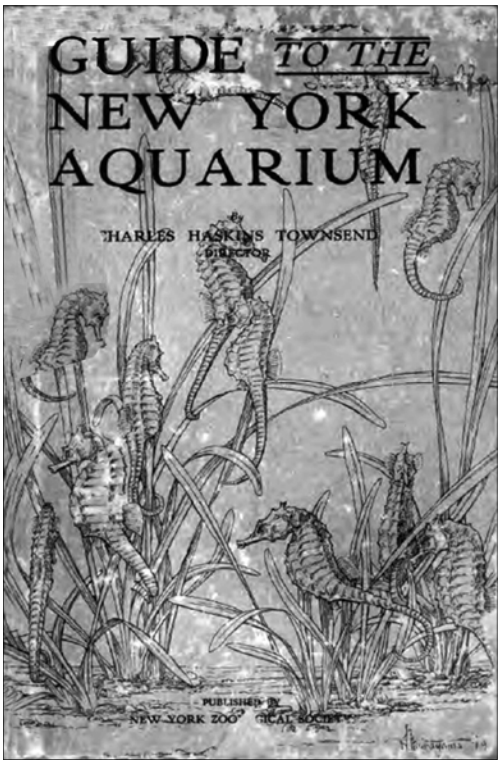
Breder was a careful observer. The following is taken from the handwritten diary he kept that documented his field activities in Florida in 1938. While studying the habits of the blenny, *Auchenopterus*, he found one fish and some eggs in the lumen of a yellow sponge and commented as follows:

> "There are three distinct patches evident each in a different state of development. Since these eggs seem to be both light sensitive and have a relatively high oxygen requirement, as based on the difficulty there is in rearing them, together with the fact that they are agglutinated in a flat mass many eggs deep, it would seem that some such special environment as the interior of some fast pumping sponge such as the yellow ones would be necessary for their successful incubation. The species is evidently pugnacious as evidenced by their behavior towards each other in aquaria or even in a collecting bucket. They advance open mouthed with their pectoral fins spread toward each other or for instance a large snapping shrimp and give a sudden lurch forward snapping their jaws which is usually followed by the retreat of the intruder. It would thus seem that the gnarling parent does little more than 'guard'. A peculiar trick of this species is to walk along the bottom on their delicate ventral fins, alternating them like legs."

He was also a behavioral ichthyologist par excellence. In his paper, "Fish Schools as Operational Structures" (BULLETIN, U.S. Fish and Wildlife Service, 74, pp. 471-502, 1976), Breder looked into the chaotic blur of the fish school and argued that schooling fish arrange themselves not willy-nilly, but according to a specific geometric pattern. Breder quickly dismissed the face-centered



Right: The face-centered cubic (FCC) lattice pattern. Left: The rhombic or hexagonal close -packing (HCP) lattice. A shove on one corner of the former produces the latter.



The 1919 Guide to the New Aquarium in which Mellen contributed sections on small saltwater aquaria and on salamanders and frogs. Mellen came a long way in the little over two years she had been at the Aquarium. Mellen made numerous corrections to Townsend's text.

cubic (FCC) lattice pattern whereby, arranged by this model, schools would display unnatural regimentation, like the files and ranks one sees in a marching band. He proposed a close cousin of the FCC lattice, known as rhombic or hexagonal close-packing (HCP). This configuration can be envisioned, Breder noted, by "figuratively pushing the cubic lattice askew." (Place a fish sphere at each vertex of the lattice, taking care to point them all in the same direction, and we arrive at Breder's theoretical school.)

But why would fish want to pack in this manner so closely? Breder believed that the answer lies partly in schooling's elusive hydrodynamic benefits:

> "The advantages of the regimented life in a school, as against the freedom of action common to the more or less solitary life, are evidently related to the effectiveness of the drag-reducing mucus in the vortices. The fishes with the least effective mucus appear to take advantage of the schooling life while those with the most effective mucus are more likely to be solitary."

In other words, the fluids released by each schooler's body lubricate its fellows in the water, reducing the ocean's resistance to their movement. Schooling fish close-pack, Breder argues, in order to immerse themselves in as much of their friends' slime as possible.

Although Breder is probably best known for his work on the reproductive, schooling, and other social behaviors of fishes, as well as the evolution and behavior of blind cave characins from Mexico, the investigations that gave him the greatest satisfaction, however, were the off-beat ones, i.e., unexpected productions of an ichthyologist that involved unusual observations and techniques and led to original, speculative conclusions. He did, however, harbor a dim view of taxonomy, with which he appeared to equate Systematics. This he tended to regard as a necessary evil - a point of view common among experimentalists and ecologists of his generation. Nevertheless, he himself described at least five new genera and 23 new species.

The accomplishments of Charles Marcus Breder, Jr. have never been equaled by any other experimental or behavioral ichthyologist. In 160 papers, occupying more than 2275 journal pages, he recorded an unparalleled array of field and laboratory investigations. To these must be added 609 more pages, as well as a 369 page book, devoted to 39 systematic and distributional studies. A 956 page monograph review and some 300 pages of popular pieces, most of which contain original data of scientific merit, complete his prodigious professional output.

THE TOWNSEND-MELLEN CONFLICT

In 1924, the Aquarium staff assignments were as follows:

Charles Haskins Townsend, Director
Louis L. Mowbray, Chief Aquarist
Charles M. Breder, Jr., Research Associate
Ida M. Mellen, Aquarist and Secretary

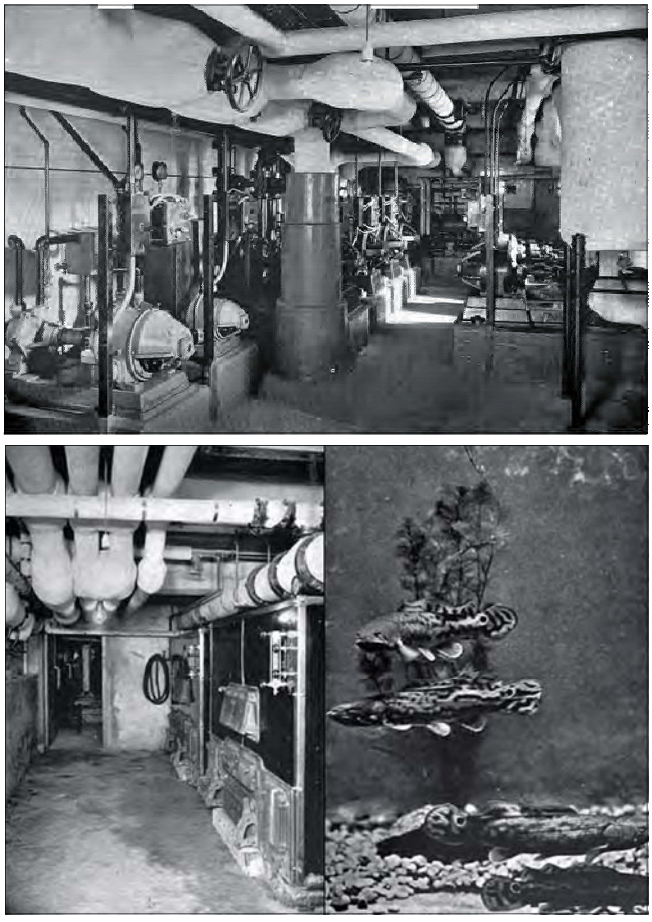
This was the year that Louis Mowbray returned to the Aquarium for a short stay before leaving for Bermuda. Ida Mellen was now recognized for her talents and was listed as Aquarist, with Secretary following this duty. From this point on, Ida Mellen produced most of the articles she had written while at the Aquarium, and began to obtain widespread recognition among New Yorkers and the aquarium world in general.

Townsend's publications, about 100 titles in all, were mainly devoted to fisheries, fur seals, whaling and oceanography but he also published several papers on birds. In fact, Breder always felt that Townsend was "at heart an ornithologist and he gave me the impression that he rather disliked fishes." Appendix C of Townsend's *The Public Aquarium* (about 11% of the book), consisting of information about the public aquariums of the world, was written by Ida Mellen, and Appendix A (about 7% of the book) is essentially a re-write of material taken from his *Guide to the New York Aquarium* published in 1919 and which Mellen most likely had edited. In any event, Mellen's papers include a copy of the 1928 edition which has been heavily scored and corrected.

Osborn and Grant wanted the Aquarium to become a center for science but this was an uphill battle with Townsend who boasted to a newspaper reporter when he retired that he had never used a microscope.

Townsend received credit with having saved three varieties of rare "critters" (his invariable term) from extinction: the giant Galapagos tortoise, the Alaskan reindeer (popularly known now in this country as the caribou) and the fur seal. However, the major credit for saving the fur seals belongs to Elliott, not Townsend, and the credit for saving the Alaskan reindeer belongs to Sheldon Jackson, Alaska's Director of Education. Although bringing domestic reindeer to Alaska was originally proposed to Congress by Townsend in 1885 it was Jackson who in 1891, unable to obtain any federal funds to implement his ideas, raised private funding to enable him to acquire reindeer from herders across the Bering Strait.

Townsend's 1925 paper, "The Galapagos Tortoises in Their Relation to the Whaling Industry" is widely cited as evidence for crediting him with saving the tortoises, but this was hardly the objective of the report which was, in Townsend's own words, "to report upon the hitherto overlooked records of the whaling fleet" and "the problem of the origin of the tortoises for which the Galapagos Islands are chiefly celebrated." Of this document of over 28,000 words, only 281 are concerned with the preservation of the tortoises.



Improvements at the Aquarium, 1921. From the top, clockwise: General view of the new electric pump room; the new boiler room; Bowfin tank.

To this list of misplaced credits we can add the name of Ida Mellen, who was responsible for much of the accomplishments at the Aquarium during her tenure. After DeNyse died in 1921, Ida Mellen, along with the tank men, in effect was running the Aquarium. Indeed, because of the high visibility she had attained as a result of her radio talks, lectures and publications, both the public and the scientific community regarded her as the head of the Aquarium. When visitors arrived and asked to see the Director, they were astonished to find out it was not she. Mellen would tell them she was not the Director and the usual reply was, "Well, we don't know him, it's you we came to see." In her book, *New York Is Everybody's Town*, published in 1931, Helen Josephy wrote:

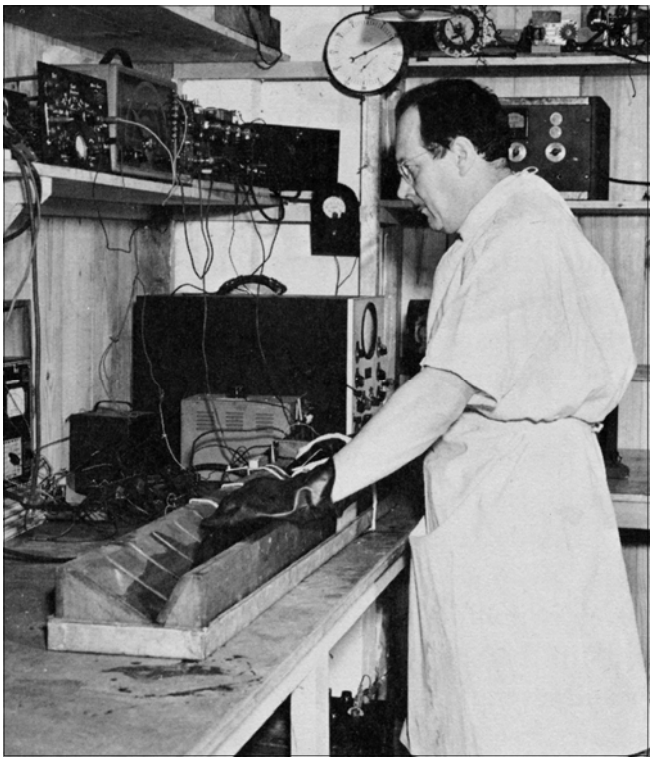
> "In our early newspaper days we learned about eels from Miss Ida Mellen of the New York Aquarium, a lady who knows more of fish and near-fish than anybody in New York. Eels, incidentally, are strange migratory creatures with curious mating habits. We also saw the Aquarium under Miss Mellen's guidance and for days were a mine of voluntary information on the length of life, value as food, and habitats of giant turtles, alligators, pig-fish, sea lions and sharks."

Mellen knew many of the important political figures of the day and it was she who suggested to Robert Moses that a new Aquarium be built at Coney Island. Moses valued her opinion and because what Moses wanted he usually got, its present location, therefore, is largely due to her.

Townsend reacted to this with an irrational jealousy, treating her in an offensive and detestable manner, spreading falsehoods about her along the way and taking credit for many of the things she did. On one occasion, for example, Townsend told his staff (to whom he referred to as "his boys") that he would give anyone a substantial financial reward for a study of the natural foods of fishes. Mellen did the study and produced the paper, but Townsend not only credited Breder for the work, he went back on his promise and Mellen was never paid. Mellen did get even, however. She joined the American Fisheries Society who published her paper, "The Natural and Artificial Foods of Fishes," cited previously. Again and again, Townsend promised raises to Mellen but gave them to others on the staff instead and when she complained, Townsend would say, "Well, I can't give raises to everybody."

Although Townsend is touted for going to the Galapagos on a mission in 1928 on the Albatross II of the U.S. Bureau of Fisheries (which happened to be idle at the time, waiting on a new government appropriation) to save the giant land tortoises, it was Ida Mellen who suggested that he go in the first place. Townsend, with inadequate preparation, rushed off without any specific objectives, much less plans for how to achieve them. Mellen was disappointed with the results, noting that rather than advancing the idea of conservation, all Townsend accomplished was to bring back 180 tortoises that in due course were distributed to the Canal Zone and the Florida keys (where they eventually disappeared), the Bermuda Aquarium, the San Diego, Houston, New Orleans and Bronx zoos, and an arboretum in Arizona. What Mellen had in mind wasn't to appear until 1959 when the Charles Darwin Foundation was founded whose primary objectives were to ensure the conservation of unique Galapagos ecosystems and to promote the scientific studies necessary to fulfill its conservation functions.

In 1929 Townsend was 70 years old. He took little part in the day-to-day decisions about the management of the Aquarium and his behavior had taken an eccentric turn. Because of this, Mellen was approached by several influential people requesting her permission for them to approach Osborn to persuade him to retire Townsend and replace him with Mellen. This she refused to do, remarking that she wanted Townsend to finish his tenure at the Aquarium. This was partly because of compassion on her part for Townsend but also because the situation of women at this time was vastly different from that today and would have placed Mellen in an even more uncomfortable position at the Aquarium. The glass ceiling at the New York Zoological Society was so firmly in place that no woman could ever expect to achieve the level of Director of the



Christopher W. Coates (1899-1974)

Aquarium. When Townsend made his trip to the Galapagos in 1928, for example, although Mellen had seniority it was Breder who was appointed Acting Director.

One of the most important things Ida Mellen did during her last year at the Aquarium was to approach Mrs. Alma C. Damon to make a donation to the New York Zoological Society. The income from the amount - $10,000 (equivalent to about $114,000 today) – was to be in memory of her husband, William Emerson Damon, who had been one of the original members of the Society's aquarium committee in 1902 and a pioneer in the history of the aquarium hobby in America.

Although this was a significant bequest, it would have been closer to $15,000-$25,000 had Mellen acceded to Mrs. Damon's request that Mellen consent to be the curator of the exhibition. This she declined to do, feeling that it would be interpreted as soliciting the donation for her own benefit when that was far from her intention.

In any event, tired of her disgraceful treatment at the hands of Townsend, Mellen resigned and went on to pursue an active independent writing career for which she is well-known in the aquarium hobby. Her 1935 book (revised in 1953), *1001 Questions Answered About Your Aquarium* (co-authored with Robert J. Lanier, a former tankman at the New York Aquarium who went on to become Superintendent of the Steinhart Aquarium), for example, is arguably the best of all the aquarium books published in this country prior to World War II.

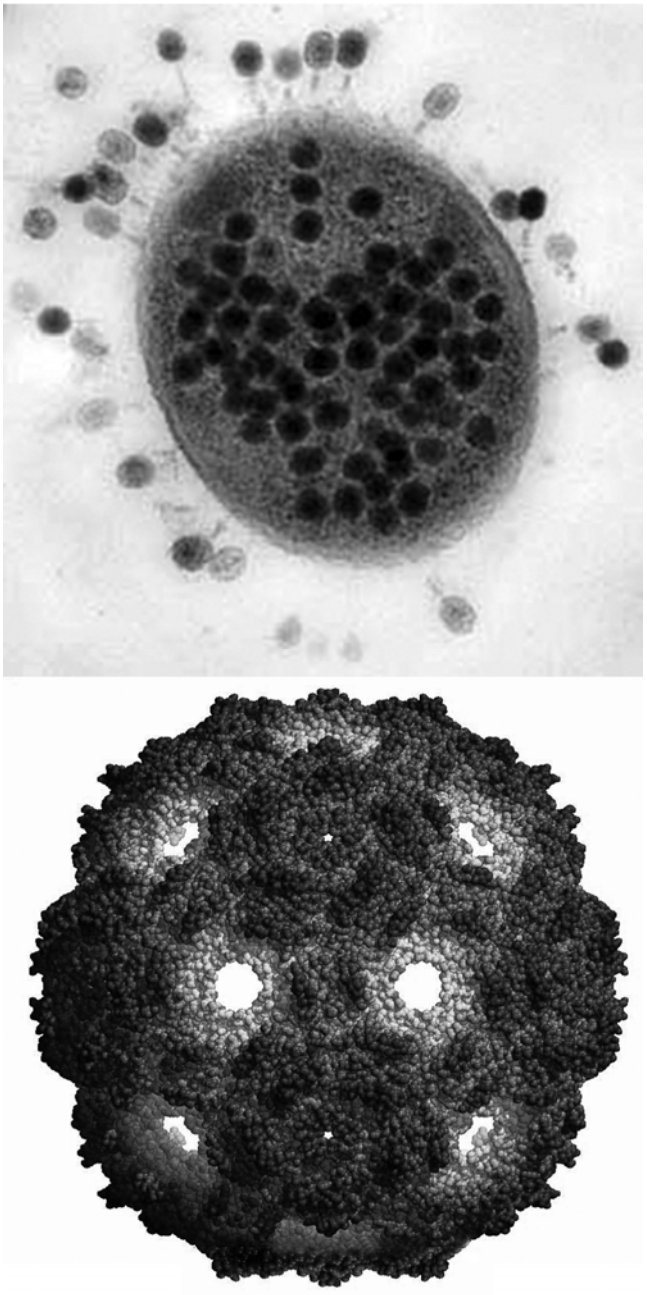
ENTER CHRISTOPHER COATES

Christopher William Coates was borne May 8, 1899 on part of what is now the site of Rockefeller Center. As a child he was presented with a bowl of goldfish and was full of questions about them but could find no one who could completely satisfy his curiosity. So, at age 17, he went down to the Battery where the Aquarium was then situated and operated by the city, and soon discovered that he often had learned more about fishes than had many adults.

Coates dropped out of high school to pursue his study of fishes, lied a little about his age to get into the Army in World War I, and later pressed on with his self-study of ichthyology, chemistry, botany, geology and ecology. Coates became a broker on the New York Produce Exchange, but continued his interest in fishes, especially tropical species. The depression had hit the trade hard and Coates was looking for other work. Then, in 1930, an unexpected opportunity came his way when Mrs. Damon's bequest of $10,000 was received by the Aquarium. It enabled the Aquarium to enter into what was essentially a new field for it: a display of freshwater tropicals in seventy-two small tanks around the balcony. Its management required a specialist; the person selected was Christopher W. Coates, and he was hired on the staff as an Aquarist.

THE COATES BACTERIOPHAGE EPISODE

Among Coates' assets was a publicity sense not equaled by anyone on the Society's staff except perhaps for Raymond L. Ditmars, the snake expert at the Bronx Zoo. Soon after his arrival, stories about



**Top—Bacteriophage.
Bottom—Graphical representation of a bacteriophage.**

the Aquarium came to be a staple of New York City newspapers. For some weeks in 1933 a Coates story had a runaway success and caused the Aquarium a certain amount of embarrassment. It concerned the discovery of a mysterious bacteriophage (bacteria eater) in the waters of the tropical fish tanks.

Breder had for some years been interested in the phenomenon of tanks that were kept clear and habitable by fishes even though fish food decayed in the water and large amounts of bacteria were formed. Something was destroying the bacteria, and in 1931 he announced the presence of a lytic (dissolving) agent - the bacteriophage - in both old aquarium water and in the intestinal contents of fish (in this case, the small-mouthed black bass), but did not publish any further reports.

The Aquarium's tank men were well aware that something was going on in the waters into which they dipped their hands so many times a day; working with glass as they did, they often got small cuts and these healed rapidly and without infection. To them it was just something that happened, but Coates sensed its news value and mentioned it to a reporter. The exact chronology of the story's development is not entirely clear, but according to most newspaper accounts the bacteriophage's wonder-working properties were realized after Coates cut his hand and the wound healed in three days while being exposed repeatedly to fish tank water in the normal course of his work. (In one account he was supposed to have asked himself, "If the phage destroyed bacteria in aquarium water, why shouldn't it destroy them in human infections?" From the intestinal contents of fish he allegedly prepared a concentrated solution of the bacteriophage and then deliberately set about getting his own hands infected, dipping them repeatedly in his phage solution and soon saw them healing up.) Whatever the real truth of the story, THE TIMES wrote about it in 1933:

> "Strange tales come from New York's Aquarium - recalling the healing springs of medieval days. People afflicted with skin diseases beg for permission to dip their hands into tanks teeming with tropical fish. Dr. Coates' own festered hand healed wonderfully when accidentally brought into contact with aquarium-water bacteriophages. Cases of skin diseases have been similarly cured. With commendable caution further treatments are denied. A mystery must first be solved."

Soon scores of sufferers from undetermined kinds of skin disease flocked to the Aquarium, which took the precaution of having them sign a form saying that the treatments were at their own solicitation and risk, and that if the expected results did not materialize the Aquarium would not be held responsible. THE TIMES quoted Coates as saying that nineteen volunteers had tried the water "and in all of them the results could be described as encouraging." One man whose hand was so afflicted that he could not close it had reported that he was now able to grasp a golf club for the first time in twenty years.

Foreseeing that it was going to be swamped by sufferers, the Aquarium turned its "patients" away and passed the problem to a couple of New York City hospitals for proper scientific investigation. As it turned out Coates was wrong; the results were inconclusive (apparently even if bacteriophages were present they were too weak to be of any therapeutic value) and the bacteriophage story died out.

ELECTRIC EELS

Coates did, however, engage in meaningful research work that justifiably earned him a reputation as an expert in the field of electric fishes. His interest in electric eels dated from his earliest years at the Aquarium. He knew that such great scientists as Sir Humphrey Davy and Michael Faraday had worked with electric fishes, and that Faraday had demonstrated that externally the eel's current flows from head to tail. But how powerful was the current? Coates tried running it through voltmeters, ammeters, and galvanometers - all of which either burned out or failed to register anything. The eels were giving off plenty of electricity, all right; many times he was knocked off his feet by discharges. But no combination of wiring would cause them to light up an ordinary electric bulb.

One Saturday afternoon in 1935 he happened to be testing a new kind of neon lamp, of the type commonly used nowadays as a night light. Tired and getting careless, he made a connection that gave him a heavy shock, and as he was falling backward he saw the neon pip (a neon bulb is made of glass sealed in two areas, one of which is called the pip) light up with an orange glow. He traced the wiring, found that the pip was in a simple direct circuit with the eel, and then he got repeated glows every time he stimulated the eel with a rubber-gloved hand. The explanation of earlier failures was simple: the lamps and electrical apparatus he had been using have a "warm-up lag," and the eel's discharge was too brief to actuate them; on the other hand the neon pip's reaction time is instantaneous.

Since it takes at least eighty volts to excite a pip, he now had a crude way to measure an electric eel's voltage, and enough general knowledge of eel behavior to interest a specialist. He found one in Dr. Richard T. Cox, at that time professor of physics at New York University, who contributed a portable cathode-ray oscilloscope to the experiments. With such sensitive instruments Coates and Cox recorded voltages up to 550 and found that an average discharge in water amounted to some forty watts. Dr. Cox was so enthusiastic about the studies that in 1937 he led an expedition to the mouth of the Amazon to study the electric eel at home, taking with him an "eel caller" devised in the Aquarium. It was a device to discharge five hundred volts in a thousandth of a second, a discharge much like the eel's natural one, and it was intended to lure electric eels into the vicinity of the electrodes where they could be captured. It worked.

The electric eel exhibit in the Lion House of the Bronx zoo.

Ross F. Nigrelli (1902-1989)

Among the scientific papers authored or coauthored by Coates are: with Charles M. Breder, Jr., "Reproduction and Eggs of *Pomacentrus Leucoris*," AMERICAN MUSEUM NOVITATES, 1933; with Abner Weisman, "Ovarian Activity of *Xenopus laevis* While in Captivity," THE AMERICAN NATURALIST, 1944; with James W. Atz, "A Remarkable Instance of Parallelism among Teleost Fishes," COPEIA, 1957; and with Carleton Ray, "A Case of Poisoning by the Lion Fish, *Pterois volitans*," COPEIA, 1958.

Unfortunately, Coates had something of a disdainful and domineering personality and was jealous of Mellen's achievements and stature and, given the times, all the more so because she was a woman and was much better educated. Coates' sneering at his peers and superiors was not confined to Ida Mellen, however. In a personal communication to the author from Dr. James W. Atz who worked for Coates for 17 years, Dr. Atz wrote:

> "I don't remember anything ever being said about Breder's not getting on with Mellen, but Coates could well have tried to convince him of her professional frailties…, *as he often did of Breder to me*." (The italics are mine.)

Perhaps Coates resented the fact that in 1938 Newark State College gave Breder an honorary Doctor of Science and that Mellen received hers a few years later. No such honor ever came Coates' way. It should also be noted that although Coates had no doctorate, earned or honorary, he let the assumption go uncorrected in the New York Times articles of July 7, 1933 ("Bacteria Eaters"), April 30, 1938 ("Strange tales come from New York's Aquarium") and August 11, 1943 ("Five Electric Eels Spark War Drive And Slip Into Secret Research Job").

Coates most likely was not pleased either when Mellen's ground-breaking March 1931 article, "Tropical Toy Fishes," appeared in THE NATIONAL GEOGRAPHIC MAGAZINE, further increasing her stature and popularity with the public. It is interesting to note that each of Ida Mellen's five scrapbooks in which she collected printed references to her work was labeled "Conceit Book." Coates undoubtedly also maintained such scrapbooks but I doubt that they were labeled as modestly.

Although Coates had a fish named after him (*Gymnotus coatesi*, LaMonte 1935), Ida Mellen also was honored in this manner. In 1927, she first noticed an outbreak of a monogenean species (monogeneans are fish parasites popularly known as "flukes") from a spadefish (Ephippidae) and an angelfish (Pomacanthidae) in the New York Aquarium that was subsequently named in her honor, i.e., *Epibdella* (now *Neobenedenia*) *melleni*. As the most common species, *N. melleni* causes problematic disease in public aquariums. As Ian D. Whittington of the South Australian Museum remarked,

> "Ida Mellen, a zoologist of note herself, probably had no inkling that her namesake monogenean would become a parasite of such notoriety!"

Clearly not only was Ida Mellen a significantly more cultivated and accomplished individual in every way

than Christopher Coates, she was a patently more important person in the history of the aquarium hobby in America. Her aquarium publications certainly surpassed anything Coates ever wrote and her *1001 Questions Answered About Your Aquarium* far out-shined his *Tropical Fishes for a Private Aquarium* published two years earlier. Had she not been forced out of the Aquarium by Townsend in 1929, there is no telling what this marvelous woman might have achieved there over the ensuing years.

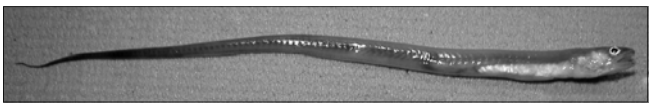
ROSS NIGRELLI

In 1934 Ross Nigrelli joined the Aquarium as its pathologist, MacCallum having retired. Born Ross Franco Nigrelli on Dec. 12, 1903, in Pittston, Pa., he did his undergraduate work at Pennsylvania State University and received his Ph.D. in biology from New York University in 1936. Nigrelli gained a worldwide reputation for his work on the diseases of fish and other aquatic animals and was among the first to discover virus-induced tumors in fish. He was also an authority on the effect of pollution and changes in salinity and water temperature on the health of aquatic animals. In 1959 he wrote a report of special interest to aquarists, "Longevity of fishes in captivity, with special reference to those kept in the New York Aquarium." in 1964 he founded the Osborn Laboratories of Marine Sciences and was director of the laboratories from that year until 1973 when he was named senior scientist. Concurrently, from 1966 to 1970, he was also director of the New York Aquarium.

Nigrelli was one of the earliest scientists to investigate the poisons released by marine organisms and to investigate plankton blooms, like the red tide that killed millions of fish along the Gulf Coast of Florida in the 1940's and off Long Island in the 1950's. He also experimented with the use of marine organisms as tools in medical research and as potential sources of drugs. A well-publicized development occurred when he discovered that when the sea cucumber is attacked, it secretes a poison that even in minute quantities is fatal to fish. (The excretion also inhibits the growth of tumors in mice.) Zoologists have known for years of the sea cucumber's propensity for defensive vomiting, but its toxic properties weren't discovered until the early 1950's, when Nigrelli noticed at the Aquarium that the creature's upchucked innards could kill. To explore the matter further, he took a one-ounce sample of the toxin and placed it in a tank holding several fish and 750 gallons of water. The fish died within 30 minutes.

The study by Nigrelli of this natural toxin (named later by other scientists as a "holothurin") reveals the hazardous existence of many small creatures that live in association with another. The sea cucumber attracts a number of such animal associates (called "commensals") and one particular species living within the shelter of the sea cucumber in which the respiratory activities of the cucumber keep supplied with well-oxygenated water very often is a small pearl fish, Fierasfer. But the well-being, and indeed the very life of the small Fierasfer seem to be constantly endangered, for the fish is actually living beside a vat of deadly poison!

Even more famous to aquarists is what is popularly known as "Fish Tank Finger." In 1953 Nigrelli published a paper describing a new disease in neon tetras ("Two diseases of the neon tetra, *Hyphessobrycon innesi*," AQUARIUM JOURNAL, 24, 203-208, 1953), but the organism wasn't identified until some years later when it was described as a new bacterium, *Mycobacterium fortuitum*. The *Mycobacteria* are slowly growing bacteria, related to tuberculosis and normally found in bodies of fresh or salt water in many parts of the world, that can cause disease in fish and people in contact with water from an aquarium. When it infects the skin, it causes localized microscopic nodules, called granulomas, to form. They occur at sites of skin trauma where there are scratches, cuts, and the like. The following is an account of a case reported in 1962:



A Fierasfer, the fish that lives besides a vat of deadly poison.

James W. Atz

"When the 37-year-old woman who ran a pet shop in a Los Angeles suburb cut her right middle finger on the metal rim of a tropical-fish tank, she thought nothing of it. The cut seemed to be clean, and it healed quickly. But within a month, abscesses formed under the skin on the back of her finger and hand. They were not painful, but they were unsightly, and occasionally one of them burst and oozed a sticky fluid until a new scab formed. The woman's 18-year-old son cut his finger on the same tank, and soon he too had an abscess on his hand."

JAMES WARD ATZ

After serving as a volunteer in 1936 (at which time he had finished his B.A. from Cornell University), James Atz was hired by Breder as a laborer by the Aquarium in the summer of 1937, but by the time he joined the army in April of 1941 he was serving as laboratory technician and tankman, and had written both scientific and popular articles on fishes. When he was discharged from the Army at the end of 1946, he became the Assistant Curator, then Associate Curator (during these times his boss was Christopher Coates), and then Curator of the Aquarium. He obtained his M.S. and Ph.D. from New York University in 1958 and 1959, respectively (his respective theses were "Narial breathing in fishes and evolution of internal nares," and "Morphological and genetic studies on the pigmentary patterns of xiphophorin fishes and their hybrids").

From 1963 to 1967 he was a Consultant and member of the Study Team for the National Fisheries Center and Aquarium, Washington, D.C. and from 1970-1981 was Curator and Dean Bibliographer of the Department of Ichthyology of The American Museum of Natural History, and Adjunct Professor of Biology at New York University. He wrote *Aquarium Fishes* (Viking Press, 1971), and his many articles and papers have appeared in leading scientific publications as well as in popular magazines, including THE AQUARIUM, TROPICAL FISH HOBBYIST, AQUARIST AND PONDKEEPER, and THE MARINE AQUARIST. He is co-author, with Grace E. Pickford, of the standard reference book, *The Physiology of the Pituitary Gland of Fishes* (New York Zoological Society, 1957).

Atz wrote an interesting article on candirús that he observed both at the Cleveland Aquarium and the New York Aquarium. This fish has been reported as attacking the anal region, gills, and fins of dead, dying, or disabled fishes, and is the only vertebrate parasite of man, attaching itself to the submerged legs of bathers and even entering the genital cavities of both sexes. The following is an excerpt from his article that involved 4 candirús, 2 to 2-1/3 inches, identified as belonging to the genus *Vandellia*:

"When the candirús arrived in Cleveland, attempts were made to feed them frozen brine shrimp, living white worms, chopped earthworms or raw smelt, minced gills from smelt or freshly killed goldfish, and goldfish blood, administered by means of an eyedropper with an extension of plastic tubing to enable the material to be presented with minimum disturbance. None of these elicited any positive response. Three days after the

arrival of the fish, a live half-pound goldfish of the black moor type was put into their aquarium. The candirús at once began what seemed to be searching movements directed mostly toward the anterior end of the goldfish, and 3 of them soon fed on blood extracted from its gills.

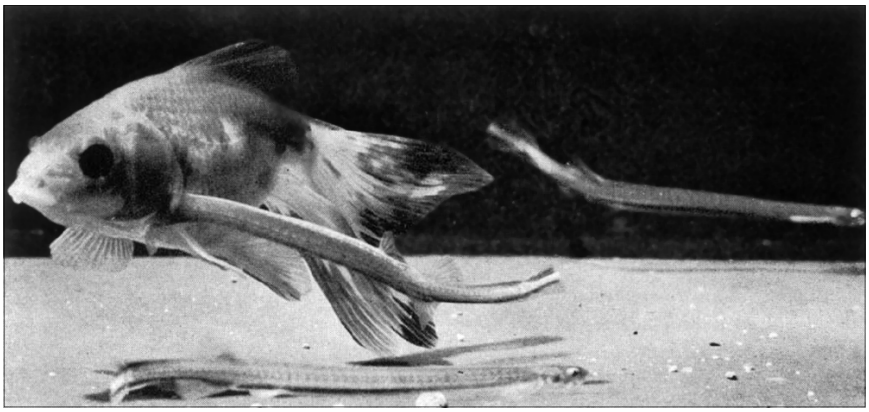
"Whenever a goldfish was introduced into the candirús' aquarium, they swam rapidly around its head, touching, or nearly touching it with their own. Frequently the candirús swam parallel to the side of the goldfish, and they usually entered the gill chamber from this position. They did not appear to force an entry, but may have taken advantage of the periodic opening of the operculum during respiration. Almost immediately after the anterior part of a candiru had disappeared under the gill cover, its belly would begin to swell with blood. In some cases, the whole feeding procedure lasted only about half a minute, but the candiru might remain in the feeding position for as long as 3 or 4 min after its belly appeared completely full. After leaving its prey, the candiru usually dropped to the bottom and lay there quietly. When not feeding, the candirús rested on the bottom, swam more or less at random about the tank, or engaged in vigorous, anguilliform swimming motions while remaining in the same place, which often was a corner, the fish maintaining a vertical, head-up position.

"The goldfish exhibited little or no reaction to the preliminary attentions paid them by the candirús, nor did they try to avoid the smaller fish. Immediately after the entry of a candirú into one of its gill chambers, a goldfish usually would flex its body once or twice, and smaller ones often settled quietly to the bottom. None was ever observed to attempt to dislodge its attacker after blood letting commenced. That damage was done to the gills was apparent because bits of tissue were commonly observed streaming from under the operculum during the feeding. On one occasion, a large goldfish ate a little of its own gill tissue while being fed upon by a candirú. Although large goldfish survived candirú attacks and, in fact, were repeatedly used to supply food, small ones sometimes died immediately or soon after a single attack."

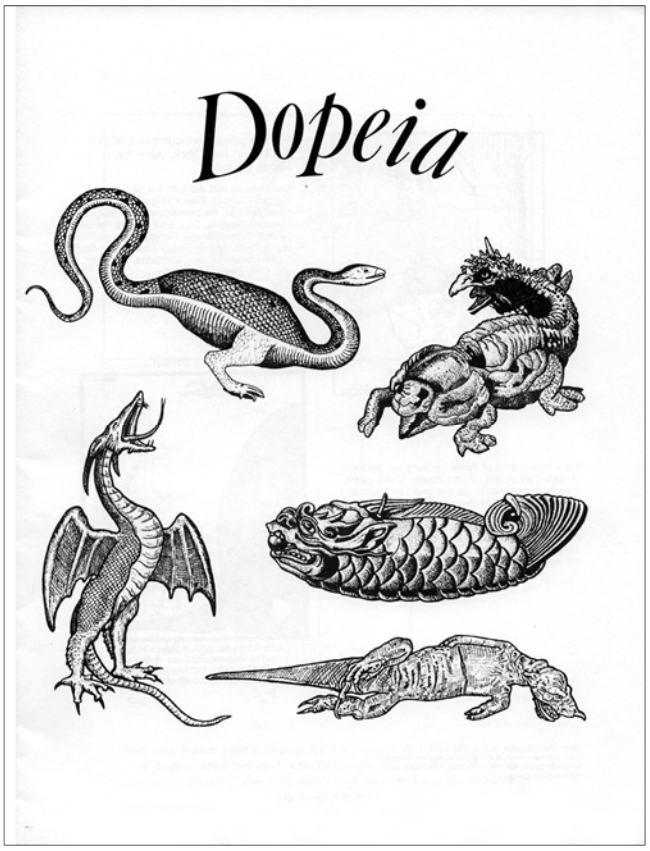
There are two things Jim Atz is especially noted for among aquarists, the first being his love of aquarium hobby history (indeed, his own interest in aquarium history predates mine by at least 17 years).

The second is his refutation of the concept of the "Balanced Aquarium." Briefly stated, the "Balanced Aquarium" is one in which the products of animal and of plant life more or less completely counterbalance each other. The fish absorb oxygen but emit carbon dioxide. The former is necessary for fish life and the latter, if exceeded, can be fatal. The plants absorb carbon dioxide, thus removing that danger to the fish, and return, under the influence of light, oxygen required by the fish. The following is the introduction to a seminal article Atz wrote in 1949 ("The Myth of the Balanced Aquarium," Natural History, 72-79, February):

"The idea that the animals and plants of an



Atz experimented with and wrote about the parasitic catfishes known as candirús.,



A June 1991 copy of DOPEIA, the satirical burlesque on COPEIA, edited by James W. Atz.

> aquarium balance each other in their production and consumption of carbon dioxide and oxygen was a little over 100 years old when it was proved wrong. Although it was disproved more than seventeen years ago, the myth of the balanced aquarium still holds sway - in the tropical fish fancy, in the schoolroom, and in the laboratory. Such is the power of the too felicitous phrase, the too trim theory."

In this article he drew heavily on a paper read by Charles M. Breder, Jr. at a meeting in 1931 before the American Society of Ichthyologists and Herpetologists titled, "On the Organic Equilibria in Aquaria." In this paper Breder found that (1) Plants release oxygen in unimportant quantities, and (2) Because of the rapidity of the transfer at the air-water interface, aquarium water is always saturated with oxygen.

Atz added to Breder's work with the following observations. (1) The major portion of the carbon dioxide in the water is released to the air via the air-water interface of the aquarium, the amount absorbed by the plants being inconsequential. (2) The transfer of carbon dioxide at the air-water interface is slow. In an overcrowded tank, therefore, fish die from carbon dioxide poisoning, not from oxygen deficiency. (3) In a poorly illuminated tank, plants produce more carbon dioxide than they absorb. The bottom line to the Breder and Atz research therefore is that overcrowding is the key to failure in fishkeeping, with neither the carbon dioxide absorption nor the oxygen production by plants being of any consequence in the aquarium.

Unfortunately, the science writers of the day completely misunderstood the Atz article, particularly with regard to the finding that in a poorly illuminated tank plants produce more carbon dioxide than they absorb. Dire warnings went out to aquarists over lurid headlines, such as the following one that accompanied an article written by Dr. Roy K. Marshall, the distinguished Science Editor of the PHILADELPHIA EVENING BULLETIN: "Your Balanced Aquarium May Be Death For Fishes." The fact is, of course, that no aquarium fish has ever been killed by living plants. Even in an aquarium where the air-water interface is covered with a thick layer of floating plants such as duckweed or *Salvia,* the fish suffer no ill effects. As William T. Innes commented: "…we have never seen nor heard of fishes showing distress after hours of darkness in a thickly planted, uncrowded tank."

Atz (personal communication) pointed out that later research showed that Breder's assertion that photosynthesis has little influence on the concentration of dissolved oxygen cannot be accepted as an accurate generalization that fits all cases. The difficulty is that its influence cannot often be calculated quantitatively because of an inadequate knowledge of the rates of consumption or evolution of oxygen by fish or plants under given conditions. However, approximate average values of these rates

for certain fishes and plants are known, and I myself have used these rate equations to predict the variation of dissolved oxygen in aquaria containing *Valisneria* and without them for zebra danios and certain native fishes. For the typical home aquarium where oxygen deficiency is not a problem, Breder's and Atz's conclusions do hold.

Not to be forgotten is that Jim Atz has a keen sense of humor. For many years, with the assistance of like-minded colleagues with a well-developed funny bone, he published a satirical burlesque of COPEIA, the publication of the American Society of Ichthyologists and Herpetologists, called "DOPEIA." The publication, which varied in size over the years, featured mostly cartoons concerning fishes and herptiles, but on occasion had some humorous written pieces as well.

MYRON GORDON

Myron Gordon (1899-1959) emigrated into the U.S. from Russia with his family when he was five years old. Although he was brought up in Harlem in the heart of populous Manhattan where he met Hermann Rabenau and other notables of the day (I have described his early life in *The Toy Fish*, loc. cit.), his interest in animals and plants soon manifested itself, and by the time he had matriculated at Cornell University he had kept innumerable fishes as pets and had worked in the Bird House at the Bronx Zoo and on a farm raising game birds.

He received a B.S. degree in 1925 and a Ph.D. in zoology four years later. In 1924, he had organized a fish genetics laboratory at Cornell under the joint sponsor-ship of three departments, Plant Breeding, Aquiculture and Zoology, and his thesis concerned the morphology of heritable color patterns in *Xiphophorus maculatus*, one of the species he maintained there. In 1937, Gordon left Cornell and for approximately one year he continued his research under the auspices of the Yale School of Medicine. He joined the Aquarium staff in 1938 and a year later he established the Xiphophorus Genetic Stock Center to provide a reliable supply of genetically identical fish to be used in cancer research, and the lines he established remain widely used today. When the original building of the New York Aquarium, which was located at the Battery, was closed down in the fall of 1941, the Genetics Laboratory was moved uptown to the American Museum of Natural History, where the Department of Birds generously provided space and facilities.

Because of Gordon's academic reputation and ability to write clearly on any level, he was recruited to write a very popular series of booklets and magazine features aimed at tropical fish hobbyists (e.g., *Guppies As Pets*, *Siamese Fighting Fish*, and *Swordtails*). He is best known for his work on the inheritance of melanoma in hybrid fishes. This pigment-cell cancer is uncommon but especially malignant in man; it occurs in many other animals but can be produced at the will of the experimenter only by crossing certain fishes belonging to the genus *Xiphophorus*. Although his work had pertinence to medical science, Gordon always looked at it from the zoologist's point of view, for his early training was not as an oncologist, but as an ichthyologist and geneticist. He focused most of his attention and almost all of his research effort on *Xiphophorus*, whose adaptability to laboratory life,

Myron Gordon (1899-1959)

The Xiphophorus Genetic Stock Center now located at Texas State University.

pigmentary polymorphism and ability to produce fertile interspecific hybrids make them uniquely useful experimental animals. He published 72 papers on the members of this genus, as well as many abstracts and popular articles and a number of summaries of his work. During his collection trips he discovered and named several new species, and in 1963, Robert Rush Miller and W. L. Minckley named *Xiphophorus gordoni* in his honor.

An interesting anecdote concerning Gordon occurred when he was part of the 1932 Cornell University Mexico Expedition, which was supported by private funds from hobbyists, commercial tropical fish breeders, and the Heckscher Research Foundation at Cornell. The Shedd Aquarium in Chicago and the New York Aquarium also promised to buy exotic fish that the expedition hoped to bring back. The expedition arrived at the border in Laredo on March 12th, where it was unexpectedly delayed. Gordon had shipped 120 one-gallon cans by the Railroad Express Agency to the border, to be reshipped to various small Mexican railroad stations near areas where the expedition hoped to collect fish. The cans, painted on the inside with asphaltum varnish, were the shipping containers. A permit had been requested to bring the empty cans across the border free of customs duty - because they would eventually be returned to the United States – but it had not yet arrived. The customs officer demanded US $1.00 per can ($13.70 in current dollars), and this was far more than Gordon could afford. Frantic telegrams exchanged between Laredo and Mexico City elicited sympathetic advice but led nowhere. “Why don’t you buy goldfish,” Gordon was told, “and place them into your jars? There is no duty on importing goldfish into Mexico, and your cans then become the shipping containers, which are not taxed.” It was an interesting exercise in Mexican economics, and Gordon eventually was forced to pay.

THE OLD AQUARIUM COMES DOWN

Although he never held elected office, Robert Moses was arguably the most powerful person in New York state government from the 1930’s to the 1950’s. He changed shorelines, built roadways in the sky, and transformed neighborhoods forever. His decisions favoring highways over public transit helped create the modern suburbs of Long Island and influenced a generation of engineers, architects, and urban planners who spread his philosophies across the nation.

In the late 1930’s a municipal controversy raged over whether an additional vehicular link between Brooklyn and lower Manhattan would be a bridge or a tunnel. Bridges can be wider and cheaper but tall ones use more ramp space at landfall than tunnels. A bridge would have destroyed Battery Park and physically encroached on the financial district. The bridge was opposed by historical preservationists, Wall Street financial interests and property owners, various high society people, construction unions (since a tunnel would give them more work), the Manhattan borough president, Mayor Fiorello LaGuardia, and Governor Herbert H. Lehman.

However, Robert Moses favored a bridge. It could carry more automobile traffic than a tunnel and would also serve as a visible monument. More traffic meant more tolls, and more tolls meant more money and therefore more power for public improvements. LaGuardia and Lehman, as usual, had no money to spend and the federal government, by this point, felt it had given New York enough. Moses, because of his control of the Triborough Bridge, however, had

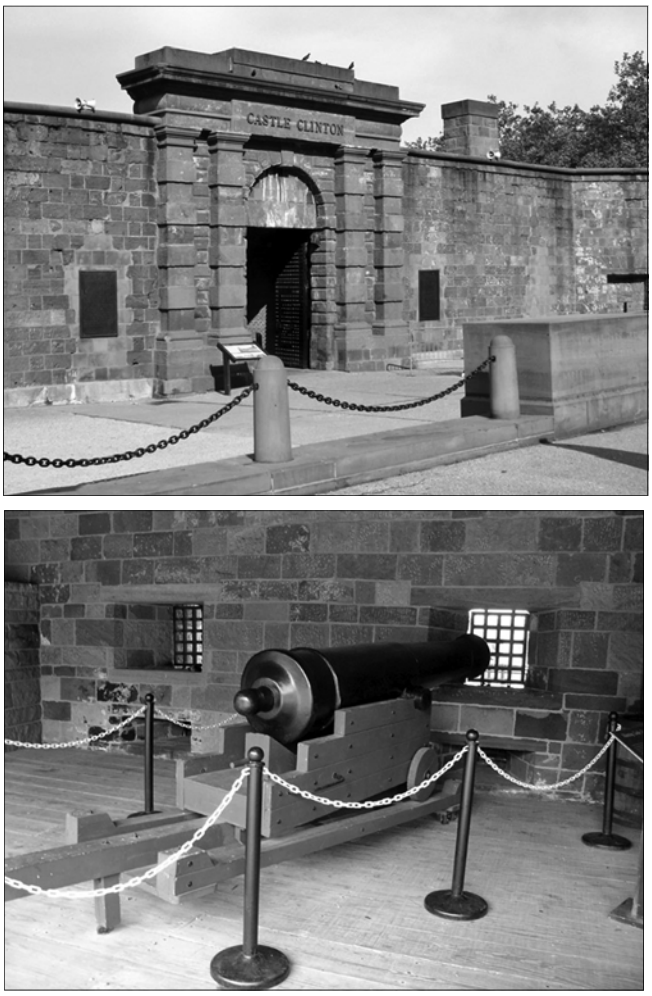
money to spend, and he decided his money could only be spent on a bridge.

Only the lack of a key Federal approval thwarted the bridge scheme. President Roosevelt ordered the War Department to assert that a bridge in that location, if bombed, would block the East River access to the Brooklyn Naval Yard upstream. Although it was a dubious claim for a river already crossed by bridges, it nevertheless stopped Moses. In retaliation for being prevented from building his bridge Moses closed the New York Aquarium in 1941. He had beams and architectural elements around the fort placed to make it appear structurally unsound, and almost succeeded in having the fort completely razed. In late summer of the year the Executive Committee of the Society reached an agreement with Commissioner Moses whereby the city would compensate the Aquarium for the loss of its valuable collection, pay the salaries of a nucleus staff and attendants for an "interim" aquarium in the lion house in the Zoo, and permit distribution of unwanted exhibits to other public aquariums.

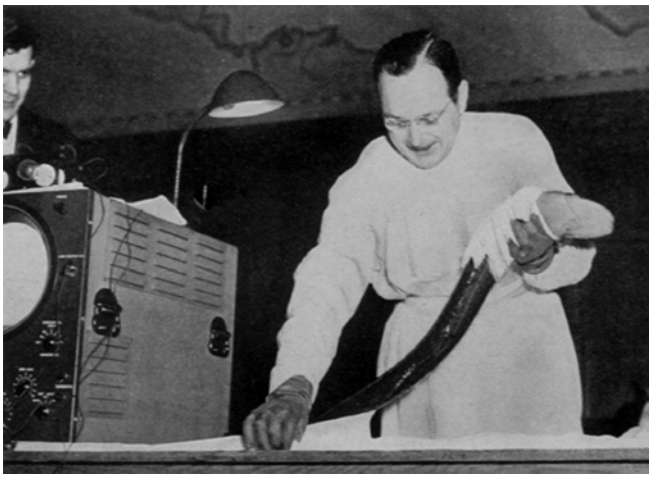
World War II stopped both the progress of the Tunnel and of the destruction of Castle Clinton. The public outcry at the loss of a popular recreation site and landmark stymied his effort at demolition. As a result of the controversy Congress declared the historic structure a National Monument on August 12, 1946. The new tunnel would be completed and the old fortress would remain. But before the building had received congressional protection, the wrecker's ball had already removed the upper story, roof, and other additions that had been added in its middle years. What was left when the National Park Service took over was the basic structure that had begun life back in the early 19th century. In the summer of 1975, after much restoration work, Castle Clinton reopened the doors that had been shut for 34 years.

It was no simple thing to dispose of some ten thousand fishes, mammals, reptiles, and birds. The sea lions, freshwater reptiles, amphibians, and penguins could be absorbed easily enough by the Zoo. The Damon collection of freshwater and marine tropicals was too valuable to let go and had to be taken to the Zoo, along with young tarpon from the Aquarium's tarpon research station on Palmetto Island in Florida, the popular electric eels, and the blind cave fish Dr. Breder had collected on an Aquarium expedition to La Cueva Chica in San Luis Potosi, Mexico in the spring of 1940. Everything else had to be given away to the aquariums at Boston, Philadelphia, and Washington, liberated in ponds and streams near New York City, or returned to the ocean. A scow hauled several hundred marine fish to Sandy Hook in mid-September where they were "liberated," no doubt, as a newspaper suggested, to their great disgust at having to forage for themselves instead of being fed by the Aquarium.

Coates and Nigrelli, on the other hand, occupied rooms at either end of the exhibit panel in the Lion House, but since there was simply no room for them



Details of the Castle Clinton reconstruction , 1975



Coates demonstrating the electric production of an electric eel, a popular show at the Aquarium.

there, Breder and Gordon found laboratory space in the American Museum of Natural History.

As an outcome of his work with electric eels, Coates hooked up a circuit connected with the tank of an electric eel on exhibition in the Lion House. At intervals during the day a rubber-gloved tankman stroked the eel until it discharged its five hundred volts, thereby causing a series of neon pips to spell out "ELECTRIC EEL," a loudspeaker to crackle with static, and wavy blue lines to flicker across the face of an oscilloscope. It was a popular show, and it still is at the new Aquarium.

However, the exhibition electric eel was not quite so popular with the Lion House keepers. Its tank happened to be directly opposite the cage occupied by Dacca, the Zoo's prolific tiger mother. (She had thirty-two cubs between 1948 and 1959.) During several of her pregnancies she took a fierce dislike to the eel, watching it intently and clawing at the wire front of her cage when the eel rose to the surface to take a gulp of air. For the sake of Dacca's peace of mind, the eel tank was kept covered during the critical weeks.

Coates pressed ahead with his studies of the electric eel, which had - it was revealed after the war - contributed to chemical warfare research. Nobody talked about it at the time, but during the last two years of the war some two hundred electric eels lived briefly in twenty-two great wooden tanks in a hideaway laboratory in the basement of the Lion House until they were sacrificed so that their electric tissue could be used to measure the activity of a deadly gas, diisopropyl fluorophosphate, which destroys nerve activity (although it is much less toxic than tabun or sarin).

Postscript: The electric eel was supposed to have other esoteric properties besides producing real electricity. In 1909 a Pennsylvania man had written to the Aquarium:

> "Can you tell me where I can get an electric eel to be used for medicine to cure my brother of drinking? It must be put into a vial with the other ingredients until dead, then taken out and the medicine given."

EPILOGUE

This early history of the New York Aquarium held a special interest for me. As a youngster I visited the Aquarium at Battery Park before it was torn down, and much later personally became acquainted with many of the aquarists discussed here. My wife and I both worked at the New York Public Library where Ida Mellen was a frequent visitor, and I particularly remember a visit in the early 1960's to the American Museum of Natural History (which I also haunted as a youngster) where my good friend Jim Atz showed me and my family a coelacanth preserved in formaldehyde in an old freezer dedicated to this purpose. My two sons and daughter, however, were more impressed with the stench of formaldehyde than with the fish! I was also fortunate to be privy to the top floor of the Museum where Myron Gordon and Klaus Kallman conducted their platyfish cancer research in a plethora of ancient aquaria under the skylights of the Museum. With all that glass it was a mystery to me how they kept that place warm in the winter, but then heat does rise and the Museum is a multi-storied building!

One of the goals I had in writing this monograph was either to verify or to refute the stories I had heard over the years to the effect that Christopher Coates

was responsible for Ida Mellen leaving the Aquarium. I now know that it was Townsend, not Coates, although neither man merits much sympathy. There are far more deserving personalities to be admired in the history of the aquarium hobby in America.

Those readers interested in a literary reference to the New York Aquarium are directed to Stuart Palmers 1931 novel, *The Penquin Pool Murder*, which featured a spinster school teacher as a crime solver - Hildegarde Withers - and her accomplice in crime detection, Inspector Piper. The novel was brought to the screen as a movie by RKO in 1932 and starred Edna May Oliver as Hildegarde and James Gleason as Piper (it airs on television occasionally and is available on DVD). The location shots of the Aquarium are excellent and while the interiors were studio recreations, they were very authentic and true to my recollections. As a result, the movie provides an excellent way to get the "feel" of the Aquarium as it was in the early 1930's. Oddly enough, the movie version of the book mirror reverses the parity of the Aquarium: what goes from left to right in the book's illustration goes from right to left in the film's sets.

The director of the museum is played very broadly as humorless and dyspeptic, and skirts the fringes of outright comedy for a character we're supposed to take much more seriously. I have always wondered what Townsend thought of this portrayal of his character and whether he had to undergo ribbing from his colleagues!

ACKNOWLEDGEMENTS

It should be acknowledged that most of what a man knows or writes is derived from other men's hard work and, for the most part, I acknowledge their contributions collectively rather than individually. Specifically, however, although my sources for this monograph were many, there are three I would especially like to mention.

Most of my information on Charles Haskins Townsend and his relationships with Hornaday, Osborn, and Grant came from William Bridges' *Gathering of Animals, An Unconventional History of the New York Zoological Society* (Harper & Row, 1974). Unfortunately, he passes over not only the importance and contributions of Mellen to the Aquarium (there are only two sentences that mention her, plus a short excerpt from an article she wrote on the plural of fish), but the controversy as well.

In the preface to his book Bridges, who at various times was publicity director and curator of publications at the Bronx zoo, writes: "I had worked alongside… Townsend and Breder… at the Aquarium." One wonders if the work consisted simply in cleaning out the tanks on weekends for, unless a conscious decision was made to cover up both her contributions and the controversy, it is difficult to explain away these omissions. But then Bridges also fails to mention the letter from Adolf Hitler to Madison Grant in which Hitler thanks Grant for writing *The Passing of the Great Race* and notes that "the book was his Bible." This raises the question of whether there was selective editing when it came to Henry Fairfield Osborn, Madison Grant, Charles B. Davenport (he was on the Aquarium committee) and others who had defects of character that would not have reflected well upon the New York Zoological Society.

Insights into the Breder-Coates years at the Aquarium came from my old friend, Dr. James W. Atz, an aquarium hobby historian of first class rank and reputation who has been a major source of inspiration for me these past forty years.

Special mention must be made with regard to the material on Ida Mellen, which was a collaborative effort with my wife, Harriet Joy Klee. Joy, as I am, is a Mellen buff and in addition to editing this monograph assisted me in data acquisition from the Mellen Papers at the New York Public Library, a daunting and time-consuming task. For this I express my appreciation and heartfelt thanks.

The New York Aquarium and Judge Crater: Sleeping With the Fishes

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, November 22, 2009)

Joseph Force Crater (1889 – date of death unknown) was a judge in New York City who suddenly disappeared on the night of August 6, 1930. He was last seen leaving a restaurant and entering a taxi. He had stated earlier that he was planning to attend a Broadway show. His disappearance became one of the most famous in American history and pop culture, and earned him the title of, "The Missingest Man in New York."

Crater was an Associate Justice of the New York Supreme Court. He had been appointed to the state bench by then-Governor Franklin D. Roosevelt just four months before his disappearance. He had been educated at Lafayette College (Class of 1910) and Columbia University.

In the summer of 1930, Judge Crater and his wife, Stella Mance Wheeler, were vacationing at their summer cabin at Belgrade Lakes, Maine. In late July, he received a telephone call but offered no information to his wife about the content of the call, other than to say that he had to return to the city "to straighten those fellows out."

The next day, he arrived at his Fifth Avenue apartment, but instead of dealing with business he made a trip to Atlantic City in the company of a showgirl. He returned to Maine on August 1, and traveled back to New York on August 3. Before making this final trip, he promised his wife he would return by her birthday, on August 9. Crater's wife stated that he was in good spirits and behaving normally when he departed for New York City. On the morning of August 6, Crater spent two hours going through his files in his courthouse chambers. He then had his assistant, Joseph Mara, cash two checks for him that amounted to U.S. $5,150 (equivalent to about $60,000 in 2006). At noon, he and Mara carried two locked briefcases to his apartment and he let Mara take the rest of the day off.

Later that evening, Crater went to a Broadway ticket agency and bought one seat for a comedy called "Dancing Partner" that was playing that night at the Belasco Theater. He then went to Billy Haas's Chophouse on West 45th Street for dinner. Here, he ate dinner with his friend, a lawyer, and his mistress, a 22- year-old showgirl called Sally Lou Ritz. The lawyer later told investigators that Crater was in a good mood that evening and gave no indication that anything was bothering him. The dinner ended a little after 9 pm, a short time after the curtain rose on the show for which Crater had bought a ticket, and the small group went outside.

Crater then waved goodbye to his friends and hailed and entered a cruising taxi on West 45th Street. What happened to him after that remains a mystery. Theo-

Joseph Force Crater

ries about his disappearance have suggested that he was murdered, that he ran off with another woman, or that he had been involved in corrupt practices that were about to be revealed.

Strangely, there was no immediate reaction to Judge Crater's disappearance. When he did not return to Maine for 10 days, his wife began making calls to their friends in New York, asking if anyone might have seen him. Only when he failed to appear for the opening of the courts on August 25 did his fellow justices become alarmed. They started a private search but failed to find any trace. The police were finally notified on September 3 and after that, the missing judge was front-page news.

The story captivated the nation and a massive investigation was launched. The official investigations started vigorously, but quickly slowed. Detectives discovered that the judge's safe deposit box had been emptied and the two briefcases that Crater and his assistant had taken to his apartment were missing. These promising leads were also quickly bogged down by the thousands of false reports coming from people claiming to have seen the missing man.

In October, a grand jury began examining the case, calling 95 witnesses and amassing 975 pages of testimony. The conclusion was that "The evidence is insufficient to warrant any expression of opinion as to whether Crater is alive or dead, or as to whether he

has absented himself voluntarily, or is the sufferer from disease in the nature of amnesia, or is the victim of crime."

None of the investigations succeeded in discovering the judge's fate or possible whereabouts, and Crater was officially declared dead "in absentia" on June 6, 1939, and his case — Missing Persons File No. 13595 — was officially closed in 1979. Sally Lou Ritz, by the way, disappeared in August or September 1930, and was never seen again.

On August 19, 2005 authorities revealed they received a letter written half a century before by Stella Ferrucci-Good. It - a handwritten letter – was in an envelope marked "Do not open until my death," found by her granddaughter, Barbara O'Brien, in a metal box in her grandmother's home. The metal box also contained yellowed clippings about Crater's disappearance, with scribbled notations in the margins. In it, the woman identified a location near West Eighth Street in Coney Island, Brooklyn, at the current site of the New York Aquarium, where she claimed the judge was buried under the boardwalk. Moreover, the letter identified Crater's killers as her husband, Robert Good, NYPD Officer Charles Burns, and Burns' brother Frank, a cab driver. Ferrucci-Good claimed that Charles Burns was one of the cops guarding the notorious Murder Inc. killer, Abe "Kid Twist" Reles when he somehow plummeted to his death from the sixth-floor window of a Coney Island hotel in 1941. Reles had become a mob informant to escape the electric Chair, testifying against a slew of Murder Inc. killers; his suspicious death plunge came just hours before he was due to rat out mob boss Albert Anastasia.

Police confirmed that five skeletal remains had been discovered at that site in the 1950s. Modern DNA techniques, unavailable in the 1950s, would have made it easy to determine whether a set of remains were Judge Crater's. However, the bones discovered were almost immediately reburied in a Potter's Field on Hart Island, New York, among hundreds (if not thousands) of other unmarked and unidentified remains, and it would now be a daunting task to find those bones among so many. Police sources also confirmed that a police officer named Charles Burns served with the NYPD from 1926 to 1946, and that he spent part of his career assigned to the 60th Precinct in Coney Island.

Ferrucci-Good was 91 when she died in April 2005. Her husband, Robert Good, a Parks Department supervisor and lifeguard, died in 1975. Crater's wife remembered his disappearance every year for the rest of her life by visiting a bar in Greenwich Village on August 6. She'd sit by herself, order two drinks and down one after saying, "Good luck Joe, wherever you are."

If the letter left behind by Ferrucci-Good is right, he's been sleeping with the fishes all these years.

Excavation of supposed grave of Judge Joseph F. Crater.

WHO INVENTED THE AQUARIUM?

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, November 17, 2012)

INTRODUCTION

Any attempt to pin down "firsts," such as "the first aquarist," is fraught with difficulties. The following is from Newman (1873):

"The birth of the aquarium is of such remote antiquity that we fail to ascertain the date with any certainty. The point at which, any vessel containing water and fishes becomes an aquarium is equally open to discussion. There is abundant reason to suppose that the Chinese and the Japanese had their fresh-water aquariums thousands of years before the Christian era; the Romans certainly had theirs; but in neither of these instances is there any evidence of their being considered, as now, a noteworthy institution; by the Romans they were established for economic purposes and nothing more."

Newman goes on to mention Pepys, who established the fact that fishes were kept in confinement at Lady Pen's in 1665, but was not aware of Guillaume Rondelet's wife, Jeanne, whom Rondelet claimed had kept a fish alive in a glass of water for three years (Klee, 2003). In 1790, Sir John Graham Dalyell (1775-1851) - who might be termed a legal consultant but one who had a keen interest in natural history - managed to keep a sea anemone alive for twenty-eight years (and numerous other marine animals for lesser periods), but only because he was wealthy enough to be able to arrange for a fresh supply of salt water to be brought round to his house every morning. This was an expensive proposition until about 1850 when the development of the railroad system facilitated access to the coasts. However, Sir John knew nothing of employing plants to evolve oxygen and so did not apply any particular principles of fish keeping.

Figure 1: Charles Robert Alexandre des Moulins (1798-1875)

THE FRESHWATER AQUARIUM SANS FISHES

Charles Robert Alexandre Des Moulins (1798-1875) was a French (Bordeaux) botanist and malacologist. He was president of la Société linnéenne de Bordeaux. Moulins named and described numerous species of snails and in turn, in recognition of his services to malacology, a number of species of mollusks were named after him, e.g., *Pisania desmoulinsi* and *Nerita desmoulinsiana*. These species included both fossil and recent, both bivalves and gastropods and were mainly non-marine. In 1831 he published his "Etudes sur les échinides."

Perhaps the earliest mention of keeping aquatic life alive in artificial containers was by Moulins in his "Note on the means of preventing the corruption in jars in order to keep aquatic animals alive" (Moulins, 1830a):

Le 25 Avril, je rapportai de la campagne une pincée de Riccia fluitans et de Lemna minor que je mis dans le bocal avec des Planorbes, des Physes et des Limnées que je voulais étudier. J'y versai en même temps l'eau que j'avais rapportée des fossés stagnans où j'avais récolté ces divers objets. Elle contenait de gros Cyclopes verts avec leurs paquets d'œufs, et une autre espèce plus

petite, blanchâtre, ainsi que des Daphnies. La température était élevée pou la saison, et l'eau, recueillie depuis plus de 24 heures, était fort sale et déjà sensiblement puante. Mon étonnement fut grand, lorsque le lendemain, je trouvai toute l'eau du bocal pure et transparente comme du cristal, et absolument sans, odeur. Je résolus de ne plus changer l'eau du tout, cette expérience m'a parfaitement réussi. Je me suis borné, lorsque l'évaporation en avait enlevé un demi-pouce ou un pouce, à y ajouter soit de l'eau propre, soit de l'eau de ruisseau ou d'étang que je rapportais de mes excursions. Je me suis procuré un bocal plus grand où; j'ai versé tout le contenu du petit; là, la touffe de Riccia a triplé de volume; les lentilles d'eau ont pullulé dans la même proportion, et les détritus qui proviennent de leur décomposition successive forment au fond du bocal une sorte de vase très-fine et peu abondante qui suffît pourtant à la demeure des animaux qui ne vivent pas habituellement en pleine eau. Il est donc hors de doute que c'est à la végétation vigoureuse de ces plantes flottantes que je dois la conservation de la transparence, de la pureté et de la salubrité du liquide.

"L'expérience que je viens de relater nous conduit à une remarque générale et bien importante : sans les plantes flottantes que la bonté de la divine Providence a répandues avec tant de profusion sur les eaux stagnantes, les habitant des contrées marécageuses périraient dévorés par les fièvres épidémiques. Mais le carbone dégagé par la décomposition des tissus organiques est absorbé par ces végétaux aquatiques, employé à leur nutrition, et ils fournissent en échange une exhalation abondante d'air respirable et salubre.

What follows is my translation:

On April 25, I brought from the countryside a pinch of Riccia fluitans and Lemna minor that I put in the jar with the Planorbis and Physa snails I wanted to study. I used the same water from the stagnant ditches where I collected these objects. It contained large Green Cyclops with their packages of eggs, another smaller species (whitish) and Daphnia. The temperature was somewhat high because of the season, and the water, collected over 24 hours, was very dirty and already stank significantly. My astonishment was great when the next day I found the whole jar of water pure and clear as crystal, and absolutely free of odor. I decided not to change the water at all and my experience has been very successful. I restrained myself when evaporation removed half an inch or an inch of water, or to add clean water or water from a stream or pond that I brought from my excursions. I bought a larger jar and poured the entire contents into it from the smaller one; the clump of Riccia has tripled, the duckweed has multiplied in the same proportion and the detritus from their successive decomposition formed at the bottom of the jar was of a very fine mud and that will do, however, for the abode of animals that do not usually live in open water. There is no doubt that it

is the vigorous vegetation of these floating plants I have been able to conserve the transparency, purity and safety of the liquid.

The experience I have just described leads us to a general remark and a very important one: without floating plants that the goodness of Divine Providence has showered so profusely on stagnant water, the inhabitants of marshes would perish, devoured by an epidemic of fever. But the carbon released by the decomposition of organic tissue is absorbed by these aquatic plants and used for their nutrition, and in exchange they provide abundant and healthy oxygen for breathing.

Moulins also set out the type of vessel to be used, i.e., a shape where the animals are not distorted by the glass, i.e., cylindrical with a flat bottom and thin enough so the colors of the animals can be observed. He recommended canning glass available from pharmacies.

In another article (Moulins 1830b) Moulins wrote, "Notice sur la ponte de la Planaire lacteé (Instructions on spawning the Milky Planar)" on breeding *Planaria lactea*, a non-parasitic flatworm, he states: **Enfin, le 26 Avril, j'ai mis dans le bocal un paquet de *Riccia fluitans* et de *Lemna minor* qui, jointes aux conferves , entretiennent par leur végétation la pureté de l'eau** (**Finally, on April 26, I placed in the jar a bundle of Riccia fluitans and Lemna minor which, together with conferva, maintain the purity of the water**).

It should be noted, however, that Moulins' experiments were with univalve and bivalve snails, microscopic crustaceans (such as planaria, daphnia and cyclops) and leeches. He mostly used floating plants such as *Riccia* and *Lemna.* He also used *Myriophyllum* but let it float.

THE FRESHWATER AQUARIUM WITH FISHES

In short, Nathaniel Bagshaw Ward (1791-1868) was an English doctor who popularized a case for growing and transporting plants which was called the Wardian case, the forerunner of the modern aquarium tank. (A much more detailed biography can be found in Klee, 2003.) A case for the development of the freshwater aquarium by Nathaniel Bagshaw Ward (and also for the marine aquarium by Anna Thynne) was made by Ward's son, Stephen H. Ward (Ward, 1859):

"Now, these counterbalancing actions of animal and vegetable life which are ever going on in the world without, and which are among the greatest marvels in the economy of Nature, may be realised most completely in one of these cases. Mr. Ward felt this, and accordingly in 1841 established in his largest fern-house, in a capacious earthenware vessel given to him by Mr. Alfred White, an aquarium for fish and plants. In this vessel, which contained twenty gallons of water and which he surrounded with rock-work raised several feet above its margin, he placed gold and silver fish in Company with several aquatic plants, viz. Valisneria spiralis, Pontederia crassipes, Pistia stratiotes, and Papyrus elegans.

Figure 2: Nathaniel Bagshaw Ward (1791-1868)

In this miniature lake, the water of which was never changed, but kept in a constantly pure state by the action of the associated plants, the animals lived in a healthy condition for many years. This aquarium or vivarium soon gave the hint to Mr. Bowerbank who procured a large glass-jar, in which he placed stickle-backs, minnows, and snails, with plants of *Valisneria*, and covered in the jar with a piece of glass. Mr. Mitchell of the Zoological Society states that the jar just noticed, gave him the suggestion for the interesting vivaria at the Gardens. Aquaria in open bottles would seem to have been ornaments of the philosopher's study nearly a hundred years ago, as a coloured illustration in a work by Leder-müller, published in 1763 will prove. All that Mr. Ward claims credit for, is the having introduced them into his closed cases, and depended for success entirely upon the counterbalancing actions of animal and vegetable life."

The problem here is that Ward did not publish his findings. All of his publications had to do with growing plants in "closely glazed cases," as the expression of the day went; fish were never mentioned, not even in his 1842 book. Although fish were mentioned in his 1852 edition, Warington had published his findings two years previously. I have no doubt that what his son said was true, but publishing priority is a generally accepted and important factor in deciding who gets the credit. After all, if you discover something but don't tell anyone about it, it does no one any good at all.

William Stimson is another one who is credited with the invention of the freshwater aquarium (James, 1858):

In our own country William Stimson, the collector and curator of the aquaria in the Smithsonian Institution at Washington, without any previous knowledge of Dr. Johnson's experiments in England, had, as early as the year 1849, made seven or eight small aquaria, which were perfectly successful; inasmuch as he kept some of them in a healthy condition for several months without change of water. He published no account of his success, not knowing that it was a subject which was just beginning to awaken attention in England, and fated eventually to excite such universal interest. To him may safely be assigned the credit of having made the first systematic attempt at constructing an aquavivarium, although in all the works before us that honor is given to Mr. Robert Warrington, who in 1850 communicated to the Chemical Society of London a paper On the Adjustments of the Relation between the Animal and Vegetable Kingdoms.

The difficulty here is the same as just mentioned for Nathaniel Bagshaw Ward.

The man who did meet the criterion, however, was Robert Warington. Warington (1807-1867), a chemist, started a movement in 1839 to found the Chemical Society of London (from 1848 the Chemical Society) and was elected honorary secretary. He was appointed chemical operator to the Society of Apothecaries, a position which he held to within a year of his death. The primary purpose of the Society was to exercise control over the practice of what we should nowadays recognize as the greater part of the twin professions of medicine and pharmacy, and as such was responsible for the standardization and prevention of adulteration of drugs.

Figure 3: William Stimson (1832-1872).

In 1846 he took part in the formation of the Cavendish Society, of which he was secretary for three years, and from this time onwards he had many engagements as a chemical expert in legal cases. In the year 1844 he began a series of investigations into the adulteration of tea, and gave evidence at the parliamentary inquiry on adulteration in 1855. He was also one of the founders of the Royal College of Chemistry. In 1851 he revised the *Translation of the Pharmacopeia of the Royal College of Physicians* into English, left unfinished by Richard Phillips. In 1854 Warington was appointed chemical referee by four of the metropolitan gas companies, and held this post for seven years. In 1864 he was elected fellow of the Royal Society and the Society's catalogue contains a list of forty-seven papers written by him. In this same year, Warington was also engaged in the construction of the *British Pharmacopeia.*

In 1849 he began his investigations on aquaria and the means necessary to prevent the water therein from becoming stagnant. His position in the Society of Apothecaries was a full time occupation and Warington's interest in the aquarium perforce had to be an avocation. He wrote several papers (his work actually was the origin of our modern aquaria) and in 1857 delivered a lecture at the Royal Institution on this subject.

Robert Warington is generally acknowledged as being the first to maintain a balanced freshwater aquarium and the following is the article that establishes the claim (Warington, 1850):

Observations on the adjustment of the relations between the Animal and Vegetable Kingdoms, by which the vital functions of both are permanently maintained.—
This communication will consist of a detail of an experimental investigation, which has been carried on for nearly the last twelve months, and which appears to illustrate, in a marked degree, that beautiful and wonderful provision which we see everywhere displayed throughout the animal and vegetable kingdoms, whereby their continued existence and stability are so admirably sustained, and by which they are made mutually to subserve, each for the other's nutriment, and even for its indispensable wants and vital existence. The experiment has reference to the healthy life of fish pre-served in a limited and confined portion of water. It was commenced in May, 1849, and the subjects chosen were two small gold-fish. These were placed in a large glass receiver of about twelve gallons capacity, having a cover of thin muslin stretched over a stout copper wire, bent into a circle, placed over its mouth, so as to exclude, as much as possible, the sooty dust of the London atmosphere, without, at the same time, impeding the free passage of the atmosphere air.

This receiver was about half filled with ordinary spring water, and supplied at the bottom with sand and mud, to-gether with loose stones of larger size of limestone tufa, from the neighbourhood of Matlock, and sandstone; these were arranged so that the fish could get below them, if they wished so to do. At the same time that the fish were placed in this miniature pond, if I may so term it, a small plant of the Vallisneria spiralis was introduced, its roots being inserted in the mud and sand, and covered by one of the loose stones, so as to retain the plant in

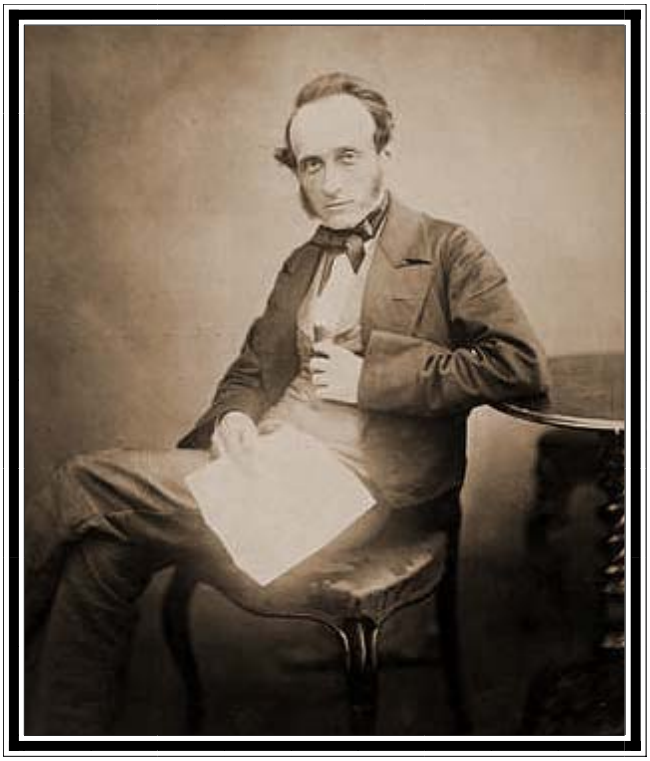

Figure 4: Robert Warington (1807-1867)

its position. The Valisneria spiralis is one of those delicate aquatic plants generally selected by the microscopist for the exhibition of the circula-tion of the sap in plants. It throws out an abundance of long, wiry, strap-like leaves, of about a quarter of an inch in breadth, and from one to three feet in length; these leaves, when the sun shines on them, evolve a continued stream of oxygen gas, which rises in a current of minute bubbles, particularly from any part of the leaf which may have received an injury.

The materials being thus arranged, all appeared to go on well for a short time, until circumstances occurred which indicated that another and very material agent was required to perfect the adjustment, and which, from my not having thought of it at the time of commencing the experiment, had not been provided against. The circumstances I allude to arose from the internal decay of the leaves of the Vallisneria, which became yellow from having lost their vitality, and began to decompose; this, by accumulation, rendered the water turbid, and caused the growth of mucus, or green, slimy matter on the surface of the water, and on the sides of the receiver. If this had been allowed to increase, I conceive that the healthy life of the fish must have suffered, and probably their vital functions have been destroyed. The removal of these decaying leaves from the water, therefore, became a point of permanent importance to the success of the experiment. To effect this, I had recourse to a very useful little scavenger, whose beneficial functions have been too much overlooked in the economy of animal life,—I mean the water-snail, whose natural food is the very green, slimy growth, or mucus and decaying vegetable matter, which threatened to destroy the object which was wished to be obtained. Five or six of these creatures— the Limnaea stagnalis—were consequently introduced, and, by their continued and rapid locomotion and extraordinary voracity, soon removed the cause of interference, and restored the whole to a healthy state, thus perfecting the balance between the animal and vegetable inhabitants, and enabling both to perform their vital functions with health and energy.

So luxuriant was the growth of the Vallisneria under these circumstances, that, by the autumn, the one solitary plant that had been originally in-troduced, had thrown out myriads of off-shoots and suckers, thus multiplying to the extent of upwards of thirty fine, strong plants; and these threw up their long, spiral, flowering stems in all directions, so that, at one time, more than forty blossoms were counted lying on the surface of the water. The fish have been lively, bright in colour, and appear very healthy, and the snails also—judging from the enormous quantity of gelatinous masses of eggs which they have deposited on all parts of the receiver, as well as on the fragments of stone—appear to thrive wonderfully, and, besides their functions in sustaining the perfect adjustment of the series, afford a large quantity of food to the fish in the form of the young snails, which are devoured as soon as they exhibit signs of vitality and locomotion, and before the shell has become hardened. Thus we have an admirable balance sustained between the animal and vegetable kingdoms, and that in a liquid element.

The fish, in its respiration, consumes the oxygen held in solution by the water as atmospheric air; furnishes carbonic acid; feeds on the insects and young snails; and excretes material well adapted as a rich food to the plant, and well fitted for its luxuriant growth. The plant, by its respiration, consumes the carbonic acid produced by the fish, appropriating the carbon to the construction of its tissues and fibre, and liberates the oxygen in its gaseous state to sustain the healthy functions of the animal life, at the same time that it feeds on the rejected matter, which has fulfilled its purposes in the nourishment of

the fish and snail, and preserves the water constantly in a clear and healthy condition, —while the slimy snail, finding its proper nutriment in the decomposing vegetable matter and minute confervoid growth, prevents their accumulation by removing them from the field, and, by its vital powers, converts what would otherwise act as poison, into a rich and fruitful nutriment, again to constitute a pabulum for the vegetable growth, while it also acts the important part of a purveyor to its finny neighbours.— Robert Warinqton.

The paper was subsequently published in the *The Zoologist* (Vol. 8, pp. 2868-2870, 1850), the *Quarterly Journal of the Chemical Society of London* (Vol. 3, pp. 52-54, 1851), and also in the *Literary Gazette*, *Gardeners Chronicle*, and *Bicks Floristry*. Talk about literary overkill! In some of these papers the following addendum appeared: **Since the reading of this paper, twenty-eight strong plants of Vallisneria have been weeded out of the glass receiver as being more than sufficient for the purpose required. — R.W.**

Warrington also added additional material in the *The Garden Companion, and Florists' Guide* a few years later that showed he was actively pursuing an interest in the marine aquarium as well (Warington, 1852):

At present I am attempting the same kind of arrangement with a confined portion of sea water, employing some of the green sea weeds as the vegetable members of the circle, and the common winkle or whelk to represent the water snails.

In addition to technical journals, Warington published his material in many of the popular periodicals of the day, especially those involved in gardening. However, when pressed to give to the world a little manual of instructions for amateurs, he always stated as a reason for non-compliance with the request, that the book market was overcrowded already with the **"worthless compilations of many scribblers on the subject."**

THE MARINE AQUARUM SANS FISHES

Although there was really never any disagreement that Warington was the first with regard to freshwater, the marine aquarium is quite a different case. Ward's name is also mentioned in this case: "As early as June, 1849, Mr. Ward stated, at a meeting of the British Association at Oxford, that he had succeeded, not only in growing sea-weeds in sea-water, but in sea-water artificially made. This must certainly be regarded as the first stop towards realizing the marine Aquavivarium. [Lankester, 1856, p. 10-11]." However, priority is established only by being published.

Another contender for the title of inventor of the marine aquarium is Félix Dujardin (1802-1860), a French biologist born in Tours. He is mostly remembered for his research on protozoans and other invertebrates. In 1840 he was appointed professor of geology and mineralogy at the University of Toulouse, and during the following year was a professor of zoology and botany at Rennes. Later in his career he became a member of the French Académie des sciences. Concerning his educational background, Dujardin was largely self-taught.

His studies of the microscopic animal life frequently found in decaying organic materials led him in 1834

Figure 5: Edwin Lankester (1814-1874)

to propose a new group of one-celled animals that he called Rhizopoda. He named the seemingly formless life substance that oozed outward through openings in certain shells *sarcode*; later it became known as protoplasm. This work led him in 1835 to argue against Christian Gottfried Ehrenberg's theory that microscopic organisms have the same organs as higher animals. Dujardin also studied jellyfish, corals, and sea stars; his study of flatworms laid the foundation for the later development of the study of parasites and parasitism.

In an article on the l'Aquarium du Jardin d'Acclimatation, the director, Etienne Rufz de Lavison, had this to say (Rufz de Lavison, 1863):

M. de Quatrefages m'a fait observer que j'avais fait tort à un savant français, Dujardin, à qui doit être rapportée l'application première du principe fondamental des aquariums; je reproduis textuellement la note de M. de Quatrefages:

Dès 1838, M. Dujardin faisait des voyages sur nos côtes dans l'intérêt de ses éludes zo-

Figure 6: Félix Dujardin (1802-1860)

ologiques. Il rapportait tous les ans à Paris de nombreux flacons contenant des animaux vivant dans l'eau de la mer, et pour entretenir la pureté de cette eau, il plaçait dans chaque flacon quelques frondes d'Ulva lactuca. Nommé professeur à Toulouse, il y transporta son musée ou son aquarium, qui s'accrut de nombreux flacons rapportés de Cette. Appelé plus tard à la chaire de zoologie de Rennes, il se fit suivre de sa collection, qui s'accrut encore d'une foule d'espèces recueillies sur les côtes de la Bretagne. C'est dans un de ces flacons qu'un des premiers, il constata l'organisation des Méduses. J'ai eu le plaisir d'observer moi-même chez mon ancien collègue une de ces Méduses développées en captivité.

The Jean Louis Armand de Quatrefages de Bréau (1810-1892) mentioned above was a well-known French naturalist. My translation is as follows:

M. de Quatrefages pointed out that I had wronged a French scientist, Dujardin, who must be credited with the first discovery of the fundamental principle of the aquarium; I reproduce verbatim, M. de Quatrefages's note:

'In 1838, Mr. Dujardin was traveling on our shores in the interest of his zoological studies. He brought back many jars of marine animals to Paris every year, and to maintain the purity of the water, he placed in each jar a few fronds of *Ulva lactuca*. Appointed professor at Toulouse, he moved his museum or aquarium, and his **collection grew. Later called to the chair of zoology at Rennes, his collection followed, which included even a greater variety of species collected on the coast of Brittany. Here, in one of these jars, is where he established his first collection of jellyfish. I had the pleasure of personally watching my former colleague growing one of these jellyfish in captivity.'**

The problem here - once again - is in priority of publication.

Anna Thynne (1806-1866) is frequently cited as the inventor of the marine aquarium. She was the wife of the Reverend Lord John Thynne, sub-dean of Westminster Abby and spent many years in the respecta-

ble surroundings of her London drawing room, studying the intricate forms and intimate sex lives of stony corals called "madrepores." Initially, she had supplies of seawater brought from the coast, which she - and later her maid - aerated by hand, pouring it repeatedly between vessels to stave off fouling of the water. In 1849, she tentatively tried adding some seaweed to her tanks, expecting them to help enrich the water with oxygen much like the captive atmosphere inside Nathaniel Ward's fern cases. In doing so, Thynne kept her corals alive for an unprecedented three years, along with clusters of other marine animals and plants.

In addition to what he had to say about his father and the freshwater aquarium, Stephen Ward (*loc. cit*) also had this to say about Anna Thynne and the marine aquarium:

The individual to whom is due the merit of having introduced marine vivaria into London is Mrs. Thynne. Having procured some living madrepores when at Torquay in the autumn of 1846, she placed them in some sea-water in a bottle covered with a bladder, and brought them safely to town. They were then transferred to two glass bowls, the sea-water being kept aerated by being daily poured backwards and forwards, and being, moreover, periodically renewed by a fresh supply from the coast. In the spring of 1847, Mrs. Thynne sent for some pieces of rock, shells, &c. to which living sea-weeds were attached, and subsequently depended upon the action of these for the purification of the water.

In addition to Stephen Ward, Thynne's biographer, Rebecca Stott (2003), also credits her as being the inventor of the marine aquarium. In addition to Dayell's experiments, Stott mentions those of Robert Grant (1793-1874), one of the foremost biologists of the early 19th century, Edward Forbes (1815-1854), a distinguished British naturalist and the young Charles Darwin (who had been a student of Grant's), all of whom had kept sundry marine creatures alive for several days at a time in the 1820s and 30s. However, as Stott points out:

But such experiments… depended upon either constant changing of the seawater or a tiring process of aeration. For these students of zoology the Firth of Förth was never more than half an hour's walk away. She (Thynne) was in London and, even with her riches and domestic servants, shipping seawater into the capital seemed a frivolous waste of money. So she had been forced to discover other means of establishing vitality in her glass tanks.

However, Stott overlooks the fact that Thynne did aerate her water. From Thynne's own account (Thynne, 1859):

"My next consideration was as to the possibility of keeping them alive, and this I accomplished in the following manner. I placed them in glass bowls, holding about three pints of water each, which I changed every other day; and as I could not have a continual supply sufficient for such a demand, I thought of having it aerated by pouring it backwards and forwards through a small watering-pot, before an open window, for half or three-quarters of an hour, between each time of using it. This was doubtless a fatiguing process; but I had a little maid, who, besides being anxious to oblige me, thought it rather an amusement; so that as the service was cheerfully performed, it was also done well; and the exer-

Figure 7: Anna Thynne (1806-1866) with her two children, Selina and Emily

Figure 8: George Johnston (1798-1855)

tion was diminished by her standing for only ten minutes or a quarter of an hour at one time.

From this time I regularly placed sea-weed in my glass bowls; but, as I was afraid I might not keep the exact balance required, I still had the water refreshed by aeration.

Stott also apparently was unfamiliar with the works of George Johnston (1798-1855), a Scottish medical doctor and naturalist. Amid his many arduous professional duties, he cultivated natural history with an enthusiasm and a success which rendered the place of his residence "one of the most classic localities in Great Britain." Apart from numerous papers contributed to the *Edinburgh Philosophical Journal* and other scientific periodicals, he published two works of first-rate importance: "History of British Zoophytes" (2d ed., 2 vols. 8vo, London, 1847) and "History of British Sponges and Lithophytes" (8vo, 1842). In 1850 his "Introduction to Conchology" appeared with an abundance of illustrations and later he published "The Natural History of the Eastern Borders" (vol. I., "Botany," 8vo, 1854). He was engaged at the time of his death upon a complete work on British annelids. He is considered one of the most accomplished contributors to the literature of natural history, and was one of the founders of the Ray society.

The following is taken from his "History of British Sponges and Lithophytes" (Johnston, 1842):

Was there a need of adding any additional proof of the vegetability of the Corallines, an experiment now in progress before me would seem to supply it. It is now eight weeks ago since I placed in a small glass jar, containing about six ounces of pure sea-water, a tuft of the living *Corallina officinalis*, to which were attached two or three minute confervae, and the very young frond of a green Ulva, while numerous Rissoae, several little mussels and annelids, and a star-fish, were crawling amid the branches. The jar was placed on a table, and was seldom disturbed, though occasionally looked at; and at the end of four weeks, the water was found to be still pure, the mollusea and other animals all alive and active, the confervae had grown perceptibly, and the coralline itself had thrown out some new shoots, and several additional articulations. Eight weeks have now elapsed since the experiment was begun,—the water has remained unchanged,—yet the coralline is growing, and apparently has lost none of its vitality, but the animals have sensibly decreased in numbers, though many of them continue to be active, and show no dislike to their situation. What can be more conclusive? I need not say that if any animal, or even a sponge, had been so confined, the water would long before this time have been deprived of its oxygen, would have become corrupt and ammoniacal, and poisonous to the life of every living thing.

It is interesting to note that Johnston used no aeration nor did he change the water during this time. One may argue that Johnston's experiment lasted only eight weeks whereas Thynne kept her madrepores for three years, but it is irrelevant here since precedence in publication once again is the deciding factor. Johnston, therefore, was the originator of the marine aquarium sans fishes. Note, however, that being first doesn't always mean being best or the

most important. Johnston's material was a short footnote consisting of 247 words; Thynne's was an article consisting of 12 pages. Her account was much more detailed and added significantly more to our knowledge of the marine aquarium of the times.

THE DRED STOTT DERISION

Stott writes: **Other individuals, however, made bolder claims for their work. And indeed Anna's description of her visitors as 'professed naturalists' may reveal a degree of suspicion or resentment on her part about their ethics. In a culture in which many naturalists saw a distinction between the-orists and mere collectors or experimenters, her visitors would have not have had any conscience about using her experiment for their own profits or to provide evidence for their own theories.**

I can certainly appreciate Thynne's situation and what she and other women of the time had to endure. Another woman for whom I have the greatest respect was Helen Beatrice Potter, best known for her children's books that featured animal characters such as Peter Rabbit. At the time, the only way to record microscopic images was by painting them, so Potter made numerous drawings of fungi, and as the result of her observations, she was widely respected throughout England as an expert mycologist. Potter was one of the first to suggest that lichens were a symbiotic relationship between fungi and algae. She studied the life cycles of fungi extensively and in 1897, her paper on the germination of spores was presented to the Linnean Society by her uncle as women were then barred from attending meetings. Similarly, the Royal Society also refused to publish at least one of her technical papers. In 1997, 100 years after she submitted her paper, the Linnean Society held a meeting in her honor and issued a posthumous official apology to Potter for the way she had been treated.

Two individuals Stott singles out as possible visitors with such ulterior motives are Robert Warington (which she misspells as "Warrington") and Philip Henry Gosse. In point of fact, however, there is no evidence whatsoever that either of these gentlemen ever visited Anna Thynne. She is particularly hard on the first:

The chemical operator of the Society of Apothecaries, Warrington began a series of experiments with the chem-ical properties of aquatic vitality in 1849. Why 1849? Was he one of the visitors to Anna's Westminster Abbey drawing-room that spring? Was this visit the motivation for his subsequent experiments?

This is, in my opinion, tantamount to a character assassination of this most distinguished gentleman. In her quest to "prove" that a woman was the inventor of the marine aquarium, some men got trampled.

THE MARINE AQUARUM WITH FISHES

In spite of Stott's attempt to show that it was Thynne rather than Warington who should get the credit for the first marine aquarium, Warington gets the credit here, also. The following is the paper that did the job (Warington, 1853):

In the published notices of my experiments of 1849, to maintain the balance between the animal and vegetable organisms in a confined and limited portion of water, the fact was demonstrated, that, in consequence of the natural decay of the vegetation, its subsequent decomposition and the mucus-growth to which it gave rise, this balance could only be sustained for a very short period, but, if another member were introduced, which would feed upon the decaying vegetation and thus prevent the accumu-

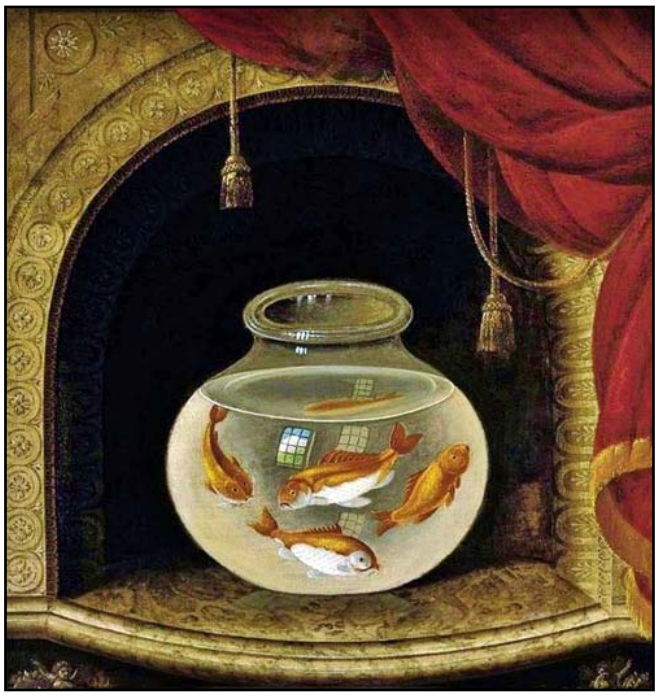
lation of these destructive products—a function most admirably performed by the various species of water-snail—such balance was capable of being continuously maintained without the slightest difficulty and I may add, that the experimental proof of this has now been carried on, in a small tank in the heart of London, for the last four years and a half, without any change or disturbance of the water; the loss which takes place by evaporation being made up with rain or distilled water, so as to avoid any great increase of the mineral ingredients originally present. It follows then, as a natural deduction, from the successful demonstration of these premises, that the same balance should be capable of being established, under analogous circumstances, in sea water. And in a paper published in January 1852 (*Gardeners' Botanical Magazine and Garden Companion*, Jan. 1852) I stated that I was, at that time, attempting the same kind of arrangement with a confined portion of sea water, employing some of the green sea-weeds for the vegetable member of the circle, and the common periwinkle as the representative of the water-snail.'

The sea water with which the experiments I am about to detail were conducted, was obtained through the medium of one of the oyster-boats at the Billingsgate fish-market, and was taken from the middle of the English Channel.

My first object was to ascertain the kind of sea-weed best fitted, under ordinary circumstances, for keeping the water clear and sweet, and in a sufficiently oxygenated state to sustain ani-mal life. And here opinions were at variance, for one naturalist friend whom I consulted, advised me to employ the Rhodosperms; another stated that it was impossible to make the red weeds answer the purpose, as he had tried them, and strongly recom-mended the olive or brown-coloured Algae; while, again, others thought that I should be more successful with those which had in theory first suggested themselves to my own mind, namely the Chlorosperms. After making numerous unsuccessful expe-riments with both the brown and the red varieties of Algae, I was fully convinced that, under ordinary circumstances, the green weeds were the best adapted for the purpose.

This point having been practically ascertained, and some good pieces of the *Enteromorpha* and *Ulva latissima* in a healthy state, attached to nodules of flint or chalk, having been procured from the shore near Broadstairs, several living animal subjects were introduced together with the periwinkle. Everything progressed satisfactorily, and these all continued in a healthy and lively condition.

My first trials were conducted in one of the small tanks which had been used for fresh water; but as it was necessary, during the unsuccessful experiments with the brown and red seaweeds, to agitate and aerate the water, which had been rendered foul from the quantity of mucus or gelatinous matter generated during the decay of their fronds, until the whole had become oxidized, and the water rendered clear and fitted for another experiment, it was, therefore, for greater convenience, removed into a shallow earthen pan and covered with a large glass shade to protect the surface of the water, as much as possible, from the dust and soot of the London atmosphere, and at the same time impede the evaporation. In this vessel then I had succeeded perfectly in keeping a large number



of beautiful living specimens in a healthy condition up to the close of 1852. I therefore gave instructions for the making of a small tank as a more permanent reservoir, and one more adapted for carrying on my observations and investigations on the economy and habits of the inhabitants.

From the experience I had obtained in my experiments with the freshwater tank, I was induced to modify slightly the construction of this vessel; thus, at the back, or part towards the light, the framing was filled with slate in the same way as the ends and bottom; for I had found that the glass, originally employed, very soon became covered with a confervoid growth which had an unpleasing appearance to the eye, and in consequence of which I had been obliged to paint the glass on the exterior to prevent this growth from increasing to too great an extent. It was also an unnatural mode of illumination, as all the light should pass through the surface of the water. The front towards the room and the observer was constructed of plate-glass, the whole being set in a stout framework of zinc, and cemented with what is known under the name of Scott's cement, and which I have found to answer for the purpose most admi-rably. Within this tank were arranged several large pieces of rock-work, thrown into an arched form, and other fragments were cemented in places against the slate at the back and ends, and at parts along the water-line, so that the creatures could hide themselves at pleasure; a short beach of pebbles was also constructed in order that shallow water could be resorted to if desired. The whole tank was covered with a light glass shade to keep out the dust and retard evaporation.

With the sea water obtained in January 1852, I have been working without cessation up to the present time, agitating and aerating when it became foul during the unsuccessful experiments on the sea-weeds, but since then it has been rarely ever disturbed; the loss which takes place from evaporation being made up, as before stated, with rain or distilled water.

For a considerable period, after commencing these experiments, I was much troubled to obtain living subjects in a healthy condition, but having alluded to this, and the success of my investigations, in a short notice appended to a paper published in the 'Annals of Natural History' for October 1852, my friend Mr. P. H. Gosse, who was then sojourning at Ilfracombe for his health, offered in the kindest manner possible to supply me with materials, and from that period he has always most heartily responded to my wants. It must not be imagined for a moment that the beautiful creatures I have thus received have been all preserved alive or always quite healthy. In experimental investi-gations this would be unreasonable to expect, as the very fact of experimenting implies a disturbance of the then state of things. Besides which, from want of a sufficient knowledge of natural history, from want of forethought and experience and other causes, I have lost many very fine specimens; and as the detail of these losses may prevent the occurrence of the like annoyances to others, I shall venture to occupy your time for a short period with their history.

My greatest loss arose from too great an anxiety to transfer the collection I had preserved in a healthy condition to the end of December 1852 into the new tank. As soon as it arrived from the maker's I lost no time in introducing my numerous family to their new abode, and dearly I paid for my precipitancy, for on the next morning I found many of my most beautiful spe-cimens dead; thus I lost two fine Holothurias (*H. Pentactes),* a small freckled Goby (*Gobius minutus*), a beautiful little Pipe-fish (*Syngnathus lumbriciformis*), and several others, and on opening the door of the case the cause of this mortality was at once evident,—an iridescent film of oily matter

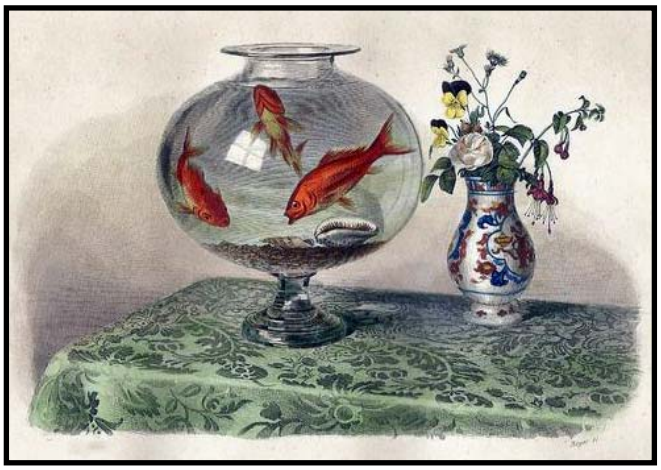
was floating on the surface of the water, arising from the paint with which the angular joints and edges of the small tank had been coloured not having become sufficiently hardened.

Another source of loss arises from the several creatures attacking and devouring each other, and it therefore becomes a point of great importance—and highly necessary to be carefully ob-served, where their preservation is an object—to ascertain what varieties may be safely associated in the same tank; as, for in-stance, I have found that the Shrimps and Prawns attack, and very soon devour, all the larger varieties of Corallines and Polyps, Sabellae, Serpulae, Rock-borers, Cirrhipeds, some of the Annelids, many Bivalve and Univalve Mollusks that are unprotected by an operculum, or have no power of closing their valves. The instances which have come under my own immediate observation have been the destruction of the *Pholas dactylus, Saxicava rugosa, Cypraea Europaea,* and several specimens of Sabellae, Serpulae, Coryne sessilis and many others.

The common Crab (*Cancer Maenas)* is likewise a most destructive agent; and the tribe of rock-fish, the Blennies, Gobies, &c. are also most voracious, devouring all the varieties of Cirrhipeds, Corallines, Polyps, Annelids, &c.; they will also attack the shrimps and prawns, and even seize upon the horns of the periwinkle, which they bite. If the mollusks do not keep a very firm hold of the rock or tank sides, they are rapidly turned over by these fish on their backs and lie helplessly exposed to their attacks. It is doubtless their seeking food of this kind which causes these little fish to be so generally found in the shallow rock-pools of the coast. In consequence of these ravenous propensities I have been obliged to establish several small tanks and imitation rock-pools, so as to separate these various depredators from each other : thus in one I have varieties of *Actiniae,* Shrimps, Nudibranchs, Holothurias, and some Annelids; in a second the rock-fish, as the Blennies, Gobies, Cottus, with Crabs and Actinia; in a third Corallines, Annelids, Polyps, Rock-borers, Sabellae, Serpulse, Holothurias, and *Actiniae.*

Another curious instance of loss I may detail which has quite recently occurred, and which may prove interesting; it was in a small rock-pool containing Blennies, Gobies, Crabs, &c. I had procured two live oysters for the purpose of feeding my numerous small fry in these vivaria, and one of these having proved ample for the purpose of one meal, the other was placed on the sandy bottom; on the second day after this the oyster was observed to have opened the valves of hid shell to a great extent, which were afterwards seen closed, but a small *Gobius niger,* in-habiting the pool, could nowhere be seen. The day after this the oyster was opened for the general feeding, when, lo! within the shell was found the unfortunate *Gobius*, quite dead. Whether this little gentleman had been attracted within the trap by curiosity or the ciliary motion of the oyster, it is impossible with certainty to say; but that he must have seized on some sensitive part of the oyster is more than probable, so as to have caused such a rapid closing of the valves of the shell as could entrap so active a burglar.

Another important point is the gravity of the sea water; this should be very carefully regulated, for it must be borne in mind that many of the marine creatures are supplied by a per-meation of water through their tissues or over their delicate and beautiful organs. The specific gravity should not rise above 1.026 at 60° Fahr., and a small hydrometer should be at short periods introduced to ascertain that this point is not exceeded, particularly during the hot months of summer. The reduction to this gravity can be readily effected by the addition of rain or distilled water. Many of the



creatures will of themselves afford indications of this increase of density; some of the *Actiniae* will remain closed and become coated with a white slimy covering within which they remain for a length of time, and if the specific gravity of the water be lowered this is very soon ruptured by their expansion, thrown off, and the tentacula become soon extended.

"All putrescent matter or excess of food or rejecta of the *Actiniae* should be carefully removed from the water, as the noxious gaseous compounds generated by the decay of such matters appear to diffuse themselves rapidly through the water, act as a virulent poison, and speedily destroy the vitality of the occupants. Thus many beautiful subjects were lost in a few hours from the introduction, into a small glass jar, of a large Pecten shell, encrusted with corallines, which had become loaded with putrescent matter by partial submersion in a foul muddy bottom.

"Great care should also be taken in moving the *Actiniae* that the foot or sucking disc with which it attaches itself to the rocks, stones, or mud, be not injured, as, when this occurs, they rarely survive, but roll about without attaching themselves, and gradually waste away and die.

"With these exceptions then, everything has gone on very satisfactorily, care being always taken not to overload the water with too large a proportion of animal life for the vegetation to balance, as, whenever this has been inadvertently attempted, the water has soon become foul, and the whole contents of the tank, both animal and vegetable, have rapidly suffered, and it has required some time before the water could be restored to its former healthy condition.

"In one of the numbers of the 'Zoologist' of last year, I stated that besides the *Ulvae, Enteromorpha* and *Cladophora,* I had found the *Zostera marina* a very useful plant for oxygenating the sea water; but this observation has reference only to the case of a tank supplied with a ground where its roots will find a sufficiency of food for its growth, as in a clear shingle or sand it soon de-cays ; and it should be associated with such animals as delight in a ground of this nature, as many of the Annelids, Crabs, burrowing Shrimps, &c. There are several interesting observations which have been made from time to time connected with this subject, which I hope to lay before the natural-history world as soon as I can find leisure time for the purpose.

"Since the reading of this paper at Hull I have received a Blenny of larger size, being about inches in length, and although it has become so tame that it will allow itself to be touched by the hand and takes its food from the fingers, yet its destructive propensities are so great, that it very soon killed four small Crabs; and to save three others, of rather a larger size, I have been obliged to remove the Blenny to a rock-pool in asso-ciation with his own species and a few *Actiniae.* The only refuge the poor Crabs had was to bury themselves in the sand, and whenever they attempted to move out of their refuge they were immediately pounced upon and only escaped by burrowing rapidly again."

It was a squeaker, however, since Gosse lost the competition by only a few months. The following is Gosse's book, "A Naturalist's Rambles on the Devonshire Coast" (Gosse, 1853):

"It is a curious circumstance that experiments exactly parallel to these, founded on the same

Figure 9: Philip Henry Gosse (1810-1888)

principles, have been simultaneously prosecuted with the same results by another gentleman, whose name is well known in the scientific world. Mr. Robert Warington of Apothecaries' Hall has now (Dec. 1852) at his residence in London a marine aquarium, with living Algae and Sea-anemones in a healthy condition. I find, on comparing notes, that Mr. Warington has precedence of me in instituting these experiments; but the particulars that I have above detailed of my own success were fully recorded before I had the slightest knowledge that the thought of such a project had ever crossed the mind of any person but myself."

Although briefly acknowledging Warington's experiments and priority, Gosse described in great detail his own marine aquarium experiments, even though they were unsuccessful and Warington's were. As time went on, Gosse believed that he should have been credited with the invention of the marine aquarium (Gosse, Edmund, 1890):

There was no sort of rivalry between these earnest and amiable investigators, but a little later on, when the aquarium had become a fashionable thing, Philip Gosse was accustomed to say that if it was needful to dispute about an invention which was virtually simultaneous, it might be said that Warington had invented the vivarium (*AJK: i.e., the freshwater aquarium*) and he the marine aquarium."

Nonetheless, the following, taken from Humphreys, 1857: pp. 27-28, pretty sums up who gets the credit for the "invention" of both the freshwater and marine aquarium:
"These successful experiments, both in freshwater and marine Aquaria, assign to Mr. Warington, beyond dispute, the credit of being the originator, or inventor, if the term may be so used, of these charming additions to our conservatories, corridors, and even living-rooms, to which they are certainly a much more attractive and instructive addition than the old globe of blank water, with its pair of goldfish swimming around and round in ceaseless gyrations, tiresome to behold, in the vain hope of escaping from their glaring and inconvenient prison; in which they would inevitably have perished very shortly but for the daily changes of water, which, previous to our knowledge of air-emitting plants and their use, was absolutely necessary."

MUSINGS ON "WHO INVENTED THE AQUARIUM?

Before one attempts to pin down a "first," one must devise a set of criteria. In Great Britain in the early 1850's the de facto definition of an aquarium in the sense of the whole concept, not just the container, was a vessel containing water and plants, plus aquatic animals (excluding, of course, mammals and water fowl) in which the water was not aerated nor changed. Note that fish were not necessarily included. Implicit in this definition was that basis for the aquarium be the relationship between plants and the animals, i.e., that plants absorbed the carbon dioxide that the aquatic animals generated whilst the animals absorbed the oxygen that the plants generated.

Another part of the requirement for "first" was priority of publication, a criterion required in the 1800's and also present-day. "Previous to the year 1850, many experiments had been made in London of keeping sticklebacks, gold fish, and other animals in jars containing Vallisneria. I find, from some of my

own notes, that I had sticklebacks in a jar containing Vallisneria and Water Starwort, in 1849 [Lankester, p. 11, 1856];" However, none of these would vie for "first" because they were not published.

To simplify the analysis, I have considered four categories for "firsts" in this monograph: freshwater aquarium sans fishes, freshwater aquarium with fishes, marine aquarium without fishes **and marine** aquarium with fishes. Using these criteria, Charles des Moulins - a man mostly overlooked in aquarium hobby history - comes in first (1830) for the freshwater aquarium sans fishes, Warington (1850) for the freshwater aquarium with fishes, Johnston (1842) for the marine aquarium sans fishes and Warington for the marine aquarium with fishes.

If, however, we add another criterion, that of the impact on the aquarium hobby in the Nineteenth Century, then Warington remains in the first place for the freshwater aquarium, with Gosse and Warington in a close tie for the marine aquarium title. It is difficult to break this tie, since Warington published first whereas Gosse had the greater impact.

In today's hobby, neither plants, aeration nor water changes are a part of our definition of the aquarium. Plastic plants abound, water is frequently changed and aeration (either directly or through filtration) is almost a given. The only criterion is that there is at least one fish in the container; thus a Betta in a jar qualifies as an aquarium today. Even in Great Britain in the 1870's the aeration criterion was modified or removed. Lloyd (1872), for example, relaxed the aeration requirement but maintained the necessity for plants: **The water must be kept not only in a pure and respirable condition by its absorption of atmospheric air at its surface, which absorption may or may not be increased by putting the water in motion in any convenient manner, but this purity must be assisted by the presence of vegetation growing in it…** Hughes (1876) relaxed the aeration criterion even more: **The word Aquarium is, therefore, in use popularly as signifying a collection of aquatic animals maintained in health by plants, or by artificial means supplying their place…**"

In 1846, Jean Jacques Marie Cyprien Victor Coste published his paper, "Nidification des épinoches et des épinochettes," i.e., "The nest building of sticklebacks" (Coste, 1846). (Coste, by the way, was never recognized in the literature with a forename, and he never gave the secret away! He was mostly referred to as M. Coste, the French abbreviation for Monsieur; in American publications he was frequently given the initial P, but sometimes B and C.)
Coste (1807-1873) studied medicine at the Faculty of Medicine of Montpellier and, after graduating, he taught anatomy at the Ecole Pratique de Paris from 1836 and embryology at the Collège de France from 1844. He devoted himself to the study of the natural sciences, notably of embryogeny. His work attracted the attention of learned men, and the Academy of Sciences awarded him a gold medal in 1834. He became a member of the Academy in 1851and later was a recipient of the Cross of the Legion of Honor.

During the later years of his life Coste was much occupied with the art of increasing fish populations via artificial insemination. The art of pisciculture, although discovered in Germany in the previous century, was not yet applied. In 1851 Coste designed

Figure 10:
Jean Jacques Marie Cyprien Victor Coste (1807-1873)

and built a model piscine establishment at Huningue that, in two years, supplied 600,000 salmon and trout for the seeding of the Rhone. In 1852, he was appointed by Napoleon III to head a mission to study the production of natural oyster beds and is generally accredited with saving the oyster fisheries of the country. Close to the Emperor and the Empress Eugenie, to whom he was her personal physician, he was appointed by the Emperor in 1862 as Inspector General of the rivers and coast fisheries of France. Using a circular tank a little over 6-1/2 feet in diameter and 13 inches high, Coste placed in it a large number of male and female sticklebacks. The tank contained plants, but were mostly intended as material for the nest-building. Because of its large size and physical configuration, it did not need aeration or a change of water. In this tank Coste observed the fish court, lay eggs, care for and rear their young. Clearly this satisfies the criteria for the first freshwater aquarium with fish.

Other than impact, (Coste's paper had non), what then is the difference between Warington's and Coste's experiments with regard to who is first? The difference is in intent. Coste was not concerned with showing that fish can survive without aeration of water changes by utilizing plants, i.e., the "balanced aquarium" principle; he was only interested in describing the breeding behavior of sticklebacks. Technically Coste had the priority, but not the spirit of the criteria. However, using today's relaxed criteria, Coste is inventor of the freshwater aquarium with fishes (and, by the way, because of his paper, the stickleback might therefore be considered as the first fish - excepting perhaps the goldfish - bred in an aquarium).

We are all familiar with the following discourse from "Alice in Wonderland":

ALICE: I don't know what you mean by "glory."
HUMPTY: Of course you don't — till I tell you. I meant "there's a nice knock-down argument for you!"
ALICE: But "glory" doesn't mean "a nice knock-down argument."
HUMPTY: When I use a word, it means just what I choose it to mean — neither more nor less.
ALICE: The question is, whether you can make words mean so many different things.
HUMPTY: The question is, "which is to be master" — that's all.

We consider this to be a bit of nonsense and smile, but if Humpty Dumpty had answered, **"…what are your criteria— that's all,"** it would have been regarded as a sage remark, indeed!

THE ARTIFICIAL SEAWATER CONTROVERSY

William H. Brock (Brock, 1991) published a paper involving a controversy over the composition of artificial seawater between two of the best knows aquarists of the day, Robert Warington and Philip H. Gosse (an abridged version can also be found in Klee, 2003).

Gosse had written a paper (Gosse, 1854b) describing his experiments with an artificial seawater formula based on analysis of seawater in the English Channel near Brighton by a chemist in Brighton who sold the salts of evaporated seawater for medicinal use (Schweitzer, 1839). Shortly afterwards, Warington wrote a paper (Warington, 1854a) pointing out a number of errors Gosse had made in converting Schweitzer's formula to his own. Although Brock thought that the differences between Warington's and Gosse's formulae "were not all that significant," I disagree. The table below is a comparison between the two and there are considerable differences.

Gosse admitted the errors but defended his formula, citing the omission of the three components as being unimportant and an attempt to simplify things for the average aquarist, a somewhat puzzling argument since he kept the potassium bromide but omitted the calcium sulfate which was twice as important. His main argument, however, was that it worked, citing his own experiments with his formula and those of William Alford Lloyd (Lloyd, 1855) who also had success with it. However, neither of these gentlemen had ever used fish in their experiments, so although it was certainly a success for the marine aquarium sans fishes, it was not a successful formula for the marine aquarium *in toto*. In discussing the use of Gosse's artificial sea-water, Humphreys [1857: p. 111] stated: "The artificial salt water has been found sufficient for Zoophytes, but not for fish and other of the higher class of marine animals, except for a certain given time."

However, it not the chemical side of this controversy that I wish to explore here, but the basic reason for the dissention between the once amiable friends. The following is Gosse's introduction to his paper (submitted on June 9, 1854):

The inconvenience, delay and expense attendant upon the procuring of sea-water, from the coast or from the ocean, I had long ago felt to be a great difficulty in the way of a general adoption of the Marine Aquarium. Even in London it is an awkward and precarious matter; how much more in inland towns and country places, where it must always prove not only a hindrance, but to the many an insuperable objection. The thought had occurred to me, that, as the constituents of sea-water are known, it might be practicable to manufacture it; since all that seemed necessary was to bring together the salts in proper proportion, and add pure water till the solution was of the proper specific gravity. *Several scientific friends to whom I mentioned my thoughts, expressed their doubts of the possibility of the manufacture; and one or two went so far as to say that it had been tried, but that it had been found not to answer; that though it looked like sea-water, tasted, smelt, like the right thing, yet it would not support animal life.* Still, I could not help saying, with the lawyers, 'If not, why not?' Experientia docet. I determined to try the matter for myself.

I have italicized the part that was the cause of the dissention between Warington and Gosse. There is no doubt that this was included in the introduction to assure readers that he, Gosse, had no assistance from any of the scientific community. This, however, is not true since Gosse visited Warington in 1854 on two occasions at Apothecaries Hall, on January 16th

TABLE I
THE SCHWEITZER, GOSSE AND LAURENS FORMULAS COMPARED
The numbers are lbs./ 100 lbs. of water (= 10 Imperial gallons).

COMPONENT	(1) SCHWEITZER	(2) GOSSE	% INCREASE (1) OVER (2)	(3) LAURENS
Sodium chloride	2.7060	2.1875	24%	2.722
Potassium chloride	0.0766	0.0563	36%	0.001
Magnesium chloride	0.3666	0.2813	30%	0.614
Magnesium bromide	0.0029	-	-	-
Calcium sulphate	0.1407	-	-	0.015
Magnesium sulphate	0.2296	0.1563	47%	0.702
Calcium carbonate	0.0030	-	-	0.009
Magnesium carbonate	-	-	-	0.011

and again on January 21st to discuss, among other things, the feasibility of using artificial seawater. One can imagine Warington's surprise when he read Gosse's introduction. Accordingly, he replied thusly (Warington, 1854a), submitted on November 1, 1854:

In the 'Annals and Magazine of Natural History' for July last, you published a short communication from Mr. Gosse, on the artificial formation of sea water, and having lately had my attention especially directed to this paper by a friend who wished to put the formula given into practice, I was surprised at the difference in the proportions of the ingredients as compared with what I had myself employed in the course of 1853, more par-ticularly from the circumstance, that when Mr. Gosse called upon me in January last, and consulted me on the feasibility of the plan, I told him that there could be no difficulty in the matter, as I had made and had then in use several small quantities artificially produced, and that all that was required was that a good analysis should be taken as the basis for deducing the proportions, and at the same time referred him to the source from which I myself had worked, namely Dr. E. Schweitzer's analysis of the water of the English Channel taken off Brighton. Now, as numerous parties have been inquiring respecting this subject, and the erroneous formula has been copied into other journals, it may prevent much annoyance as well as disappointment if this matter is set right.

Gosse's reply (Gosse, 1854c) submitted on December 20, 1854 was shorter:

If Mr. Warington supposes that I obtained from him one atom of information previously unknown to me, on the subject of making seawater from its constituent salts, he is most thoroughly mistaken. He is no less wrong in saying that I "consulted" him; since I merely mentioned what was on my mind in familiar conversation. With this, however, the public are of course not concerned, and I shall say no more on that head.

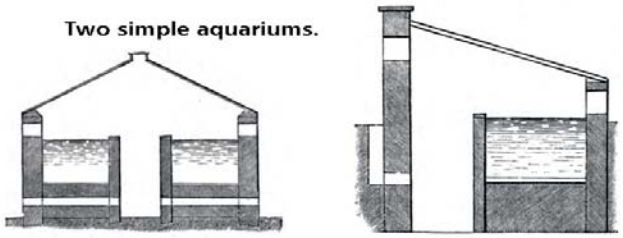
Not all believed him. The following appeared in the *Leisure Hour*, January 25, 1855:

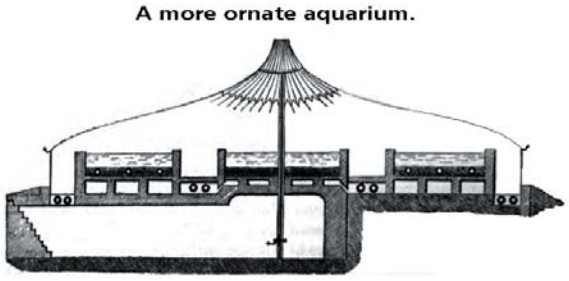
It is now some months ago that Mr. Gosse, the gentleman on whom the care of the marine vivarium belonging to the Zoological Society devolves, and to whom the public are indebted for some most interesting works on natural philosophy, published a formula for the generation of sea-water artificially, and having supplied some marine pets with the liquid, found that they thrived in it well. The analysis of sea-water chosen by Mr. Gosse was that made by Dr. Schweitzer, the formula of which it appears was suggested to that gentleman by Mr. Warington of Apothecaries Hall."

Brock may be putting the cart before the horse when he opines that the reason the relationship between the two men soured was because Warington was jealous of Gosse's success in which he had made the major scientific breakthrough. Since it was Gosse who precipitated the controversy, it was more likely because Gosse was jealous of Warington's standing in the scientific community in spite of his overwhelmingly popular successes with "A Naturalist's Rambles on the Devonshire Coast" and "The Aquarium: an unveiling of the wonders of the deep sea." Perhaps we can agree that both men were to blame.

In any event, Warington and Gosse never communicated again. However, the seawater contro-

versy was never mentioned in Edmund Gosse's biography of his father, so it was apparently not the sort of bitter rife that characterized the famous fossil-finding competition known as the "Bone Wars" between Edward Drinker Cope and Othniel Charles Marsh.





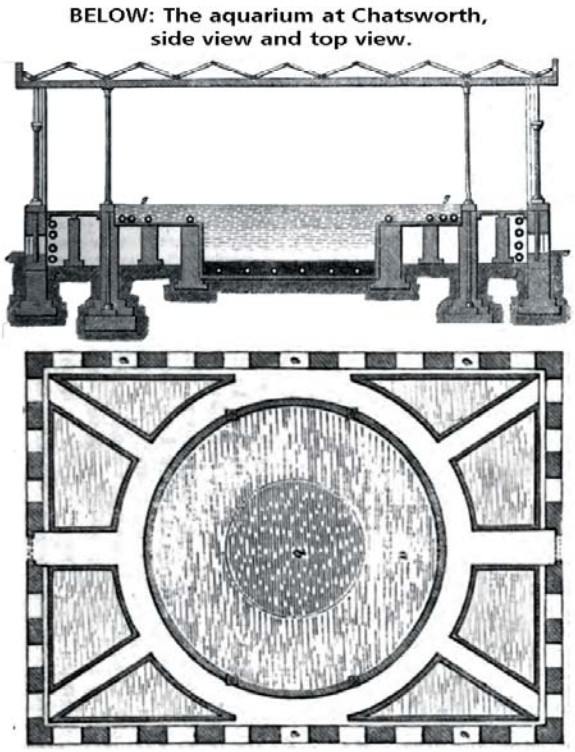


Figure 11: Examples of the gardeners "aquarium."

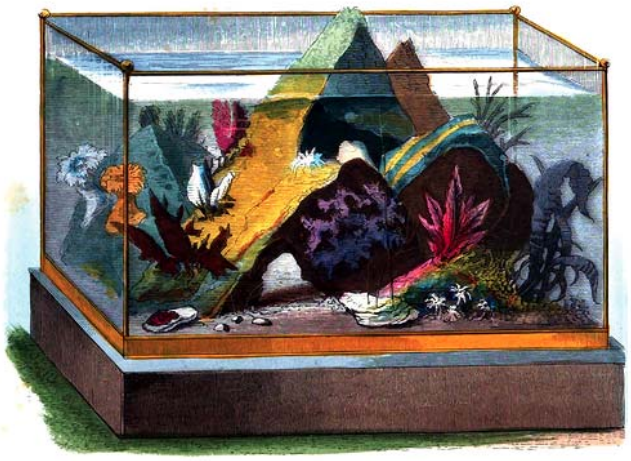
Finally ,it should be noted that Gosse's artificial sea water was not a success: from Hibberd, 1856: "But artificial water is quite unsuited for animal life of any kind, until it has been brought into condition by means of growing weeds for eight or ten days, and for Crustaceans, Starfishes, and Fishes proper, it is not suitable till it has been in use for many months, and even then some species lose their health in it, and at last perish, and from Hughes, 1874: "Much has been said about artificial sea-water, but my experience is not very favourable to it - I found it crude and harsh in its effects on the anemones, they refused to expand, and shrank up and died."

WHO WAS THE FIRST AQUARIST TO USE THE WORD "AQUARIUM"?

"Aquarium" existed in the Vulgar Latin but in Roman times it meant a watering place, in particular a drinking place for cattle. As the world entered into the Nineteenth Century, however, gardeners used the term as a place for growing aquatic plants. In essence they were greenhouses, either stand-alones or attached to a house, containing tanks (gardeners called them "cisterns") that held the water and plants. Some were simple structures but others were exceedingly complex and ornate as shown in Figure 11.

John Claudius Loudon (1783-1843) was born in Lanarkshire, Scotland to a respectable farmer and, as he was growing up, developed a practical knowledge of

Figure 12: John Claudius Loudon (1783-1843)



plants and farming. As a young man, Loudon studied chemistry, botany and agriculture at the University of Edinburgh and in 1815, he was elected a corresponding member of the Royal Swedish Academy of Sciences. Loudon was a prolific horticultural and landscape design writer and his first published work was An Encyclopædia of Gardening (Loudon, 1824), an immediate success. In his book Loudon suggested that fish might be added:

It is almost needless to add, that exotic aquatic fowls and fishes might be kept in such an aquarium, and either of the sea or fresh water rivers, according as salt water or fresh was used.

In a later gardening book (M'Intosh, 1853) the author quotes from the *Liverpool Chronicle* that chronicles the miniaturization and exportation of the aquarium to the home:

Few, perhaps, are aware of the great beauty which the tropical aquatic tribes present under good cultivation. They are not well adapted for small houses, but look best in houses having a vestibule, or circular centre. They may be made in various forms, according to the taste of the proprietor: if in a square or oblong vestibule, the aquarium should be of the same shape; if in a circular house, or part of the house, the form may be varied and much ornamented; a vase-shaped basin, circular cistern, or any other form suitable to the style of the building: a jet-de-eau in the centre is a great improvement. The interior must be of various depths, to suit the plants of various sizes, for which reason steps are usually formed from the circumference to the centre, the water being thus made shallower at the edge, to suit the smaller plants. Upon these steps or shelves pebbles and soil are laid, in which the roots are planted; and gold and silver fishes may be made to add to the interest of this group.

It is odd that M'Intosh made no mention of the "Parlour Aquarium," a term that entered the vocabulary of gardening magazines and other journals the previous year, but once again there is the suggestion that gardeners might combine fishes with the plants in their aquaria.

The earliest reference I have found to the word aquarium in the sense of a fish tank is in the article by Warington, "The Aquatic Plant Case, or Parlour Aquarium (*The Garden Companion, and Florists' Guide*, January, 1852). If we define the aquarium as a vessel consisting of at least one transparent side in which water-dwelling plants and animals are kept, then here is perhaps the first reference to the word "aquarium" in the literature. I say "perhaps" since one can never be sure that an earlier reference won't be discovered.

Although it is likely that either Arthur Henfrey, Thomas Moore or William P. Ayres (the regular authors of the publication) was responsible for the title of the article, on page 7 Warington himself uses the term, and since his submission to the journal preceded the use of the term in the title, Warington must be given credit for its first recorded use.

The Garden Companion, and Florists' Guide was preceded by *The Gardeners' Magazine of Botany, Horticulture, Floriculture, and Natural Science*, edited by Thomas Moore and William P. Ayres (Arthur Henley was listed as an Assistant). This magazine, however, was dedicated more to the professional than to the amateur gardener and so was experiencing subscription problems, hence the change of name and favoring of a different audience. I thought it wise, therefore, to examine *The Gardeners' Magazine of Botany, Horticulture, Floriculture, and Natural Science* for 1851 to see if the word aquarium had been used. Indeed it had, in an article by Mr. George

Lawson titled “Contributions to the Aquarium.” However, its use was in the traditional gardener’s sense, not in the sense of a fish tank.

In another article, this one titled “Visits to Remarkable Gardens,” the author (Thomas Moore) visited the suburban residence of Nathaniel Bagshaw Ward at Clapham. The Wardian case was mentioned in this article, and included quotes from Ward himself. The author ends with the following:

We have left ourselves but little space to notice the many interesting plants crowded into Mr. Ward's small house. Passion-flowers, Manettias, Aristolochias, and such like, cover the pillars and festoon the roof, from which also Orchids are suspended. The raised rocky mounds on either side give pasturage to various small Palms, Ferns, Bamboos, Musas, Cannas, Colocasias, Clerodendrons, Achimenes, and hosts of smaller plants. The Cuphea ignea here grew, and flowered from year's end to year's end, until it became too large for the space. Fuchsias, too, which grew luxuriantly and flowered profusely, became too large, and had to be rooted out. A tank at the end affords accommodation for gold fish, and some of the smaller aquatic plants. The whole forms a beautiful miniature tropical forest scene.

It seems safe, therefore, to conclude that Warington was the first to use the word “aquarium” in the sense of a vessel to hold fish.

In any event, the modifier “parlour” is easily understood. If gardeners are going to bring the aquarium into their homes, they need a new descriptor to distinguish it from the external greenhouse concept and what better one than “parlour,” since that is the best room in the house (indeed, the parlour was often colloquially called just that) and where parlour aquaria were usually sited (although if there was room, as mentioned previously, the entryway was also popular). In any event, it is during the remainder of the year 1852 that we find an increasing use of the term (Chambers, 1852):

An interesting companion to the Wardian Case has lately been presented in the Aquatic Plant Case, or Parlour Aquarium, due to the ingenuity of Mr. Warington, and which has for its object, as its name indicates, the cultivation of aquatic or water , plants. It may be described as a combination of the Wardian Case and the gold-fish globe, the object being to illustrate the mutual dependence of animal and vegetable life.
The Parlour Aquarium affords valuable, we might say invaluable, facilities to the naturalist in the prosecution of his researches. The botanist can now conveniently watch the development of aquatic plants under conditions not unnatural, throughout the entire period of their existence, from their germination to the production of flowers and the perfection of seeds; and we are in hopes that much of the obscurity that invests many aquatic vegetables will in consequence be cleared up. The zoologist is perhaps even more indebted to the invention. The habits, not only of the fishes, but of the mollusca, can be accurately studied under natural conditions, and many important facts of their history ascertained and illustrated. The water-beetles and other aquatic insects will also come in for a share of attention.

Figure 13: This is the replica in the Natural History Museum of Vienna of Warington’s early setup showing the globular bowl he first used.

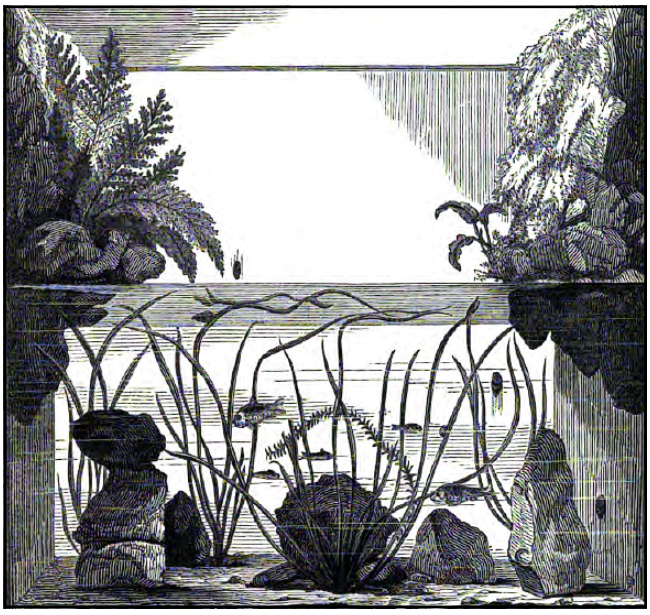


Figure 14: Warington's sketch of his idea of what became to be known as the "Warington Case" and later the "Warington Aquarium."

Warington uses the word "aquarium" with an interesting modifier (Warington, 1852, p.7):

Since the reading of my paper before the Chemical Society, on March 4, 1850, respecting the Miniature Aquarium (Quarterly Journal of the Chemical Society, iii 62), I have continued the investigations, introducing other water plants, and also three other varieties of water snail. But the principal alteration has been the construction of a better form of vessel for holding the water, as I found that the globular form of the glass receiver, produced a distortion in the vision of the fish, besides being very inconvenient for observation (see Figure 13). I have therefore adopted the form of vessel, of which a sketch is appended, having flat surfaces of plate-glass at the back and front, the bottom and ends being formed of slate, and supplied with a loose plate of glass at the top to keep out dust and soot (Figure 14 To render the whole more ornamental, as it was to stand in a sitting room, some pieces of tufa, or sandstone, were attached to the ends by means of Roman cement, so as to form ledges and slopes rising from the water line, on which mosses and ferns, such as luxuriate in an atmosphere loaded with moisture, could be grown. These materials are set in a stout angular zinc framework, and connected with a mixture of white-lead ground in oil, to which about an equal quantity of red-lead is added. This arrangement I have found to answer all my expectations, as it has been going on most flourishingly since January 1851. The plants consist chiefly of Hymenophyllum tunbridgense, and H. Wilsoni, Trichomanes speciosum, Blechnum boreale, Adiantum Capillus-Veneris, and several mosses. The whole of the interior can be viewed with the greatest ease, so that the natural habits of its living inhabitants can be watched and accurately noted in every particular.

Note that Warington was also one who needed to modify the gardener's "aquarium." Using the term "miniature aquarium" made sense since Warington was comparing the parlour aquarium to its forebears, in general rather large constructions. Warington followed the use of the word "aquarium" in print by using the plural in his 1854 article, "Memoranda of observations made in small aquaria..." (Warington, 1854b).

Although Warington provided the editors with a drawing showing the basic idea of his aquarium, in another article in this issue the editors show the result of a commission they gave to A. Aglio, a teacher of drawing and civic engineering:

We have already given a view of the parlour aquarium, contrived by Mr. Warington, and which may well bear his name; and have also explained in his own words the principles on which success depends. These principles, it must be obvious, admit of various modes of application so that our former illustration is to be regarded rather as an exemplification of the principle than as a model. We now subjoin another design for an aquarium, or Warington case, with the view to indicate, to some extent, the variety which may be attained, by combining this with the Wardian case. It will be obvious that this combination will afford scope for a much greater variety of form than would have been brought out by confining them chiefly to the growth of aquatic plants, and this amount of

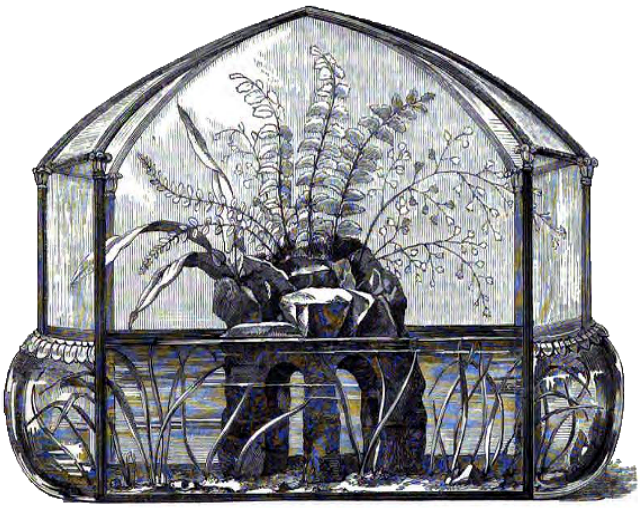

Figure 15: The "Warington's Plant Case" designed by A. Aglio

variety will afford opportunity for the display of a greater amount of ornamentation.

The design now submitted (Figure 15), from the pencil of A. Aglio, Esq., jun., is intended to consist of an ornamental zinc frame-work, a slate bottom, and the whole of the sides to consist of glass, used in plates, as large as the fittings will allow. The front and back will thus each consist of a single plate, and the absence of frame-work of every kind will admit of the whole interior being viewed without obstruction. The convex ends of the basin portion are also intended to be of glass formed into the exact shape and size required.

The mass of imitation rock in the centre must be formed expressly for the reception of the plants, good drainage being an essential feature, so that the soil may not become soddened. The whole is supposed to be supported by an appropriate and elegant stand.

It is interesting to mention that the Zoological Society intend to fit up a case on Mr. Warington's principle in their garden in the Regent's Park.

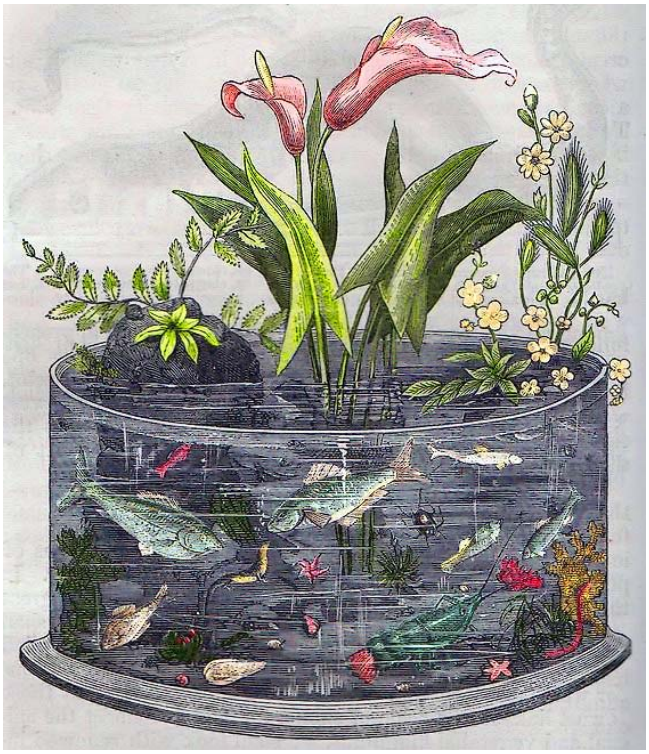
As I have shown, although the term aquarium was used for the vessel to hold aquatic animals before Gosse's book "The Aquarium" (Gosse, 1854a) appeared on the scene, there was no general agreement on the matter. The moment the book was published, however, it became the name that everyone used. Although Gosse had discussed the true origin of the term, the public thought he was its architect; thus it might be said that he invented it de facto. Indeed, it forced the Regent's Park Aquarium, established a year earlier, to discard aqua-vivarium in favor of aquarium. Many authors (but not the London Zoo itself) claim that the word aquarium originated there, but this clearly is not true.

It may seem strange that the origin of the word "aquarium" rests with the gardening community. However, gardeners needed a word that denoted a container for aquatic plants and if the Romans could use "aquarium" for a vessel to supply water to cattle, why not use it for a vessel to supply water to aquatic plants? As Gosse argued (Gosse, 1854a), "The term had already been in use among the botanists, to designate the tanks in which aquatic plants were reared; and the employment of the same term for our tanks is not forbidden by the character of the service to which they are put, since this is not an alteration, but only an extension. The growth of aquatic plants is still a most important and pleasing feature of our pursuit, and the addition of aquatic animals does not at all detract from the appropriateness of the appellation." Gosse had it right.

EPILOGUE

As David Allen writes in his *The Naturalist in Britain, a Social History* (1976),

Gosse was already well known for his immensely successful book, The Ocean, published in 1843. Ten years later he now repeated his success with A Naturalist's Rambles on the Devonshire Coast, in which he described the marine aquarium and forecast that it would soon be in mass-production for the parlour. A great rush of books promptly followed - and a general advance on the beaches by a large section of the British middle classes. The aquarium, almost overnight, turned into a national craze. Ladies of fashion, it is credibly recorded, had palatial plate-glass tanks erected in their drawing-rooms; the odd corners of most of the newspapers were



filled with notes for the would-be aquarist; a multitude of shops opened for the single purpose of supplying aquaria and their contents.

Then, at length, the enthusiasms faded. Nine out often aquaria were thrown out or abandoned; many of the shops folded up their shutters; 'to all appearances,' in the words of the Rev. J. G. Wood, 'the aquarium fever had run its course, never again to recur, like hundreds of similar epidemics.'

An amusing alternate explanation of the hobby's decline comes to us from France (Kete, 1995):

Although the introduction of tropical fish into fin-de-siécle Europe and American permanently reinvigorated interest in aquarium keeping - the aquarium still has a place in Western culture - its precipitous decline by around 1880 elicited comment. In France, *La Grande Encyclopédie* explained in 1886, medical warnings about pernicious miasmas accounted for this decline. It was '…above all after the doctors had suggested that effluvia released by evaporation could well produce intermittent fevers" that aquarium keeping fell into disfavor.'

The saltwater phase of the hobby laid dormant until the years after World War II when it was rescued by technology. The freshwater hobby, however, soldiered on and slowly grew over the next 175 years. I think that any one of the pioneers mentioned in this monograph would be absolutely astounded and amazed by the world-wide aquarium hobby as it exists today.

Darwin, Jenyns, and the Chanchito

By Albert J. Klee, Ph.D.

(Buntbarsche Bulletin, No. 223, pp. 13-21, August 2004)

In the June 2004 issue of Modern Aquarium (Greater City Aquarium Society—New York), Claudia Dickinson wrote about the Chanchito. The Chanchito is probably the first of our aquarium hobby cichlids, having been imported into Germany in 1894 and into this country in 1895. In the course of preparing the material, Claudia and I had an exchange of e-mails concerning the author of the species, Leonard Jenyns. The Jenyns name is fairly well known to those aquarists interested in species authorship since he also described Corydoras paleatus, the ten-spotted livebearer (Cnesterodon decemmaculatus), and Galaxia maculatus (the spotted Galaxia, one of the rainbowfishes). In addition, the genus, Jenynsia (Anablepidae), was named after him.

So, who was Leonard Jenyns? A little research uncovered some absorbing facts and provoked some fascinating questions about Charles Darwin and what might have been, all because of an article about a cichlid!

Leonard Jenyns (1800-1893) was the youngest son of the Rev. George Leonard Jenyns of Bottisham Hall, Cambridgeshire. Jenyns was related through his mother's family to Dr. William Wollaston, a famous English chemist and physicist who, among other things, discovered two new metals, palladium and rhodium. (Another link to well-known names was that Jenyns' mother had her portrait painted by Gainsborough.)

By 1812, encouraged by his great uncle, the Rev. Leonard Chappelow, he took up the study of natural history and in 1813 he departed for Eton. There he read Gilbert White's "Natural History of Selborne," copying it out and memorizing most of it by heart. White's lifestyle and methods Jenyns later took for his own. In those days the only model to whom field naturalists could turn for inspiration was Gilbert White and those who are familiar with Lynn Barber's "The Heyday of Natural History" or David Elliston Allen's "The Naturalist in Britain, A Social History," will appreciate White's importance in the early decades of the nineteenth century.

In 1818 Jenyns entered St. John's College, Cambridge and during his second year his interest in natural history came to the attention of John Stevens Henslow (1796-1861), later to become a famous botanist of the nineteenth century, as well as a distinguished teacher. Henslow and Jenyns worked together on various natural history pursuits until Henslow's death. The two were extremely close, Henslow marrying Jenyns' sister Harriet in 1823. Henslow's relevance to this story will be made clear a bit later.

Jenyns took his degree in 1822, became a Fellow of the Linnaean Society and of the Cambridge Philosophical Society and, with Henslow, set up the latter's Museum. In May 1823 he was ordained a Deacon and in 1824 he was ordained a Priest. In this same year he published a "Scientific Journal Book" for the making of Meteorological and other observations, and in 1825 he proceeded to his M.A. degree and read his first paper on the "Ornithology of Cambridgeshire" to the Cambridge Philosophical Society.

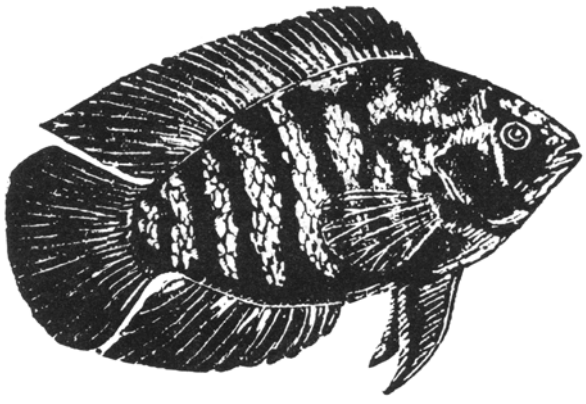

Figure 1: The image of the Chanchito that appeared in the April 1895 issue of Mulertt's *The Aquarium*.

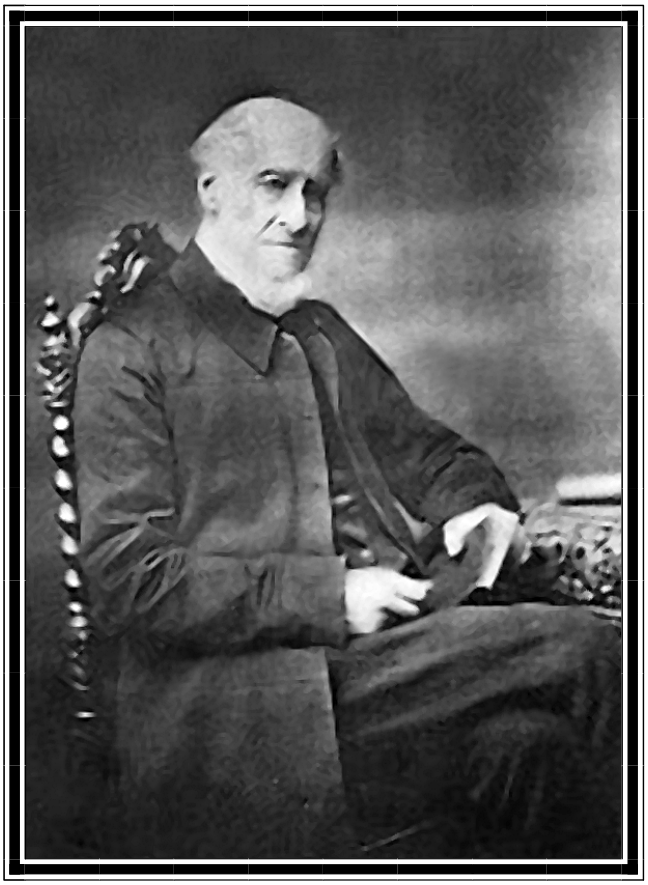

Figure 2: The Rev. Leonard Jenyns (1800-1893), British naturalist and author of the fish volumes of "The zoology of the voyage of H. M. S. Beagle, under the command of Captain Fitzroy, R. N., during the years 1832 to 1836."

In December 1827 he became the Vicar of Swaffham Bulbeck. However, this did not slow down his scientific output. In 1828 he read a paper to the Linnaean Society on "Two British Species of Plecotus" and a year later declined a Zoological Professorship being contemplated at Cambridge. In 1829 his publications included "The Common Bat of Pennant," and "On Incisor Teeth of Rodenta." In 1831 he published "On a Peculiar Parasitical Mite found on Slugs," and a paper on squids, i.e., "On the British Species of Cyclas and Pisidium." He also found time that year to read a series of lectures on Ornithology to the Cambridge Philosophical Society. It is clear, therefore that, although a clergyman, Jenyns was also a widely respected naturalist by the time the HMS Beagle was set to sail at the end of 1831.

For the next forty years Jenyns published widely in the scientific literature. Jenyns, by the way, was a supporter of Darwin's "Origin of Species" (published in 1859) and, for a clergyman at the time, this was both courageous and risky. (In 186o Darwin wrote to Asa Gray, "Several clergymen go far with me. Rev. L. Jenyns, a very good naturalist. Henslow will go a very little way with me, and is not shocked with me.")

In July 1871 Jenyns was left the property of a cousin of his father, Francis Blomefield, but to inherit he had to assume the name of Blomefield. At the time the estate was worth more than £7000 (big bucks in those days!) and it came with 140 acres in Norfolk. Jenyns continued to publish scientific papers under the Blomefield name up until a year before his death. By 1891 he had suffered bronchial attacks and gout but was able to rally enough to give two lectures, "Records of a Rookery" and "Remarks on the Distribution and Movements of British Animals and Plants." He remarked at the time, "Perhaps I am the only scientific man in England who ever gave lectures in his ninety-second year!"

Although this answers the question of who was the mysterious "Jenyns, L." noted as the describer of some of our best-known aquarium fishes, this is only part of the story. In Jenyns' diary entry for 1831 he writes, "This year I had the offer of accompanying Capt. Fitzroy, as Naturalist, in the Beagle, on his voyage to survey the coasts of S. America, afterwards going round the globe:—declined the appointment which was afterwards given to Charles Darwin Esq. of Xts' College Cambridge."

In July of 1831, Fitzroy had proposed to Captain Francis Beaufort the idea of a naturalist accompanying him on his expedition. If the name sounds familiar, Beaufort was the one who developed the "Beaufort Scale," a means by

which one could judge the speed of the wind visually, and Fitzroy made wide use of it during the Beagle's second survey. Beaufort was at a loss as to who to suggest, so he sought the advice of his old Cambridge friend, George Peacock. The following is taken from Jenyns' "Chapters in My Life" (then known as Leonard Blomefield):

The appointment arose in this way. Dean Peacock, at that time Fellow of Trinity College, was intimate with Captain Fitzroy, and was applied to by the latter, as to whether he could not find some one among the Cambridge men, who would be fit and willing to accompany him in his voyage in the capacity of Naturalist. Peacock immediately thought of Henslow and myself Henslow, however, being a married man with a family, was not disposed to go under his then circumstances,—(though earlier in life no doubt he would have caught at such an offer gladly)—and he tried to persuade me to go instead. I hesitated; and, after a full day taken to consider my decision, I also declined, as well on account of my being engaged in parish work—as Vicar of Swafham Bulbeck—which I did not think it quite right to quit for a purpose of that kind, as on account of my judging that I was not exactly the right person, either in point of health or other qualifications,—to offer myself for the situation. We then agreed (Henslow and self) that Darwin, in all respects, would be a fit man to go, and on his assenting, his name was at once sent up to Capt. Fitzroy, and the appointment was confirmed.

It may come as a surprise to some, therefore, to learn that Darwin was the third choice to accompany the Beagle, not the first. That Jenyns and Henslow recommended Darwin should come as no surprise. Darwin and Jenyns had met when Darwin was an undergraduate at Cambridge, and the two of them collected insects together, especially beetles. Some years later Darwin wrote of Jenyns, "At first I disliked him from his somewhat grim and sarcastic expression; and it is not often that a first impression is lost; but I was completely mistaken and found him very kindhearted, pleasant and with a good stock of humor. I visited him at his parsonage on the borders of the Fens, and had many a good walk and talk with him about Natural History."

Jenyns also wrote later of Darwin, "He was my junior at College by ten years; but from the similarity of our pursuits, we soon became intimate after the first introduction. He was at that time a most zealous Entomologist, and attended but little—as far as I remember—to any other branch of Natural History. He occasionally visited me at my Vicarage, at Swaffham Bulbeck, and we made Entomological excursions together, sometimes in the Fens, that rich district yielding so many rare species of insects and plants—at other times in the woods and plantations of Bottisham Hall. He mostly used a sweeping net, with

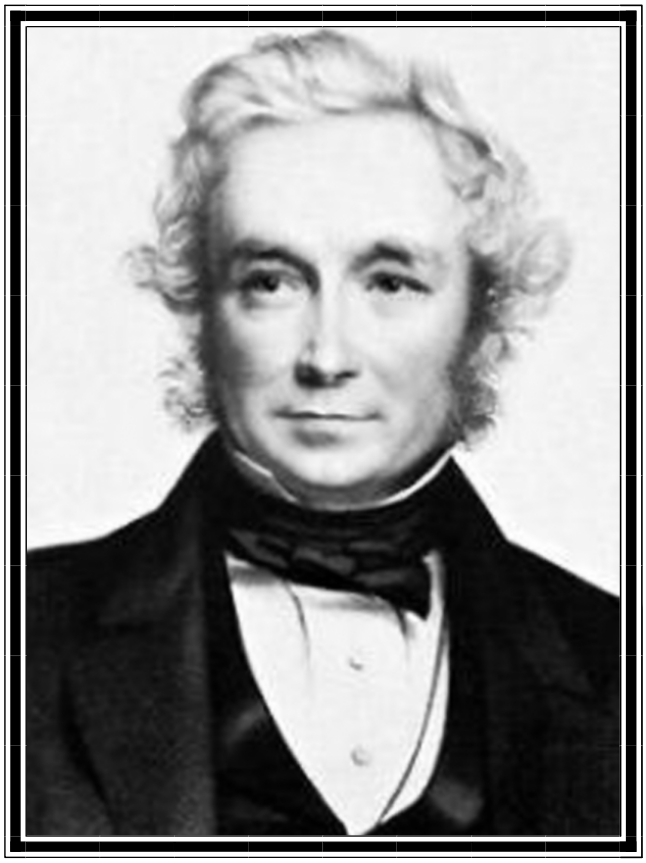

Figure 3: John Stevens Henslow (1796-1861), friend of both Leonard Jenyns and Charles Darwin. Along with Jenyns, he was instrumental in obtaining Darwin's appointment as Naturalist on the HMS Beagle.

Figure 4: The route of the HMS Beagle, showing its route to Brazil where the Chanchito was collected.

which he made a number of successful captures I had never made myself, though a constant resident in the neighborhood."

Charles Darwin (1809-1882), like many people of genius, did not at first appear to have extraordinary talents. From a young age Darwin disliked school and preferred observing birds and collecting insects to study. He was sent to medical school in Scotland when he was 16 but young Darwin found medicine "intolerably dull," and he was much more interested in attending natural history lectures. (The sight of blood made him squeamish and it is interesting to note that even before Darwin left for sea there were signs that he had a weak stomach!)

Seeing that Darwin lacked enthusiasm for becoming a doctor, his father suggested he study for the clergy. Darwin was agreeable to the idea and enrolled in the university at Cambridge, England, in 1827. Here again, Darwin admitted, "My time was wasted, as far as the academic studies were concerned." However, Darwin found that his friendship with John S. Henslow, then professor of botany at the university, made life in Cambridge extremely worthwhile. Through long talks with Henslow, Darwin's knowledge of the natural world increased and Henslow encouraged Darwin in his studies of natural history. Henslow was also a pastor, so Darwin made plans to pursue a life in the clergy.

His heart really wasn't in it, however, but since he had a summer to think about it he went on vacation. When he returned home he found two letters waiting for him: one, an offer to work as a naturalist aboard the HMS Beagle, and the other, a letter from Professor Henslow encouraging him to do so. However, like many young men and women still living at home, Darwin had to consider what his father, Dr. Robert Darwin, might think about such a trip. Darwin ultimately won his father over (Dr. Darwin even put up 30 pounds a year for Charles' food and paid to equip him for the voyage) and was soon signed on as ship's naturalist. At the end of the voyage and at the earnest request of Charles Darwin, Jenyns undertook to edit the monograph on the fishes for the trip (Jenyns, L., "The zoology of

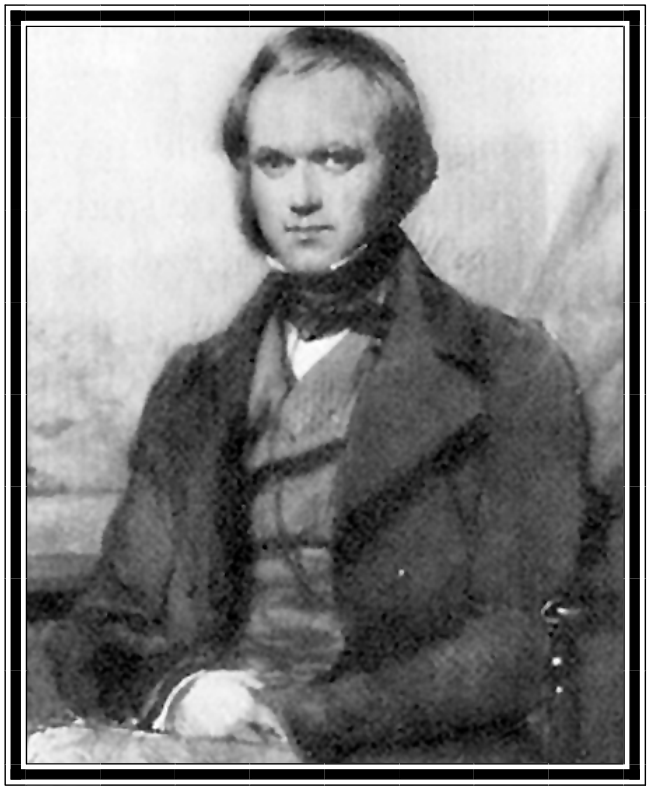

Figure 5: Charles Darwin (1809-1882).

the voyage of H. M. S. Beagle, under the command of Captain Fitzroy, R. N., during the years 1832 to 1836," London: Smith, Elder, and Co. Issued in 4 parts, Fish, 1840-42.), and the rest is, as they say, aquarium history.

We now arrive at three interesting questions, all arising from an aquarium article on the Chanchito. Assuming that Leonard Jenyns had gone on the voyage of the Beagle instead of Charles Darwin:

(1) Would Jenyns rather than Darwin have developed the origin of species concept?

Even though Jenyns was interested in species variation (he read a paper on "The Variation of Species" to the Cheltenham meeting of the British Association for the Advancement of Science in 1856, a paper that Darwin asked Jenyns to send him), I think it unlikely. In addition to his religious background, Jenyns was essentially a field naturalist and lacked the breadth of vision needed to develop such a theory.

Oddly enough, though, Jenyns was a far better field naturalist than Darwin. Henslow's letter to Darwin re the Beagle appointment read: "I have stated that I consider you to be the best qualified person I know of who is likely to undertake such a situation—I state this not on the supposition of your being a finished Naturalist, but as amply qualified for collecting, observing and noting anything worthy to be noted in Natural History. ... Captain F. wants a man ... more as a companion than as a mere collector and would not take anyone however good a Naturalist who was not recommended to him likewise as a gentleman." Far from being an enthusiastic endorsement of Darwin's scientific abilities, the letter reads as nothing more than an assurance that Darwin had the social status needed to qualify him as Fitzroy's companion and enough knowledge of natural history to qualify him as a general menial collecting samples and making general observations.

A good example of Darwin's weakness as a field collector is that in spite of the importance of "Darwin's finches" in evolutionary theory, the original type specimens from the Beagle voyage have long been a source of puzzlement to ornithologists. The localities recorded on the specimens, for example, do not seem to coincide with the various species and subspecies distributions observed today. The explanation for these anomalous specimens lies in part in Darwin's own collecting procedures while in the Galapagos. His specimens, which were largely unlabelled by island, later acquired a number of erroneous localities as a result of Darwin's own incorrect guesses, as well as the efforts of later ornithologists to make Darwin's specimens agree with his published localities.

(2) Would Darwin have developed the origin of species concept in any case?

Well, perhaps not. During the voyage of the Beagle, Darwin found fossils in South America of extinct animals that were similar to modern species, and on the Galapagos Islands he noticed many variations among plants and animals of the

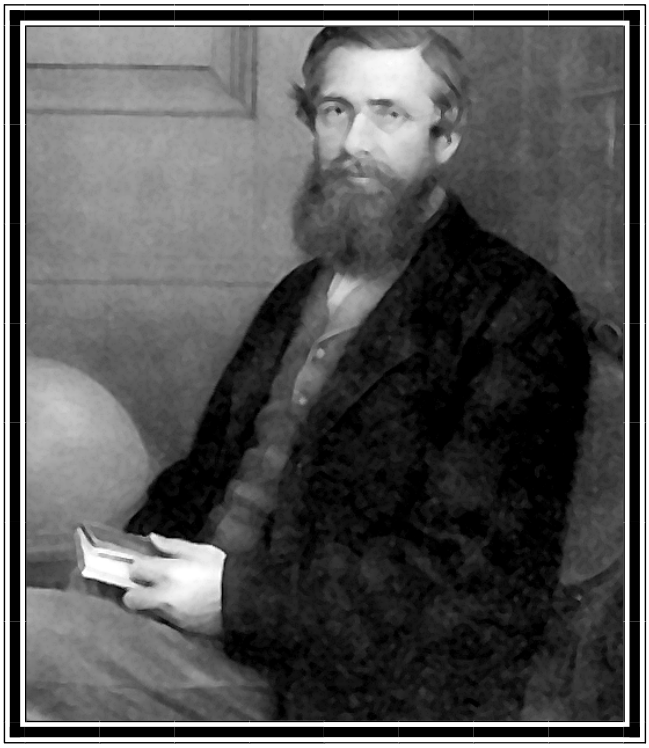

Figure 6: Alfred Russel Wallace (1823-1913).

same general type as those in South America, thus sowing the seeds of his ideas on natural selection. Darwin himself wrote in 1838 to have been "... greatly struck from about the previous March on the character of South American fossils, and species on Galapagos Archipelago. These facts, especially the latter, origin of all my views." If the Beagle voyage was the origin of all his views, then it would seem unlikely that he would have developed the origin of species concept had he not made the trip.

(3) Would Darwin have developed the origin of species theory in time to establish priority over Wallace?

In 1854, Alfred Russel Wallace (1823-1913) traveled to the Malay Archipelago to collect for various museums and private collectors. He was looking specifically for evidence that related forms were found in both the Amazon Basin and on the Archipelago. If he could find evidence that closely related species were found in widely dispersed regions of the world, this might bring into question the idea that each species was created independently.

In 1855 he published a cryptic note in guarded language entitled "On the Law Which Has Regulated the Introduction of New Species," in the Annals and Magazine of Natural History. Here he maintained that new species arose from related, pre-existing species. Darwin did not fully comprehend what Wallace was saying and considered him to be a "creationist."

In February of 1858, while on an island in the Moluccas (Indonesia), Wallace was bed-ridden and suffering from an attack of malaria. Ill and fevered, he suddenly realized the importance of Malthus' classic observations on populations and drafted his ideas on "the survival of the fittest" during a single evening. He worked over the draft the next two evenings with the idea of sending it to Darwin with whom he had prior correspondence. On March 9, 1858 he mailed his letter by mail-boat from the island of Ternate, asking if Darwin thought the ideas worthy.

Upon seeing Wallace's paper Darwin realized he was about to be scooped, and decided to end the 20-year delay in publishing his own theory. Wallace's paper and Darwin's various notes and correspondence on the subject were subsequently read at the same Linnaean Society meeting in London on July 1, 1858. The next year, Darwin published "On the Origin of Species." Although Wallace independently reached the same conclusion, it has usually been Darwin's name alone associated with the theory. In light of the close call in dates, I think a good case could be made that Wallace would have been first and therefore the one credited with the origin of species concept had Jenyns and not Darwin been on the Beagle voyage.

Perhaps you have your own answers to these questions, but whatever stance you take, it constantly amazes me that the aquarium hobby can open up so many interesting doors when one least expects it! Chalk one up for the Chanchito!

Our First Aquarium Cichlid

By Albert J. Klee, Ph.D.

(Buntbarsche Bulletin, No. 231, pp. 32-34, December 2005)

When I first became interested in tracing the roots of the aquarium hobby I was faced with the Gordian knot of defining terms. One of the most difficult was in pinning down the meaning of "hobby" in the aquarium context and, although it might not seem as if it would, even the definition of "aquarium" posed a problem. Indeed, the definition of "aquarium" was the subject of detailed analyses through the years by such renowned and respected figures as William Alford Lloyd (1876), Philip F. Rehbock (1980), and Stephen Jay Gould (1998). Trying to pin down a concise explanation of the meaning of a word or a term sometimes is sometimes akin to attempting to estimate the number of angels that can dance on the head of a pin!

One way out of this dilemma is to avoid definitions and examine the major stages in the development of the aquarium hobby instead. Consequently, I was able to distinguish four such distinct events. STAGE I started when people began to keep fish for their ornamental and entertainment value in ponds and in indoor containers, e.g., the piscina (from *piscis,* a fish, fish-pond, pool or basin – the term later took on different meanings) of the Romans, and the goldfish ponds of the Chinese a thousand years ago. Although the owner of any respectable Roman villa could look down on the animals in his fishpond, they could only be viewed from above through the opacity of rippled water. The same held for the indoor containers of the time since they also were opaque-sided.

STAGE II involved any container of glass or other transparent medium that afforded the viewing of a fish in a more direct, edge-on, eye-to-eye orientation, i.e., what we know as the "fish bowl," although the shape of the container varied widely. The first Stage II fish keeper of record was Jeanne Rondelet, who kept a fish alive in a glass of water for three years sometime in the late 1530's or early 1540's. In the mid to late 1700's, the keeping of fish in glass containers became fashionable in Great Britain and included such illustrious personages as Horace Walpole, the 4th Earl of Oxford.

The aquarium craze of the mid 1850's in Britain brought on STAGE III of the aquarium hobby, characterized by the interpretation of the aquarium as a mini-representation of a small portion of some natural aquatic environment (the marine aquaria of the time, for example, were frequently referred to as "parlour" oceans), an availability of books on the subject, and the existence of commercial establishments supplying fish and equipment. Finally, towards the end of the Twentieth Century STAGE IV appeared, i.e., the notion of

A Tilapia is shown at the right within the white frame in the lowermost image.

aquarium societies, exhibitions, and competitions, all strengthened by improved communication through the appearance for the first time of aquarium magazines, advances in travel, and the changing nature of cities.

Although Jeanne Rondelet kept a fish alive in a glass of water for three years in the Sixteenth Century, I doubt that most readers would agree that this established the aquarium hobby in France at that time. When one talks about the aquarium hobby, therefore, it makes sense to think in terms of Stage IV of the hobby. An interesting case in point, therefore, is in determining the first aquarium cichlid. If we restrict ourselves to the aquarium hobby (*sensu* Stage IV) then it is clearly the Chanchito, *Cichlasoma facetum*. If, on the other hand, we are seeking the first cichlid kept in an aquarium then the field is wide open. Some writers (e.g., Geerts, 2005) erroneously assign it to the Orange Chromide, *Etroplus maculatus*, but they are thousands of years off, as well as missing the correct fish!

It is well documented that the Egyptians kept fish in aquaria, and hieroglyphics in the tombs of the Pharaohs very clearly describe the farming of tilapia in ancient Egypt. In the mid 1970's I traveled extensively in Egypt and observed and photographed many of the hieroglyphics depicting fishes. The accompanying figure shows line drawings taken from some of them. The six in the lower left corner are drawings of a tilapia, the last showing it in a vessel of some sort, i.e., an aquarium.

The ancient Egyptians kept fish for food, to be sure. However, large quantities of fish bones have been found at various archeological sites in Egypt and, given the fact that the bones were found in accordance with the real animal shape, it is certain that the animals were deposited while still in the flesh and therefore played a religious role.

Oddly enough, the Egyptians had opposing views regarding fishes. They were often considered as unclean animals and were forbidden as offerings and food to kings, gods, and the priesthood. When the cult of Osiris became popular, fish were identified with his evil brother Seth, the god of chaos and confusion, since (according to Plutarch) people believed that the Nile Carp (*Lepidotus*) had eaten the phallus of the dismembered Osiris. Therefore, on certain feast days fishes were burned and trampled underfoot as an offering.

On the other hand, despite the belief of those just cited, fishes were often regarded as sacred animals. The elephant fish, *Sternarchorhynchus oxyrhynchus*, for example, was considered to have been created out of Osiris' wounds. This fish was also connected to the important goddess Hathor and also acted as a pilot fish for the solar bark of the sun god, Ra, warning of the approach of the snake Apophis during the sun's voyage through the underworld. The tilapia also seems to have been a

The six in the lower left corner depict Tilapia, and the last (magnified to the right) shows it in a vessel of some sort.

manifestation of Ra. As aquarists well know, a mouth brooder, it keeps its fertilized eggs in its mouth until they are fry and then spits them out. It therefore appears to be swallowing and then "giving birth" to them and, as such, is therefore a symbol of rebirth. Furthermore, this fish was associated with fertility and had a strong erotic connotation. To offer a tilapia, for example, was considered as an invitation to love.

Arthur E. P. B. Weigall (2005) writes that three thousand years ago, an Egyptian man wrote this poem about his home: "Its fields are full of good things and it has provision for every day. Its granaries overflow... they reach the sky. Its ponds are full of fishes and its lakes of birds. Its fields are green with grass and its banks bear dates. He who lives there is happy and the poor man is like the great elsewhere." These ponds certainly contained tilapia, but which tilapia?

The accompanying table lists the fish species documented from excavations in Egypt. The table is based on archeological investigations related to cultural studies that, in contrast to the antiquarianism of classical archaeology, are concerned with the explanation of cultural processes such as foods eaten and animals domesticated or farmed. The table is interesting in that it contains some very familiar aquarium fishes, e.g., elephant fishes, the bichir, labeos, a barb, and a host of well-known aquarium catfishes. Included are two species of tilapia - *Tilapia nilotica* and *Tilapia galilaea*. It is often assumed that the tilapia shown in Egyptian hieroglyphics is *Tilapia nilotica*, but as it is not possible to distinguish between the two species by looking at the hieroglyphs, it is therefore not certain which of the two is our first aquarium cichlid. As the reader can appreciate, nailing down these "firsts" is not an easy task nor is it always possible.

THE STORY of PANCHAX and KILLIFISH

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, March 26, 2011)

THE STORY OF PANCHAX

When an ichthyologist describes a new genus, it is necessary to specify a particular species as the type for the genus. This is referred to as the "type species." The rules of nomenclature that ichthyologists must follow state that, regardless of the other member species of the genus, the generic name goes with the type species like Damon with Pythias of Greek mythology. In the early days of ichthyology, however, it was not considered necessary by many ichthyologists to name a type species for a new genus. It was later realized that this was going to lead to quite a bit of nomenclatural confusion and it became necessary to designate type species for genera which had none.

Our story starts when the genus *Aplocheilus* was established in 1839 by the ichthyologist, John McClelland. However, be forewarned that what follows is a convoluted comedy of errors! McClelland placed three fishes in the genus at that time, two of which were newly-described by him. These fishes were: *Aplocheilus chrysostigmus, A. melastigmus* and *A. panchax*. The last-named species was first described as *Esox panchax* in 1822 by the Scottish ichthyologist, Francis Buchanan-Hamilton, and did not really belong in that genus or anywhere near it for that matter. McClelland, however, failed to name a type species for his new genus and since it later turned out to be composite (i.e., actually comprising two distinct genera), his oversight paved the way for considerable confusion, a bit of which has been shared with killifish fanciers.

Chronologically, the next action was taken by the French zoologist, Valenciennes when in 1846, ignoring McClelland's *Aplocheilus*, he established the genus *Panchax* containing four species: *Panchax lineatus, Panchax kuhlii, Panchax buchanani* and *Panchax pictum*. However, *Panchax kuhlii* was a synonym for *Panchax panchax, Panchax buchanani* was a synonym for Hamilton's *Esox panchax* (Valenciennes renamed it), and *Panchax pictum* really belonged in the genus *Betta*. This left *Panchax panchax* and *Panchax lineatus* and the genus *Panchax* appeared as such in early aquarium literature and widely used by aquarists.

The Dutch ichthyologist, Pieter Bleeker, was the first one to designate a type species for McClelland's *Aplocheilus*, and in 1863 in his synopsis of the genera of killifishes, named *Aplocheilus chrysostigmus* as the type species. In so doing, Bleeker committed a bit of a booboo as this was actually directly opposite to what he had intended to do for *A. chrysostigmus* is a synonym of *A. panchax* and Bleeker, in the same synopsis, placed *A. panchax* in the genus *Panchax*. There is good reason to believe that he had intended to name *melastigmus* as the type species but under the mistaken impression that *melastigmus* was a synonym of *chrysostigmus*, he used the latter name instead. Confusing, isn't it? But, the damage was done and the genus *Aplocheilus* henceforth had to be associated with the species *panchax* (= *chrysostigmus*).

Since *Aplocheilus* predates *Panchax* by seven years, the correct genus for *panchax* and related species such as *lineatus* has to be *Aplocheilus* by the Law of Priority, one of the formal rules that taxonomic ichthyologists are expected to follow.

In 1906, the eminent American ichthyologist, David Starr Jordan and his colleague, John Otterbein Snyder, established the genus *Oryzias* for the Japanese cyprinodont then known as *Poecilia latipes*. This genus was snubbed by other ichthyologists for many years, for they considered *Oryzias* to be merely a synonym for *Aplocheilus*. Later, however, it was accepted as a valid genus (in which we

now place the medaka and related fishes). Since McClelland's *melastigmus* was really related to *latipes*, it was ultimately transferred to *Oryzias*.

Therefore, when all the evidence was in, species in *Panchax* were transferred to *Aplocheilus*, species in *Aplocheilus* were transferred to *Oryzias*, and *Panchax* was discarded, the whole business resembling an ichthyological version of musical chairs!

As hobbyists, it is interesting to note what the situation now would be had Bleeker named *melastigmus* as the type species for *Aplocheilus* as it is thought he had intended. If he had done this, all fishes now called *Oryzias* would be placed in *Aplocheilus*, leaving *Panchax* open to accommodate *panchax* et al., and leaving *Oryzias*, the newcomer, vacant.

At the beginning of the 1900's, American killifish fanciers were strongly influenced by their German counterparts and by German immigrants to this country who brought their interest in killifishes along with them. In Germany, the name given to killifishes was "eiergelegende zahnkarpfen," translated as "egg-laying toothcarps." Killies at the time were placed in the family Cyprinodontidae, a name meaning "toothcarps," and the Germans merely translated it into their language. However, "egg-laying toothcarps" is a real mouthful, so in due time Americans resorted to calling them panchax since that name had yet to be discarded in the aquarium literature and "killifish" was not yet in vogue.

Up to the mid-1950's and early 1960s, if one walked into fish store and asked to see some killies, all you would have received would have been a blank stare. Ask for "panchax," however, and you would immediately be taken to the killifish section, including species that never had any association with the name "panchax," such as African, South and Central American and North American killifishes. The objection to the use of "Panchax" as a general term for killifishes is not only based upon the fact that it is a scientific name no longer used, but, more importantly, that it applied originally to only a few species of killifishes from a small part of the world.

THE STORY OF KILLIFISH

Kill is a common Germanic word. The Old Norse form meant "bay" or "gulf" and gave its name to Kiel Fjord on the German Baltic coast and thence to Kiel, the port city founded there in 1240. In Middle Dutch the word is "kille" (the modern Dutch term is "kil" since nowadays no Dutch word ends in two consonants), meaning "riverbed" or "water channel," although the primary meaning is a deep trench between steep banks.

The term was used in areas of Dutch influence in the Delaware and Hudson Valleys and other areas of the former New Netherland colony of Dutch America to describe anything from a stream or creek to a strait, river or arm of the sea. These waters were home to fish that were new to the Dutch, who probably called them "killvis" ("fish from the kill"), but it is also possible that the name "killfish" originated in American English, after the locals had adopted the Dutch word to these bodies of water.

Although there is no connection, some people did and still do associate "kill" with "to kill," as was apparent from a controversy about the name of Fishkill, a small town in the southwest part of Dutchess County, New York. In 1996, the animal rights organization, PETA (People for the Ethical Treatment of Animals), had proposed to change Fishkill into Fishsave, claiming that Fishkill suggested cruelty to fish!

In the 1980's, I was spending my spare time at the University of Cincinnati, poring over copies of the *Bulletin of the United States National Museum*. The University had a rather complete copy of the early issues, but as hardly anyone ever looked at these books, I was covered with dust

and grime every time I made a library visit. Nonetheless, in this I have been fortunate since today, these tomes are located away from the University library in storage, and it takes three days for them to be brought up to the library for patrons to examine.

One day, I came across a reference to "*Cobitis killifish*," a scientific name given by Johann Walbaum in 1792 on the basis of a paper written by Johann Schoepff in 1788 wherein the latter described a fish he called "killfish" (note the absence of the "i") that we now know as *Fundulus heteroclitus macrolepidotus*. "Killfish," of course, literally means "fish of the kill." This was exciting since it provided new information as to the origin of the name, which up to this time had been thought only to have been a common name not a scientific one. However, I had some unanswered questions and to answer them, I was on my own.

For one thing, Schoepff had previously published the term in a scientific journal, the *Berlinische Gesellschaft Naturforschender Freunde*, so why wasn't he given the credit for being the first one to describe it scientifically? For another, Walbaum's description was published in an edition of Peter Artedi's *Ichthyologia* that he, Walbaum, edited; how did this description get into something he was just supposed to edit? Artedi, it should be noted, is credited with being the founder of modern ichthyology, and his posthumously published *Ichthyologia* was fundamental in establishing modern ichthyological methods.

Figure 1: Johann Julius Walbaum (1724-1799).

Johann Julius Walbaum (1724-1799), a native of Lübeck, was a physician, naturalist and taxonomist. He was the first to describe many previously unknown species from remote parts of the globe, such as the Great Barracuda (*Sphyraena barracuda*), the Chum salmon (*Oncorhynchus keta*) from the Kamchatka River in Siberia, and the curimatá -pacú (*Prochilodus marggravii*) from the São Francisco River in Brazil. He was also the first to observe gloves as a preventative against infection in medical surgery. In 1758, the gloves he observed were made from the cecum of the sheep, rather than rubber, which had not yet been discovered. The Naturhistorische Museum in Lübeck, opened in 1893, was based on Walbaum's extensive scientific collections.

As were most of the scientific books of the day, the Walbaum-edited book was written in Latin, its title being: "*Petri Artedi sueci genera piscium in quibus systema totum ichthyologiae proponitur cum classibus, ordinibus, generum characteribus, specierum differentiis, observationibus plurimis: Redactis speciebus 242 ad genera 52.*" The last part translates to "242 species and 52 genera added by the editor." Walbaum described the fish scientifically - within the lenient standards of the time - in six lines, using Schoepff's account for location information, i.e., "Habitat ibidem tam in aquis dulcibus, quam salsis" ("Habitat in fresh as well as salt water"). He also made clear in the title of the book that he had added material to Artedi's monumental work.

Well, that answered one question, but what about Schoepff's contribution? Schoepff was a German

botanist, zoologist and physician. He was born in Bayreuth and traveled to New York in 1777 as the chief surgeon for the Ansbach regiment of Hessian troops fighting for King George III of the United Kingdom. During the war Schoepff was stationed in Rhode Island. Determined to study the Americas as a scientist once the war ended, he travelled for two years in the United States, British East Florida and the Bahamas. Schoepff returned to Europe in 1784, where he worked for a time at the United Medical Colleges of Ansbach and Bayreuth. He is well known among present-day herpetologists for his 1792 "Historia testvdinvm iconibvs illvstrata" (Illustrated History of the Iconic Turtles, "iconic" in this sense meaning the British definition, i.e., "well-known").

Tracking him down was not easy since his name can be spelled Schoepff, Schoepf or Schöpf. Also, the literature citations I came across were fraught with errors. *The Northeastern Naturalist*, published by the Humboldt Field Research Institute, for example, cited Schoepff's paper as "Beschriebung einiger nordamerikanishen fische vorzuglick aus den neu yorkischen seewasser," not only misspelling Beschreibung but stating "seewasser" instead of the correct "Gewässern" and other minor errors as well. The correct citation is "Beschreibung einiger Nord-Amerikanisher Fische, vorzüglich aus den Neu-yorkischen Gewässern."

Incidentally, the English translation of "vorzüglich" gave me an additional problem as well. If one goes to the standard dictionaries, hard copy or on-line, one usually gets two basic meanings for the word: (1) ideal, excellent, exquisite or first-rate, and, to a less frequent extent, (2) those associated with food and cooking, such as delicious and cordon bleu, none of which makes any sense when you try inserting any of these definitions into the brackets in "A description of some North American fishes, [vorzüglich] from New York waters."

In such cases, one needs to go to a reference work that presents a list of all synonyms for the word, both past and present. The disadvantage is that these are usually wholly in the language under consideration. The one I used listed 14 different basic meanings and over 339 synonyms. I picked the basic meaning of "besonders," which gave me synonyms that included "notably," "primarily" and "chiefly," which solved the problem, my translation being: "A description of some North American fishes, mostly from New York Waters."

From the Bielefeld University Library (Universitätsbibliothek Bielefeld) site I found Schoepff's article in digitized form. The text was digitized as an image and this difficulty was compounded by the fact that this was in a 1788 German publication and printed in Fraktur, a Gothic font. Furthermore, Schoepff's killfish description pages were especially blurry as Figure 3 shows.
I have outlined the excerpt "Diese beyde Fische, der Yellow bellied Cobler und Killfish, halten sich um Neuyork, in Kriken und Teichen von sowohl gesalzenem als frischen Wasser auf,"

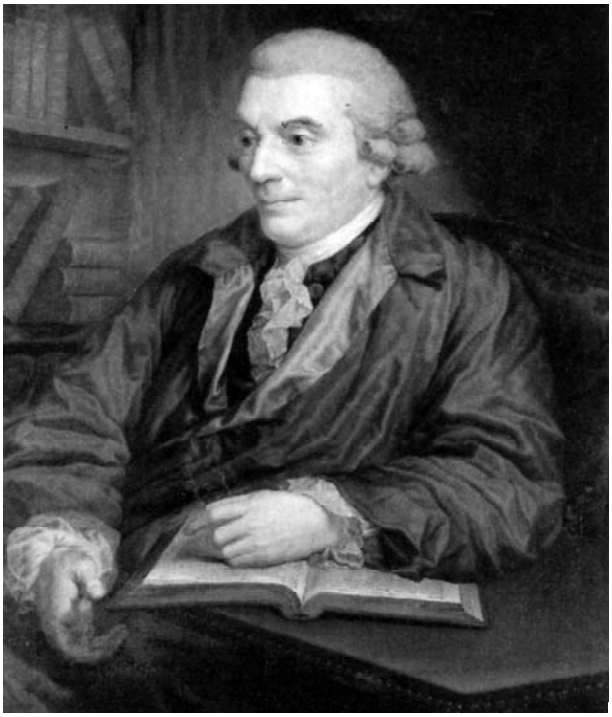

Figure 2: Johann David Schoepff (1752-1800).

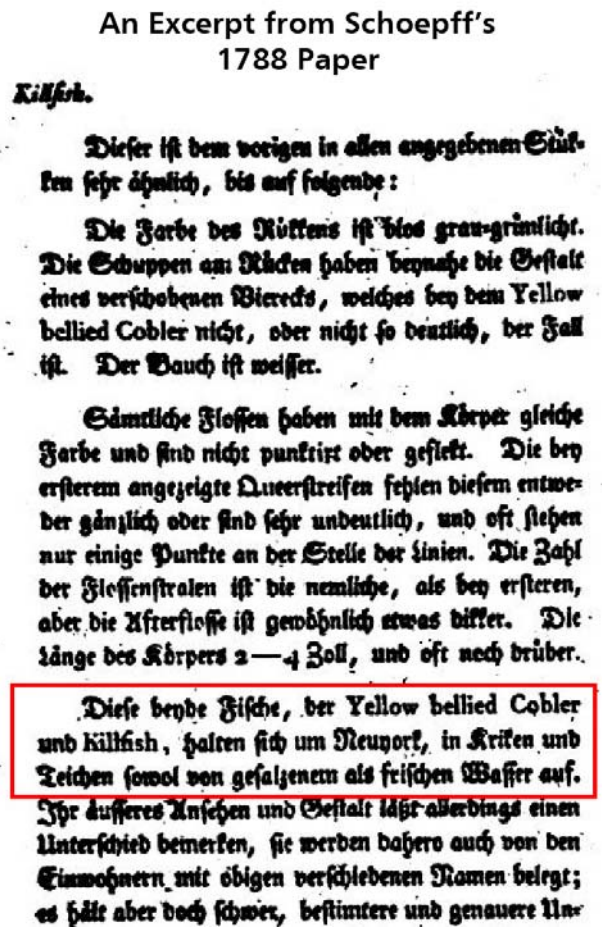

An Excerpt from Schoepff's 1788 Paper

Killfish.

Dieser ist dem vorigen in allen angegebenen Stücken sehr ähnlich, bis auf folgende:

Die Farbe des Rückens ist blos grau-grünlicht. Die Schuppen am Rücken haben beynahe die Gestalt eines verschobenen Vierecks, welches bey dem Yellow bellied Cobler nicht, oder nicht so deutlich, der Fall ist. Der Bauch ist weisser.

Sämtliche Flossen haben mit dem Körper gleiche Farbe und sind nicht punktirt oder gefleckt. Die bey ersterem angezeigte Queerstreifen fehlen diesem entweder gänzlich oder sind sehr undeutlich, und oft stehen nur einige Punkte an der Stelle der Linien. Die Zahl der Flossenstralen ist die nemliche, als bey ersteren, aber die Afterflosse ist gewöhnlich etwas dicker. Die Länge des Körpers 2—4 Zoll, und oft noch drüber.

Diese beyde Fische, der Yellow bellied Cobler und Killfish, halten sich um Neuyork, in Kriken und Teichen sowol von gesalzenem als frischen Wasser auf. Ihr äusseres Ansehen und Gestalt läßt allerdings einen Unterschied bemerken, sie werden dahero auch von den Einwohnern mit obigen verschiedenen Namen belegt; es hält aber doch schwer, bestimtere und genauere Un-

Figure 3: An excerpt from Schoepff's 1788 paper.

which I have translated as "Both these fishes, the Yellow-bellied Cobbler and Killfish, are found in creeks and ponds in both brackish and fresh waters about New York." Figure 3 shows that Schoepff did not provide a binomial name for his "Killfish" and so it was not, even for the times, scientifically described. In other parts of his paper fish were provided with a binomial name, and so his "Labrus Burgall" is referred to in today's scientific literature as "*Labrus burgall* Schöpff 1788." Since his "Yellow bellied Cobler" and "Killfish" were not named scientifically, it remained for Walbaum to do so four years later.

One of the earliest references to killifish is Samuel Latham Mitchill's "The Fishes of New York" (Mitchill, 1815), but he refers to "killifishes" as names only, sans descriptions. One of the earliest descriptions of killifish, on the other hand, can be found in Samuel Akerly's "Economical history of the Fishes sold in the markets of the City of New York" (Akerly, 1818). Akerly (1785-1845) was a surgeon, naturalist, geologist, founder of the New York Institution for the Instruction of the Deaf and Dumb and author of many articles and books on medical and scientific subjects (one of the books he wrote was "An essay on the Geology of the Hudson river, and the adjacent regions illustrated by a geological section of the country, from the neighbourhood of Sandy-Hook, in New-Jersey, northward, through the highlands in New-York, towards the Catskill mountains: read before the Lyceum in August, l8l9"). American Ichthyology is dated from the feeble beginnings of Rafinesque and from Samuel Latham Mitchill (1764-1831) so it is interesting to note here that Akerly was Mitchill's brother-in-law. The following is from Akerly's 1818 paper:

"The killifish frequent the shallows of the bays and the small streams of salt water, following the recess of the tides and advancing with the flood. There are several species of them, and they afford sport to children during the summer months, and they fish for them with worms on a pin hook. In the winter they do not bite, but collect in great numbers and reside in the deep holes of creeks and bays. At such limes they are taken by sweeping their haunts with a small scap-net (Author's Note: A scap-net is a dip net), and though they are not larger than the finger, they are brought to market for sale, and are esteemed an excellent little pan fish. They are sold tor twelve cents a quart. They are put into blood-warm water, which causes them to vomit the contents of their stomachs, and thus they are prepared for cooking. The white-bellied killifish is the one under consideration, and is the *Esox pisculentus* of Mitchill's memoir. [Author's Note: the "memoir" mentioned here is Mitchill, 1815). Killifish is a provincial word for all small fish in New-York, and appears to be derived from the Dutch word kill, applied to all small streams by the original settlers of New-York.]

It has always been assumed that the "kill" in both of these descriptions refers to the Dutch word. However, due to the fact that killifish - and especially *Fundulus heteroclitus* - were often used as bait fish, an alternate derivation of this term was suggested by Ken Lazara in an article (now removed) that appeared on the first AKA web site titled, "On the Origin of the Term Killifish."

There is documented usage that in angling publications from at least 1676 until 1885, a very successful bait was referred to as a "killing bait," as in **"Now, the cadis, or cod-bait, which is a sure killing bait…"** (Walton and Cotton, 1676), **"As killing a Bait as any whatever."** (Chetham, 1681) and **"Fishing with the young frog is a very killing method of fishing for chub"** (Francis, 1867). In these examples, "killing" is used as an adjective, not as a verb or a noun.

Lazara contended that the transitions from "killing bait" > "killing fish" > "killfish" > "killifish" were perhaps how the term "killifish" was derived. However, although the last two transitions are certainly plausible, the transition "killing bait" > "killing fish" is a jump for which there is no documentation in the literature whatsoever. For another, during this period, anglers used the terms "killing" and "catching" interchangeably, so "killing bait" means "catching bait," and so the transition to "killing fish" makes no sense whatsoever.

Furthermore, the derivation relies on references to British publications, namely the Oxford English Dictionary and the Chetham and Francis books. The idea that "killifish" was derived from "killing fish" first appeared in the Oxford dictionaries. For example, under "Killifish" in my copy of the Oxford Universal Dictionary of 1933, updated to 1955, there is the following: **"1836 [? f. KILL + FISH; but cf. (i.e., a standard dictionary abbreviation meaning confer or compare) KILLING]." Under "Killing" appears: "of bait: sure to kill 1681."** The "killing bait" term originated in 1681 in England, over a century before the term "killifish" ever appeared in print.

However, in the current on-line Oxford Dictionary site of the Oxford University Press, it is now stated for the origin of killifish, "early 19th century: apparently from KILL and FISH." Oxford has thus abandoned the idea of "killing fish" as a possible origin of the word. (Although I myself would have cited 1792 as the date of origin, I have no real problems with "early 19th century"; I am thinking here of Mitchill, 1815 and Akerly, 1818.)

The question also arises as to whether any of these British references have any relevance to the name "killifish," since British usage is one thing and American usage quite another. To this end, I have consulted three of the earliest books on American Angling (Forester, 1850; Norris, 1864; Scott, 1869).

One of the most obvious differences between the British and American references cited in this monograph is the infrequent use of the terms "killing" and "kill" in the latter. American anglers favored "catch" and "take" over "kill" and on page 129 of his book, Norris states that "Pickering (Ellis, 1835) in his Piscatorial Reminiscences, speaks of a Pike killed (caught) in Loch Spey that weighed one hundred and forty-six pounds." Norris used the American equivalent in the parentheses, thus making sure that the reader was not confused by the term "killed." Kill, by the way, is mentioned frequently throughout the Forester, Norris and Scott books in place names, such as Kill van Kull, Bashe's Kill and Fishkill Landing.

With regard to bait, although "killing bait" and related terms do occur with some frequency in the American literature, they do not appear in connection with killifish. The reason is simple. Early on, not only were killifish referred to as "minnows," but "minnows" referred to killifish and killifish alone, as the following (with its ar-

chaic spellings preserved) confirms (Forester, pg. 176-177):

"MINNOWS
***Hydrargyra*; Auctorum**

[Author's note: "Minnow" has its roots in Old English menow and Anglo-Saxon myne, meaning a very small freshwater fish, perhaps influenced by Old French, menuise meaning small fish. Hydrargyra is an old synonym for Fundulus. Auctorum (abbreviated auct. or auctt.) in zoology is a term used to indicate that a name is used in the sense of a number of subsequent authors and not in its (different) sense as established by the original author.]

"The minnow proper of Europe, *Cyprinus, Leuciscus, Phoxinus*, is unknown to the waters of North America, but as their equivalents, and analogous to them, we have innumerable species of the *Hydrargyra*, or American Minnow; which, in general appearance, habits and haunts, are very nearly assimilated to the European fish.

"Its food consists of aquatic plants, small worms, and minute portions of any animal substances. It bites boldly and readily at small red worms, gentles, or the larvae of any of the *Phryganea*, known as caddis-baits, stick-baits, and the like, on the least Limerick hooks, number twelve; and is constantly taken by boys with a worm alone tied to a fine string, which the little fish swallows so greedily that he is pulled out before he has time to disgorge it.

"Under many local names this beautiful little *Cyprinus* is found in every swift-running stream with a gravelly bottom, and in the shallows of every pond or lakelet throughout the country. They are generally known as Killy-fish, and are an excellent bait for fish of almost every kind that prey on other fish.

"As live bait for Pike, Pearch or Catfish, they are not to be equalled; and in spinning or trolling they are excellent for the noble Striped Bass, the Pike, the Salmon, the Lake Trout in all its varieties, and for the Brook Trout - especially those which are found in the tide-creeks, where they are less willing than in other waters to take the fly. A more particular description of so common and well-known a fish would take up space needlessly, which is more required for other parts of my subject; and the species are, I was almost about to say, innumerable. Three of the commoner varieties, and those most useful as bait, are represented on the preceding page."

Among the other bait fish mentioned by Forester were dace, shiners and other small cyprinids (especially of the subfamily Leuciscinae), and in later years the term "minnow" included these fish as well, as evidenced in the Norris and Scott books. Webster's Revised Unabridged Dictionary (1913) includes among its three definitions for "minnow" the following: "Any of numerous small American cyprinodont fishes of the genus Fundulus, and related genera. They live both in fresh and in salt water. Called also killifish, minny, and mummichog." Therefore, even when the bait in question was a killifish, the name originally used by American anglers was "minnow," not "Killy-fish," "killfish" or "killifish." There never was a need to use the lethal meaning of "kill" to modify "bait" when the object in consideration was a killifish.

When I first became interested in the origin of the term "killifish" (over half a century ago!), I posit-

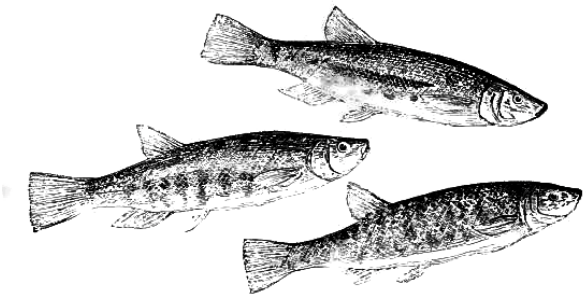

Figure 4: Figures from Forester's "Fish and Fishing of the United States," 1850.

ed that it could have come from only three possible communities: science, angling and aquarium. With regard to the science community, there are two hypotheses, i.e., that Schoepff and Walbaum had location on their minds or fishing. Throughout ichthyological history, location, patrimony and physical attributes have been the source of almost all names, and fishing is not included in any of them. Occam's razor (Ariew, 1976), often expressed in Latin as the *lex parsimoniae* or the law of parsimony, is a principle that generally recommends selecting the competing hypothesis that makes the fewest new assumptions when the hypotheses are equal in other respects. Clearly, location wins on this count and I have documented here one of the earliest (i.e., 1818) usages of "killifish" in a scientific reference appearing after Schoepff and Walbaum descriptions in the prior century.

The American angling community was never a contender since their word for killifish was "minnow," a term that originally only referred to *Fundulus* although later, anglers included dace, shiners and other small cyprinids under the rubric of "minnow" as well. Thus the origin of the term "killifish" could not have come from the angling community since it was a term they never used until a century after its use in the scientific community.

With regard to the aquarium community, in 1955 in *Tropical Fish Magazine*, published by a consortium of New England aquarium societies, Dr. George S. Myers (Myers, 1955) proposed two new popular names: "killifish" for the egglayers (and he based this on its long-term usage in the ichthyological community) and "gambusino" for the livebearers. However, the publication was largely unknown to any but those living in the New England area and so neither term caught on with aquarists at the time, panchax remaining in common use among killifish fanciers. However, I had read the article and it prompted me to use "killifish" in my own writings, all this quite a few years before the founding of the AKA. The establishment of the American Killifish Association in 1961, of course, made "killifish" the pro forma term used by most aquarists on both sides of the Atlantic.

Although it can be argued that, just like "Panchax," "Killifish" is based upon a no longer-used scientific name that applied to just a few killifishes (i.e., the fishes of the New York/New Jersey area), the latter is not actually based upon a scientific name but on a common name. Furthermore, it seems appropriate and desirable that an American organization should base its name on fishes found in this country, rather than in foreign ones.

Finally, there seems to be some confusion about the correct spelling of killies in the singular, i.e., is it "killie" or "killy"? In the December 1969 issue of KILLIE NOTES in the "Letters to the Editor" column, Editor Joseph F. Ricco reported on a letter he had received:

"And finally an item from Dr. George Myers of Stanford University. Dr. Myers informed me that the name KILLIE NOTES is incorrect and the correct name should be KILLY NOTES. The reason being that KILLY is singular and KILLIES is plural."

In English, adjectives are always singular and thus whatever preceded "Notes" had to be singular. However, contrary to Dr. Myers' opinion, "killie" is singular and had been known as such for many, many years in both the scientific and lay literature. A good example is Henry Fowler's report on the fishes of New Jersey (Fowler, 1905) in which the following common names (all singular as common names are) were included in the list for *Fundulus heteroclitus macrolepidotus*: "Killy," "Killie" and "Killy Fish." The following were included for two other killifish species, "Killie Fish" and "Killi Fish," making a grand total of five different names for the singular of killifish!

In any case, usage out-trumps any grammarian and that which is "correct" changes with the times, as is shown clearly by Fowler's report. Maugham, in his 1938 book, "The Summing Up," wrote: **"It is necessary to know grammar, and it is better to write grammatically than not, but it is well to remember that grammar is common speech formulated. Usage is the only test."** Therefore, KILLIE NOTES is correct, and either "killie" or "killy" can be used safely for the singular.

Incidentally, when the AKA was founded in 1961, my own preference for the shortened singular of killifish was "killy," since it was consistent orthographically with the ending of other well-established aquarium names, such as "molly" and "platy." However, Jorgen Scheel had used "killie" prior to this and, as it was accepted among many well-known killifish fanciers, I decided against my better judgment to use it.

HOW CLADISTS WORK

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, October 21, 2007)

THE IDEA BEHIND CLADISTICS

It is generally understood that classifications ought to reflect the phylogeny of organisms, where each taxon (a genus, for example, is a taxon) should originate from a single ancestral form. The emergence of “cladism” or “cladistic taxonomy” in the 1960’s, therefore, is expected to supplant Linnaean classification in the future since, in classifying species, cladists place a priority in achieving coherence with the Darwinian principle of common descent.

In grouping species, cladists look for “derived similarities,” meaning those aspects that species can be expected to share by virtue of a common evolutionary ancestry. This approach differs from that of phenetics, which associates species based on overall similarity and does not address ancestry. This was the way aquarium species were classified in the old days. It also differs also from classification based on ad hoc “key characters,” a device known to aquarists looking up identification in a book based on such keys. Cladists, on the other hand, avail themselves of all the types of evidence available, including DNA sequences and hybridization studies, biochemistry, and traditional morphology.

They often make use of computerized algorithms to identify the most likely phylogeny or “family tree” that relates the species they are considering. A cladistic analysis therefore is applied to a certain set of information. To organize this information a distinction is made between characters, and character states. Consider the color of fish scales; this may be blue in one species but red in another. Thus, “red fish scales" and “blue fish scales” are two character states of the character “scale-color.” The researcher decides which character states were present before the last common ancestor of the species group and which were present in the last common ancestor by considering one or more outgroups. An outgroup is an organism that is considered not to be part of the group in question, but is closely related to the group. This makes the choice of an outgroup an important task, since this choice can profoundly change the topology of a tree. Note that only character states present in the last common ancestor are of use in characterizing clades.

CLADOGRAMS

Cladistics provides systematists with one very handy feature. Due to its bipolar character states (a species has a given character or it doesn't — there's no in-between), cladistics lends itself very readily to computer analysis. Computers can analyze hundreds or thousands of characters in a fraction of the time that a human systematist could. Computers then use the results to generate branching diagrams — called "cladograms" — which graphically represent how the included species are interrelated. The example on the following page is an example of a cladogram:

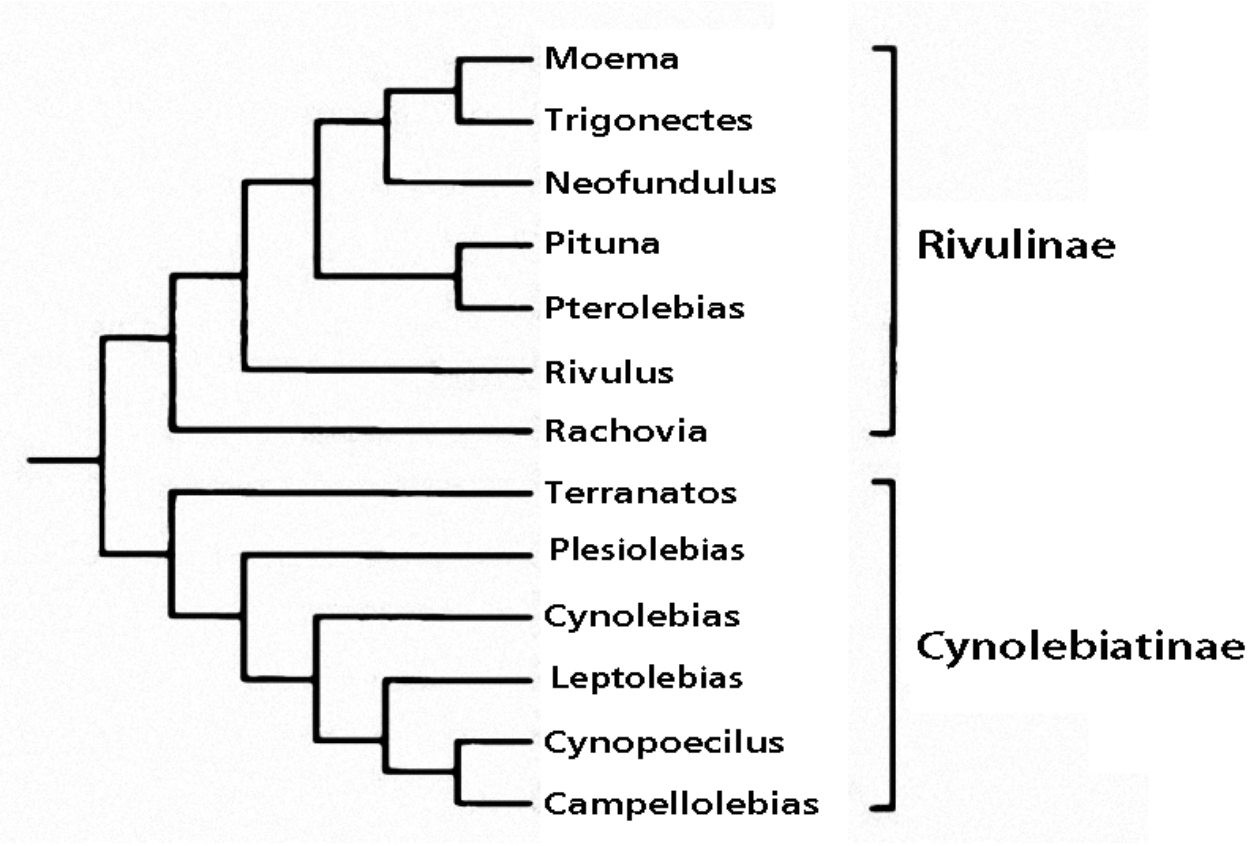
Clades ideally have many “agreeing” character states present in the last common ancestor. Ideally there are a sufficient number of them to overwhelm characters caused by convergent evolution (i.e. characters that resemble each other because of environmental conditions or function, not because of common ancestry). A well-known example due to convergent evolution would be a character “presence of wings”. Though the wings of birds and insects serve the same function, each evolved independently, as can be seen by their anatomy. If a bird and a winged insect were scored for the character “presence

of wings", this would confound the analysis, possibly resulting in a false picture of evolution.

HOW CLADOGRAMS ARE OBTAINED

Many cladograms are possible for any given set of taxa, but one is chosen based on the principle of parsimony, i.e., the most compact arrangement, that is, with the fewest character state changes. Though at one time this analysis was done by hand, computers are now used to evaluate much larger data sets. Sophisticated software packages allow the statistical evaluation of the confidence we might expect, these methods are difficult to explain to those not versed in statistics or mathematics but I'll give it a try.

The maximum likelihood method is based on a model and on a distribution. The model is the probability of an event dependent on a model parameter, p. The likelihood of the parameter given the data is the probability of observing X given p. The maximum likelihood method consists in optimizing the likelihood function. The goal is to estimate the parameters p which make it most likely to observe the data X. In this example I'll use the



can put in the veracity of the nodes of a cladogram. Using a parsimony criterion is only one of several methods to infer a phylogeny from molecular data: maximum likelihood and Bayesian inference, which incorporate explicit models of sequence evolution, are also ways to evaluate sequence data. As you

binomial distribution, often used to calculate the probability of the outcome of coin tossing. Suppose we throw a coin three times where the probability of observing a head (1) is p=1/4 and the probability of observing a tail (0) is p=3/4. We can compute the proba-

bility of each possible data set (X) of three tosses in Table I.

TABLE I				
X			Computation	
0	0	0	(3/4)*(3/4)*(3/4)	.4218
0	0	1	(3/4)*(3/4)*(1/4)	.1406
0	1	0	(3/4)*(1/4)*(3/4)	.1406
0	1	1	(3/4)*(1/4)*(1/4)	.0468
1	0	0	(1/4)*(3/4)*(3/4)	.1406
1	0	1	(1/4)*(3/4)*(1/4)	.0468
1	1	0	(1/4)*(1/4)*(3/4)	.0468
1	1	1	(1/4)*(1/4)*(1/4)	.0156

Now in a toss of coins three times, the probability of obtaining a head followed by two tails (the fifth entry in the table) clearly is: 1/4*3/4*3/4 = 0.1406. Inversely, if we observe the outcome of three throws as “1 0 1” we can compute the likelihood, L, of the probability that produced this outcome in Table II.

For example, in a toss of coins three times, if the probability of obtaining a head is 0.8, the probability of obtaining a head, then a tail, and then a head is (the eighth entry in the table) is: 0.8*0.2*0.8 = 0.128.

We can see from the table that the result “1 0 1” is most likely for p = 0.7. Substitute a set of observations on a group of fishes rather than a set of observations on a group of coin tosses, and substitute a postulated clade for the probability in the last table, and you have the basic idea of one way cladists form their cladograms using the maximum likelihood principle.

TABLE II		
p	Computation	L
0	0*1*0	0
0.1	0.1*0.9*0.1	0.009
0.2	0.2*0.8*0.2	0.032
0.3	0.3*0.7*0.3	0.063
0.4	0.4*0.6*0.4	0.096
0.5	0.5*0.5*0.5	0.125
0.6	0.6*0.4*0.6	0.144
0.7	0.7*0.3*0.7	0.147
0.8	0.8*0.2*0.8	0.128
0.9	0.9*0.1*0.9	0.081
1.0	1*0*1	0

POINT OF VIEW

THE NAME GAME

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, April 16, 2009)

I give you now Professor Twist,
A conscientious scientist,
Trustees exclaimed, " He never bungles!"
And sent him off to distant jungles.
Camped on a tropic riverside,
One day he missed his loving bride.
She had, the guide informed him later,
Been eaten by an alligator.
Professor Twist could not but smile.
"You mean," he said, a crocodile."
Ogden Nash

One change that stands out markedly to me in the aquarium writing that has evolved between the close of World War II and the present– and I refer here to magazine articles and even more particularly to the journals of specialist associations – is the plethora of changes of, and additions to, aquarium genera. One often has to wade through a nomenclatural mini-dissertation before one gets to what is of real importance to the reader, i.e., the fish's origin, description, behavior, requirements and (hopefully) its breeding.

Since it removes all doubt as to what fish is being referred to, aquarists have always been legitimately interested in pairing a common name for a fish with a scientific one. If one knows the species name it is a simple task to include it in an article without miring down the text in matters more of interest to a professional than to an aquarist.

Historically, one usually acquired the name of a species in three ways: (1) finding a match using aquarium references, (2) attempting to identify it oneself, or (3) sending a specimen to an ichthyologist for identification.

The first method was really hit-or-miss, since the pre-World War II aquarium literature available at the time was based upon illustrations, many of which were of doubtful accuracy or lacking in detail. The second method was mainly the province of specialist associations like the American Killifish and American Cichlid Associations whose members took the time and trouble to obtain the original descriptions and who had access to the equipment needed – such as a good microscope, preferable a binocular type – to count scales and fin rays and to calculate certain distance ratios. Since pre-World War II descriptions were often based mainly on these variables, some of these efforts were successful. However, amateurs are not professionals so the results were tentative at best. Furthermore, the examination of bone structure was fast becoming an additional and important tool with which to describe a fish, so the DYI approach to fish identification became untenable even for the specialist associations.

Although most ichthyologists were cooperative, the third method was not always successful either since one really needed to contact a professional whose primary interest was in the group the specimen was related to, and this was not always an easy search. When the first wave of African importations that included *Distochodus* species arrived in this country shortly after World War II, for example, it made more sense to contact a British ichthyologist such as Peter Humphrey Greenwood than an American ichthyologist such as Robert Rush Miller since the latter was not that familiar with these species nor was he interested in them.

By whatever means the names were supplied, however, if a mistake had been made then sooner or later it would be corrected. Although most of the changes during the immediate Post-World War II period involved species names, there were some changes in genera as well, e.g., *Haplochromis multicolor* to *Hemihaplochromis multicolor* and *Aplocheilichthys macrophthalmus* to *Micropanchax macrophthalmus* to cite a cichlid and killifish example, respectively. Aquarists found no fault in accommodating these changes either, since they were few and far between and it took very little effort to be "correct."

In any event, a change in generic name had no real effect upon the hobby since it provided little or no new information about a fish's origin, description, behavior, requirements or breeding that was not known previously. In short, except for being part of the species name, the genus was – and still is - of no appreciable value in the aquarium hobby. Indeed, I will shortly suggest that even for Science it is becoming as obsolete as the classical Linnaean system of classification it is part of.

THE INTERNATIONAL CODE OF ZOOLOGICAL NOMENCLATURE

During these early years some aquarists, especially those in the specialty groups, became familiar with the International Code of Zoological nomenclature (ICZN or the "Code"). This is a comprehensive document consisting of 18 Chapters, broken down further into Articles and sub-Articles. Its aim is to stabilize and provide uniformity in the scientific naming of animals. In spite of its apparent complexity, the Code can be summarized in two words: bookkeeping and priority.

The bookkeeping part of the Code deals with rules for naming. The Code, for example, requires that a generic name should be treated formally as if it were a Latin noun with a definite gender, and specifically rules that generic names formed from words included in the standard Greek or Latin dictionaries take the genders of those words. For example, if a species name is Latinized, the gender of its ending must agree with its generic name. An example is the old killifish name, *Fundulus bivittatus*. *Fundulus*, since it ends in –us, is masculine so the species name also ends in –us. However, when the fish was deemed later to be in the genus *Aphyosemion*, which is neuter since it ends in –um, the name had to be changed to *bivittatum*. It is not mandatory, however, for the author of a new genus to specify its gender; I could, for example, propose a new generic name, *Zwibac*, and have the ichthyological community guessing as how to assign the endings of the names of new species to the genus.

The Code expressly states that, with a few exceptions, a difference of a single letter is sufficient to make two species or generic names different; *londonensis* and *londinensis,* for example, could be accepted as names for different species of the same genus. The botanical code, on the other hand, rules that what is called "orthographic variants of the same name" are to be treated as homonyms. Here the botanists show greater respect for tradition and common sense.

The Code has no restrictions as to the number of letters in a name nor does it have any mandatory provisions for the combination of letters in names. Thus, *Xqnal* would be perfectly acceptable although no one would be able to pronounce it. There are, of course, procedures whereby one can petition the Commission for an exception. An example of where common sense prevailed was when Dybowski proposed the name *Gammaracanthuskytodermogammarus loricatobaicalensis* for a type of shrimp-like crustacean in 1927. It would have been the world's longest scientific name, but was rejected by the International Commission for Zoological Nomenclature on the grounds that it was unpronounceable, although I suspect that its

length had more to do with it. In actuality, if one breaks the name down into its components it is no more unpronounceable than the average scientific name. The honor, by the way, of having the longest scientific name approved by the ICZN actually goes to a species of soldier fly - *Parastratiosphecomyia stratiosphecomyioides*, while the shortest appears to be that of a carnivorous bat - *Ia io*, although there is a thrip with a single-letter species name - *Plesiothrips o*.

In passing I note that the official language of the Code is English but with preference for British written conventions. Therefore, words such as "parasitise" are often found in written opinions, rather than their American counterparts, i.e., "parasitize."

These are trivial examples of bookkeeping; a more consequential one is the designation of what is known as a "holotype." Suppose an ichthyologist receives a batch of fishes and finds it to be a new species. A **holotype*** is the single specimen upon which the original author of the species designated as such, if he bothered to do so that is, since it was not a requirement under the Code until 1999. The remaining specimens are designated as **paratypes**. Now the naming of a holotype can be important. Suppose, for example, that the batch of fishes actually contained two new species and a holotype was not designated. Which one then has the new name? There are sections of the Code that deal with such matters.

The current rules make type designation the all-important act as far as nomenclature is concerned. We have, for example, types for species as I have just explained, plus those for genera and families. The type for the species we have seen is the holotype, the type for a genus is a species, and a type for a family is a genus. Note that with the exception of the species, for which the type is an actual museum specimen, all the other types are just names and note that names change.

This system places a tremendous legal weight on the holotypes, the theory being that a single specimen can only belong to one species, whereas it always remains possible that a group of specimens might prove to contain more than one species. Although one cannot argue with this logic, a single specimen does not by itself provide a sufficient criterion to define a species. Yet, a whole family of fishes is, in effect, defined by a single specimen.

A further objection to this exclusive reliance on the type system is that holotypes are all too perishable, and if they receive the frequent and intensive study which the present system demands, their useful life will not be very long. In practice, the use of holotypes is restricted because in most groups they are scattered widely throughout the museums of the world, which as a rule are very reluctant to send them outside their own doors for study.

The founders of modern zoological nomenclature did not specify types for genera and it is doubtful whether the majority of genera had types specified for them before 1910. The citation of a type species for a new genus did not become legally obligatory until 1931, and during the last fifty years various taxonomists have taken it upon themselves to propose types wholesale for old genera which seemed to lack them. Such designations have only too often been made in a casual manner with no serious study of the issues involved; hence spring many of our present nomenclatorial troubles.

The problem is that the current code incorporates provisions to the effect that the original specifier of a species name as the type for a genus is assumed to have used that name correctly. This means, in effect, that the type for a genus is the name itself rather than an actual species; if later discoveries or rulings of the ICZN lead to a change in the application of the species name, this means that a different species

*Although I am not a big fan of professional jargon, admittedly it does simplify writing so I will define useful technical terms and boldface them as they first appear in this document.

becomes the type of the genus. I bring all this up because in addition to introducing problems for the professional, these problems in nomenclature are ultimately passed down to aquarists as well.

The original purpose of the priority principle in the code was to adjudicate instances where two zoologists, ignorant of reach other's activities, had described the same species under two different names. However, over time it included other categories as well. The principle of priority in the Code, and it should be noted that the principle is responsible for most of the name changes at the species level in the aquarium hobby, states that "…the valid name is the oldest available name…," an "available" name being one that meets certain criteria in the Code or does not fall entirely out of the province of science.

An interesting example of the latter criterion is the genus *Echidna.* In ancient Greek mythology, Echidna (Greek for "she viper") was called the "Mother of All Monsters," being described as a female monster spawned in a cave who mothered with her mate every major horrible fiend in the Greek myths. If one attempted to give a scientific name to this creature it would not be considered "available" under the Code since it clearly falls outside the realm of science.

In 1797 Georges Cuvier proposed the genus *Echidna* for the spiny anteater, basing the name on the Greek myth since the spiny anteater on a small scale admittedly did resemble some creature out of Hell, although it is actually quite a docile creature. Since this was an actual animal the name was deemed available and the spiny anteater became not only *Echidna* scientifically but Echidna commonly as well. However, Johann Reinhold Forster had published the name *Echidna* in 1777 for a genus of moray eels and therefore it had priority. It is ironic to note that although today everyone uses Echidna as a common name for the spiny anteater, the scientific name, *Echidna*, still belongs to the moray eels!

CLASSIFICATION, SYSTEMATICS AND TAXONOMY

The words classification, systematics and taxonomy unfortunately are now commonly treated as synonyms. Originally and properly, classification would have denoted the activity of placing things in classificatory groups, whereas systematics would be the body of general theory underlying this activity. The word taxonomy, though proposed long ago, has come into general use recently and has become a vaguer synonym of classification and systematics. Thus a taxonomist is generally thought of as an ichthyologist (in our case) who specializes in the classification of fishes into groups on the basis of their structure, origin or behavior. The groups are called **taxa** (from the Greek taxis meaning order or arrangement) and the singular is a **taxon**; a species, for example, is a taxon as is a genus, family, etc. **Genus**, by the way, is derived from the Latin word meaning race, stock or kind.

Systematics, on the other hand, is the study of the diversification of life on the planet Earth, both past and present, and the relationships among living things through time. These relationships are visualized as evolutionary trees, referred to as phylogenetic trees or simply phylogenies. The word **phylogeny** has its roots in the Greek words, phyle or phylon meaning tribe or race and genesis or genetikos meaning relative to birth.

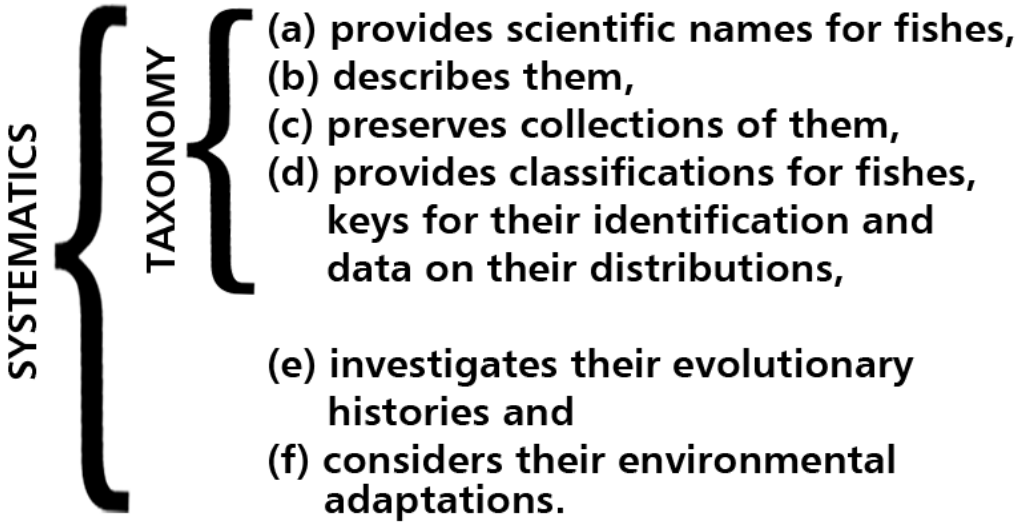
Phylogenies have two components: (1) a branching order showing group relationships, and (2) branch length showing the amount of evolution. Phylogenetic trees (sometimes called **cladograms** from the Greek word klados meaning branch) of species and higher taxa such as genera are used to study the evolution of traits, which can be anatomical like scale counts or molecular like DNA, and the distribution of organisms which we term biogeography. Systematics, in other words, is used to understand the evolutionary history of life on Earth. Figure 1 summarizes the relationship between systematics and taxonomy.

As mentioned previously, systematics and taxonomy are terms that are often confused and used interchangeably. Figure 2 shows how these two terms are related. On the plane denoted as "Current Time," the circles represent current existing species. The tree in the diagram is a phylogenetic tree, and has implied ancestries and a relative time axis. Our interest here, however, is in genera and so in the Current Time plane three are represented by the colored rectangles (counting the large gray one; if you are viewing this in black and white, the green would be the smallest rectangle and the red the next largest) that represent species grouped into genera based upon two measurements in each species, some common possibilities being fin count, height-to-length ratios or even behavioral information. Thus, species 1, 2 and 3 are in the genus denoted by the red color, species 4 and 5 are in the genus denoted by the green color, and species 6 is the only one in its genus.

The taxonomist historically based his groups on measurements made on existing species and not on information based on the evolutionary path hypothesized for these species. This approach is called **phenetics** (from the Greek, pheno, meaning display), i.e., the classification of organisms based on overall similarity, usually in morphology or other observable traits, regardless of their phylogeny or evolutionary relation. There are no hard and fast rules that a taxonomist has to follow in deciding what does and what does not belong in a particular taxon. The ICZN, for example, does not require any criteria for defining a genus - except for specifying a type species - because the Code is concerned with the nomenclatural rules, not with taxonomy.

Typically, a phylogenist - or cladist since cladistics is by far the most common method for determining phylogenetic trees - begins by collecting information on certain features of all the species in question, and then deciding which versions were present in their common ancestor and which have been derived since then. Usually the latter is done by considering some outgroup of fishes known not to be too closely related to any of the species in question. Certain characters are useless for showing common ancestry relationships because they evolved independently. For example, many fishes with sucker-like mouths originate from fast-moving waters where the sucker allows the fish to "stick" itself down without too much difficulty.

FIGURE 1



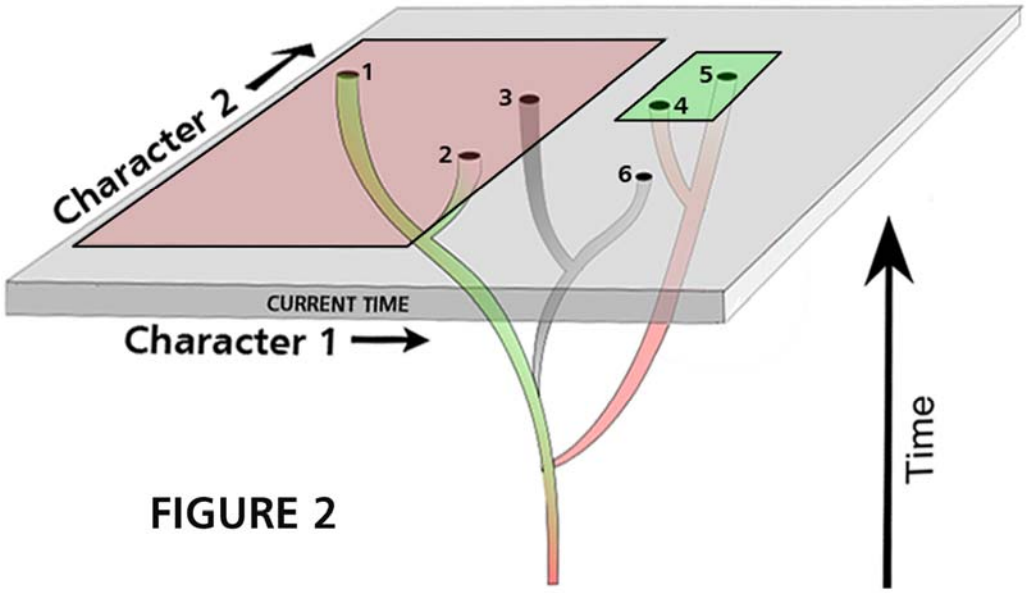


FIGURE 2

Despite their superficial similarity, this type of mouth can be found in fishes that are far from having a common ancestry, e.g., catfishes and Cypriniformes.

As a real world aquarium-related example of a phylogenic analysis, consider the Central Anatolian species of *Aphanius*. Since there a limited number of distinct morphological and phenotypical characteristics in Turkish *Aphanius* species, there are therefore few diagnostic morphological differences among the species. The classification of the genus *Aphanius* is based mainly on scalation, the number and shape of cross-bars and the characteristics of teeth, all of which are regarded as morphologically unstable. Therefore molecular data are likely to be much better suited for the determination of phylogenetic relationships of *Aphanius* species.

In 2004 the Turkish ichthyologists, Bardakci, Tatar and Hrbek studied the genetic relationships between Central Anatolian species and subspecies of *Aphanius* where they used a type of DNA analysis to classify *Aphanius asquamatus, A. fasciatus, A. danfordii, A. anatoliae anatoliae, A. anatoliae transgrediens, A. villwocki* and *A. mento*. Two populations of *A. danfordii*, one from Kayseri Lake and the other from Kocabey Lake, were included, indicated by (1) and (2) after their names.

A cladistic analysis was conducted using a well-known computer program called PAUP (Phylogenetic Analysis Using Parsimony; at this writing the program costs $85). Parsimony is one of the two main methods in cladistic analysis, the other being maximum likelihood. As I have already explained the latter elsewhere on this Forum (see “How Cladistics Works” in the Files Section), I’ll briefly talk about the parsimony method.

Most simply, parsimony is a principle that states that the simplest explanation that explains the greatest number of observations is preferred to more complex explanations. More specifically, it is defined as “a scientific rule that states that if there exists two answers to a problem or a question, and if, for one answer to be true, well-established laws of logic and science must be re-written, ignored, or suspended in order to allow it to be true, and for the other answer to be true no such accommodation need be made, then the simpler of the two answers is much more likely to be correct.”

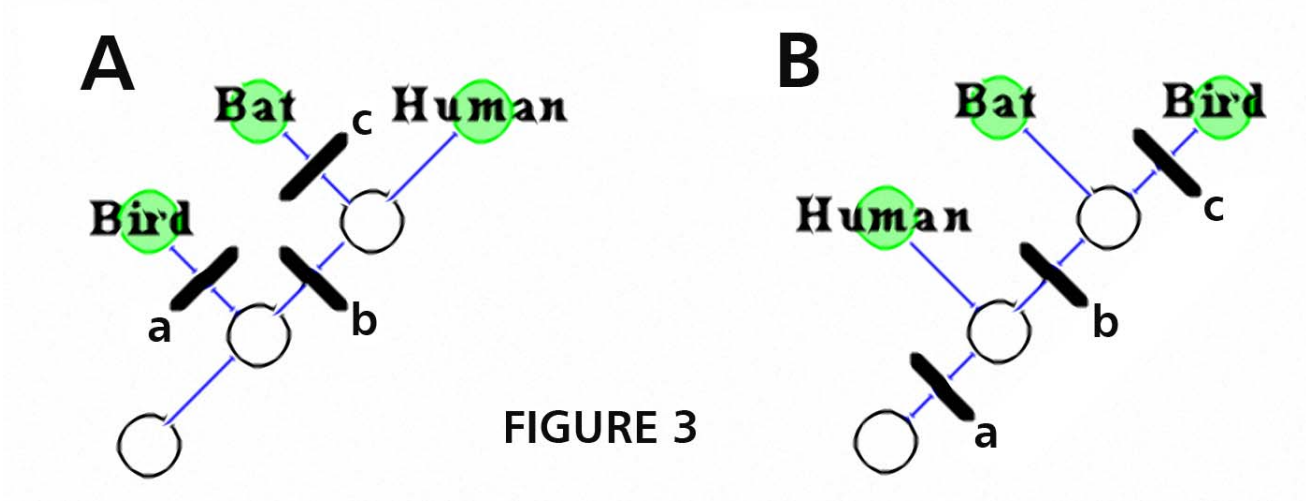

FIGURE 3

For example, consider two cladograms of birds, bats and humans shown in Figure 3:

In cladogram A, the following evolutionary steps occur:

1. At **a:** wing structures
2. feathers

At **b:**

3. hair
4. mammary glands

At **c:**

5. wing structures

In cladogram B, the following evolutionary steps occur:

1. At **a:** hair
2. mammary glands

At **b:**

3. wing structures

At **c:**

4. loss of hair
5. loss of mammary glands
6. feathers

However, cladogram A requires five evolutionary steps while cladogram B requires six. Because cladogram A requires fewer evolutionary steps it is the simplest, and parsimony dictates that this is the preferred cladogram. Further, one could legitimately argue that the combination of the loss of hair and mammary glands and the evolution of feathers would require that the well-established laws of logic and science must be re-written, ignored, or suspended in order to allow cladogram B to be "true." No such accommodation need be made for cladogram A, thus, again, making it the most parsimonious and preferred cladogram.

Using the parsimony method, the results of this investigation showed that (see Figure 4 and move down vertically from *A. asquamatus* to *A. mento)*:

(1) The Central Anatolian species of *A. anatoliae, A. danfordii* and *A. villwocki* forms a sister clade to *A. asquamatus* from Eastern Turkey (the two taxa on either side of a split in the tree are called **sister clades**). The authors point out that based on other research, the timing of the diversification of this clade is concordant with the geological history of Turkey.
(2) *A. fasciatus* (found a little East of the above species) forms a sister clade to all the Central Anatolian species of *Aphanius* including *A. asquamatus*.
(3) *A. mento* from Southern Turkey is only distantly related to the other Turkish species.

Returning now to Figure 2, a cladist would describe the red genus as **polyphyletic**, i.e., having more than one source or origin. The

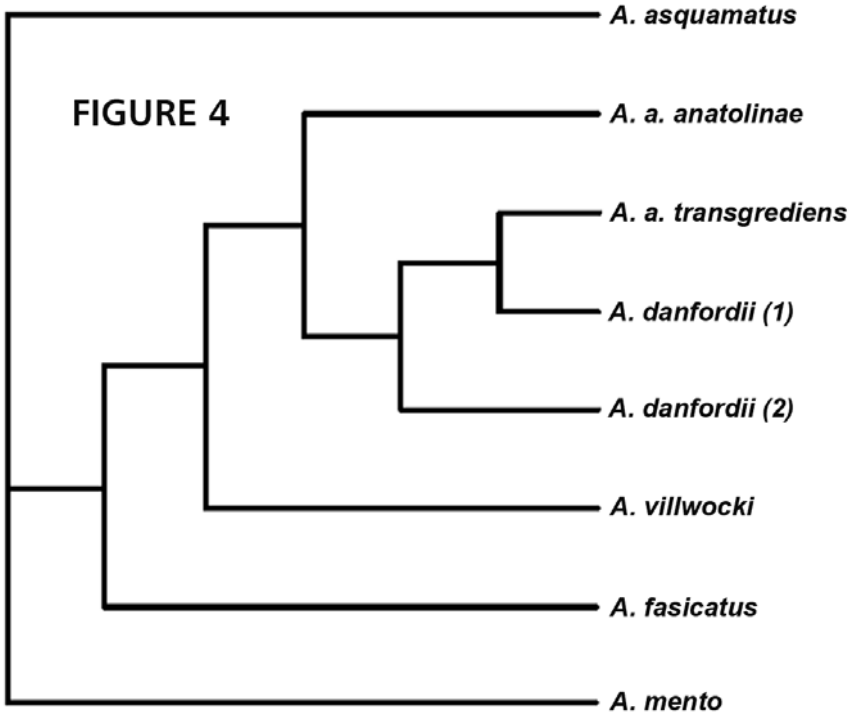

FIGURE 4

have valuable medicinal properties. Because the species is rare and difficult to propagate, attempts are made to locate the compound in other species. The search naturally centers on the genus to which the fish belongs, based on the widespread – but not always reliable - assumption that generic classifications will be predictive. If the genus is polyphyletic, however, it will obscure the fact that the compound can also be predicted to occur in species that have been excluded from the genus because of their marked divergence in some more obvious character or characters.

green genus, on the other hand, is **monophyletic**, i.e., having only one source or origin, and this is what cladists strive for. Finally, a cladist would consider species 3 and 6 to constitute what nomenclaturally we might call a genus (actually, cladists do not use the term; they would refer to it as a "**clade**"). The two classifications, therefore, are not entirely in agreement in this example.

Which of these two classifications is to be preferred? Some strongly oppose cladistic classification as a dangerous challenge to the traditional taxonomic system arguing that "readily recognizable" genera would have to be abandoned, destroying the taxonomic system without producing anything useful to replace it. My own view is that a system of classification should accurately reflect common ancestry, even if it means abandoning traditional genera. Cladists point out that systems that reflect cladistic relationships help users to avoid mistakes, such as analyzing character evolution and historical biogeography, and in making predictions.

Suppose, for example, that a compound in the mucus from a certain fish has been discovered to

In 1978 McAllister and Coad constructed a test between relationships based on phenetic and cladistic taxonomic methods, based upon the axiom that hybridizing taxa are, on the average, more closely related than non-hybridizing taxa. They used data on North American cyprinids and the study concerned 304 pairs of genera that live in the same area but which do not successfully reproduce, but 50 of which hybridize. For each pair they calculated similarity or matching coefficients for both the hybridizing and non-hybridizing genera for both methods.

With regard to the coefficients, as a simple example suppose that among our group of friends we wish to see who is similar to each other with regard to hair color, eye color and height. If two of our friends both had brown hair, blue eyes and were very tall, then the three characters match and the matching coefficient would be is 100%. If one of them had brown eyes, however, then only two of the three characters would match and the matching coefficient would be 68%. If the only matching character was that they were both tall, then the matching coefficient would be 33%.

TABLE I: PROPOSED CLASSIFICATION OF LIVING TELEOST FISHES ACCORDING TO REPRODUCTIVE BEHAVIOR (Balon, 1975)		
NON-GUARDER	GUARDER	BEARER
Open Substrate Spawner	Substrate Chooser	External
Brood Hider	Nest Spawner	Internal
No Parental Care	Some Parental Care	Intensive Parental Care
High Fecundity		Low Fecundity
Indirect Development	Direct Development	
High Number of Eggs		Low Number of Eggs
Investment at Low Cost		Investment at High Cost

For the phenetic method McAllister and Coad found that the proportion of matching coefficients for hybridizing genera above the mean coefficient, 62%, was not significantly higher than for non-hybridizing genera, 54%. On the other hand, for the cladistic method the proportion of values for hybridizing genera above the mean coefficient, 72%, was significantly higher than for non-hybridizing genera, 32%. The cladistic method, therefore, provided a better measure of phylogenetic relationships than did the phenetic method.

One goal of taxonomy is reasonable compactness, i.e., a genus should not be expanded needlessly nor have too many species. In an attempt to reduce the number of species in *Cichlasoma*, ichthyologists have increased the number of new genera significantly since World War II, and although understandable from the taxonomist's point of view, from the aquarist's perspective it often becomes an annoyance. The average aquarist was quite happy with most of the South and Central American cichlids residing in the genus *Cichlasoma*; the need to memorize the names of a slew of tongue-tying new replacement genera was about as appreciated as a root canal sans an anesthetic.

Taxonomists sometimes claim that knowledge of genera is an aid in identification but in fishes, as with birds, real-world identification is rarely made with keys. Species are usually identified directly by comparison with pictures or reference collections and aquarists never learn to attach any particular significance to the generic names.

This is not to say that there is no value in classification to aquarists or in using the genus as shorthand to refer to more than one species. Aquarists can put to good use classifications such as the very general one shown in Table I where genera are not mentioned all, and the more specific one shown applied to African fishes in Table II where a mixture of generic and species names are used. The genera in Table II, it should be pointed out, are simply convenient groupings for this classification and does not necessarily have anything to do with taxonomy or phylogeny. In this respect the generic name does have practical use for the aquarist.

SPLITTERS AND LUMPERS

Historically, lumpers are those who take two or more genera (or any other taxa) and lump them as one because they feel there is not enough variation to justify the extra names and divisions. The opposite of this is splitting - pulling apart one genus to make two or more. From one perspective, splitters recognize more

TABLE II: SIMPLIFIED CLASSIFICATION OF REPRODUCTIVE TYPES IN AFRICAN FISHES (Balon, 1984, Bruton & Merron, 1990)
NON-GUARDERS
Open Substratum Spawners
Pelagic Spawners: *Stolothrissa, Limnothrissa, Lates, Ctenopoma muriei, Alestes*
Rock and Gravel Spawners: *Opsaridriam microlepis*
Brood Hiders
Annual Fishes: *Nothobranchius*
GUARDERS
Clutch Tenders
Plant Tenders: *Polypterus*
Nesters
Froth Nesters: *Hepsetus odoe, Ctenopoma ansorgei*
Hole Nesters: *Protopterus*, many Tanganyika cichlids
Sand Nesters: *Tilapia zilli* and other cichlids
Plant Material Nesters: *Pollimyrus, Gymnarchus, Heterotis*
BEARERS
External Brooders
Mouth Brooders: *Oreochromis* and *Sarotherodon* spp., *Haplochromis, Arius*
Pouch Brooders: *Syngnathus*

genera than really exist, and lumpers go around fixing the resulting damage. From another perspective, lumpers are indiscriminating bunglers incapable of appreciating the subtleties of nature.

Each approach has its well known problems. Lumping tends to create more and more unwieldy definitions with members having less and less mutually in common. Splitting often leads to "distinctions without difference," ornate and fussy categories, and failure to see underlying similarities. While it may or may not be a factor in any individual case, it is also to be observed that there is more glory in "discovering" a new genus than there is in discovering a new species, despite the fact that the former can be done in one's own living room whereas the latter requires one to get his feet wet.

> *"Say what's the rest but empty boast*
> *The pedant's idle claim,*
> *Who* having *all the substance lost*
> *Attempts to grasp a name."*
>
> (From *Solomon*, an oratorio by George Frideric Handel.)

The practicality of the binomial system has, in any event, been seriously undermined by the changes that have occurred since Linnaeus. Enormous numbers of species have been added to those recognized by Linnaeus; we are now approaching a million species of animals, compared with a few thousand in Linnaeus's time. The binomial system could have absorbed this enormous increase without serious loss of utility if most of the additional species had been incorporated in already established genera so that the number of the latter did not rise very greatly. In practice, however, the multiplication of species since Linnaeus's time has gone hand in hand with the splitting of his genera, and the average number of species per genus has actually declined - a figure of about five would probably be a reasonable estimate today.

In some groups (e.g. birds) generic splitting has gone to such lengths that the average number of valid species per genus is down to something between two and three, and among present-day ornithologists there is serious question whether the generic names serve a practically useful purpose at all. One effect of this has been the discrediting of the genus as a practical category among ornithologists, some of whom have even proposed that the generic names should be dropped from practical use altogether. Although I don't favor this drastic discarding of the baby with the bathwater approach for fishes (where the situation is fast approaching that in birds), I wish that ichthyologists would make more use of the subgenus. Botanists, by the way, have a

easier time of it in that they have five categories of taxa between genus and species – i.e., subgenus, sectio, subsectio, series and subseries – than the zoologist's only one.

For example, on the basis of behavior and reproduction, the *Nothobranchius* species can be separated biologically into the subgenera as follows (the subgenus *Zononothobranchius* was based on the color patterns of the males rather than on biological grounds as in the other subgenera):

Genus *Nothobranchius* Peters, 1868.
Subgenus *Nothobranchius* s.s. Peters, 1868.
Subgenus *Adiniops* Myers, 1924
Subgenus *Zononothobranchius* Radda, 1969
Subgenus *Aphyobranchius* Wildekamp, 1977
Subgenus *Paranothobranchius* Seegers, 1985

Aquarists are at leisure then, to use the single generic name *Nothobranchius* for all of the species. If, for some reason, such as discussing the reproductive aspects of these fishes, recourse to the subgenera is helpful, then the aquarist is free to use them.

In conclusion, I do suggest placing less importance upon the "genus du jour" in aquarium writing. To dwell upon this taxon is often taxing, and we all know what happened in 1763 when King George imposed taxonation without representation!

NOMINOPHILIA*

Consider the volatile splitter,
Excited and all of a twitter.
At the fun in the game
Of adding a name
For each little variant critter.

If you make up a different name,
For forms that just might be the same;
You can use the confusion,
To support the illusion
That the effort will add to your fame.

But it's not always praxis that leads
To the multiplication of breeds;
Nor the glory of God,
But the conceit of the clod
With his ego-aggrandizing needs.

Now, a lumper's a different kind;
He thinks the world is designed,
Of similar bits
That won't addle the wits
In the limited scope of his mind.

Specify! somebody flutters;
Simplify! one of them mutters;
The lumpers and the splitters
Will never be quitters,
So the field is a patchwork of splutters.

As names blossom forth anew,
There's much to be said for the view
That puts its store
In "less is more,"
And errs on the side of the few!

CURRENT TRENDS IN TAXONOMY

by Albert K. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, January 26, 2006)

INTRODUCTION

Binomial nomenclature is a standard convention used for naming species. As the word "binomial" suggests, the scientific name of each species is the combination of two names: the genus name and the species or trivial name. The name of the genus (generic name) is always capitalized, while the specific or trivial name is not, and both are usually typeset in italics, e.g. *Homo sapiens*.

The names used are usually derived from Latin. Although Latin derivation is not universal (names sometimes come from Ancient Greek, sometimes from local languages, and often from the name of the person who first described a species), the names are always treated grammatically as if they were Latin words. For this reason the binomial name of a species is sometimes called its "Latin name," though this usage is frowned on by biologists. The term "Scientific name" is more acceptable. For a name to be scientifically complete, an author label and publication details have to be added.

The Linnaean system made it easy to identify unambiguously any given species of plant or animal. Linnaeus proceeded further to introduce into his system a series of groups: genus, order, class. The system works by placing each organism into a layered hierarchy of groups. Each group at a given layer is composed of a set of groups from the layer directly below. Simply knowing the two-part scientific name makes it possible to determine the other six layers.

The groupings (taxa) of taxonomy from most general to most specific are:

* Kingdom
* Phylum (animals) or Division (plants)
* Class
* Order
* Family
* Genus
* Species

An amusing note is that several acronym mnemonics have been made for these groupings, e.g., "King Phillip called out for good soup," or "Kings Play Chess On Funny Green Squares."

Intermediate ranks may be created by adding prefixes, for instance:

* Superorder
* Order
* Suborder
* Infraorder

In addition, species are often subdivided into subspecies and other infraspecific categories (subspecies, variety, subvariety and form). When a species in further subdivided, a trinomial nomenclature is used, e.g. *Astrophytum myriostigma* subvar. *glabrum*.

CLADISTICS

Cladistics (or **phylogenetic systematics**) is a branch of biology that determines the evolutionary relationships between living things based on derived similarity. Cladistics differs from phenetics, which groups organisms based on overall similarity, and from more traditional approaches based on "key characters."

Based on a wide variety of information, which includes genetic analysis, biochemical analysis, and analysis of morphology, rela-

tionship trees called "**cladograms**" are drawn up to show different possibilities. A cladogram showing the relationship between various insect groups using horizontal parallel lines joined by vertical lines. In some cladograms of this type, the length of the horizontal lines indicates the amount of time that has passed since the last common ancestor between two groups or species.

In a cladogram, all organisms lie at the endpoints, and each split is ideally binary (two-way). Each branch, whether it only contains one item or a hundred thousand, is called a **clade**. A correct cladogram should have all the organisms contained in any one clade share a unique ancestor for that clade, one which they do not share with any other organisms on the diagram. Each clade should be set off by a series of characteristics that appear in its members but not in the other forms it diverged from. These identifying characteristics of a clade are called **synapomorphies** (shared, derived characters). For instance, hardened front wings are a synapomorphy of beetles, while circinate vernation, or the unrolling of new fronds, is a synapomorphy of ferns.

CLADISTIC METHODS

Typically, an analysis begins by collecting information on certain features of all the organisms in question, and then deciding which versions were present in their common ancestor (**plesiomorphies**) and which have been derived since (**apomorphies**). Usually this is done by considering some outgroup of organisms we know are not too closely related to any of the organisms in question. Only apomorphies are of any use in characterizing cladistic divisions.

Next, different possible cladograms are drawn up and evaluated. Clades are typically drawn so that they can have as many synapomorphies as possible. The idea is that a sufficiently large number of characteristics should be large enough to overwhelm any examples of convergent evolution. In other words, there are many ways in which plants and animals, etc., may evolve features that resemble each other because of environmental conditions. A well-known type of convergent evolution is insect mimicry, in which some insects that are edible come to superficially resemble other insects that are inedible, and so escape being eaten.

In practice, neutral features like **exact ultrastructure** (a term for extremely fine structure, microscopic or molecular composition of cellular structure) tend to do just that, to provide evidence for real relationships even when the appearance of organisms makes it otherwise difficult. When equivalent possibilities turn up, one is usually chosen based on the **principle of parsimony**: the most compact arrangement is likely the best (a variation of Occam's razor). Another approach, particularly useful in molecular evolution, is **maximum likelihood**, which selects the optimal cladogram that has the highest likelihood based on a specific probability model of changes.

Cladistics has taken a while to settle in, and there is some questioning over in just what sort of circumstances cladistics is applicable. In particular, apomorphies are not always easy to distinguish and data are often unavailable due to a sparsity of available forms or a lack of knowledge of characters, and these may invalidate cladograms. There is also concern that use of widely different data sets, for instance structural versus genetic characteristics, may produce widely different trees. However, by and large cladistics has proven a useful and coherent extension of other methods and has gained general support.

MODERN APPROACHES

The approach Linnaeus took to classifying species and the majority of his taxonomic groupings remained the standard in biology for at least two centuries. Over time, however, our understanding of the relationships of living things has changed. The greatest change was the widespread acceptance of evolution as the mechanism of biological diversity and species formation. After this, it became generally understood that classifications ought to reflect the phylogeny of organisms, where each taxon should originate from a single ancestral form. The emergence of "cladism" or "cladistic taxonomy" in the 1960's, therefore, is expected to supplant Linnaean classification in the future since, in classifying species, cladists place a priority in achieving coherence with the Darwinian principle of common descent.

In grouping species, cladists look for "**derived similarities**," meaning those aspects that species can be expected to share by virtue of a common evolutionary ancestry. This approach differs from that of phenetics, which associates species based on overall similarity and does not address ancestry. It also differs also from classification based on ad hoc "**key characters**." Cladists avail themselves of all the types of evidence available, including DNA sequences and hybridization studies, biochemistry, and traditional morphology. They often make use of computerized algorithms to identify the most likely phylogeny or "family tree" that relates the species they are considering.

A group in a biological taxonomy is **monophyletic** (greek: of one stem) if all organisms in that group are known to have developed from a common ancestral form, and all descendants of that form are included in the group. Taxonomic groups that contain organisms but not their common ancestor are called **polyphyletic.**

For an example of monophyly versus polyphyly, all organisms in the genus *Homo* are believed to have come from the same ancestral form in the family *Hominidae*, and no other descendants are known. Thus the genus *Homo* is monophyletic. If, on the other hand, it were discovered that *Homo habilis* had developed from a different ancestor than *Homo sapiens*, and this ancestor was not included in the genus, then the genus would be polyphyletic. Since biologists by and large prefer groups to be monophyletic, in this case they would likely either split the genus or broaden it to include the additional forms.

We've met!

Groups that contain some but not all descendants of a given form are called **paraphyletic**. A paraphylic group is similar to a monophylic group, but excludes some of the descendants that have undergone significant changes. For instance, the traditional class Reptilia excludes birds even though they developed from the ancestral reptile.

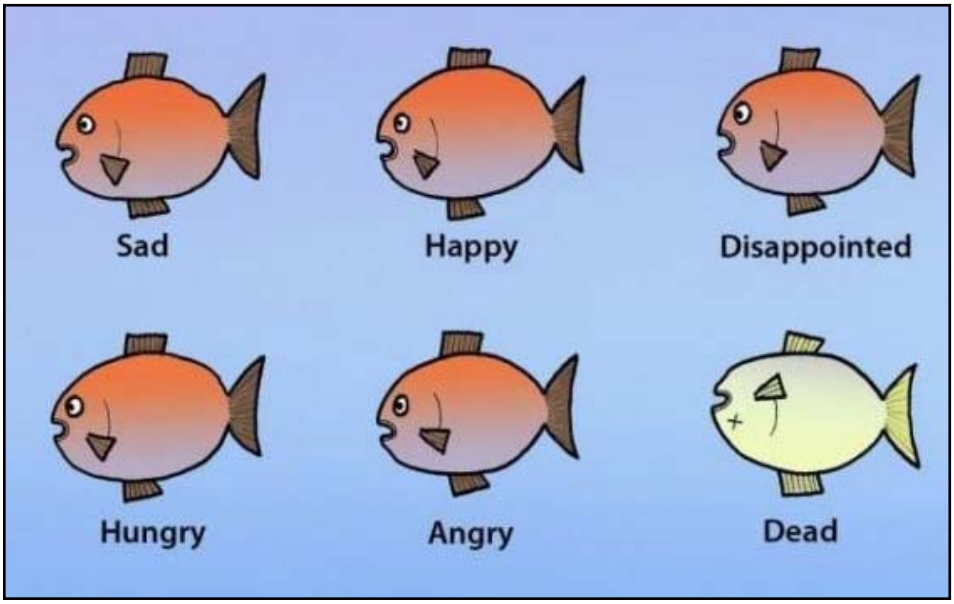
In biology, **phenetics**, also known as **numerical taxonomy**, is an attempt to classify organisms based on overall similarity, usually in morphology or other observable traits, regardless of their phylogeny or evolutionary relation. Phenetics has largely been superseded by cladistics. However, some biologists continue to use certain phenetic methods, such as neighbor-joining, as a reasonable approximation of phylogeny when cladistic methods are too computationally expensive.

As DNA sequencing has become easier, phylogenies are increasingly often constructed with the aid of molecular data. Computational systematics allows the use of these large data sets to construct objective phylogenies. These can more accurately filter out true synapomorphy from parallel evolution.

Cladistics does not assume any particular theory of evolution, only the background knowledge of descent with modification. Thus, cladistic methods can be, and recently have been, usefully applied to non-biological systems, including determining language families in historical linguistics and the filiation of manuscripts in textual criticism.

Cladists argue the classification system should be reformed to eliminate all non-clades (paraphyletic and polyphyletic groups). In fact, some cladists have argued for entirely abandoning the Linnaean system of ranked taxa in favor of clades. To this end, a formal code of phylogenetic nomenclature, the **Phylocode**, is currently under development for a cladistic taxonomy that abandons the Linnaean structure.

The denial of recognition to paraphyletic groups has been very controversial in biology and remains so among a number of more traditional evolutionary taxonomists. They feel that abandonment of paraphyly leads to loss of information in the classification system about significant changes in organisms' morphology, ecology, or life history. Accordingly, they argue that the notions of clade and taxon should be kept distinct, and that paraphyletic taxa are necessary if every group is going to be broken down completely into subgroups. Cladists counter that "significant changes" recognized by evolutionary taxonomists are often too subjective to be a basis for classification.



Understand your fish.

TILAPIA - AN ARCHAEOZOOLOGICAL MYSTERY

By Albert Klee, Ph.D.

(Buntbarsche Bulletin, No. 239, pp. 14-20, April 2007)

Fish were important in ancient Egypt both in religion and in aquaculture (Klee 2005). In the latter, tilapia (notably *Oreochromis* and possibly *Sarotherodon*) reigned supreme. In the Ti Saqqara wall paintings, for example, although clearly meant to present a wide range of different Nile fish, virtually all of the fish being processed for consumption in the illustrations seem to be tilapia. It is also the most mentioned fish in Old Kingdom texts (von den Driesch, 1983).

My interest in this subject was prompted by an attempt to identify those species associated with early ornamental fishkeeping that were also kept by later-day aquarists, and tilapia certainly fills the bill. There is an ornamental fish pond at the Temple of Amon in Luxor (see Figure 1) in which embedded in its walls were ceramic vessels to shade the fish and to provide refuge. It is evident, therefore, that the Egyptians not only knew how to build fishponds but were knowledgeable about the requirements for keeping fish as well. However, since there is no evidence that tilapia were kept in this pond, this is pretty much a dead end in the quest as far as Egypt goes. Like the Egyptians, the Romans also kept fish for religious purposes. Fish sacred to Zeus were kept in the Jovis fountain, fish functioned as oracles at the Apollinis and Limyrae fountains, and at other temple ponds fish were kept for decoration. In addition to aquaculture, the Romans also kept fish for ornamental reasons. The question now is did they keep tilapia for this purpose?

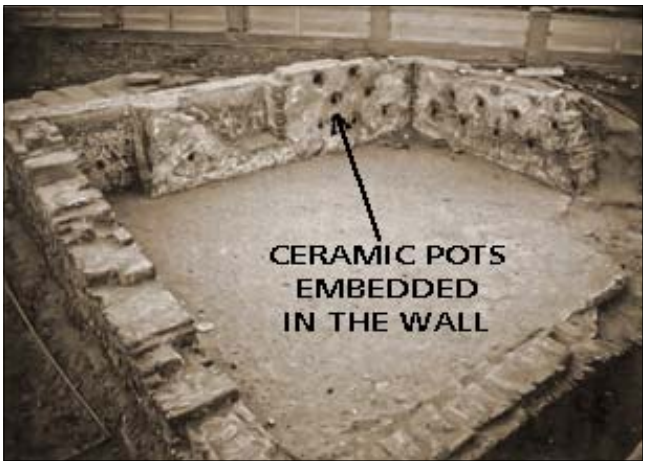


Figure 1: A sketch by the author (after Higginbotham) of the fish pond at the Temple of Amon in Luxor, showing the ceramic vessels embedded in the walls to provide shade and refuge for the fish.

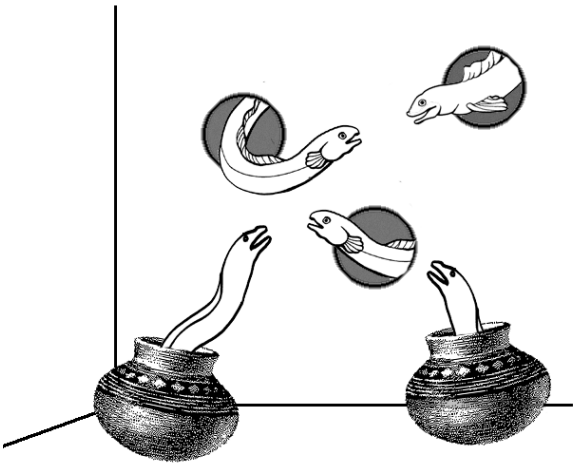

Figure 2: A sketch by the author showing how ceramic vessels were used in Roman fishponds for shade and refuge. These were placed both on the bottom of the pond and also incorporated into the walls.

It is easy to show that the Romans were true experts in fishkeeping. Lucius Iunius Columella (4 -70 AD), a Roman writer, discussed the importance of constructing a "natural environment" within a fishpond and went on at some length about the diets for various fish (e.g., decaying fish parts, salted fish, milk curds, dried figs, as well as small fish). The Romans also included ceramic vessels in the design of their fish tanks, placing them in the walls or on the bottom of the ponds (see Figure 2). These provided both

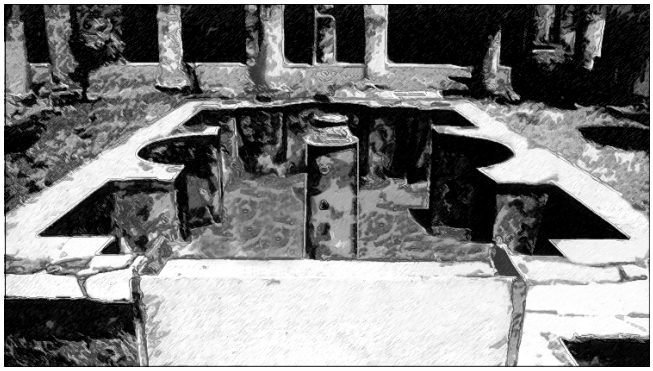

Figure 3: A sketch by the author (after Higginbotham) of the freshwater fishpond at the Casa di Meleagro in Pompeii showing the niches built into the walls for shading the fish and for refuge.

shade and hiding places for the fish. They also incorporated niches in the walls for the same purpose (see Figure 3). Columella also wrote, "Many people think that, in ponds of this type, deep recesses and winding hollows should be made in the sides for the fishes where there may be shadier refuges from the heat. However, similar recesses, like cells, ought to be excavated in the sides so that they may protect the fish, seeking refuge from the heat of the sun, and let the water, which they have received, flow out easily."

The importance of water changes also were recognized by the Romans, and provisions were made for water circulation in both their freshwater and marine tanks. They also recognized that certain fish could exist peacefully side by side but that others had to be kept strictly with their own species. Publius Nigidius Figulus (c. 98-45 BC), a savant of ancient Rome and friend of Cicero, is quoted as saying that the lupus (a member of the Labridae family) and the mullet do get along on occasion but when they do not, the lupus would eat the mullet's tail. Nigidius adds that there is no need for concern because the mullet can live without its tail! Thus, what the Romans knew about fishkeeping could easily form the basis for any beginner's aquarium book today.

As to whether the Romans kept tilapia, this is a difficult question to answer for a number of reasons. For one thing, since the Roman aristocracy preferred saltwater to freshwater fish, the historical record deals almost exclusively with the former. Because of their many excesses, the aristocracy presented a clear target for the critics of the day. Pliny the Elder (23-79 BC), for example, tells a story where a man bought an extra large mullet and remarks that the price of the fish was equal to that of nine horses!

In point of fact, fish and meat were high-status foods and not a significant part of the Roman diet. Cereals, along with beans and legumes, formed the basis for their diet, to which supplements such as meat, fish, vegetables, and fruits were added. Fish were not dependable sources of food, however. Although saltwater fish were plentiful, the supply was unpredictable and could not be guaranteed at expected times and large single fish were difficult to catch and expensive. The latter was especially true of freshwater fish which were generally caught singly. Freshwater fish also had another strike against them. To quote from the Roman physician Galen (129-200 AD): "And some of them that dwell in rivers running through a large town, eating human dung and certain other bad foods, are worst of all, as I said. So that even if they remain for a very short time after death, they straightaway become putrid and smell most unpleasantly. They are all unpleasant to eat and concoct and contain little nutriment but much residue. Accordingly it is not surprising if they produce an accumulation of unhealthy humors in the body of those who eat them on a daily basis."

Nevertheless, based on Diocletian's "Edict of Maximum Prices" issued in 301 AD, we do know that the Romans ate both fresh and salt water fish, and that it was more expensive than simpler meat types. The price of freshwater fish was 12 denarii for first quality and 8 denarii for second quality (by way of comparison, a clerk made 25 denarii a day). Saltwater fish were even

more expensive, i.e., 25 denarii for first quality and 16 denarii for second quality. The Edict, by the way, was an attempt to control runaway inflation and poverty in the Empire. The penalty for exceeding the prices of the Edict or refusing to sell the goods at the stated price was severe, i.e., death. Not satisfied to execute just the seller, Diocletian also decreed that the buyer was to be executed as well!

A recent approach to ancient nutrition is the analysis of skeletons from ancient cemeteries. Such chemistry enables us to construct a picture of prehistoric diet and lifestyles. Recent research (Nicholls, 2005) has shown that the low analyses of carbon-14 in the human remains of this period can only be explained if the Romans ate a lot of freshwater fish, which is particularly low in this material. The verdict is not just in, therefore, regarding how much freshwater fish the Romans actually ate.

Although we know that the Romans farmed brackish water species, such as eels, mugils, labrids, porgy and flatfish, and also predominately marine species such as parrot fish and mullets, we do not know whether they farmed freshwater fish or, if they did, what species were involved. Dumont (1988), in his "Cultural criteria of the choice of the fishes in antique Greek nutrition," showed that both the Greeks and Romans admired and prized tilapia (identified via mitochondrial DNA) as one of the better food fishes of the Mediterranean. Detailed archaeozoological studies (Arndt and others, 2003) of fish bones recovered from the Roman and Byzantine strata in Pisidia, located in present-day Southwestern Turkey about 66 miles north of the capital city of Antalya, have also revealed the presence of tilapia. Tilapia bones have also been found at Mons Claudianus, a quarrying settlement in the mountains of the present-day Egyptian Eastern desert about midway between the Red Sea and the Nile.

This, however, does not prove that tilapia were actually farmed in these areas. Arndt, for example, suggests that the tilapia bones might have come from salt fish (i.e., fish preserved in salt) regularly imported from the Nile Valley. Another explanation involves the discovery of the bones of the African catfish (*Clarias gariepinus*) in the same sites containing the bones of the tilapia (see Figure 4). In fact, the bones of *Clarias gariepinus* seem to crop up all over ancient Roman sites, including Rome itself, an oddity in that the Romans expressed disdain for most species of catfish. (Actually, salted catfish seems to be mentioned most often in relation to its medicinal use, as it apparently was used to recover from childbirth.[1]) Taken together, this evidence provides us with an argument for tilapia cultivation in ancient Rome.

Kron argues that the most plausible solution to the riddle of the prominence of the African catfish in these sites can be found in its highly productive symbiosis with the much more valuable

[1]Oddly enough, the spines of *Clarias* were also used for removing spines, much like we use a needle today to remove splinters.

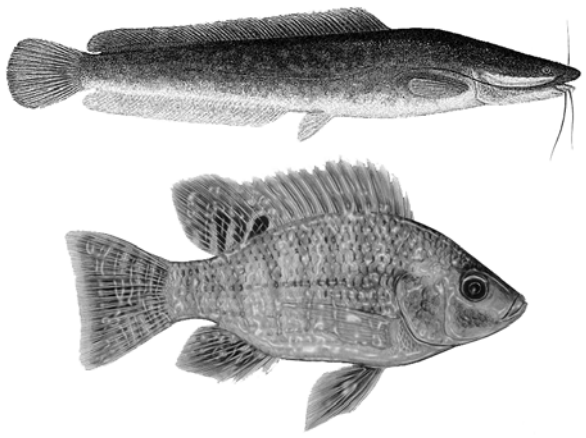

Figure 4: *Clarias gariepinus* (TOP), a police-fish for tilapia (BOTTOM) polyculture. In a polyculture, the catfish consist of about 4% of the fishes.

tilapia (Kron 2005). Both in its natural environment and in modern aquaculture, the African catfish has proven one of the most popular and effective species for use as a police-fish. A police-fish is a natural predator used to restrain the otherwise explosive reproduction of most tilapia species, particularly the mouthbrooders such as the highly prized Nile tilapia (*Oreochromis niloticus*).

The tilapia is an extremely prolific fish that reaches sexual maturity relatively young. The females have a short reproductive cycle and are able to reproduce many times over their life. Most importantly, adult tilapia protect their fry extremely carefully. As a consequence, tilapia tend to become stunted and fail to reach marketable size if raised in monoculture. If allowed to breed freely in the absence of predators, 28-70% of the total biomass of tilapia consists of fingerlings. The resultant intense competition for food between adults and their ever-burgeoning numbers of young prevent the tilapia from reaching their natural optimal size of up to almost 24 inches.

Studies in the Ivory Coast (Moehl, 1999) have shown that yields of 4 to 5 tons per acre per year of tilapia can be boosted to 9-11 tons per acre per year when the tilapia are combined with *Clarias gariepinus*. Not all of this boosted production consists of the more valuable tilapia, of course, but the vast majority generally does and the catfish are also suitable for human consumption, albeit at a lower price. Although a number of other species can also be used effectively as a police-fish, the African catfish and the Nile perch (*Lates niloticus*) are far more common. Lazard (1980), however, reported higher yields with *Clarias gariepinus*. This fish is able to control tilapia development with a stocking rate of only one catfish for every 27 tilapia, higher than the 1:37 ratio for the Nile perch but with less danger of the destruction of the tilapia if the balance is miscalculated.

The most plausible explanation then for these striking finds of African catfish all over the Roman Empire is that Roman fish farmers imported it in order to facilitate the more efficient cultivation of tilapia, which would have been a very prolific and delicious food fish for them. The African catfish was clearly an important fish in the normal habitat of the Nile tilapia, so it is very likely that Egyptian fish farmers would have quickly recognized the natural symbiosis between this species in the wild and realized the value of maintaining this relationship in tilapia fishponds. When trying to understand the culture of unfamiliar and exotic species such as tilapia, it is logical that Roman fish farmers would have drawn upon the experience of the Egyptians and imported both the tilapia itself as well as the most suitable local fish, i.e., *Clarias gariepinus*, for its polyculture. If this is the case, then it is not much of a leap to suppose that the Romans also kept tilapia for ornamental purposes as well.

One could argue that the African catfish bones found in ancient Roman sites were salt fish and not a result of fish farming. However, one would then have to explain why they were imported when much more attractive species, such as tilapia and the Nile perch, were available for salting. Large fish such as the African catfish would generally have their head, vertebrae and dorsal spines removed before being salted; yet the dorsal spines of *Clarias gariepinus* are commonly found at the sites. Indeed, if *Clarias* were used as police-fish then this would be a supply of fish that could be marketed to Romans disinclined to eat catfish in general, thus explaining the prevalence of *Clarias* bones throughout the Roman Empire.

There is one problem, however, and it is not trivial. Although tilapia species are far more common and more important than the African catfish, tilapia bones are found on fewer sites and in smaller quantities. Kron hypothesizes that there may be some taphonomic (i.e., the conditions and processes of fossilization) peculiarity

about the tilapia, or about its preparation, which tends to cause the disproportionate destruction or loss of the more readily identifiable bones of this species. Von den Driesch also noted these oddities in Egypt where we know tilapia were farmed extensively.

In any event, the question of whether the Romans farmed and perhaps kept tilapia as ornamentals is a fascinating mystery that has piqued the curiosity of classical archaeologists and archaeozoologists, and now aquarists as well.

Did You Know???
In early 1965, Albert J. Klee initiated the idea of establishing a national cichlid association. Taking on the responsibilities as Publisher and Editor of the new magazine, AQUARIUM ILLUSTRATED, the first issue appearing in January 1966, Dr. Klee was unable to devote the necessary time to the project, and Dick Stratton enthusiastically and efficiently took over. To our great fortune, the insight of these two gentlemen was the motivation behind what is now the American Cichlid Association.

AN AQUARIUM PATENT PRIMER

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, December 8, 2007)

The aquarium historian traditionally has had recourse to two major sources of information: (1) interviews, oral or written (and this includes the historian if he or she has information relevant to the subject at hand), and (2) printed material such as books and magazines, whether as hard copy or in electronic form as might be gathered from the Internet. However, because equipment is such an important part of the aquarium hobby, there is a third major source, i.e., patents.

Fortunately for the historian, the United States Patent and Trademark Office (www.uspto.gov) maintains a database of patents available for examination on-line to any and all free of charge (the database also includes information regarding copyrights). Patents issued from 1790 through 1975 are generally searchable only by the three field codes of patent number, issue date, and Patent Office classifications (the Patent Office refers to these as "Full-Page" images). Patents issued after 1975 are in a full-text database and are searchable by all 31 different field codes as well as by keywords or phrases in Boolean combinations (the Patent Office refers to these as "Full-Text" images). A full-text database, for example, allows one to search field codes for such things as title, abstract, and inventor, or on keywords or phrases such as "aquarium heater." The latter can be of a Boolean nature such as "aquarium heater" AND "aquarium thermostat" or "aquarium heater" OR "aquarium heating."

EXAMPLE 1, FOR PATENTS ISSUED BEFORE 1975: ISD/1/$/1950->12/$/1974 and CCL/119/257.

This will retrieve all wall aquarium patents awarded between January 1, 1950 and December 31, 1970. The ISD and CCL are Field codes for issue date and classification, respectively. For patents issued before 1975, only the Field codes ISD, CCL and PN (patent number) can be used. Note that searches are not case-sensitive. You can, for example, use ccl rather than CCL. Also note that the $ symbol is a "wild card," i.e., the date field is month, day, and year so I used $ to indicate any day in January through December.

The retrieval for this search is shown in Figure 1. In the actual retrieval, the terms "Full-Text" and "Full-Page Image" are indicated by the icons after the patent number. The first patent turns out to have been issued in 1973 but the Patent Office has converted it to full-text as indicated by the title which is in text. The other three patents are available only as Full-Page images their titles being replaced by relevant classification codes. Consequently their titles are available only when one clicks on the patent number and examines the patent. As will be seen later, this causes a problem when the classification codes used involves other than aquarium-related patents.

EXAMPLE 2, FOR PATENTS ISSUED AFTER 1975: ISD/1/$/1975->12/$/2004 and IN/Danner-Eugene$ and "aquarium filter."

This will retrieve all aquarium filters awarded to Eugene Danner between January 1, 1975 and December 31, 2004. Since this search is after 1974, the inventor name field was permissible.

FIGURE 1: RETRIEVAL FOR EXAMPLE 1

	PAT. NO.	Title
1	3,735,738	WALL MOUNTABLE AQUARIUM
2	3,276,428	**119/257** 392/451
3	2,814,895	**40/538** 119/257 40/779 40/800 428/14 47/41.01
4	2,595,085	**362/101** 119/246 119/253 119/257 362/122 47/66.6 D11/145 D26/51

Clearly the full-text database is ideal since it enables one to find patents that meet predefined requirements quickly and with precision. The situation with patents issued prior to 1975, however, is not anywhere near as satisfying. One seldom knows the patent numbers or the issue dates of the patents sought, leaving the researcher at the mercy of the classification system for these patents.

The classification code that includes almost everything dealing with the aquarium hobby is Class 119, "Animal Husbandry" (there is one exception that will be discussed later). As stated by the Patent Office, "This class provides for methods or apparatus for the propagation, rearing, training, exercising, amusing, feeding, milking, grooming, housing, controlling, handling, or general care of a living animal unless provided for elsewhere." Fortunately, there are subclasses that narrow the search further, and these are defined in Table I.

Unfortunately, only subclasses 245 through 269 are really specific to the aquarium hobby; the remaining subclasses include aquaculture patents as well. This

TABLE I
U.S. PATENT CLASSIFICATION CODES RELEVANT TO THE AQUARIUM HOBBY

	CODE 119 ANIMAL HUSBANDRY
51.04	FEEDING FOR AQUATIC ANIMAL, e.g., A FISH Subject matter wherein the nourishment supplying structure presents a food substance to an animal which lives in the water. Note. This subclass includes a device which may dispense feed above or below the surface of the water which may be in a time release form which dissolves in water to release food.
51.11	TIMER-CONTROLLED FEEDER Feeding devices in which the time at which an element of the feeding device is actuated, or the length of time of a feeding operation, is controlled by a timer.
51.15	RELEASED BY CLOCK ALARM MECHANISM FEEDER Feeding devices in which the trip includes the alarm mechanism of an alarm clock.
THE FOLLOWING CLASSIFICATIONS ARE UNDER AQUATIC ANIMAL CULTURING	
201	HANDLING AND TRANSPORTATION Subject matter including the preparation of and apparatus for sustaining one or more living aquatic animals during transfer, shipment, and temporary storage.
203	FISH TRANSPORTATION Subject matter wherein the aquatic animals transported are fish.
210	WITH FEEDING Subject matter including apparatus for providing a supply of food to each compartment.
215	FISH CULTURING Subject matter relating to the care and propagation of fish.
217	SPAWNING, HATCHING, AND EARLY DEVELOPMENT Subject matter including method or apparatus relating to fish egg fertilization, incubation, and emergent fry culturing.
218	FISH INCUBATOR OR HATCHING TRAY Subject matter including apparatus by which fish eggs are hatched artificially under controlled environmental conditions.
219	FISH DIVERTER OR BARRIER
223	FLOATING FISH REARING ASSEMBLY Subject matter including means to prevent or control the movement of fish past or through certain objects or locations.

TABLE I CONTINUED U.S. PATENT CLASSIFICATION CODES RELEVANT TO THE AQUARIUM HOBBY	
224	TANK ARRAY Subject matter including a plurality of interconnected or cooperatively arranged water containment structures for housing fish.
225	SEQUENTIAL OR STEPWISE TANK ARRAY Subject matter wherein the tanks are connected such that water serially flows therethrough.
226	FISH ENCLOSURE - RECIRCULATING TYPE Subject matter including a water containment structure for sustaining fish and having means for removing a portion of the water and returning it to the containment structure after treatment to improve its life sustaining properties.
227	WITH BIOLOGICAL FILTER Subject matter wherein the recirculated water is treated by a pass-through apparatus in which living organisms are utilized for water treatment.
228	FISH ENCLOSURE – NON-RECIRCULATING TYPE Subject matter including a water containment structure for sustaining fish life and absent any removal and return of treated water into such structure.
229	WITH HEAT EXCHANGER Subject matter including apparatus to affect the temperature of the water contained in the fish enclosure by heat transfer means.
230	FEEDING METHOD Subject matter relating to a process for the nourishment of fish.
231	WATER TREATMENT COMPOSITION Subject matter comprising chemical treatment including additives or other means to affect the life sustaining properties of the fish containing aqueous medium.
232	CLEANING-SWEEPER OR MECHANICAL AGITATOR Subject matter including apparatus utilizing pressurized water circulation to aid in removing fish tank sediment or apparatus to mechanically cause suspension of such sediment to aid in its removal.
233	COVER, LIGHT OR RAY AFFECTING Subject matter including means to selectively intercept visible light and other radiation impinging upon the water surface of a fish pond or tank.
245	AQUARIUM Subject matter relating to a water containing tank or vessel which ordinarily houses aquatic animals and which has one or more transparent portions so that the inhabitants thereof can be observed from the exterior. Note. This subclass includes aquarium equipment and accessories not elsewhere provided for. In certain instances, the aquarium may be partially or fully emptied and used to house small land animals, for example.
246	AQUARIUM COMBINATION (e.g., AQUARIUM-TERRARIUM, ETC.) Subject matter wherein there is in cooperation with aquarium structure additional structure directed to the housing and display of other life, such as plant, insect, or land animal life.
247	COMBINED Aquariums claimed in combination with subject matter not provided for in this class and which perform a function other than to perfect means that are provided for in the class, for example, aquariums combined with lamps or articles of furniture are proper for this subclass.

TABLE I CONTINUED U.S. PATENT CLASSIFICATION CODES RELEVANT TO THE AQUARIUM HOBBY	
248	MULTICOMPARTMENT Subject matter wherein the aquarium consists of a tank or vessel which is divided by structural means into two or more separate spaces.
249	SUPPORTED WATER COLUMN Subject matter wherein atmospheric air pressure is utilized to support a portion of the aquarium water media above the ordinary atmospheric exposed water surface of an aquarium.
250	FOR JOINING AQUARIUMS Subject matter wherein a water column provides a bridge between at least two separate aquariums.
251	TANK WITHIN TANK Subject matter including an enclosure for water which is adapted to be at least partially submerged in cooperative relationship inside another such enclosure such as a larger aquarium.
252	BREEDER TYPE Subject matter including structure for allowing the escape of live babies from a fish giving birth in the innermost submerged tank.
253	ORNAMENTAL Subject matter including aquarium apparatus and structure of the kind to embellish or adorn the basic visual attractiveness of the aquarium. Note. Ornamental features include, among others, aquarium shape, underwater decoration, toys, aesthetic use of a water or aeration device, and aesthetically improved fish viewing apparatus. Certain structures which conceal aquarium life support elements may be considered as visually enhancing and are included herein.
254	AIR OPERATED Subject matter including ornamental means which utilize pressurized gas to produce a visual effect such as a bubble driven ornament or device.
255	LIQUID DISPLAY Subject matter including ornamental means which utilize water beyond that ordinarily contained in the aquarium to produce a visual effect such as a waterfall.
256	SUBMERGED DISPLAY Subject matter wherein the ornamental structural feature is situated and viewed underwater while contained in the aquarium.
257	WALL-TYPE AQUARIUM Subject matter wherein the aquarium is structured to be mounted on or in a side or inner portion of a building or other such vertical structure.
258	EMPLOYING MIRROR Subject matter wherein one or more reflective surfaces are utilized to enhance the visual appearance of the aquarium.
259	FILTER Subject matter including means cooperating with the aquarium structure to cause recirculation of the contained water while removing contaminants therefrom as it passes through a media holding device.
260	BIOLOGICAL TYPE Subject matter wherein the filtering system contains organisms which process wastes to decontaminate the circulated water.

TABLE I CONTINUED U.S. PATENT CLASSIFICATION CODES RELEVANT TO THE AQUARIUM HOBBY	
261	WITH AERATOR Subject matter including means to provide oxygen enrichment to water in the aquarium.
262	AND HEAT EXCHANGER Subject matter including means to raise or lower the aquarium water temperature.
263	AERATOR Subject matter including apparatus providing oxygen enrichment to water in the aquarium.
264	AQUARIUM CLEANING (NON-FILTER TYPE) Subject matter including apparatus for removing contaminants from the aquarium environment without utilizing a water filter.
265	COVER Subject matter including a device extending over an air exposed opening of an aquarium to exclude dust or prevent the escape of an inhabitant therefrom.
266	WITH LIGHT Subject matter including an illumination device in connection with the cover.
267	AQUARIUM ILLUMINATION Subject matter including means cooperating with the aquarium structure to provide enhanced interior lighting thereof.
268	CHEMICAL TREATMENT Subject matter wherein selective chemical substances are utilized to alter certain properties of the aquarium water and environment.
269	AQUARIUM STRUCTURAL ELEMENTS AND ASSEMBLY Subject matter including aquarium structure such as floor, wall, and sealing means necessary to permanently contain the water environment therein and apparatus or a method of associating such elements.
	CODE 219 ELECTRIC HEATING
$	This searches all subcodes under 219 (the "$" is a "wild card."
	CODE 392 ELECTRIC RESISTANCE HEATING DEVICES
$	This searches all subcodes under 392 (the "$" is a "wild card."

means that each patent retrieved prior to 1975 in subclasses other than 245-269 must be examined individually to determine whether it is an aquarium patent or an aquaculture patent since, as previously shown in Example 1, the patents that are returned are listed by patent number only, not by title. This is a time-consuming, tedious process and especially frustrating since the number of aquarium-related patents are few and far between in most of these subclasses.

Patents describing aquarium heating are not included within Class 119, "Animal Husbandry," but in mostly two other classes, i.e., Class 219, "Electric Heating" (which also includes welding, microwave heating, auto windshield heating, etc.) and Class 392, "Electric Resistance Heating Devices" (which also includes hair driers, towel warmers, etc.).

An applicant for a patent must list related U.S. patents in their application, and these can be used to find many relevant patents listed prior to 1975. For example, one can examine the related aquarium patents issued prior to 1975 that were listed in the patents found for the period 1975 to 2004. This is only a partial solution, however, since related patents are listed only by patent number, date of issue, and inventor's name. One must therefore look at each of the related patent numbers to see if the patent is relevant to the search, a tedious process if there are many related patents.

TABLE II
PATENTS ISSUED BETWEEN 1945 AND 2004 IN FIVE-YEAR INTERVALS

CLASS CODES	1945-1949	1950-1954	1955-1959	1960-1964	1965-1969	1970-1974	1975-1979	1980-1984	1985-1989	1990-1994	1995-1999	2000-2004	TOTALS

258	0	1	2	1	1	3	0	0	2	4	0	2	16

Table II lists the number of patents issued between 1945 and 2004 in five-year intervals. It is interesting to plot the number of patents issued against time and this is shown in Figure 2. As might be expected, the number of patents issued generally increased yearly, although there was a marked decrease in the 1975-1979 time interval. In descending order, the most patents issued were in aeration (261 and 263), filtration (259 and 260), heating (HEAT, 219, and 392), and feeding (51.04), a not unexpected result.

TABLE II CONTINUED
PATENTS ISSUED BETWEEN 1945 AND 2004 IN FIVE-YEAR INTERVALS

CLASS CODES	1945-1949	1950-1954	1955-1959	1960-1964	1965-1969	1970-1974	1975-1979	1980-1984	985-1989	1990-1994	1995-1999	2000-2004	TOTALS

*Since Class 392 is considered to be an integral part of Class 219 and thus often contain the same results, this line was obtained by using key phrases and a Boolean operator, i.e., “aquarium heater” OR “aquarium thermostat.” For patents issued after 1974 (and sometime even somewhat earlier), the use of key phrases and Boolean operators is often useful in reducing the number of non-relevant retrievals in Class 119 subclasses 51.04 to 233.

THE CASE OF THE CONTESTED FILTER PATENT

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, November 25, 2005)

One aspect of aquarium hobby history that I have explored in some detail is that of patents relating to the hobby. Although the patents themselves are interesting and serve to add to our knowledge of such history, another element also is fascinating, i.e., the area of patent litigation. A good example is the following case history that concerns two very prominent filter designs, i.e., the Dynaflow and the AquaClear filters.

BACKGROUND

The story starts with Allan H. Willinger who, as a boy, had become interested in the aquarium hobby. He later worked for a manufacturer of aquarium heaters, eventually opened an aquarium shop, and finally became a manufacturer of aquarium supplies. He knew of the need for a filter that would be efficient, inexpensive, trouble-free, and reasonably quiet. Reading an article about automobile speedometers in the magazine POPULAR MECHANICS, Willinger learned about magnetic coupling.

This is a device by which a motor can drive a mechanism without a mechanical link. The driving mechanism moves a plate containing a magnet, and reacts to a second magnet located on another plate. When the two plates are placed near each other, the attraction of each set of magnets compels the plates to move in unison. In other words, the plate in the driving mechanism turns the plate in the driven mechanism and its attachments (See Figure 1 for a typical example).

The inherent virtue of this mechanism is that the driving and driven plates can be separated by a glass or plastic divider. The driven plate and its operating mechanism can thus be enclosed in a sealed unit without danger of contamination from outside substances. In the automobile speedometer mentioned above, for example, the delicate mechanism that turns the gauge seen by the driver is in an enclosed unit. The sealed unit contains the driven plate with its magnets; this is turned by a driving plate operated outside the unit. No dirt, dust, oil or water can enter the sealed speedometer. If there is a defect in the driving mechanism, it can be repaired without touching the sealed unit.

This principle had been used for other applications. Lunch counters, for example, frequently display juice dispensers in which orange juice or some other beverage is propelled in a spray around the walls of a clear plastic bowl. The customer is thus attracted by the sight of the foaming juice, and the spray impeller keeps the juice aerated and foaming. In this application the liquid inside the bowl is sprayed by a pump operated through magnetic couplings by a

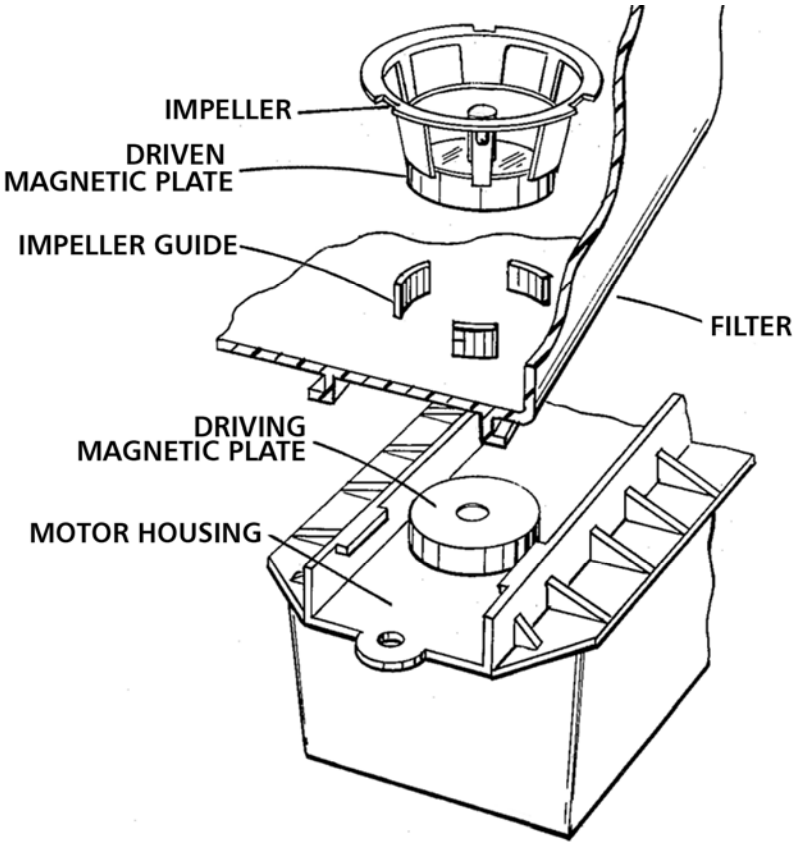

FIGURE 1: THE MAGNETIC COUPLING CONCEPT

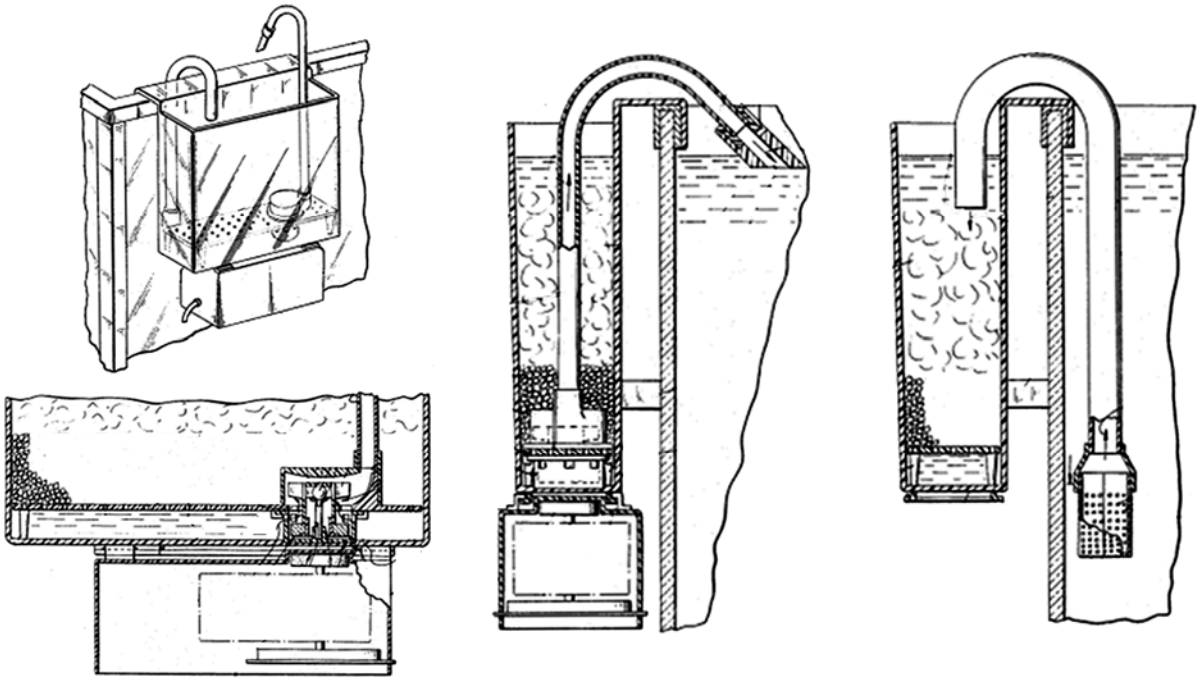

FIGURE 2: THE WILLINGER PATENT

driving plate and driving mechanism outside the juice container. The sealed container keeps the beverage free from contamination, and divides the pumping mechanism into two physically separate units.

Willinger knew nothing of these other applications, nor had he observed that the magnetic coupling had been previously used in this manner in the aquarium hobby. It was this POPULAR MECHANICS article that directed his thoughts to an application for fish tanks. He was able to produce a model using parts readily available in the commercial market. Later he obtained the patent that was involved in the lawsuit, a description of which is shown in Figure 2. This patent (U.S. 3321081) was applied for on June 18, 1964 and was awarded on May 23, 1967.

Basically, the Willinger patent describes an aquarium filter that is hooked to an aquarium tank. Water is siphoned from the tank into the filter where it is cleaned; then it is returned to the tank. The water enters the filter from the top. The filter material, e.g. charcoal, is placed on a horizontal divider in the filter chamber. The water flows down by gravity, filters through this material and passes into a clean water chamber. A centrifugal pump, supported in the divider, returns the filtered water to the aquarium tank through a water outlet. The centrifugal pump is operated by an electric motor that is coupled to it magnetically. The pump itself is located outside the aquarium tank, but inside the filter device. Beneath the impermeable bottom wall of the filter device outside of the fish tank is a driving magnet, directly connected to the electric motor. Thus the motor turns the driving magnet, and the driving magnet turns the driven magnet, motivating the pump. In this way, the water cannot be contaminated by oil or foreign material from the driving magnet or motor nor can water enter the motor. This is the filter, assigned to Aquariums Inc. of Maywood New Jersey (a forerunner of the Metaframe Corporation), that was placed on the market in the mid 1960‘s as the “Dynaflo.” It was extremely popular and was “THE” power filter of its time.

However, on March 25, 1970 an International Patent Convention application for a filter was filed by the Biozonics Corporation of Natick, Massachusetts (a description is shown in Figure 3). It was also filed on June 30, 1970 as a British patent (GB1300176), the complete specification being published on December

20, 1972. The inventor was Richard C. J. Palson, and the filter was marketed as the Biozonics 3-Stage Power Filter. The Rolf C. Hagen Corporation of Mansfield, Massachusetts acquired the rights to this filter and it was the forerunner of the series manufactured by Hagen under the name "AquaClear" (the name was first used in commerce in 1979).

Although The Biozonics patent described mounting facilities for four filter cartridges, only three are shown in detail in the patent drawings and the commercialized version also used just three (hence its name as a 3-stage filter). However, it used a magnet drive similar to that of the Willinger patent to draw the water through the filter media and pump it out and back to the aquarium. The similarity of the Willinger device in this regard to the Biozonics filter caused the suit for infringement to be filed. Because Biozonics admitted to the similarity, the single issue was the validity of Claim No. 3 of the Willinger patent, in particular the matter of the electric motor being magnetically coupled to the pump for moving the water. If the court decided that this claim was valid, then Biozonics would be liable for damages and its filter forced from the market.

ELEMENTS OF PATENT LAW

The lawsuit was brought before United States District Court for the District of Massachusetts and heard by Judge Carl B. Rubin. That Judge Rubin was somewhat of an aquarist himself is attested to by his opening opinion:

> "In a competitive struggle, almost as determined as that of two male betta splendens, or Siamese fighting fish, the manufacturers of concededly similar aquarium filtering devices, one the patent assignee, the other its challenger, here join battle to determine the validity of the patent. Since the patent is virtually conceded to possess utility, the victory turns on whether the two other legislative requisites are met: whether the device was obvious at the time it was conceived to a person of ordinary skill in the art, and whether the concept was novel. The issues are clear, but the waters are deep."

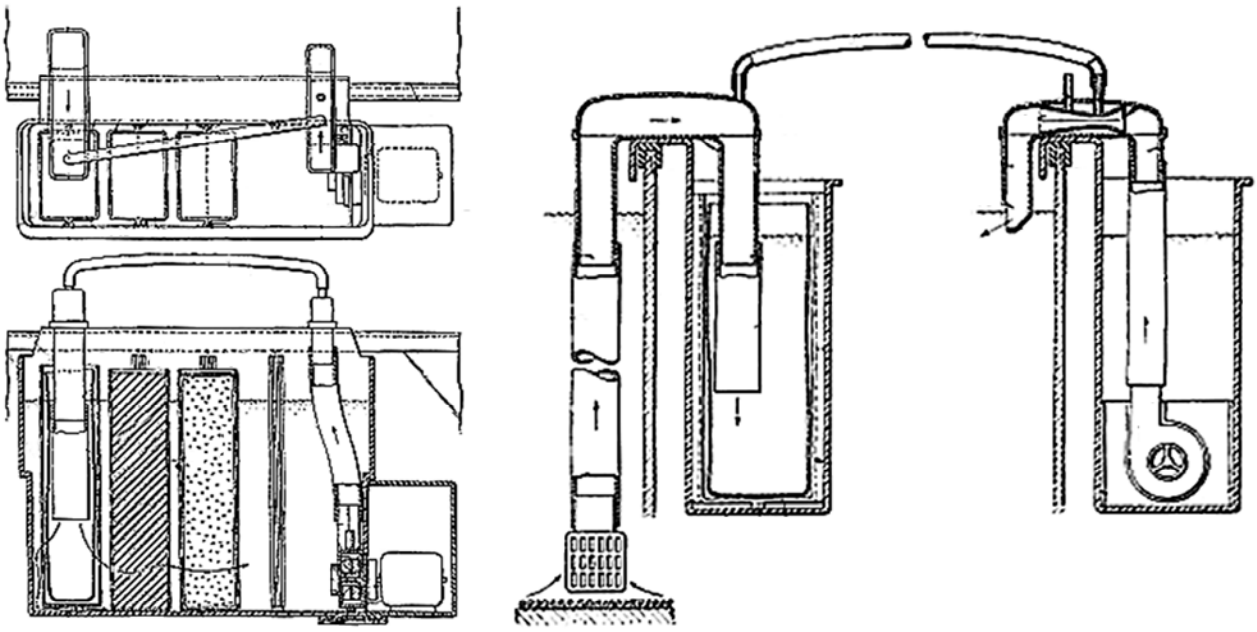

FIGURE 3: THE BIOZONICS PATENT

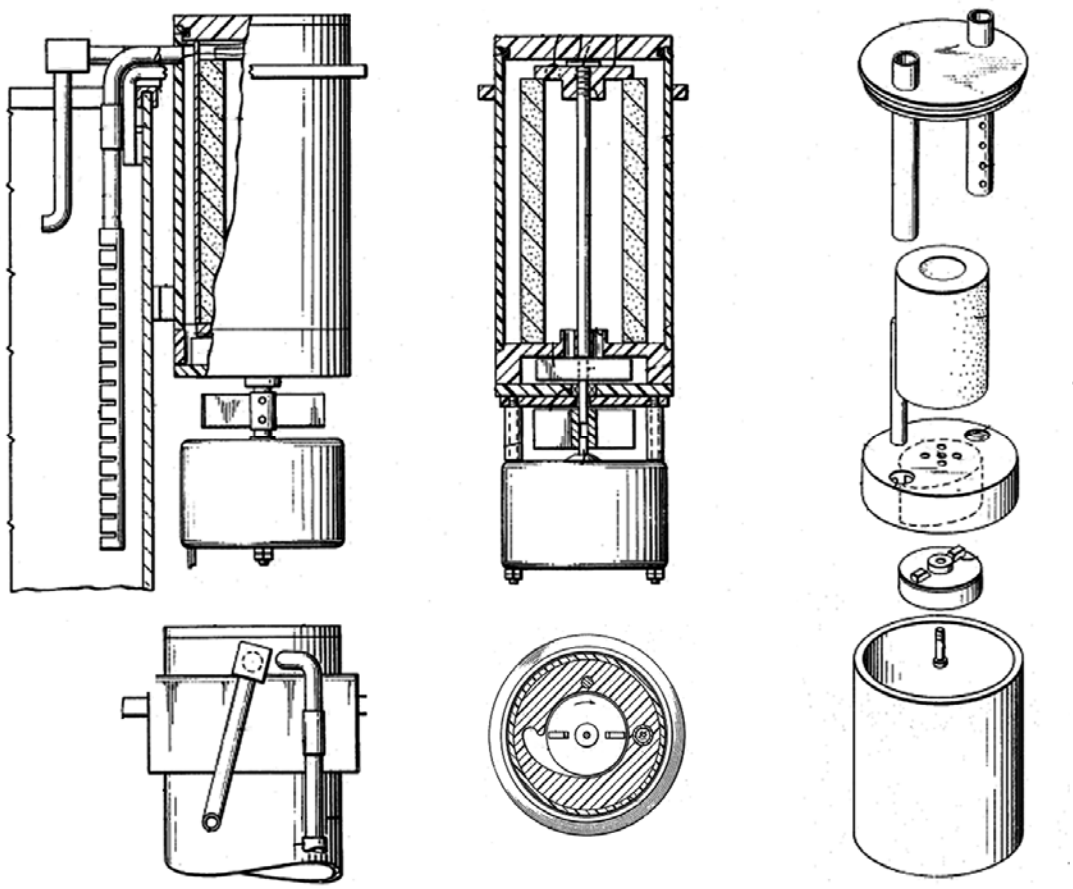

FIGURE 4: THE CANTERBURY PATENT

Prior to the development of the Willinger patent, magnetic coupling devices were in common use, e.g., a driven and driving magnet on opposite sides of a fluid impermeable wall had been used to couple a motor to a pump-impeller for pumping fruit juices and similar beverages; for deep well pumps and power transmission arrangements; for gas and fuel pumps; for refrigeration systems; for chemical and dairy pumps; and for centrifugal pumps generally. The use of an open tank raising water by siphon, aerobic filtration by charcoal, employing gravity for filtration - all of these were likewise in common use. All in all, Judge Rubin cited 10 patents. Willinger's patent consisted of a combination of these previously existing elements.

THE CANTERBURY PATENT

However, there was another patent of special importance, one for a "Combination Filter and Aerator" was filed by Howard M. Canterbury on October 2, 1963, more than eight months before Willinger's application. It was issued in September, 1966 (U.S. 3273717), at which time it was made public (a description of which is shown in Figure 4). Although Canterbury incorporated a magnetic coupling device into an aquarium pump, it utilized a sealed suction system, rather than the unsealed, open topped, siphon fed, aerobic filtration of the Dynaflo. (It also had a round shape, quite distinct from either the Willinger or Biozonics patents.) The record indicated that the examiner was aware of the Canterbury patent during the course of his assessment of the Willinger application, but there is no evidence that Willinger or his attorney at that time attempted to establish an invention date prior to the filing of Canterbury. The relevance of Canterbury in this case was contested by Willinger who argued that although Canterbury was filed prior to Willinger, he asserted that his conception and reduction to practice occurred prior to the filing date

of Canterbury. His testimony in this regard was uncorroborated, however, and it was not credited.

The judge took an easy way out here, stating that it was unnecessary to consider and resolve the questions of burden of proof, presumptions of priority, and the availability of procedures within the patent office to resolve such conflicts, because the questions of obviousness and novelty in this case could be determined without reference to Canterbury. He argued that the prior art utilizing magnetically driven pumps was exemplified in a host of other applications already noted. He also noted that even if Canterbury was not prior art, its application of the magnetic clutch principle demonstrated that the knowledge of such a possible use was gaining currency even in aquarium devices. To aquarium historians it also meant that it was not Willinger who was the first to apply the magnetic principle to an aquarium filter, but Canterbury. Willinger, however, was the first to commercialize it.

THE QUESTION OF OBVIOUSNESS

Willinger maintained that his inventiveness lay in devising the first use of such a device in aquarium filters, arguing that this drive mechanism was not known in the aquarium industry. Overlooking Canterbury for the moment, a preponderance of the evidence established that indeed no one had used magnetic couplings for aquarium filters before Willinger. Metaframe and Willinger both conceded that engineers were well acquainted with magnetic couplings and that manner of operating a pump was well known to mechanical engineers. Indeed, Willinger at all times asserted the invention resided in the novel combination and not in the elements of the combination.

The elements to assemble the device were commercially available and the theory was widely applied. Clearly this application would have been obvious to a person with mechanical engineering training in 1960. Indeed, there was testimony by a witness who satisfied the court as being both expert and reliable that the problem would have been too elementary for him to assign to an undergraduate mechanical engineering class if he were seeking to require them to develop a creative application. It is unchallenged that if the applicable art is “fluid dynamics” the application of the magnetic coupling would have been obvious to the ordinary person in that field. Is the test then the obviousness of an application to persons working in a particular field, such as the aquarium trade? Or does the test apply to persons having ordinary skill in the basic mechanical or scientific field, such as fluid dynamics, even though they are not actually working in a particular field that might call forth their skill?

The adaptation of a magnetic coupling to an aquarium pump would have seemed elementary to one with ordinary skill in the field of fluid dynamics. Here the original patentee, Willinger, had no experience or training in that area, but this does not restrict the test of obviousness, which presumes that “the inventor would have that ability to select and utilize knowledge from other arts reasonably pertinent to his particular problem which would be expected of a man of ordinary skill in the art to which the subject matter pertains.”

The bottom line is that the Willinger concept was obvious to one with ordinary skill in the applicable art. The combination it made was merely the intelligent use of mechanical ability to continue a previously existing magnetic coupling to the previously existing elements of an electric motor powering a centrifugal pump, an open top filter receptacle with a siphon tube, and a divided filter action chamber. (Various minor issues, said the judge, were of no significance. The argument that water pumped from Willinger's unit was clearer because of the divided chamber ignored the fact that the small filtration device processes only water taken from and returned to a contaminated source; the suggestion that it “polishes” the water was merely a result of the relative efficiency of the filtration process and rapidity of the cycle. None of these was the result of any inventive combination.)

THE QUESTION OF NOVELTY

Willinger's invention was a combination patent. It was conceded that all of its elements had long been known, but it was asserted that the invention was in the novelty of the combination. Such a patent must

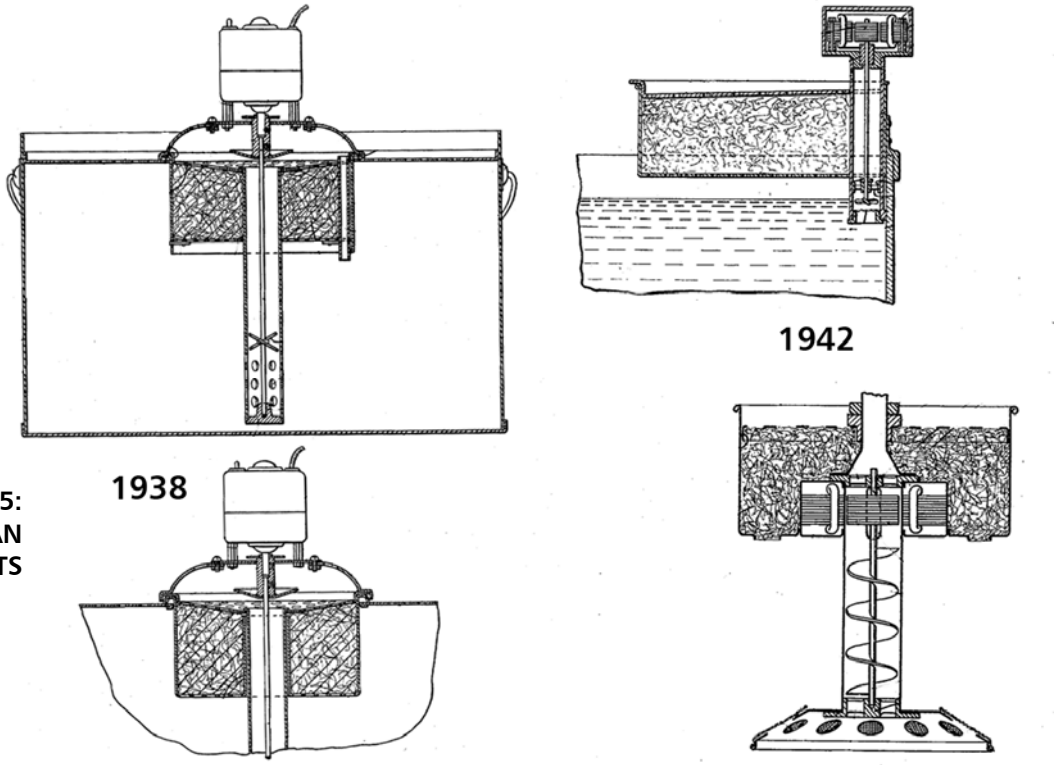

FIGURE 5: THE HALDEMAN PATENTS

of course satisfy the test for novelty. In the area of combination patents, the examination of a patent for novelty involves the consideration of many facts identical to those weighed in determining non-obviousness, but as the judge pointed out, these tests are discrete in the statute. The question of novelty, being one of judgment, is necessarily not susceptible of precise determination. But there seemed to the judge that there was such a close relation between the prior applications of magnetically driven pumps to the Willinger use that his concept lacked the requisite novelty.

ATTORNEY'S FEES

Biozonics brought up the matter of another filter, the Supreme (inspired by the 1938 and 1942 patents of James F. Haldeman - See Figure 5.), which unquestionably was issued years prior to Willinger. This was for an aquarium filter essentially identical to the Dynaflo filter except that the Supreme secured the electric motor above the filter receptacle and coupled it directly rather than by magnetic couplings to the centrifugal pump. Though the Supreme was not commercially popular because of its expense, vibration difficulties, difficulty in priming the siphon tubes, and the hazard of having an electric motor not designed to get wet in close proximity to water, it was technically part of the prior art considered in the case. However, the acknowledgment of prior developments was implicit in the Willinger's position that his invention was based not in the development of any element of his combination, but rather in the novelty of the combination.

Biozonics pointed out that since the Supreme patent was identical to the Dynaflo except for the magnetic coupling, it should have been cited to the patent office in the Willinger application. They argued that the effect of this absence diminished the presumption of validity of the Willinger patent, and therefore entitled them to attorney's fees.

The court, in exceptional cases, may award reasonable attorney fees to the prevailing party. However, the judge argued that the absence of a citation of the prior Supreme filter was not such an act of bad faith as to justify attorney's fees in this case even though Willinger was aware of the

Supreme filter. At the time Willinger developed his pump, the Supreme unit was not commercially significant. It was an expensive pump that Willinger himself had never carried in his shop. Though the Supreme was prior art, relevant to the issues of obviousness and novelty, Willinger's omission of it as a reference was deemed not motivated by an intent to deceive or mislead, or by lack of good faith. The judge pointed out that an applicant has no duty to cite every publication of which he knows merely because the publication is one likely to be referred to by a vigilant examiner in the Patent Office or by a rival in some future proceeding.

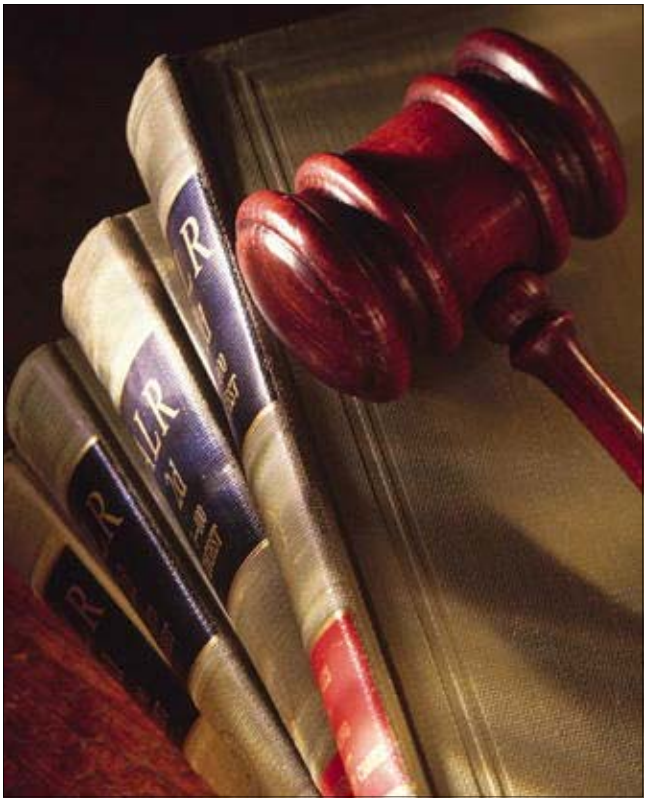
OUTCOME

On December 7, 1972, the Court rendered a judgment declaring the Willinger patent invalid, having failed to meet the tests of non-obviousness and novelty. It also rejected Biozonics demand for attorney's fees.

COMMENTARY

It is my opinion that Judge Rubin made the right decisions in this case. Other than the magnetic coupling, filter designs similar to that of Willinger's were common. In addition, Canterbury did have the prior patent on the coupling, although if his patent had gone through litigation similar to that of the Dynaflo, it too would most likely have been declared invalid because of the prior art in this area.

That being said, although the judgment went against the Willinger patent, it should be pointed out that the Dynaflo filter was revolutionary for its time and generated a host of competing designs that formed the basis for the power filters that are popular to this day. For this, Allan H. Willinger deserves the historical credit.



THE HISTORY OF THE UNDERGRAVEL FILTER - A CASE HISTORY

by Albert J. Klee, Ph.D

(Aquarium Hobby Historical Society, Yahoo Files, November 25, 2005)

Neil Foster, among others, has often lamented the lack of information regarding the historical development of aquarium equipment, such as air pumps, filters, lighting, etc., and I share his feelings. As one with an engineering background I have an inherent interest in such matters and have spent the past few years in trying to learn more about how we came to the hobby equipment of today and who got us there.

However, I have found that this is not an easy task. Pumps, filters, and lighting, for example, often have their origin in other areas, such as water purification or even fields not remotely connected with water, let alone aquarium water. Furthermore, if one takes this backward journey to its ultimate starting point we may well be delving into the invention of the wheel or the lever itself!

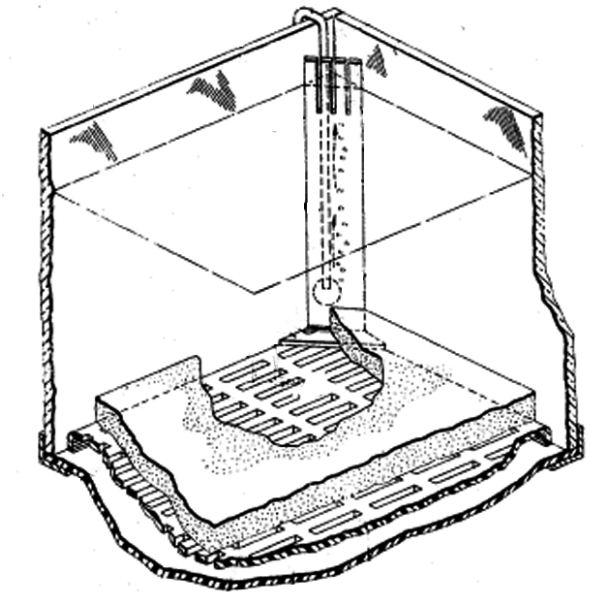


FIGURE 1: UNDERGRAVEL FILTER, 1968 Inventors: William E. Kelley, Euclid, OH and Robert J. De Fassele, Gates Mills OH.

The process can be simplified by restricting the search for a particular item to its first application in an aquarium. In some cases, however, this may take us back to the middle of the 19th Century, i.e., the days of Warington and Gosse, so even this might present a burden.

I wanted to give an example of the process so I selected a topic that was introduced after World War II, i.e., the undergravel filter (UGF), and I started with a model that appeared around the year 1970 since they haven't changed all that much since then (the changes mostly involve how they are powered).

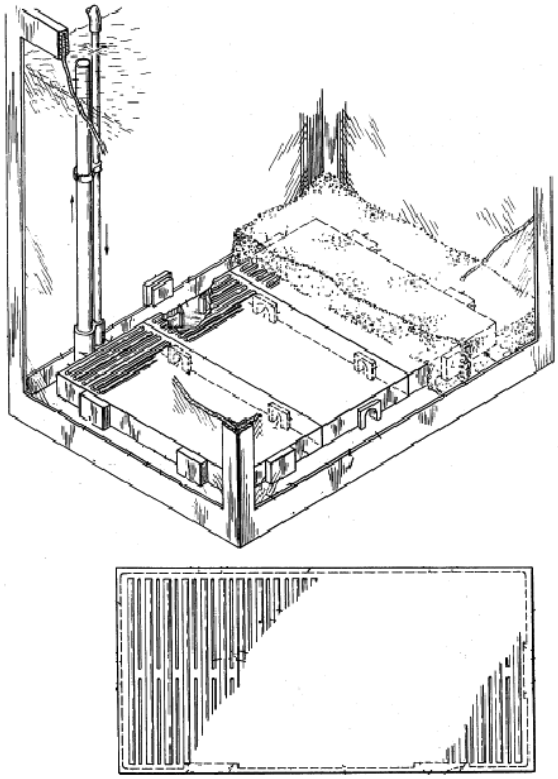

FIGURE 2: UNDERGRAVEL FILTER, 1968 Inventor: Walter Sesholtz, Park Ridge, N.J.

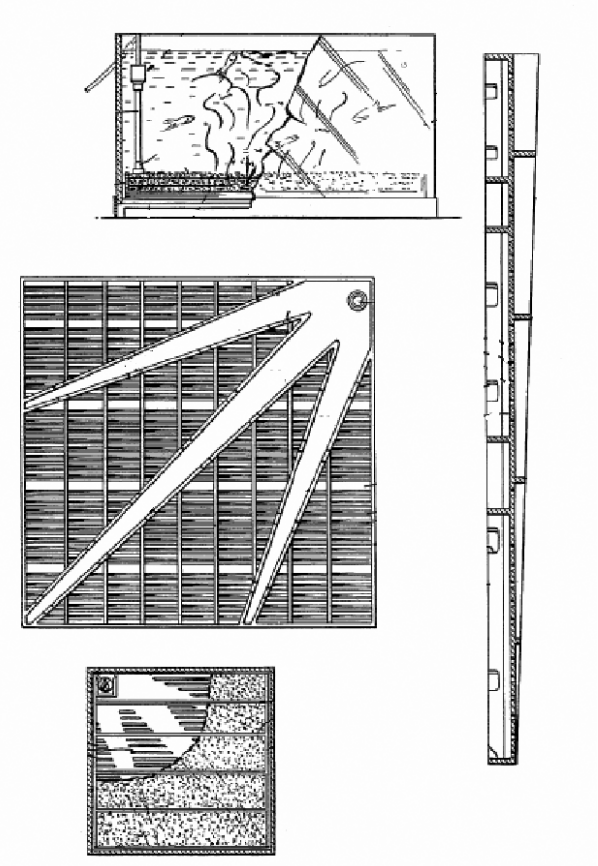

FIGURE 3: UNDERGRAVEL FILTER, 1958
Inventor: Alan H. Willinger,
New Rochelle, NY.

Figure 1 shows a UGF that dates back to 1968 (it was later manufactured by Aquarium Systems, Inc.) and I picked this one because it shows the typical slotted-box design of the time. Although simple in design and inexpensive to manufacture, it is not the origin of the original UGF. The improvement claimed for this particular design was the incorporation of a triangular corner plate that solved the problem of fish getting caught between the corner of the aquarium and the cylindrical return air/water mixture tube then commonly used. The 1968 design in Figure 2 (it was later manufactured by Sternco Industries, Inc. of Harrison, New Jersey) shows this typical cylindrical return air/water mixture tube. Aquariums come in different sizes so the box was constructed of interlocking modules so that various tank sizes could be accommodated, keeping its cost low. Again, this was not the origin of the original UGF.

Taking a leap back ten years to 1958, Figure 3 (an invention of our old friend, Alan Harding Willinger) shows another slotted box type but one that slopes towards the front, thus providing a more even suction to make up for the greater thickness of gravel that is usually found in the rear of aquaria. To further even out the suction, the water is not drawn out directly from the box but to a three-armed chamber that is narrower at the farthest point away from the vertical air/water return tube. Figure 4 shows an UGF design that appeared in 1955. The design left space in front so that the aqua-

rist manually could siphon the sediment that usually gravitated to the front of the tank. The odd-looking design at the top of the air/water return tube was to minimize the splashing of water when an excessive amount of air was used.

The earliest (1955) design for a slotted-box UGF is shown in Figure 5. It was invented by Norman G. Hovlid and was subsequently manufactured by the Miracle Filter Company of Long Beach, CA. However, previous inventions provided the background for all of these UGF designs. Figure 6 shows one such 1954 design that simply uses a funnel set into the gravel with a vertical air/water return tube attached to the narrow end and an ordinary air stone in the main part of the funnel. The problem, of course, is that the water was pulled on-

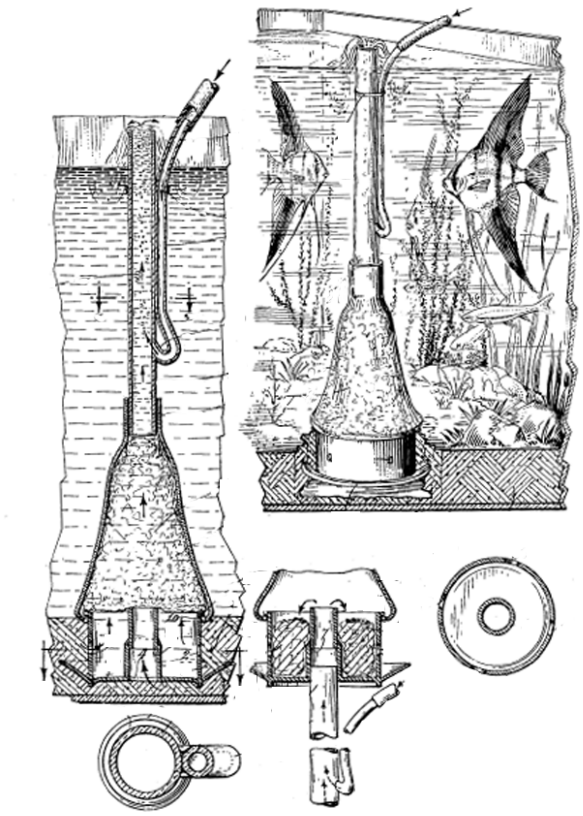

FIGURE 8: UNDERGRAVEL FILTER, 1952
Inventor: Constant Pettas,
Montreal, Canada.

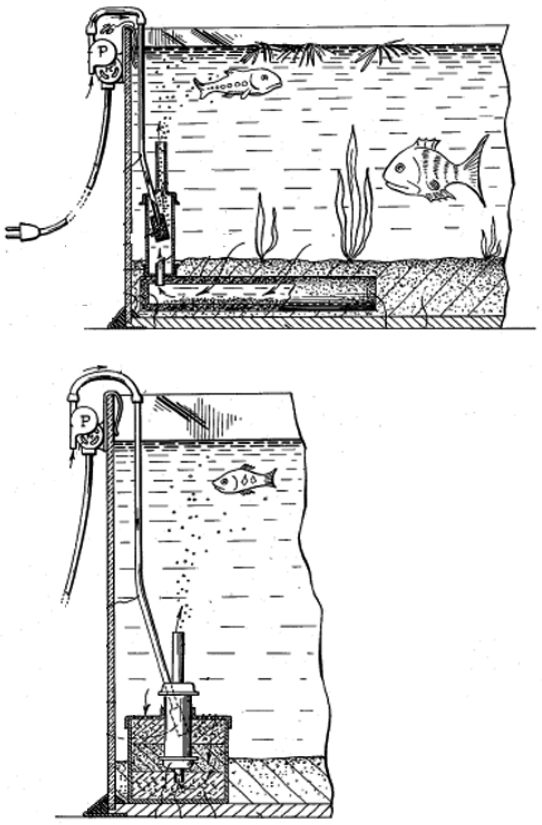

FIGURE 9: UNDERGRAVEL FILTER, 1950
Inventor: Mary L.M. Vansteenkiste,
Montgeron, France.

ly through the gravel situated near the funnel.

A design that appeared one year earlier (Figure 7) was better in that it utilized a perforated tube below the gravel. It had a vertical air/water return tube that could be elongated or shortened via a sleeve that surrounded one portion of it, and it had cleanout plugs at various strategic places, although these could be utilized only when the filter was taken out of the aquarium. The lower part of the diagram shows the air chamber that allowed a greater volume of air to be introduced, thus increasing the air/water flow through the outlet tube. Another device of the funnel design appeared in 1952 and is shown in Figure 8. It was designed to fit in the corner of the tank although it was also designed to be used as a mulm collector as well. Unlike the design in Figure 6, the funnel could also be packed with a filter material such as fiberglass. Because they did not pull water through all parts of the bottom gravel, these designs were in and of themselves not successful.

In 1950, Mary L.M. Vansteenkiste, of Montgeron, France, invented the filter shown in Figure 9. It was essentially a hollow porous cylinder, embedded with carbon so that when the water passed through the gravel certain impurities not removed by the gravel would be removed when it passed through the cylinder. Along with her husband, Vansteenkiste later modified this design and it was advertised and sold in this country during the 1960s and 1970s as the “Invisible French Filter & Aera-

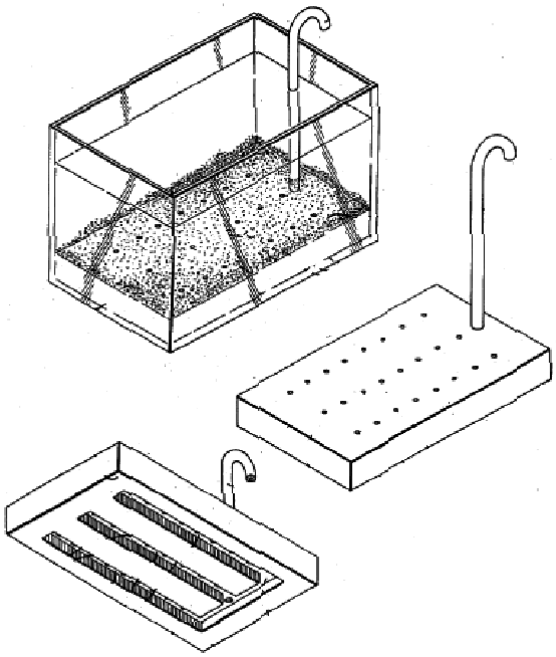

FIGURE 10: UNDERGRAVEL FILTER, 1951 Inventor: Albert J. Schwartz and Samuel H. Barbour of Philadelphia, PA .

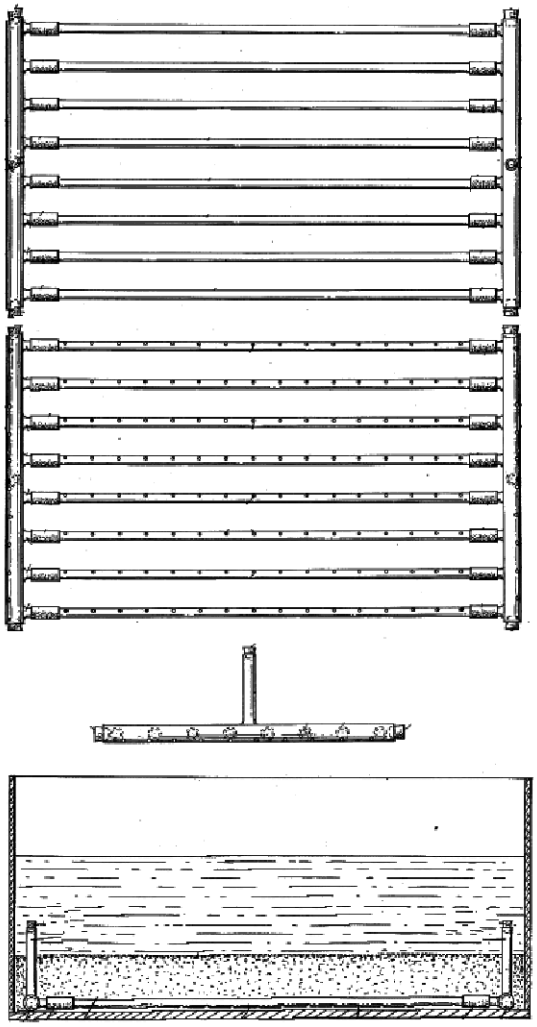

FIGURE 12: UNDERGRAVEL FILTER, 1950 Inventor: George W. Ludwick of Philadelphia, PA .

tor." Since it involved inserting a cylinder, it could be installed and uninstalled without taking down the tank.

Albert J. Schwartz and Samuel H. Barbour of Philadelphia, Pa invented the design in 1951 shown in Figure 10. It consisted of a solid plate with three channels drilled into it. A number of holes were drilled through each of the tops of the channels and all three emptied into a common channel. The curved siphon tube was used to draw the water from the tank into a standard filter (not shown) from where it

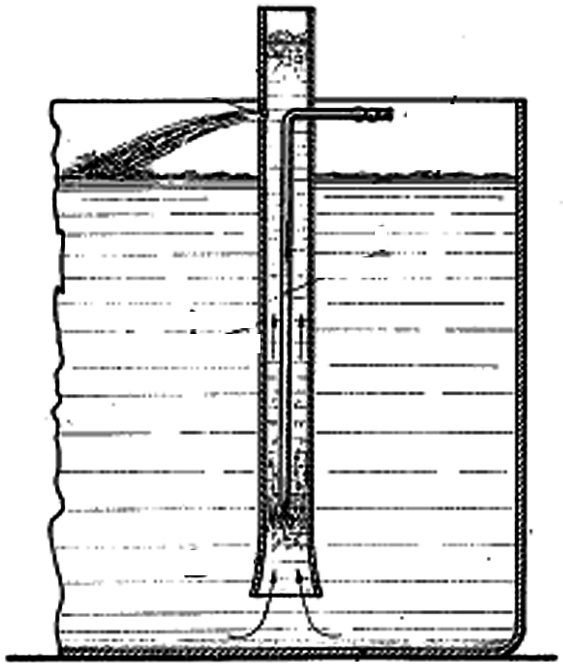

FIGURE 13: AIR LIFT, 1925
Inventor: Evert Willem Beth,
The Hague, The Netherlands.

was returned to the aquarium. If Schwartz and Barbour had incorporated air into the siphon tube, converting it into a vertical air/water return tube, we could credit them as being the first to invent the flat-bottomed UGF.

An early variation (1951) that later became the inspiration for the funnel type is shown in Figure 11. In this design what ultimately was to become the funnel was a cylinder that was open at the bottom so that it could be pressed down into the gravel. Like the funnel designs, it did not pull water through all parts of the gravel layer throughout the tank and so was ineffectual.

Figure 12 shows the tube-type UGF that was invented by George W. Ludwick of Philadelphia, Pa. in 1950. The vertical tube was capped but at intervals a hose was attached and the water within the tubes was siphoned. Again, close but no cigar. If Ludwick had incorporated air into the siphon tube, converting it into a vertical air/water return tube, we could credit him as being the first to invent the box-type UGF. However, the airlift had been invented many years prior to this (1925, by Evert Willem Beth of The Hague, The Netherlands – see Figure 13). As a consequence, this was coupled with Ludwick's tube grid and the resulting UGF was widely used during the late 1950s.

It took several inventors, therefore, each adding a piece to the puzzle, to arrive at a true UGF. This case history shows that it is not always easy to identify the first person responsible for a piece of aquarium equipment. Often the credit must be shared with many others.

UNUSUAL POST WORLD WAR II AQUARIUM PATENTS

By Albert J. Klee, Ph.D.
(Aquarium Hobby Historical Society, Yahoo Files, February 3, 2008)

This paper describes fourteen patents issued between 1966 and 2007 that are unusual, innovative and, at the same time, decidedly fanciful. None of them were commercially produced, although two of them were singled out by well-known manufacturers to whom the patents were assigned (what were they thinking?).

1. PATENT NUMBER 3265388 A RHYTHMIC AERATOR ACTUATED FLOAT FOR INDICATING WATER LEVEL

This patent was awarded in August of 1966 to Frank A. Kane, III of Stratford, Connecticut. Its purpose was two-fold: (1) To provide a form of aeration that "renders the aquarium more interesting and attractive," and (2) also functions as a means for indicating when the level of liquid in the tank has fallen below a proper predetermined level.

Patent Number 3265388

FIG. 1

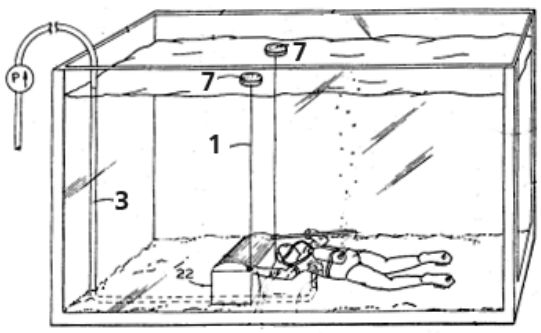

FIG. 2

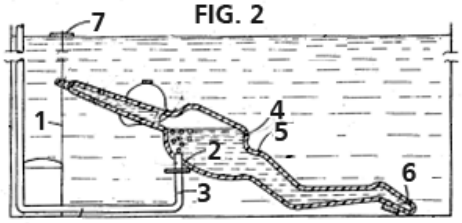

FIG. 3

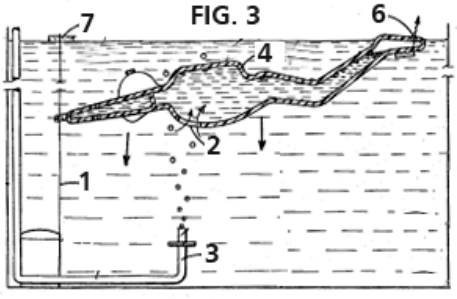

The key object in this invention is a hollow form, the inventor indicating that it can be shaped to assume any simulated object such as a deep sea diver, a fish, or a submarine. Kane elected to use a scuba diver in his description. The hand of the diver is outstretched with a hole in it through which one guide line (no. 1) is threaded. The other hand is holding a spear through which the other guide line is threaded. When the diver is filled with water an opening (no. 2) in the underside rests against the opening of an air tube (no. 3). There are several smaller openings on top of the diver (nos. 4, 5, and 6). The guidelines are supported by floats (no. 7).

When air enters the diver at point no. 2 it displaces the water and causes the diver to rise. Since the trapped air is located for the most part within the head and shoulder portions of the diver, the figure in rising assumes a natural rising or swimming position in surfacing. As the figure rises, small amounts of the air may be exhausted through the port opening no. 4, giving the indication that the diver is actually breathing while ascending to the surface.

When the figure has reached the surface, water is taken on through the inlet opening no. 2, causing the air that made the diver buoyant to be displaced through ports no. 6 in the feet. The diver sinks, guided into its starting position by the guidelines. When it reaches the air tube opening the cycle is repeated and the diver will rise and sink as long as the aerator is operating.

A change in the water level causes the guideline to slacken, thereby stopping the diver from rising or sinking. As the inventor states: "When this occurs, one becomes appraised that the liquid level has reached a point at which additional liquid should be introduced into the tank."

Patent Number 3265388 Continued.

FIG. 4

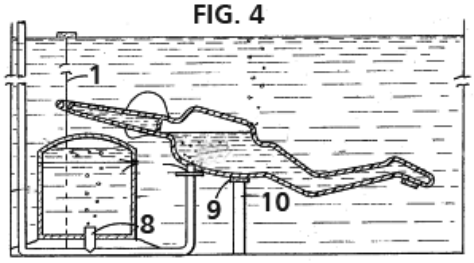

FIG. 5

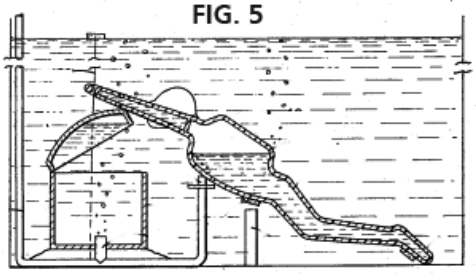

FIG. 6

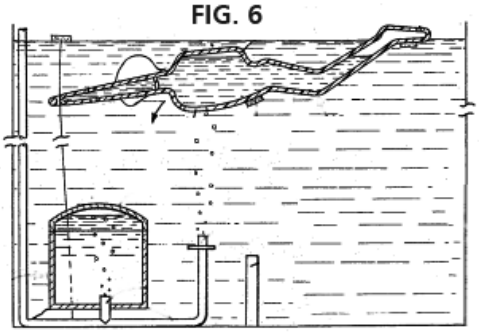

The second shows a modification involving a treasure chest whose top also opens and closes as air is trapped when it is closed and then released as the top opens. The air is supplied by the additional nozzle, no. 8. An additional means for positioning the diver when at rest is a small magnet on the diver (no. 9) and a magnetic post (no. 10). When the lid of the chest opens it forces the diver up, breaking the magnetic connection and allowing the diver to rise as before.

In addition to taking up a great deal of tank space, not to mention the guideline wires, evidently it did not occur to the inventor that a drop in water level would be the first thing an aquarist would notice, diver or no diver!

2. PATENT NUMBER 4029050 FISH HANDLING APPARATUS

This patent was awarded in June of 1977 to Earl Wilfred Genest of Tarzana, California. This was a device for collecting and removing fish from aquarium tanks and was designed to minimize the amount of disturbance to the fish and to the aquarium environment.

The basic part of the design is a rectangular box with a triangular catch basin at the bottom. This is shown in the Figure 2 side view. The upper part of the container (the rectangular box part) has perforations to allow water to enter and escape as the container is inserted into the aquarium and removed. The triangular catch basin has solid sides all around (although the diagram shows an X-ray view of the fishes therein). The triangular part at the top forms a handle for inserting and removing the container.

Patent Number 4029050

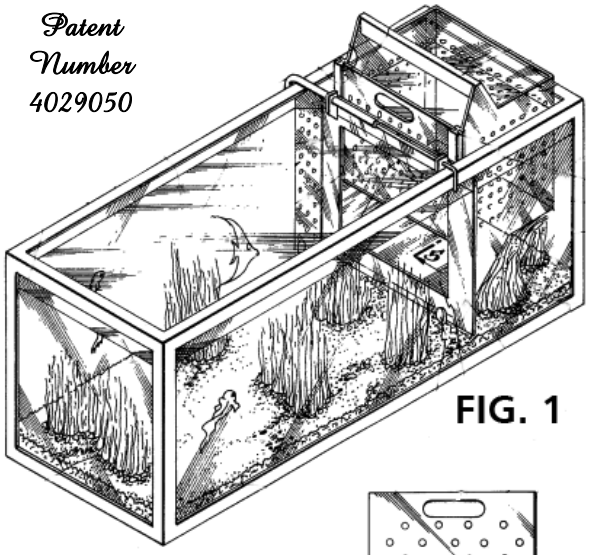

FIG. 1

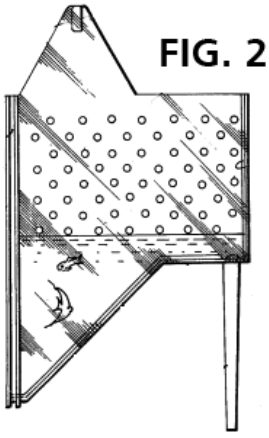

FIG. 2

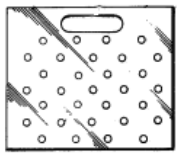

FIG. 3

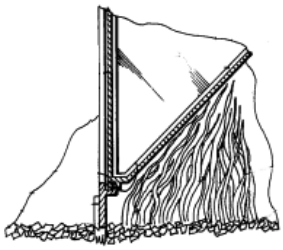

FIG. 4

The front of the container has flat plate that fits snugly against the side of the tank. It has two vertical grooves that accommodate the sliding door (also perforated) shown in Figure 3. The triangular design of the catch basin permits to device to be moved against any vegetation at the end of the tank without disturbing the roots (Figure 4). Hangers are provided

In practice the device is lowered into the tank and pushed towards the end of the aquarium, bending the plants but not uprooting them. The sides of the front panel are adjusted (or cut to size; the inventor specifies that the device is to be made of thin plastic) material to make a reasonably tight fit against the sides of the glass.

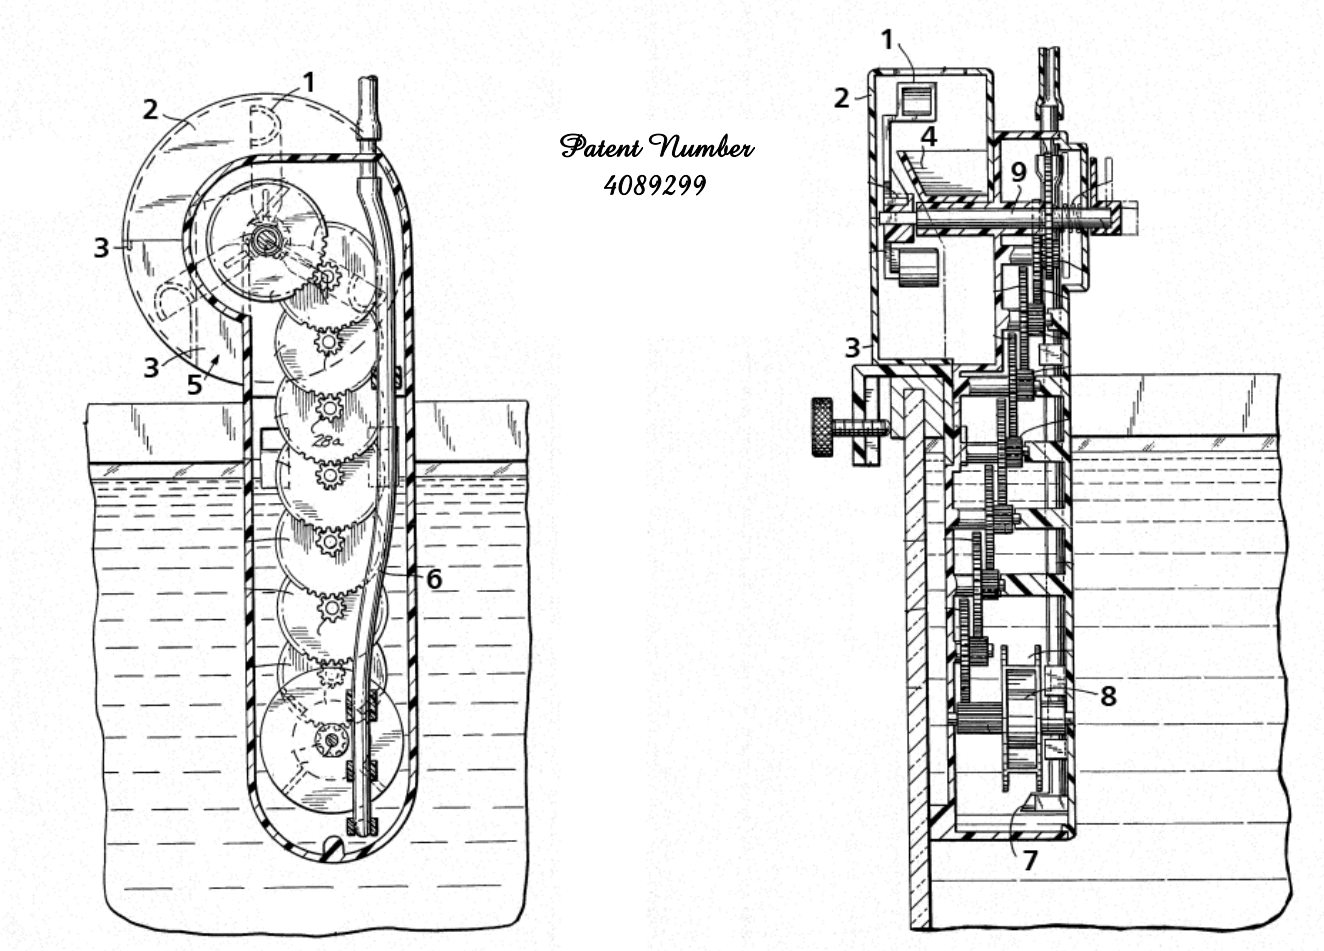
The fish are coaxed into the device (a hand in the water will do) and when they are in the sliding door is lowered. The device is then slowly lifted out of the aquarium, the water draining from the perforated sides of the box and the perforated door, leaving the fish to swim in the catch basin (the only water removed from the tank is that in the catch basis).

Although the design was carefully thought out, it is an awkward piece of equipment to be inserted and removed in any aquarium.

3. PATENT NUMBER 4089299 AN AIR-OPERATED FISH FEEDER

This patent was awarded on May 1978 to Bernard Suchowski of Marlboro, New Jersey but was assigned to Hartz Mountain who evidently seriously considered marketing it. What is unusual about this invention is that it is an air-operated fish feeder.

The feeder is essentially a vertically elongated housing composed of clear plastic such as polyethylene, secured to the side of the tank via a set screw. The housing is not sealed and is open to permit water to circulate between the housing and the aquarium tank. The upper portion of the feeder



includes a cylindrical food hopper containing rotatable feed cups. (no. 1)

The hopper is in two parts, an upper and lower portion, the upper portion (no. 2) being removable to admit the food, the bottom (no. 3) being the storage space for the food. Within the upper portion is a dispensing chute (no. 4) which has an outlet opening at its lower end (no. 5) which is located above the aquarium. As the cups rotate and fill with food they are inverted over the hopper, dropping their contents which then fall into the tank by gravity.

An air tube (no. 6) extends into the housing and opens at its end (no. 7). The air drives a paddle wheel (no. 8) which in turn drives a series of gears causing the shaft (no 9) to which the food cups are attached to rotate at a relatively slow rate. The aerated water ions released to the aquarium toward the upper portion of the open housing and water to be aerated is drawn into the housing in the lower portion. The inventor sized the apparatus so that there was one revolution of the shaft every 24 hours.

Although a clever design, since it simultaneously aerated the water and drove the feeding apparatus, the gearing was expensive and would have caused maintenance problems over time. Electric motors were cheap and could have provided a much more reliable power source and one that could easily been adapted to provide the aquarist with a means of varying the feeding schedule.

4. PATENT NUMBER 4094788 AQUARIUM GRAVEL CLEANER

This patent was awarded on June 1978 to Denzel J. Dockery of Flint, Michigan.

The invention comprises a housing having an upper and a lower chamber (Figure 1 shows the component parts). The upper chamber is open to the lower chamber and a hinged closure lid encloses and forms the bottom wall of the lower chamber. A fluid outlet on the upper chamber is adapted to be coupled to the intake line of an aquarium filter pump, while one end of a tube is connected to a fluid inlet in the upper housing chamber. A sieve is located in the upper housing chamber between the fluid inlet and the outlet.

In operation the pump draws water up through the tube, into the upper chamber, through the sieve and out through the fluid outlet (Figure 2). Thus, as the other end of the tube engages the aquarium gravel, the gravel is drawn up through the tube and into the upper chamber. The sieve retains the gravel within the upper chamber while the fluid flow washes the debris from the aquarium gravel. The water carrying the debris then flows through the sieve and out through the fluid outlet. Once cleaned, the gravel drops into the lower housing chamber.

The cleaned gravel accumulates and collects within

Patent Number 4094788

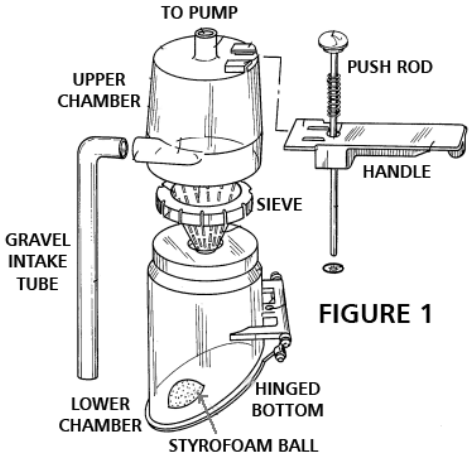


FIGURE 1

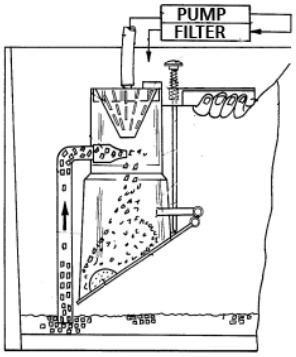

FIGURE 2

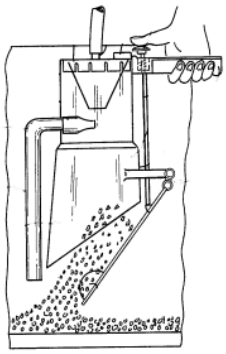

FIGURE 3

the lower housing chamber. When desired, the closure lid is opened by means of a push rod mounted to the housing which dumps the cleaned gravel back into the aquarium (Figure 3). The procedure is repeated until the desired amount of gravel within the aquarium has been cleaned.

This is another piece of equipment that would be awkward to insert into an aquarium. A cheaper and more efficient way to clean the gravel would be to use a plastic bucker, a food strainer suspended on top of the bucket, and a self-starting siphon hose typically used for siphoning gasoline or other fluids. The strainer would catch the gravel where afterwards it could be returned to the aquarium, and the dirty water could be discarded. A change of water is, after all, highly desirable for any aquarium.

5. PATENT NUMBER 4130089 AUTOMATIC AQUARIUM FEEDING DEVICE

This patent was awarded on December 1978 to Daniel J. Moran of Wrightsville Beach, North Carolina.

The invention is a simple automatic feeding apparatus operated directly by the evaporation of water. The device consists of a number of balance arms that pivot, attached at an intermediate point to a bracket clamped on the side of the aquarium. Each balance arm has a feed cup on one end suspended over the surface of the water in the aquarium, and a cup containing water attached to the opposite end.

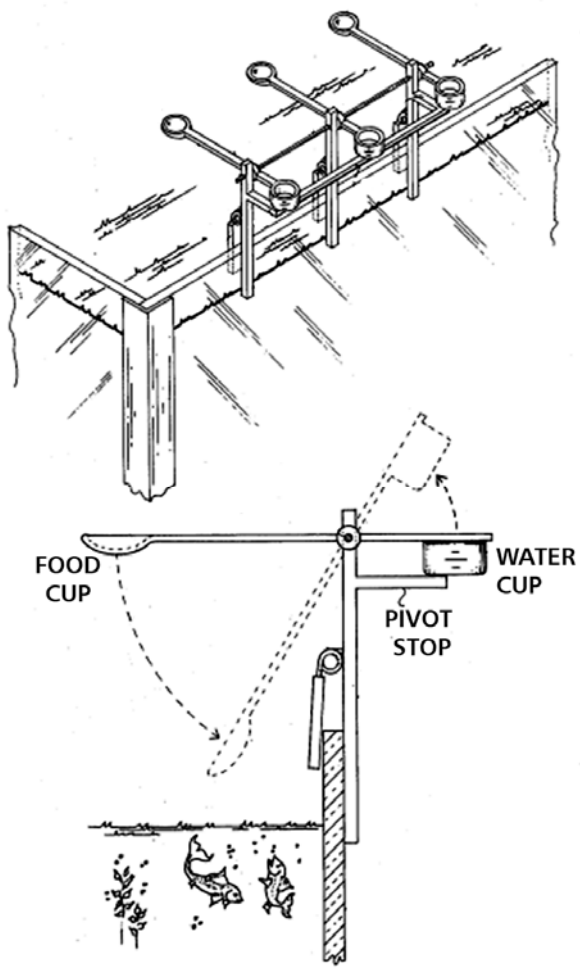
In operation, the feed cup is filled with an amount of food (of any type: flakes, pellets, etc.) equal to one feeding; the liquid cup is filled with water to a level whereby the force on each side of the pivot point is equal and the arm is balanced. Additional water is then added in an amount known to evaporate in a given period of time before feeding is desired.

When the second, pre-measured amount of water has evaporated the food bowl will begin to tilt downwardly and the food will spill into the aquarium. If more than one automatic feeding is desired, additional arms are attached to the aquarium and the water levels incrementally adjusted to cause activation of the arms at pre-selected intervals, thereby emptying the food bowls at intervals.

Construction materials may vary, including any light -weight but rigid plastic, wood, or metal etc., but the preferred material is any of the moldable polymers. The bracket or clamping device is a simple clamping spring mechanism which may be clipped to a side wall of the aquarium.

If a single reciprocating arm is employed for a single feeding it may be attached directly to the bracket by a pivot pin or other pivot means. If a series of arms is necessary, an elongated pivot pin is mounted between two of the upright supports or brackets which are clamped to one side of the aquarium. The food (of any type: flakes, pellets, etc.) equal to one feeding; the liquid cup is filled with water to a level

Patent Number 4130089



whereby the force on each side of the pivot point is equal and the arm is balanced. Additional water is then added in an amount known to evaporate in a given period of time before feeding is desired.

When a multiple apparatus is utilized a pivot stop device is placed to the rear of the bracket in a position extending just underneath the liquid containing cups. The pivot stop prevents the downward tilting of the liquid cups past the horizontal when they are filled with liquid which amounts to a weight or force heavier than that of the food bowls. The liquid cups thereby rest on the top surface of the pivot stop until the liquid evaporates to a predetermined level which will activate the downward tilting of the food bowl.

This an ingenious device, to be sure, but aside from the problems in adjusting the amount of water in the cups for multiple days' feedings, the inventor failed to realize that fish can go without food safely for at least 10 days and even more. The plethora of pivot arms needed would be mind-boggling!

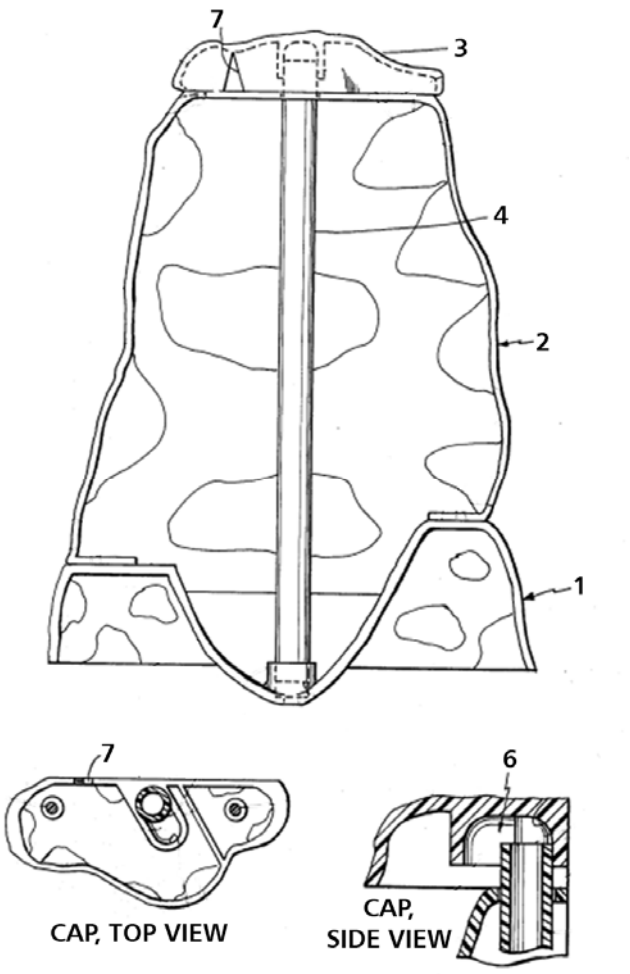
6. PATENT NUMBER 4160427 AQUARIUM WATERFALL

This patent was awarded on December 1979 to Arthur J. Holbrook of Lynnfield, Maine. This invention is a simulated waterfall designed to be mounted on the gravel bed of a home aquarium. Although not the first patent of this type, it was more realistic and better hid the more unnatural parts of the structure which detracted from the appearance of the unit.

In this design, the waterfall is simulated by a directed flow of water and sand down a simulated cliff having several outcroppings that redirect the falling sand in a prescribed path to create maximum interest. There is no reservoir or other artificial collection point forming part of the waterfall at the top of the unit to detract from its appearance, and the force flow allows the unit to function with a minimum amount of sand.

The waterfall is composed of three major molded elements: a base (20), a vertical member (22, and a

Patent Number 4160427

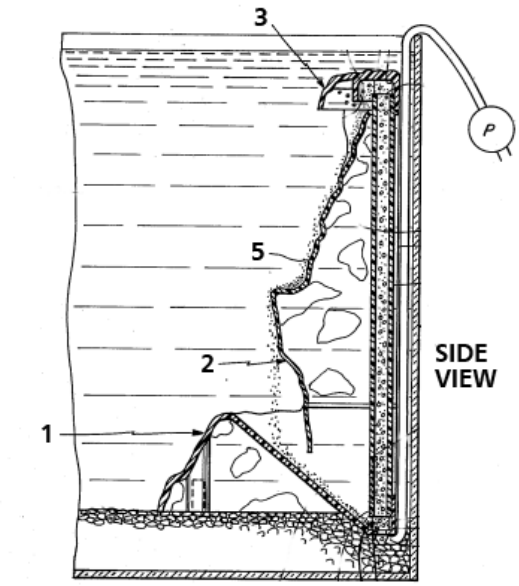


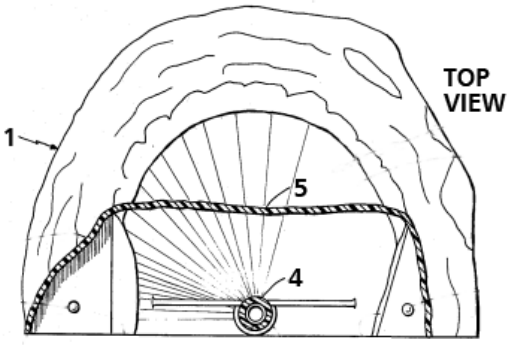
cap (24). The assembly also contains an air lift tube (26). The vertical member has a front surface (60) that simulates a rock surface. A fine grade of sand having a particle diameter of approximately 004" in diameter is used to simulate the falling water over the front surface.

The mixture of air, water, and fine gravel rises to the top via the air lift to a trough (80) under the cap where the water and sand are directed downward over the front surface. The air is released through a slot in the cap (90). The falling sand gives the optical illusion of a substantial flow while only a small amount of sand actually moves in the system (about 1/2 teaspoon).

One of the problems with these sand waterfalls is

Patent Number 4160427 Continued.

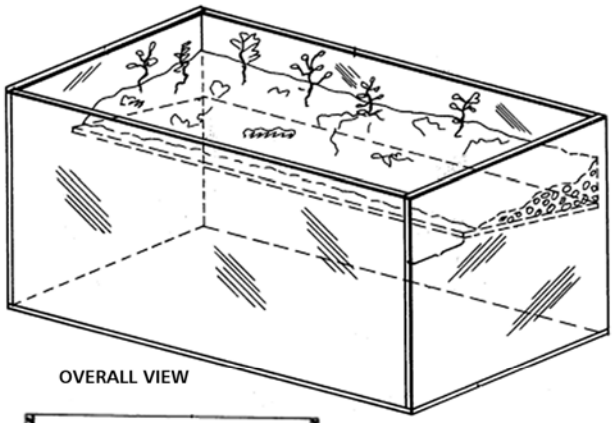


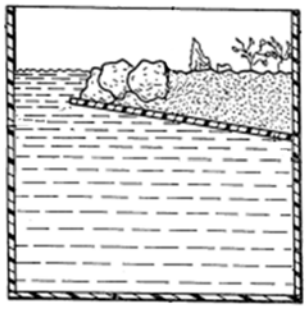


that one must be very careful in placing the sand in the well, as the fine particles are easily dislodged. The same is true if there is a substantial flow of water in the tank. They have, however, achieved some measure of success in the marketplace (this particular patent was assigned to Rolf C. Hagen, the maker of the AquaClear and Fluval filter lines).

7. PATENT NUMBER 4176620 AQUARIUM-TERRARIUM TANK

This patent was awarded on December 1979 to Thomas G. Kassos of Pittsburg, Pennsylvania.





Patent Number 4176620

The object of the invention is to provide a tank adapted for use as an aquarium and a terrarium, to enhance the aesthetic appearance of the tank, and increase the usefulness of the aquarium. Most prior designs for combination aquarium-terrariums incorporated ungainly rafts and/or ramps that protruded above the tank. This design incorporates the terrarium portion entirely within the tank.

The design is simple and pretty much self-explanatory. The problem is that this design basically is nothing more than a sheet of plastic, silicon-cemented to the inside of an aquarium. One wonders that a patent can be awarded for a rectangular piece of plastic! One also wonders how it would be marketed. Does the consumer open the box to find nothing more than a sheet of plastic?

This is a job that anyone can do in minutes, given a sheet cut to size. If the aquarist is not up to cutting plastic sheet, there are local plastic fabricators that can do the job for him.

Patent Number 4194620

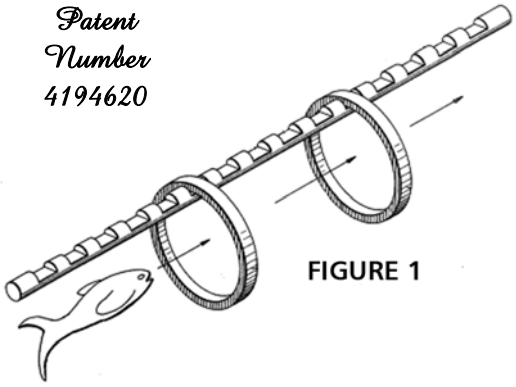


FIGURE 1

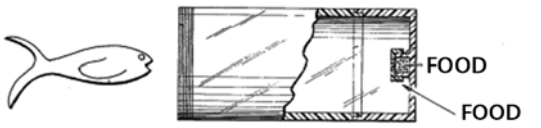

FIGURE 2

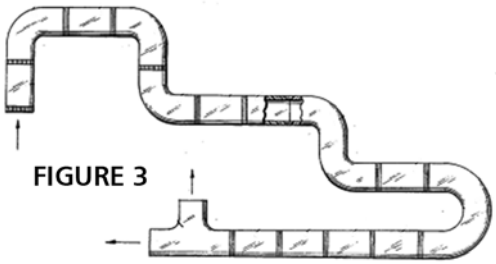

FIGURE 3

8. PATENT NUMBER 4194620 TROPICAL FISH TRAINING KIT

This patent was awarded on March 1980 to Natalie Soloway of Sherman Oaks, California.

A main object of this invention is to provide a novel tropical fish training kit. It includes a number of inter -connectable tubes, forming a maze through which a fish swims.

Another object of this invention is to provide a device for a simulated horse race game in which a housing is provided through which fish swim toward a gate having means thereon for holding fish food.

Lastly, another object of this invention is to provide a device for playing tic-tac-toe with the fish.

Figure 1 shows a notched rod holding a pair of rings through which the fish are trained to swim (one starts with one ring and then adds others as the training progresses). The training device is used by holding the rod at or just below the surface of the water. To quote the inventor: “It is presumed that the fish can be finger fed and the rod is held in one hand while fish food is held in the other.”

Figure 2 is a side view (with a portion broken away for clarity) and shows a tube having an open end into which a fish is attracted by food (F1) carried by a removable cap (19) at a closed end of the tube. Once the fish is conditioned by the rings, its natural curiosity prompts it to enter the tube where it is rewarded by the food.

Figure 3 is a side elevation view (with a portion broken away for clarity) of a tubular maze and

Patent Number 4194620 Continued.

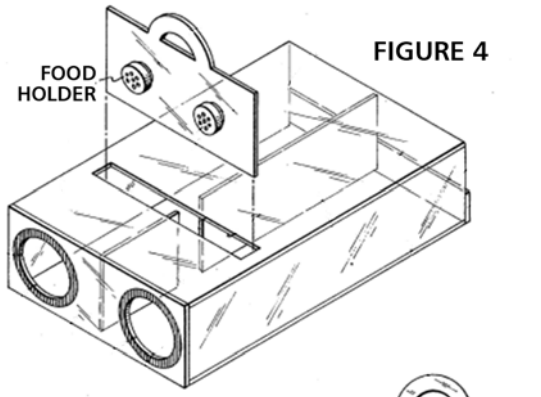

FIGURE 4

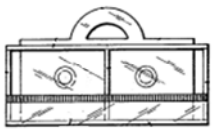

FIGURE 5

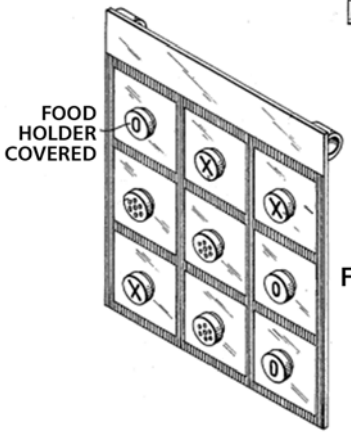

FIGURE 6

illustrates a variety of differently contoured individual tubular elements forming the maze. Once the fish is conditioned to swim through a shot tube it is ready to tackle the maze.

Figure 4 is a perspective view of another device of the kit, and illustrates a housing having a pair of entrance openings through which fish swim into individual chambers. Each as a gate (carrying fish food—57, 58) which can be moved to an open position to permit fish to swim along confined paths of travel toward an exit opening of the housing much in the manner of a simulated horserace. The rear of the device is only half-closed (its lower portion), providing a means for the fish to escape. Figure 5 is an end or rear view of the housing and illustrates the exit openings of the housing.

The final device is shown in Figure 6 and consists of a rectangular board each of which holds fish food and is meant to be slide into a nine-compartment housing similar to that shown in Figure 5. Eventually a fish will swim into one of the compartments and eat the food there. The food container is now covered by a cap with an “O” or an “X” on it, depending upon whose turn it is (i.e., the competing aquarist’s turn). The play continues until three “O”s or three “X”s are obtained in one of the usual tic-tac-toe patterns, indicating a winner.

I had to force myself to stop laughing as I read this patent. Perhaps fish can be trained, but I am reminded of the proposition advanced by statisticians, that given enough time, a room full of typewriters and chimpanzees will type out all the manuscripts in the British Library. I imagine that anyone playing the tic-tac-toe game and waiting for the fish to make the next move would be eligible for his Social Security checks when the game was over, even if he started out playing it when he was but ten years old!

9. PATENT NUMBER 4223471 AQUARIUM CRIB TOY

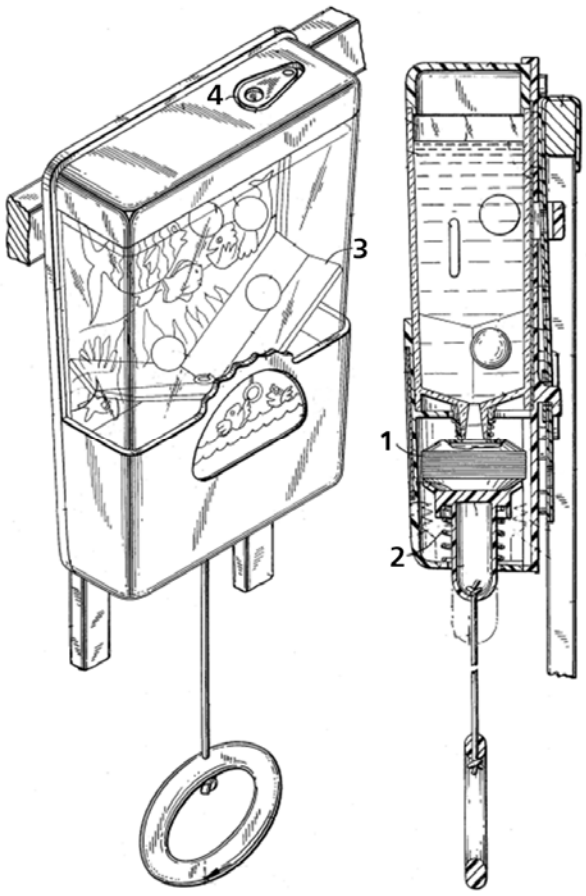
This patent was awarded on September 1980 to Sheldon Greenberg of Fort Lee, New Jersey. The object of the invention is: “... to provide an aquarium crib toy which is simple and easy to operate by a baby, infant or small child.”

The invention simulates an aquarium, and basically is a transparent enclosure made of polyethylene or a similar plastic. The enclosure is filled with water and contains a number of movable objects in the form of fish and other aquatic objects, constructed of hollow plastic, the density of the objects being greater than the density of the water.

A flexible, resilient bellows (e.g., neoprene - no. 1 in the diagram) is mounted to the bottom of the enclosure and attached to it is a pull cord or string with a terminal plastic ring. When the ring is pulled the bellows expands, drawing some of the water from the simulated aquarium into the bellows.

When the bellows is pulled down it compresses a circular spring (no. 2) located beneath it. When the

Patent Number 4223471



ring is released, the spring then forces the bellow upwards, sending water from the bellows back into the aquarium, whereby the objects in the simulated aquarium are agitated and swirl and move about within the water of the simulated aquarium.

A sloping trough with a hole in the bottom (no. 3) directs the objects to a central position when they drop to the bottom, and a closable opening (a rubber plug - no. 4) in the top provides a means for filling the aquarium with water as needed to fill it and replace any water lost by evaporation. The device is intended to be mounted inside of the crib.

Objects intended to be placed inside a baby's crib must be designed with much care. The rubber plug for filling the device is entirely removable in this design and could, if loosened, be a hazard to infants who will tend to swallow anything they can put in the mouths. If the aquarium is tipped, the small objects within may be released into the crib, affording further hazards of this kind. Furthermore, on general principles parents might be reluctant to place a vessel container water anywhere near a crib. Sooner or later the bellows would most likely fail.

. 10. PATENT NUMBER 4270489

FISH-OPERATED AQUARIUM FEEDER

This patent was awarded on June 1980 to Osmo K. Joronen of Victoria, B.C., Canada. The invention is an apparatus that can be operated by the fish to dispense a small quantity of dried fish food.

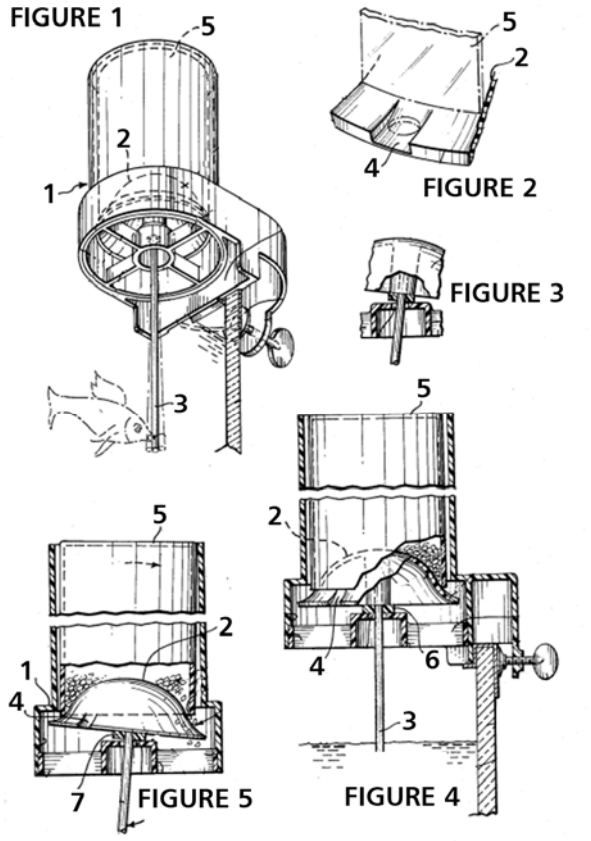
The inventor points out that previous U.S. patents typically dispensed fish food using an actuator rod of some sort in response to forces applied by the fish. These devices, however, presented one or more disadvantages or drawbacks. For example, because fish of various sizes are kept in aquariums and because of differences of the habits and feeding practice of various types of fish, certain fish may not be capable of displacing an actuator rod by the amount required to dispense the food. On the other hand, if the food dispenser is configured such that a relatively small force is required to actuate the food dispenser, overfeeding may result.

Furthermore, the reliability of these fish food dispensers is affected by the structural features of their designs. Such devices, for example, often become partially or wholly inoperative because of moisture that reaches the stored food supply. Furthermore, such structural complexity also often means that the procedure required to install and/or refill the dispenser is not as convenient as would be desired.

The inventor also argues that many prior patents are relatively complex in structure and therefore cannot be manufactured and sold at a cost that is economically attractive.

The feeder (no. 1) is attached to the side of the aquarium as shown in the figures. It contains a dome -shaped valve (no. 2) having a downwardly extending actuator rod (no. 3) that pivots with the feeder housing. The periphery of the valve contains a series of grooves (no. 4) each containing a hole. An

Patent Number 4270489



inverted food container (no. 5) rests on the top of the dome-shaped valve surface to form a substantially closed storage chamber for the fish food when the valve is in its equilibrium position, i.e., when the actuator rod is in its vertical position.

As the actuator rod is deflected by the fish, the dome -shape portion of the valve rotates within the opening of the storage container so that a portion of the valve periphery moves inwardly toward the edge of the inverted container. If this portion of the periphery includes one of the channel-like grooves, a small portion of fish food is allowed to flow from the container and fall into the water. Since the channel-like grooves are dimensioned to permit only one or a few particles or flakes of food to pass outwardly during the time required for the valve to return to the equilibrium position, a single deflection of the actuator can only supply a small, substantially controlled amount of food.

Since frictional contact between the lower edge of the feeder and the valve head upper surface may tend to also tip the feeder during deflection of the actuator rod, the inverted food container which is a bit smaller in diameter than the feeder maintains a near vertical position. Thus, should the feeder tend to tip along with the valve head, the food container comes into contact with the feeder wall, remaining in a substantially upright position in which the food dispensing operation just described can occur.

As is shown in Figure 3, a small crack-like opening (no. 6) is momentarily formed between the valve head upper surface and the lower edge of the food container. This permits relatively fine particles of fish food that often accompany a flaked-type fish food to pass outwardly and fall into the water. Further, movement of the valve head relative to the food container and the feeder agitates or disturbs the stored food in a manner which causes both the full sized food particles and any dust-like accompanying particles to flow smoothly and continuously toward the peripheral flange region.

Replaceable washer-like discs (no. 7) that form the contact region between the valve and the housing permit the force required to actuate the feeder to be adjusted for properly feeding fish of various species and size.

As for training the fish, the inventor has this to say:

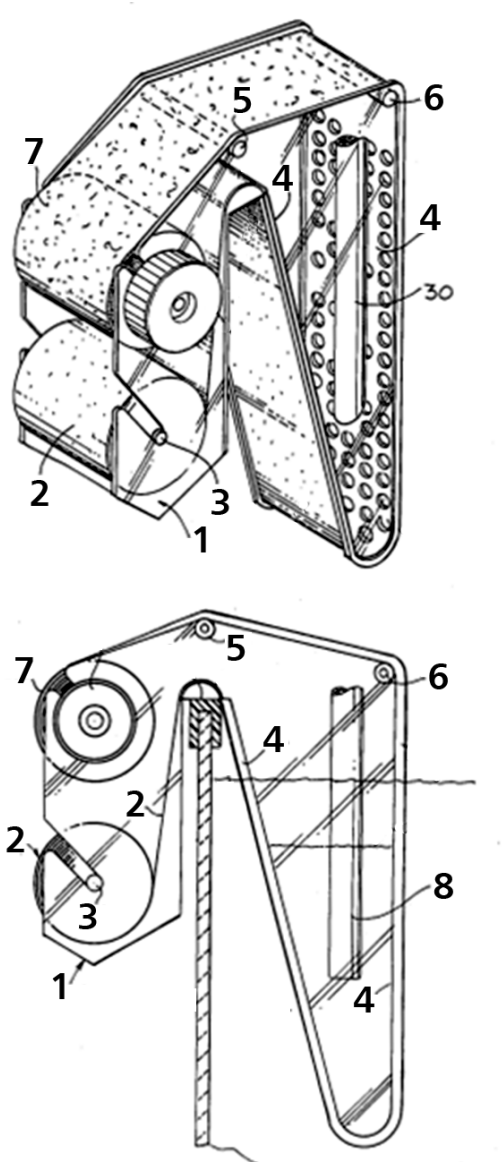
> "Little or no 'training' is generally required to acquaint the fish with the operation of the invention. In this regard, the submerged portion of the actuator rod includes a mark or other dot-like indicator that is preferably brown or another color that is highly visible under water. Since the mark appears to be food or another small foreign object, most fish will investigate in a manner that displaces the actuator rod. For example, various fish exhibit different behavior patterns and may bump the region of the actuator rod that includes the mark, may direct a stream of water at the mark by rapid action of their mouth and gills, or may strike out at the mark with their tail or other portion of their body. Once the fish have operated the food dispenser a number of times and cause food to fall into the water during at least some of the operations, an association is formed between the behavior utilized to displace the actuator rod and the act of feeding. The fish will then operate the food dispenser whenever they desire food."

Devices like this one rely on unclogged passages. Dry fish food contains fines and feeders are near a humid environment, i.e., an open aquarium. The combination is ready-made for these particles to set up like concrete and prevent the disbursement of the food. The replaceable washer-like disks allow the aquarists to set the force required to activate the feeder, but a variety of valves containing different-sized grooves would be required to regulate the size of the food portions. All in all, this is an iffy way to feed fish while the aquarist is away. A motor-driven feeder would be a much more reliable.

11. PATENT NUMBER 4282095 AQUARIUM FILTERING SYSTEM

This patent was awarded on August 1981 to Parker I. Tsuhako of Gardenia, California.

Patent Number 4282095



This invention involves a filtering device providing for easy change of filtration material, external supply and take-up of the filter material, and an immersed filtering surface traversed by a filtering medium.

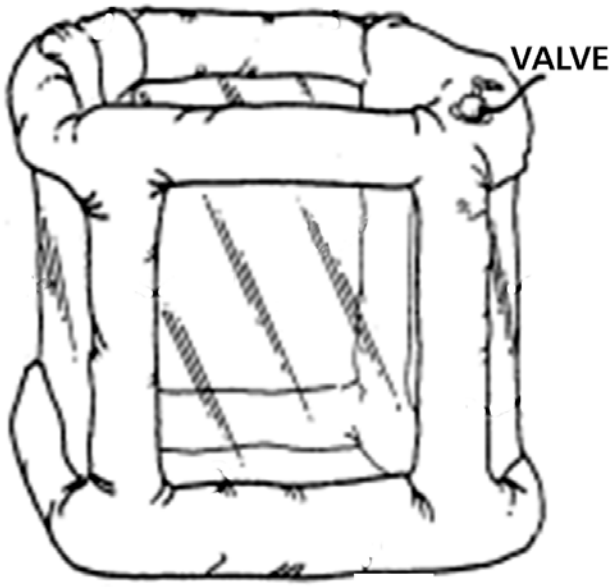
The basic part of the device is a filtration housing (no. 1) that is immersed in an aquarium along one of its edges and is perforated on its opposed walls (no. 4) and along its lower or bottom surface. The preferred form (shown) has perforated walls that are joined at the bottom to form a “V” or “U: shaped structure, but more rectangular shapes may be used. The housing is provided with one or more extensions that form an external support for both used and unused filter material. In Figure 1 the new filtration material (no. 2) is on reel (no. 3) which is placed in the housing. Rollers (no. 5 and 6) guide the filtering material through to the take-up reel (no. 7) located outside of the aquarium. Aquarium water passes through the holes in the housing, then through the filtration material, and then passes out of the aquarium to a pump (not shown) where it is returned to the tank.

As a result, the filter medium supply and used medium storage are external to the aquarium, and can be renewed without disturbing the aquarium itself. A new supply can be drawn over the edge of the aquarium, utilizing a connection between the depleted and new supply of filtration medium as a means to guide the new medium over the perforated surface of the immersed housing, and return it to the used filtration material take-up mechanism. The latter can be combined with either mechanical, electrical, electro-mechanical, or any other drive means to pull the material through the immersed housing. If a manual fed is used, when the filter material in the aquarium becomes clogged or dirty, the filter may be manually advanced, clean filtering material replacing the old material.

The aquarium water is either fed to the central portion of the housing by, for example, a pipe (no. 8) placed centrally in the housing and externally connected to the water circulation/heating pump, or the same tube may be utilized as a pickup tube to draw the water in the tank through the filter material, into the central portion of the housing, and back to the tank via the pump.

The design is reminiscent of the continuous towel dispensers in washrooms but there are a number of problems with the concept. For one thing, the spent filtering material would be wet and therefore some sort of drip container would be needed under the take -up roll. Changing the roll of filtration material would also be an awkward and dirty process. Finally, the cost of the filtration material would make this a very expensive way of filtering aquarium water.

Patent Number 4858755



12. PATENT NUMBER 4858755 INFLATABLE DISPLAY CONTAINER

This patent was awarded on August 1989 to Lawrence J. Kuivanen of Stanford, Connecticut.

The invention comprises at least four flexible side panels and an inflatable, tubular, flexible framework surrounding the side panels. The material used is a clear or transparent flexible film material such as a vinyl film. The framework includes an upper tubular rim, a lower tubular rim and at least four upstanding tubular columns. Each of the side panels is joined to the upper and lower tubular rims and to two of the tubular columns. A flexible bottom panel is joined to the lower tubular rim and a valve is provided in the framework for inflating the container. The joining is effects by heat-sealing. Since the concept is simple, the diagram is pretty much self-explanatory.

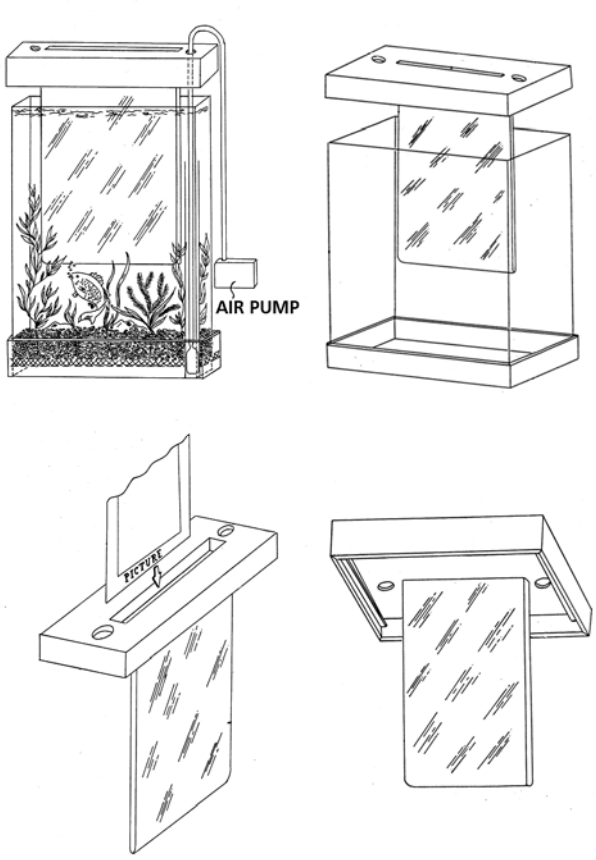
Actually, this is not a bad idea and I would have welcomed such a device on my collecting trips in remote rainforests, although I probably would have modified it so that one side was replaced with a pane of a good optical-quality plastic so the device could be used as a portable photographing tank. Since only one side would then be rigid it still could be folded up for traveling.

13. PATENT NUMBER 5078093 AQUARIUM WITH AN INTERNAL DISPLAY DEVICE FOR A PICTURE

This patent was awarded on January 1992 to Daniel G. Flaherty of Irving, Texas.

Generally speaking, proposals for including a picture in combination with an aquarium have included structures for mounting a picture directly to the backside of the tank. These pictures, however, are mounted on the exterior of the aquarium and present only an imperfect illusion of a picture within an aquarium. In one patent a proposal was made to indent the rear side wall of the aquarium so as to mount a picture more interiorly of the aquarium. However, such constructions are often difficult and/ or expensive to manufacture in order to assure that the indentation formed in the backside wall of the aquarium will remain water-tight. Further, such constructions do not serve effectively to position a

Patent Number 5078093



picture within the aquarium for viewing from the rear.

The object of the present invention is to provide an aquarium having internal structures for displaying a picture such as a photograph within the aquarium that do not need extensive manufacturing techniques in order to assure that the aquarium will remain watertight, and display a picture from more than one direction.

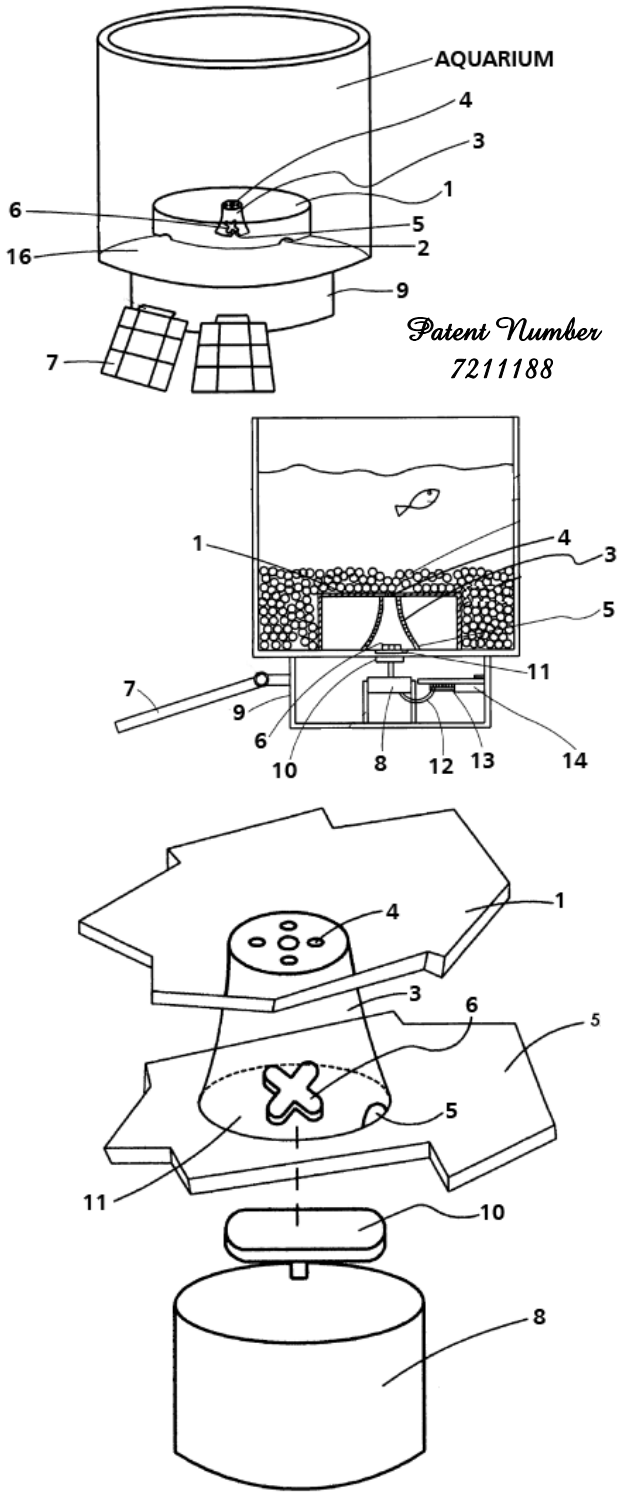
The invention is simple, so the accompany images pretty much explain all. This display device for a picture includes an aquarium of conventional design. A cover member is positioned over the open top and has a slot for receiving a picture. Hanging from the slot in the cover is a water-tight member formed of a transparent material that is adapted to receive the picture to display it inside of the aquarium.

This invention does do all it claims. A nice feature is the fact that, when the picture holder becomes covered with algae it can easily be removed for cleaning. An added advantage to the design is that two photographs may be inserted back-to-back so a picture is displayed no matter where the viewer is standing. However, since this is a simple invention, any aquarist with rudimentary skills can manufacture the top insert picture holder himself to tailor-make it to any tank. It would, therefore, have little commercial interest.

14. PATENT NUMBER 7211188 SOLAR POWERED AQUARIUM

This patent was awarded on May 2007 to Jeffrey G. Lawson of San Francisco, California.

This invention relates to a solar powered aquarium. Within the aquarium is a compartment (1), the side wall of which has a number of notches or openings at the bottom (2) that allow the passage of water. Within the compartment is a small flared cylindrical member (3). Holes (4) on the top of the cylinder allow water to flow into from the tank. A hole (5) at the bottom of the cylinder allows water to exit. The spinning of a magnetic stirring member (6) causes a pumping action that causes water to be drawn into the holes on top of the cylinder and then out through the hole at the bottom. The total area of the holes at the top is approximately equal to the area of the hole at the bottom so that no excess water pressure is built



up within the cylinder, thereby allowing for the smooth flow of water into and out.

Solar panels (7) power a small DC motor (8) located within bottom skirt (9). The motor shaft terminates in an iron plate (10). By magnetic attractive force, it spins the magnetic stirring member. The addition of a thin foam plastic layer (11) under the magnetic stirrer helps create a more silent spinning action so that when the aquarium is in place in a quiet environment such as a desk, the sound of the spinning magnetic member is not objectionable.

Wires (12) connect the DC motor to a charging circuit (13) that includes rechargeable batteries (12). A spinning metal plate (15) is located just under the base plate (16) primary object of the invention is to but not touching it. Because the force to rotate the magnetic spinning member is so small, the motor uses very little power, approximately one hundred and fifty milliamps, which can be fairly easily generated by the solar panels in moderate daylight. The inventor's experiments indicated that exposure to direct sunlight is not necessary, and that enough electrical power is stored in the rechargeable batteries during the day that the motor continues to spin through the night on the stored energy.

The pumping action caused by magnetic spinner 20 causes fish related debris in the water to be drawn into the gravel bed (10) where it is trapped. Periodically, the user has to exchange the debris filled gravel for new clean gravel. The solar cells 28 are mounted on frictional hinges 30 so that they can be optimally adjusted to face a light source. Additionally, the solar panels can be folded to be close to the skirt for purposes.

The idea has a number of problems. For one thing, the solar panels are fragile and are easily damaged since they would stick out from the aquarium. Assuming the motor was powerful enough to move water through the gravel, even the inventor points out that the user has to exchange the used gravel for clean gravel. In this case it means that the fish must be removed, as well as any aquascaping (plants, rocks, etc.) that might have been set up in the tank. I also have my doubts about the power generated by solar panels that would be practicable on a desktop. One also might ponder where one could find those DC-rechargeable batteries for the device.

CONCLUSION

It is fun to read aquarium patents, especially those devised by inventors with inquiring, creative minds as exemplified here. One does come away, however, with the thought that the majority are not really experienced aquarists, since the design defects are readily apparent to anyone who has kept fish for any reasonable amount of time. Two patents were assigned to manufacturers whose aquarium equipment is well-known among fish keepers, so I wonder at their expertise as well (perhaps it is I who has the wrong end of the proverbial stick, not realizing that some people will buy anything if the marketing is persuasive enough).

In any event, practical inventions come about by people who are not afraid to take chances. However we might laugh at the failures, we should always remember the successes as well for these have made our hobby a lot easier for all of us.

Now that transparent aluminum is available for beverage cans, who'll be the first to patent its use as an aquarium?

THE INVENTIVE MIND OF ALLAN H. WILLINGER (1927-2001)

by Albert J. Klee, Ph.D.
(Aquarium Hobby Historical Society, Yahoo Files, December 21, 2007)

Probably the most prolific and best-known inventor in the aquarium field, Allan Willinger started his creative journey at age 11, when he figured out how to encase a 15-watt hair curler from Woolworth's in a glass test tube, and thereby got his aquarium water warm enough to keep his tropical fish. Along with his brother, Harding, he founded Metaframe (a descendant of the old Potts Aquarium Company of Caldwell, New Jersey) which, in addition to publishing THE AQUARIUM magazine, became one of the world's best known firms producing air pumps, air stones, filters, heaters, cleaners, spawning devices, and other aquarium-related products. Over the course of his lifetime, Allan Willinger was awarded 116 patents of which, with few exceptions, he was the sole or senior inventor.

The Willinger Brothers foray into aquarium patents actually started with his older (by six years) brother Harding, who obtained his first patent in 1954, an improved filter stem for an inside filter that reduced splashing of the return water; his second, also in 1954, was for a breeding trap, and his third, in 1955, was for a dip tube. However, his most successful patent was for the bottom filter shown in Figure 1, an immensely popular filter for the time. Along with his brother Allan, he patented five additional inventions between 1963 and 1978 that concerned aquariums, air pumps, and an aquarium thermometer. This essentially was the last of Harding's patent activities until 2000 when he subsequently obtained three design patents for a decorative rim and a decorative base for a fishbowl, the last one awarded two weeks prior to the death of his brother.

Allan Willinger's first patent was awarded in 1960, for an undergravel filter. Prior to this, undergravel filters drew the water from the corner near the air lift, and since water travels through the path of least resistance, most of the flow through the gravel took place near this corner. Willinger's design (Figure 2) incorporated special channels and a greater amount of space below the gravel bed near the air lift,

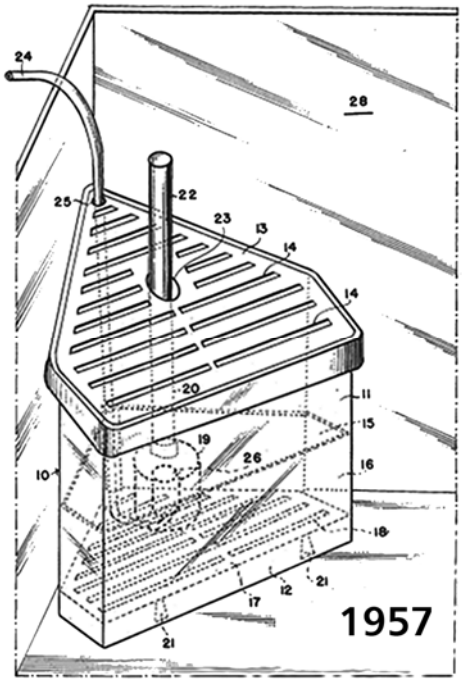


FIGURE 1

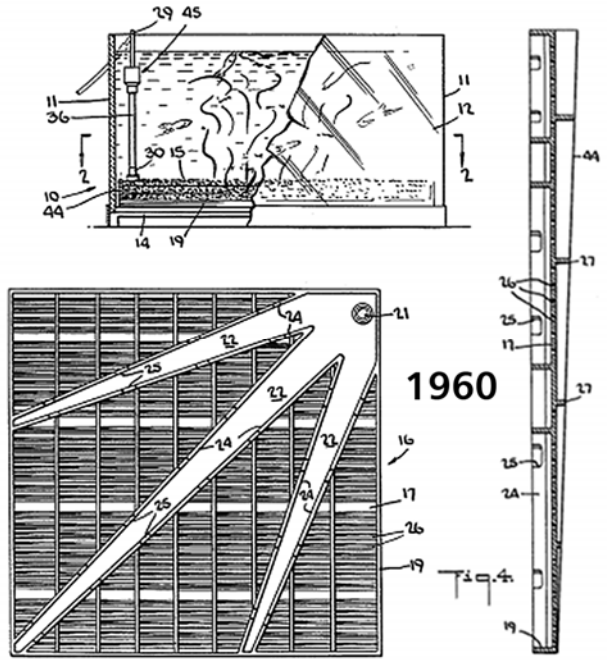

FIGURE 2

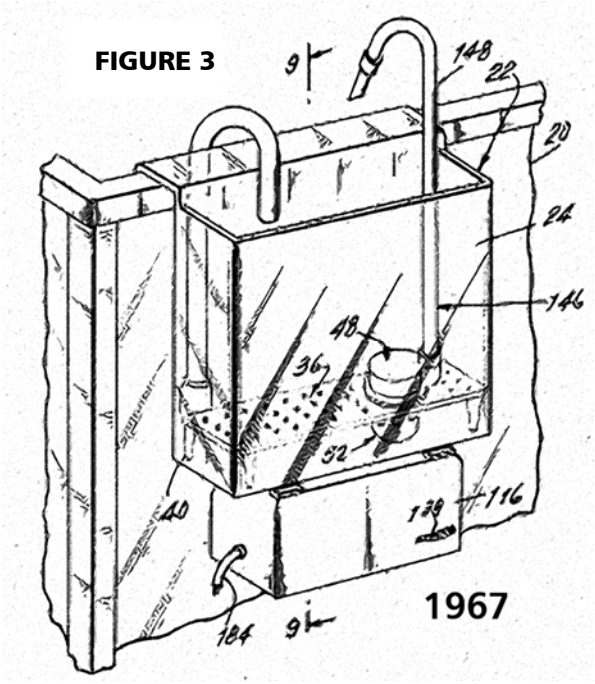
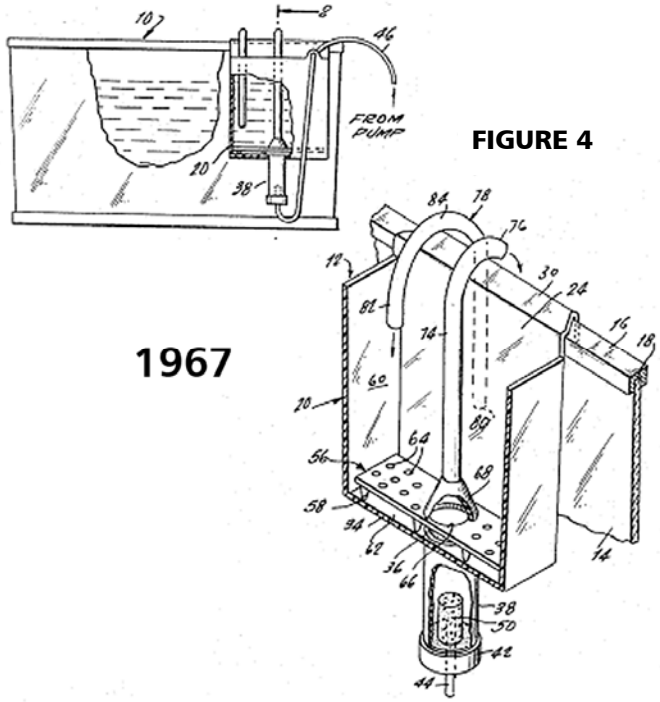
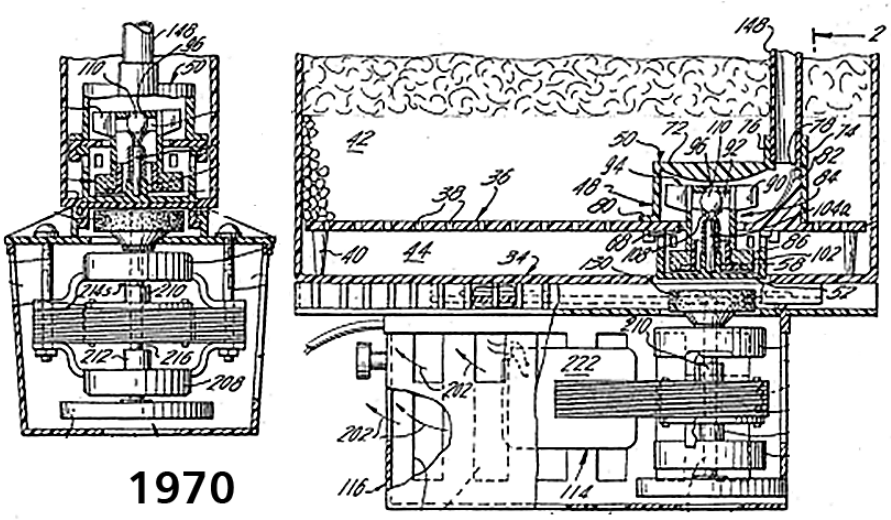


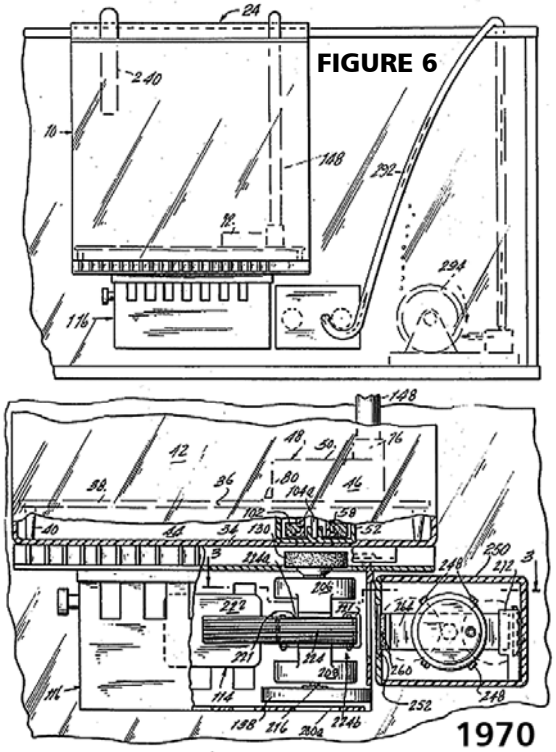


resulting in a more uniform flow of water through the filter bed. His second patent was (with his brother) awarded in 1963 for an aquarium and cover molded of plastic, and his third, in the same year, for an aquarium heater. Willinger's forte, however, was not in heaters although he did receive a total of five patents in this area. These patents involved improvements in heater repair and calibration, and in the minimization through better circuitry of malfunctions such as sticking contacts and sparking between the contacts. Two of these patents involved heater mounts that eliminated denting the metal edge of the aquarium, reduced scratching of the glass, and accommodated aquariums with various types of frames.

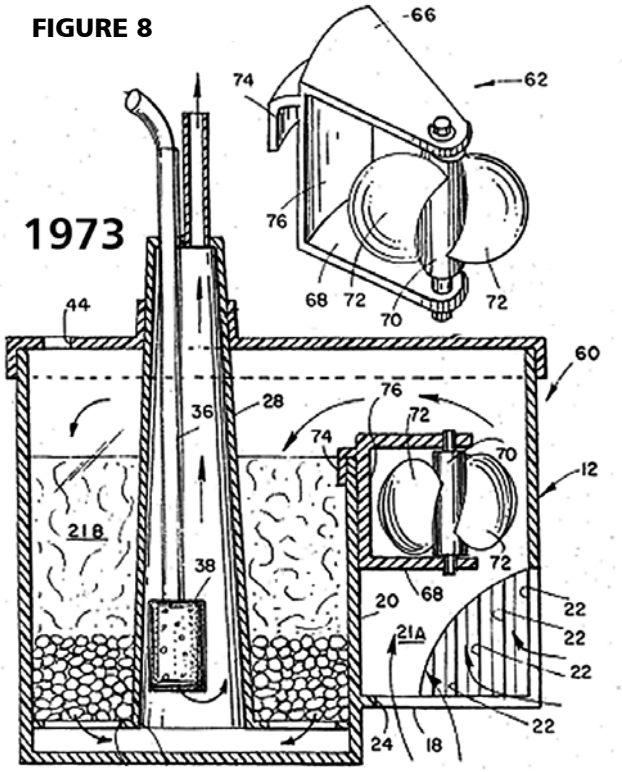
His greatest impact was in filter design, almost half of his patents being awarded in this category. In 1967 he designed an outside filter in combination with a submersed centrifugal-type pump (Figure 3) where, to ensure that no water leaked into the motor compartment, the pump impeller was fitted with a magnet, as was the rotor in the pump compartment. This magnetic connection was a real first. The pump was quiet, could not burn out even if the impeller became jammed, and it moved a relatively large amount of water for its size. Another patent awarded in the same year was for a filter that used an air lift to move the water (Figure 4). The design of this air-lift, however, permitted a larger amount to water to be moved than in prior designs. Furthermore, the inner compartment was fitted with a bottom shelf, permitting the filter contents to be removed without taking the filter off the tank.

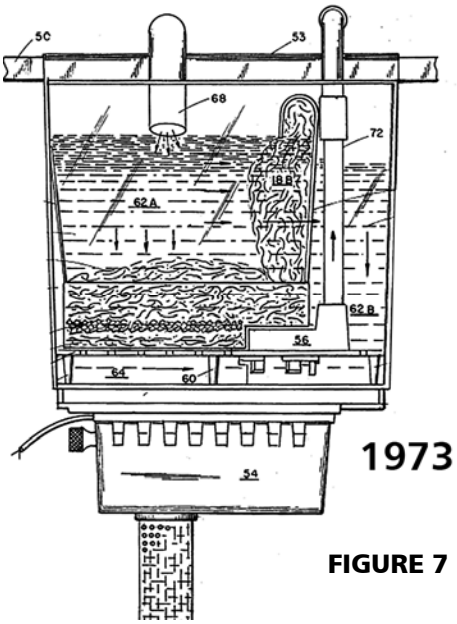
FIGURE 5

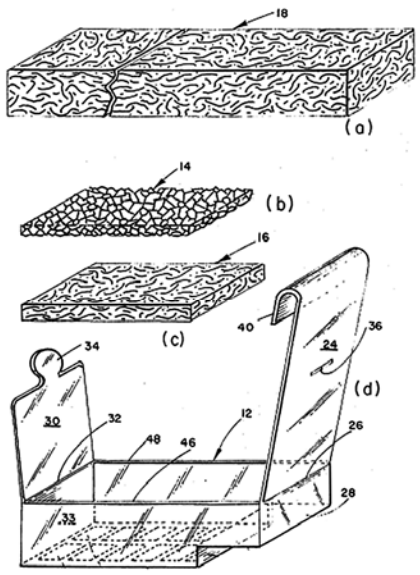




An important design patented in 1970 that was to be part of the well-known "Whisper" filter eight years later was of the outside type with a built in motor where the lower magnet was on a floating assembly, thereby taking the weight off the bottom of the rotor, reducing the friction and providing a longer life for this vital moving part (Figure 5). Willinger also provided slots in the pump housing so the heat produced by the motor could rise and warm the water in the filter. The same year he patented a similar filter, but this time the motor included a vibrating armature that drove a small vibrating air pump (Figure 6). This was less of a success because the vibrating armature did not produce much of an air stream, and it did pass the vibration onto the aquarium.







In 1973, Allan Willinger introduced an improvement on the idea of permitting the filter contents to be removed without taking the filter off the tank with the design shown in Figure 7. Basically, this is how all current-day outside filters are arranged for cleaning their contents. A more fanciful design was a novel bottom filter patented in the same year that incorporated a rotary indicator that signaled the clogging of the filter medium. This was a vane-like device that spun when water flowed past it (Figure 8). If the filter clogged, the water flow diminished, slowing the vane's

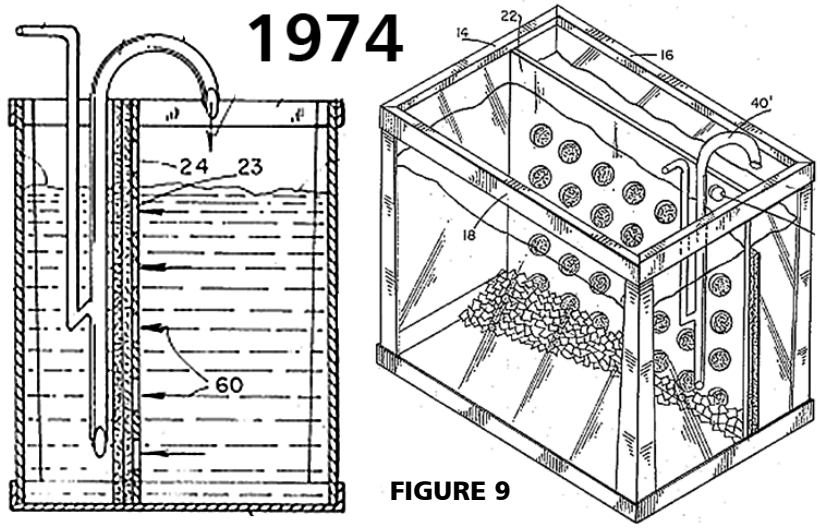


FIGURE 9

rotation. When the filter was completely clogged, the vane stopped moving entirely. Willinger argued that:

> "... there is an aesthetic value in visible movement of solid objects. This is evidenced by the popularity of air activated 'action ornaments' in aquariums, ornaments in which parts are caused to move by a stream of air bubbles which strike displace-able parts of the ornament structure. Such ornaments serve no functional purpose in an aquarium beyond adding a small amount of air to the aquarium water. If an 'action ornament' provided useful information to the aquarium owner, the value of such 'action ornaments' would be increased. Such is one function of the present invention."

One of Willinger's more unusual filter inventions was patented in 1974 and is shown in Figure 9. He argued correctly that undergravel filters were hard to clean when clogged, and that small inside filters did not have the capacity to do much biological filtration and that they had to be cleaned frequently. His solution was a vertical filter composed of a sheet consisting of a polyester floss material having two layers of two different porosity foam plastics, supported by an impervious panel on each side containing holes for the water to flow through. This was placed at the rear of the aquarium, the impervious sheet being secured to the aquarium with silicone rubber cement with enough space behind it to accommodate the air lift, a heater, and a bag of activated charcoal if desired. A hole in the top part of the sheet permitted water to flow back into the main part of the aquarium should the filter become clogged. When it was necessary to clean the filter, it was merely lifted up and out from the impervious sheets and cleaned. However, this is another design that did not see the light of day commercially, since it was unsightly and decreased the space available for the fish.

Even though some of Willinger's designs were not especially practical or even useful, his patents are nevertheless a joy to read, and the background sections of his patents can easily serve as a basis for a history of the development of aquarium equipment. The following is an example, taken from his disposable filtration cartridge patent shown in Figure 7:

> "Generally speaking, filtration housings usually incorporate an apertured partition for dividing the housing into a first chamber for receiving debris-laden fluid and a second chamber communicating with the first chamber into which cleansed fluid may pass from filtering materials extending along the partition in the first chamber. In this respect, the filtering materials may be generally constituted of a dissolved material adsorbing means such as charcoal and a particle trapping means such as plastic wool or the like, and the conventional manner of arranging the filtering materials is simply to deposit the charcoal and plastic wool randomly along the partition in the first chamber to be constrained solely by the walls of the filtration housing.
>
> "Clearly, as those skilled in the art readily understand, filtering materials, after a period of time, must be replaced with substitute filtering materials since, in fact, after a particular period, the filtering materials which entrap debris become clogged, thereby, delimiting the capacity thereof to cleanse debris-laden fluid. Obviously, since the filtering materials, such as the charcoal and

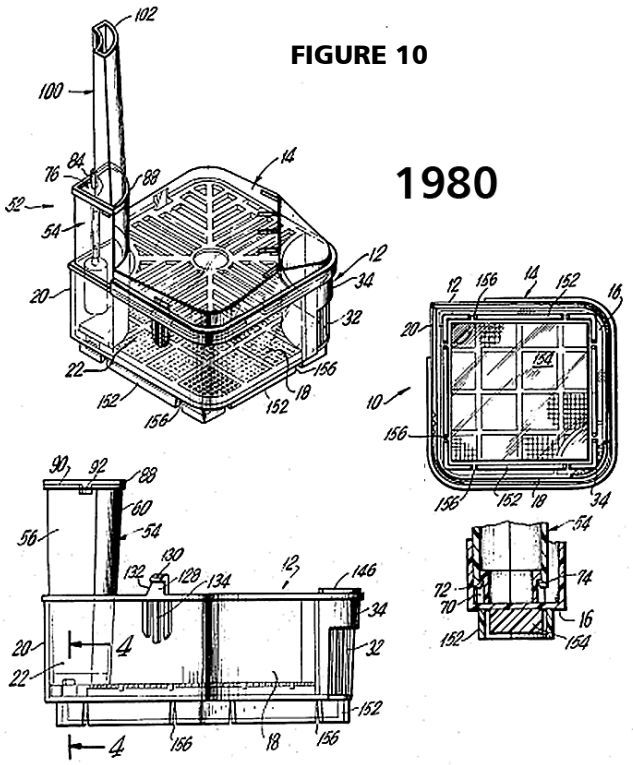

FIGURE 10

plastic wool, extend freely along the partition in the first chamber, it is often an extremely difficult and dirty process to remove the debris -laden and clogged filtering materials from the filtration housing.

"Furthermore, as those skilled in the art readily under-stand, the plastic wool generally blackens and accumulates an odor due to the debris it entraps, and there is little means for the hobbyist to recognize that the filtering materials require replacement other than by the eventually sustained black color of the plastic wool and the odor emitted thereby. Thus, the conventional type of filtration housing is not provided with adequate means for indicating that the filtration materials re-quire replacement."

Willinger patented several undergravel filters designed for round fish bowls, and also a number of bottom filters. The most interesting design in the latter category was one he devised in 1980. Bottom filters, especially those using activated charcoal and/or lightweight filter floss, tend to rise from the bottom unless weighted or partially embedded into the gravel. Also, when it came time to clean the filter, they often came apart when the filter stem was pulled. Willinger's design (Figure 10) incorporated a restraining plate to keep the filter floss from its tendency to rise within the filter, and a weighted chamber. Furthermore, even with the filter partially buried in the gravel – thus helping to conceal it – its internal parts, including the filtering media, could be lifted out without disturbing the gravel.

Drawing upon a number these prior patents, Willinger created his well-known "Whisper" filter (Figure 11). The patent was filed in January of 1983 and was awarded in April of 1985. The Willinger brothers put the filter on the market under the name "Whisper filter" the same month the patent was awarded, and the Whisper trademark was filed the following month with the registration becoming official in July of 1986. The original design incorporated a vertical filter cartridge and over time was modified in several ways (Figure 12).

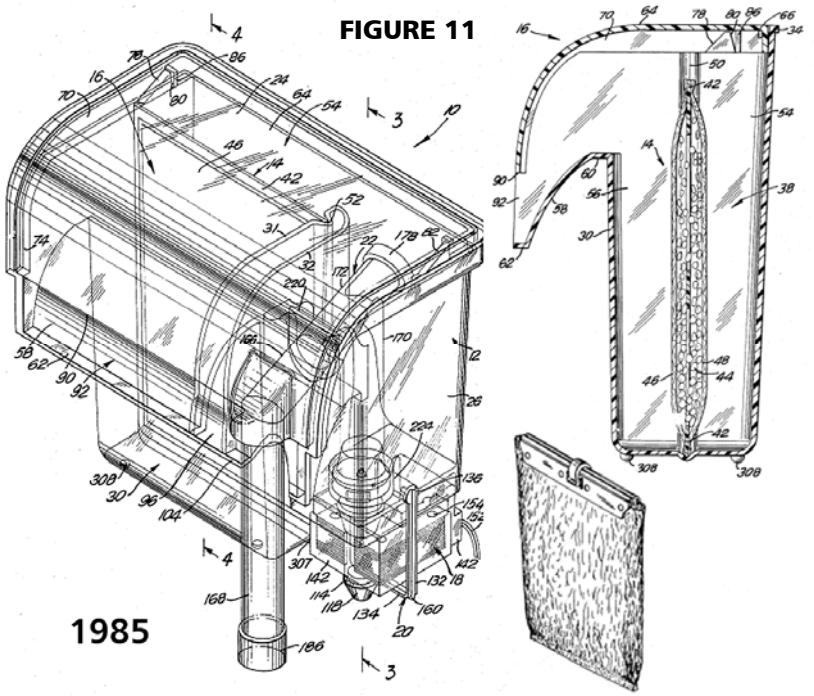

FIGURE 11

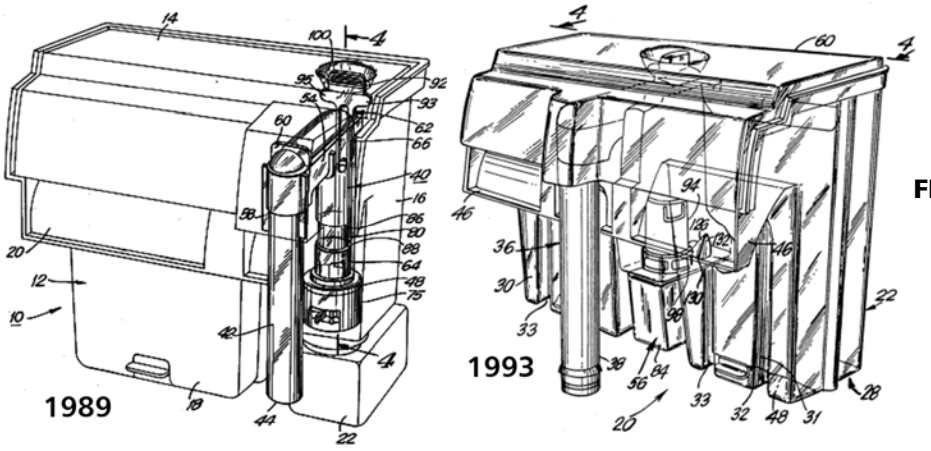

FIGURE 12

Underground filters are essentially biological filters, but they are difficult to clean when clogged and although external filters do not have these cleaning problems, their surface area is limited. In 1981 Willinger developed an external biological filter powered by an air pump that solved both problems (Figure 13). Willinger's filter could be back-flushed for cleaning, and the area available for bacterial action was at least as large as an undergravel filter. The design was unwieldy, however, and required a large horizontal surface for its location, usually the bottom shelf of the aquarium stand. His design of 1986 was based on a bag made of a porous membrane (Figure 14). As the filter clogged, the bag expanded, permitting the water to flow and continue filtering. The filter could be placed below or above the surface of the water, but one variation shows the filter built into the aquarium cover. This facilitated cleaning and also increased the aeration effect of the filter. However, it was a cumbersome design and not viable commercially.

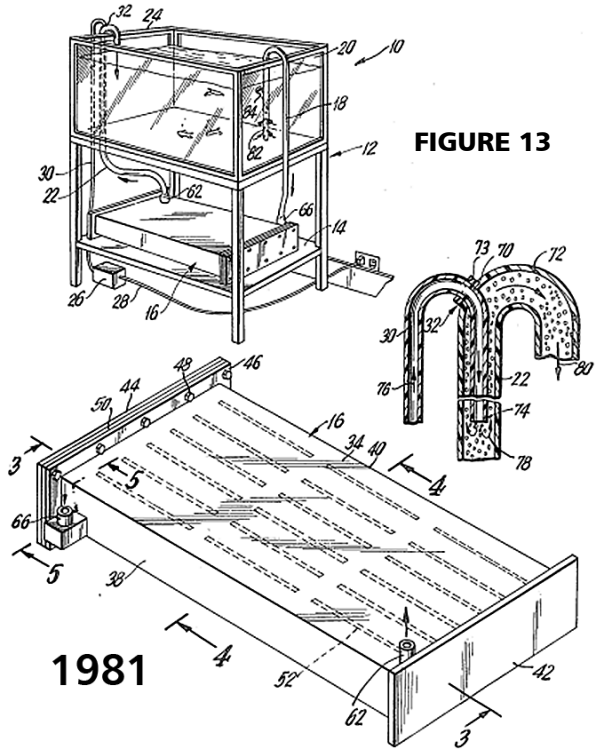

FIGURE 13

Willinger continued to patent versions of bottom filters, filter cartridges, and improvements in external hanging filters. In 1990 he patented his first canister filter (Figure 15). The filter was rather squat – thus taking up a larger footprint than those of a more vertical shape, but this shape provided a greater surface area for bacterial growth. In 1992 he patented a self-priming, diatomaceous earth filter (Figure 16).

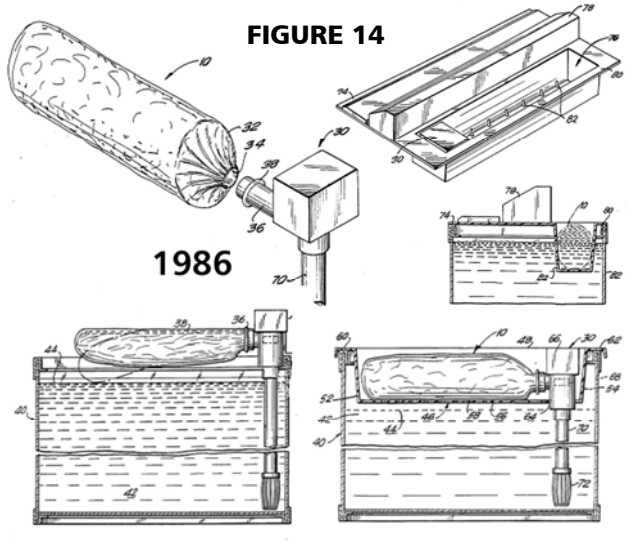

FIGURE 14

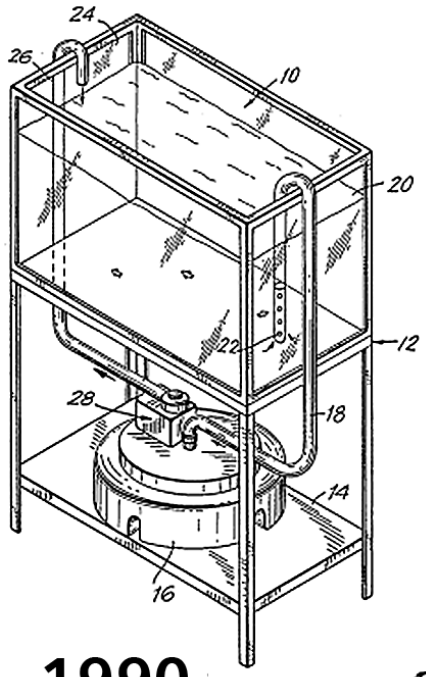
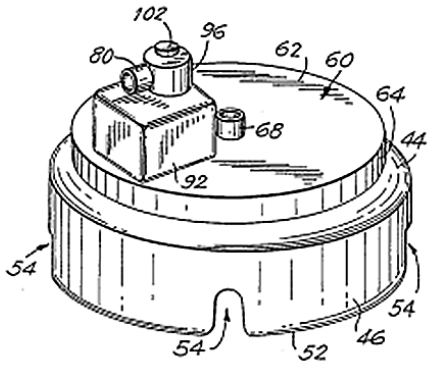


1990

FIGURE 15



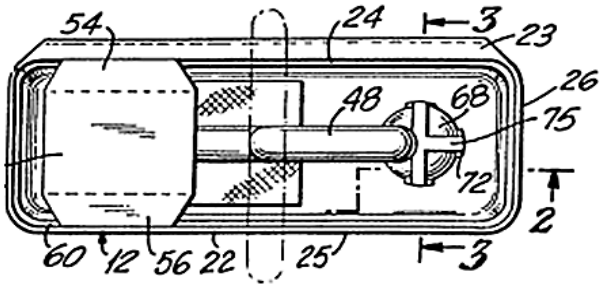


FIGURE 16

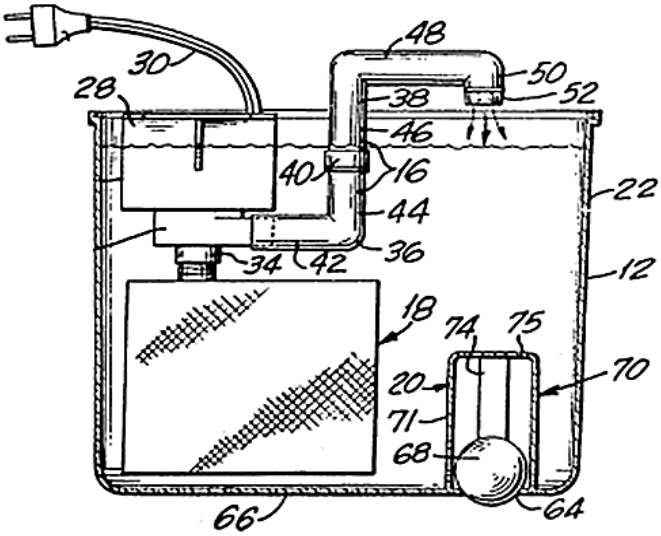
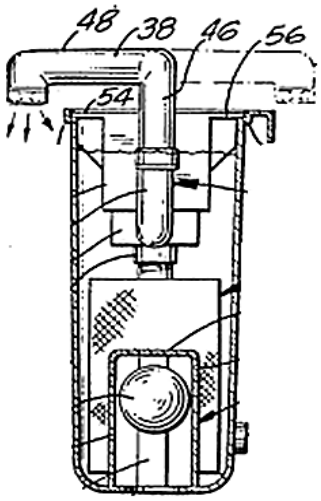
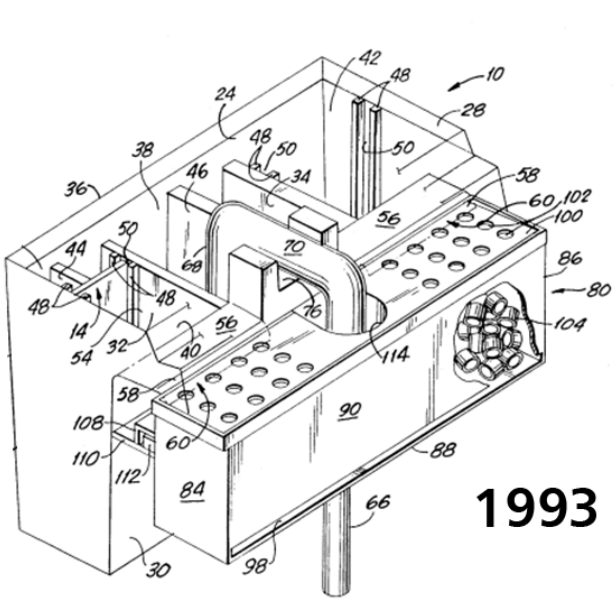
1992







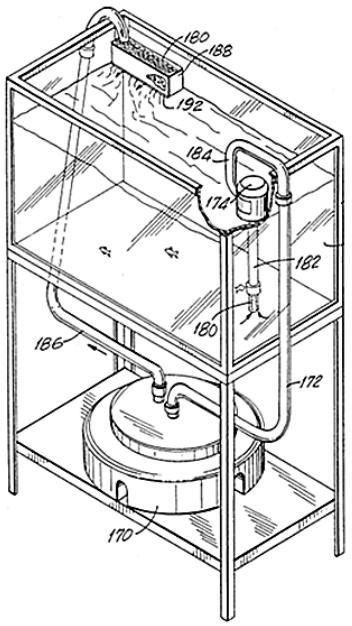


FIGURE 17

In addition to the self-priming feature, this filter did not need to be hermetically sealed, as with prior diatomaceous earth filters. It could also be used with the usual filtration media and thus served as a double -duty filter. The following he patented an add-on aerobic filter that received the output of a primary filter to enhance its biological filtration. The filter is shown in Figure 17, along with its application to a canister filter.

This is only a fraction of the filter designs invented by Allan Willinger. We turn our attention now to the area of aeration (Figure 18). His first design was for a plastic air valve (1964), his second for an air pump (1968), and the third for an air stone (1970). In the last named, Willinger pointed out that prior designs relied on cementing the rigid tube to the air stone, but that the spread of the adhesive tended to block the passage of air through the interior portion of the stone. Furthermore, the stress of attaching and unattaching the air line often chipped the stone. In Willinger's design a lip on the rigid tube preventing chipping, and since the adhesive was applied between the bottom of the lip and the top of the stone, the adhesive did not clog the stone. (Note: The air pump was a design patent, indicated by the letter "D" preceding the patent number in Table I. Unlike utility patents, design patents are a matter of form, not function, and generally are short with little or no text, the accompanying figure essentially describing the patent. However, if the utility invention is simple, inventors often file them as a design patent for convenience.)

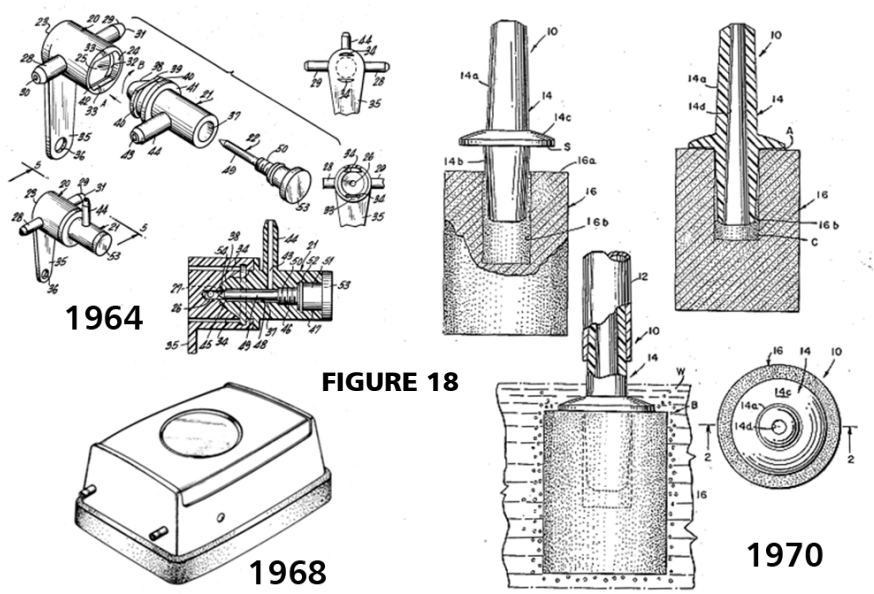

FIGURE 18

Willinger was awarded patents for a number of other air stone designs, three being shown in Figure 19. The air stone of 1971 is another familiar

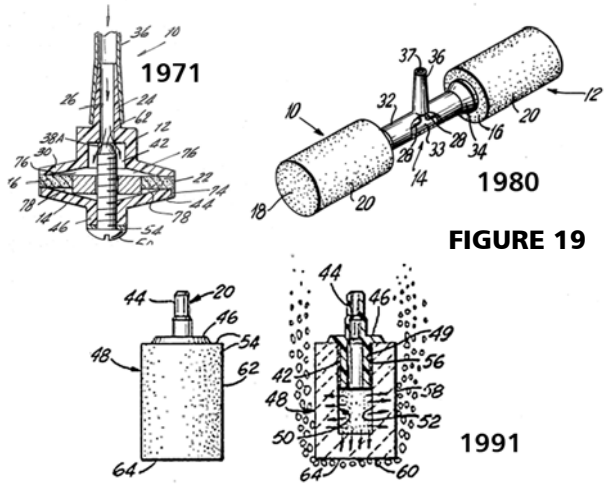

FIGURE 19

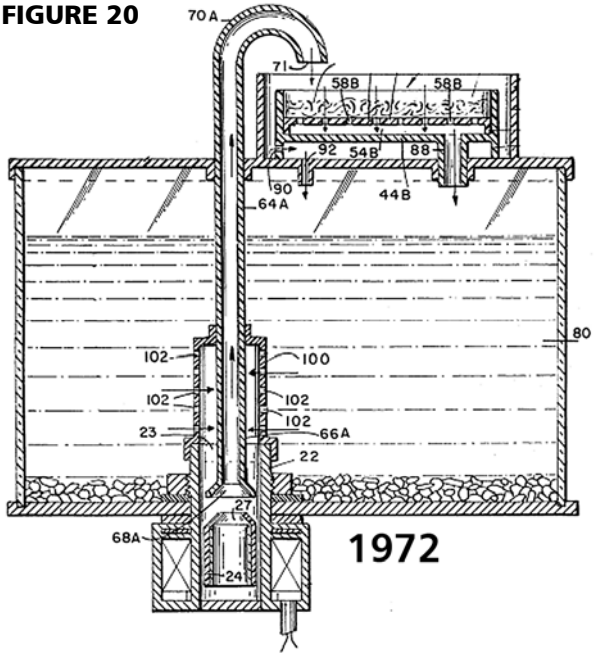
and popular design, using a fiber disk compressed within two stainless steel disks. This was held together with an adjustable screw so that the air flow could be altered to control the flow and size of the bubbles. The 1980 design addressed the problem of maintaining the position of an air stone. Air stones tend to rise since the material is porous and also contains air, both of which are lighter than water. The 1991 design addressed another problem, that of distributing the air more equally through the air stone. Willinger provided a hollow chamber through which the air could travel before passing thorough the stone. These were not trivial modifications by any means.

In addition to several ornamental air pump designs, Willinger patented four utility aeration patents. The first was in 1972 for an ingenious valveless pump mounted below a fish tank (Figure 20). The annular outside of the circular pump housed a magnetic field producing coil. The inner section (which was isolated from the motor and any electrical connections), contained a piston made of a magnetic material that, as the electric current varied, moved up and down. This moved the water that entered around the vertical tube that led to the filter (which could be placed on top of the gravel or on top of the tank, the latter placement being shown in the figure). However, the need to drill a hole in the bottom of the tank made this design impracticable. The second was in 1973 for a wall-mounted air pump, the third in 1991 for a vibrating air pump, and the fourth in 1992

FIGURE 20



for an aquarium powerhead designed for use with an undergravel filter (Figure 21). Finally, two somewhat frivolous designs patented in 1970 were for the ornamental filters, diver and water wheel, shown in Figure 22. Both incorporated improvements in introducing the air to the ornament, the water wheel for example, having the air introduced into the support base of the wheel, thus prevented the tipping experienced in prior versions patented by others.

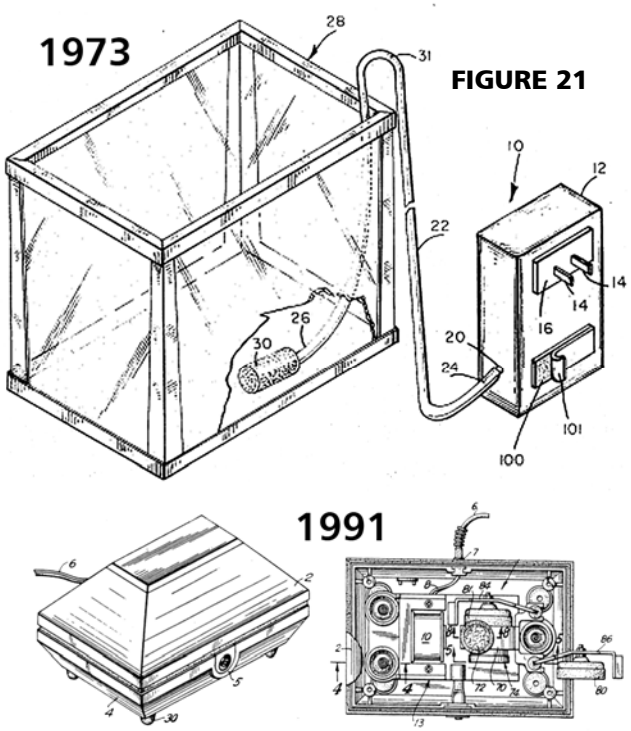


FIGURE 21

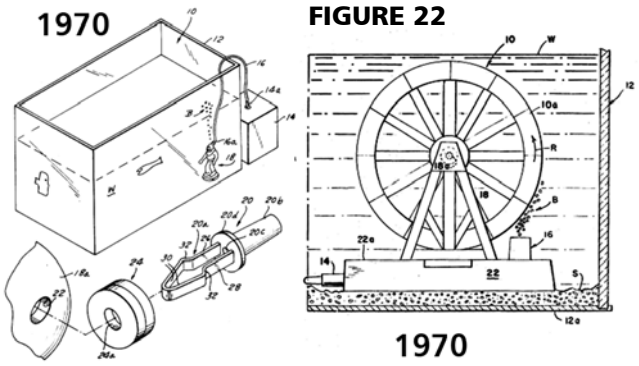

FIGURE 22

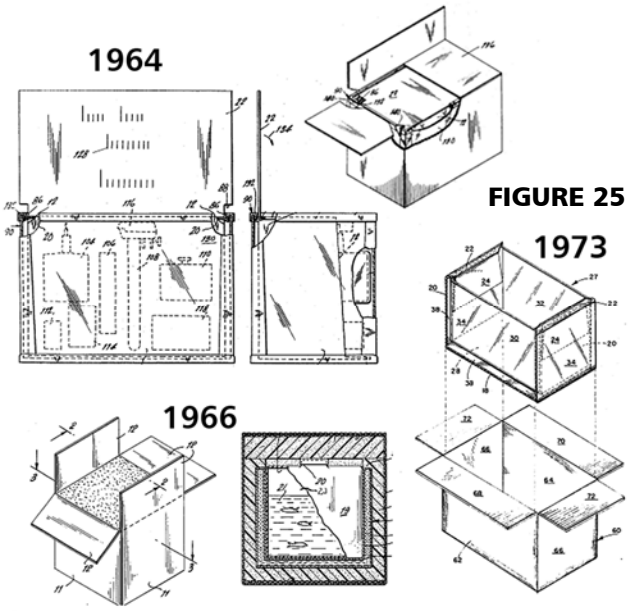

FIGURE 25

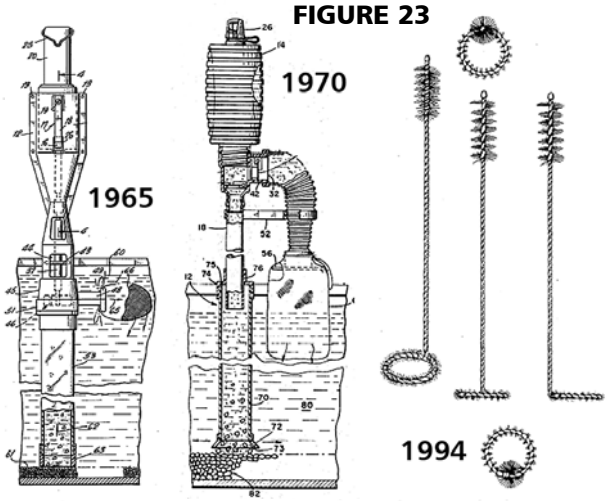

FIGURE 23

Willinger patented a number of cleaning devices and shown in Figure 23 are two bulb-operated cleaners and also some cleaning brushes. He also invented two siphon devices, one hand-held related to the bulb -operated cleaners, and the other built into a filter (Figure 24). Since Metaframe was, of course, in the business of shipping aquariums, Willinger also had two patents in this area, one awarded in 1967 and the other in 1973. These are shown in Figure 25, along

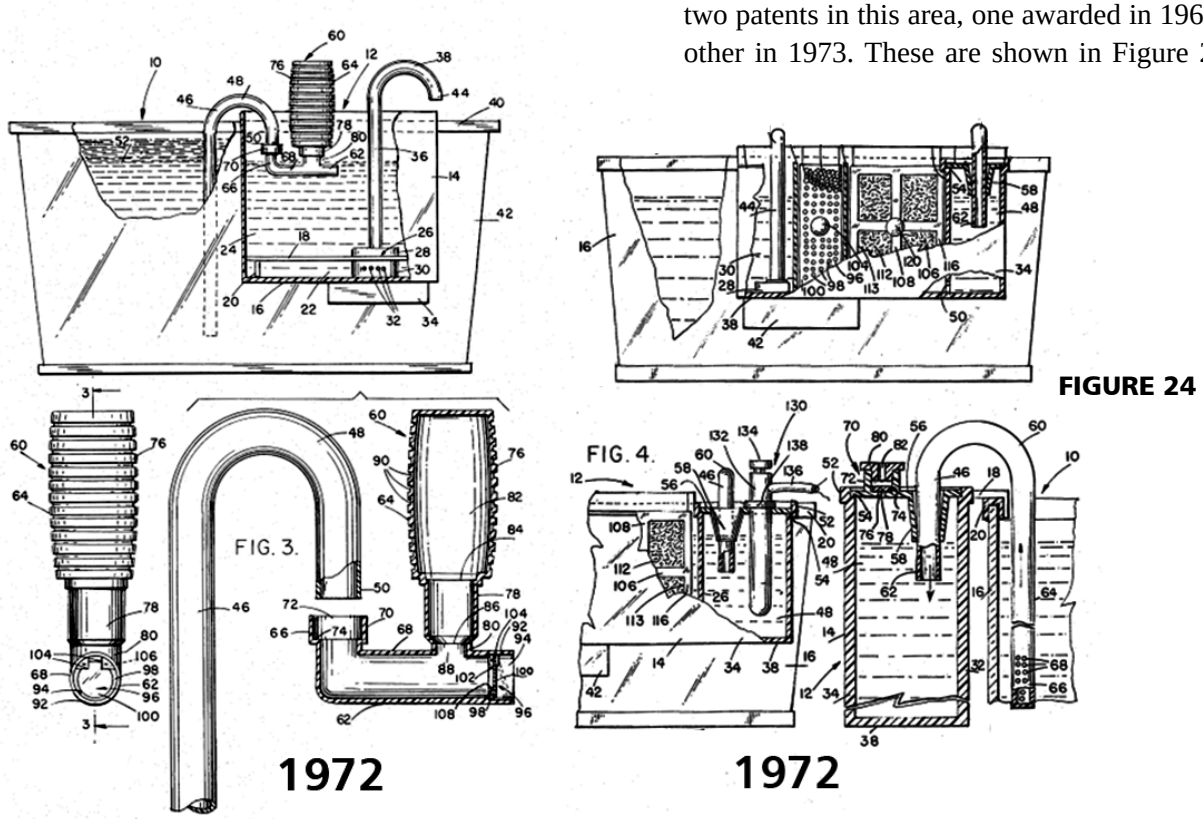

FIGURE 24

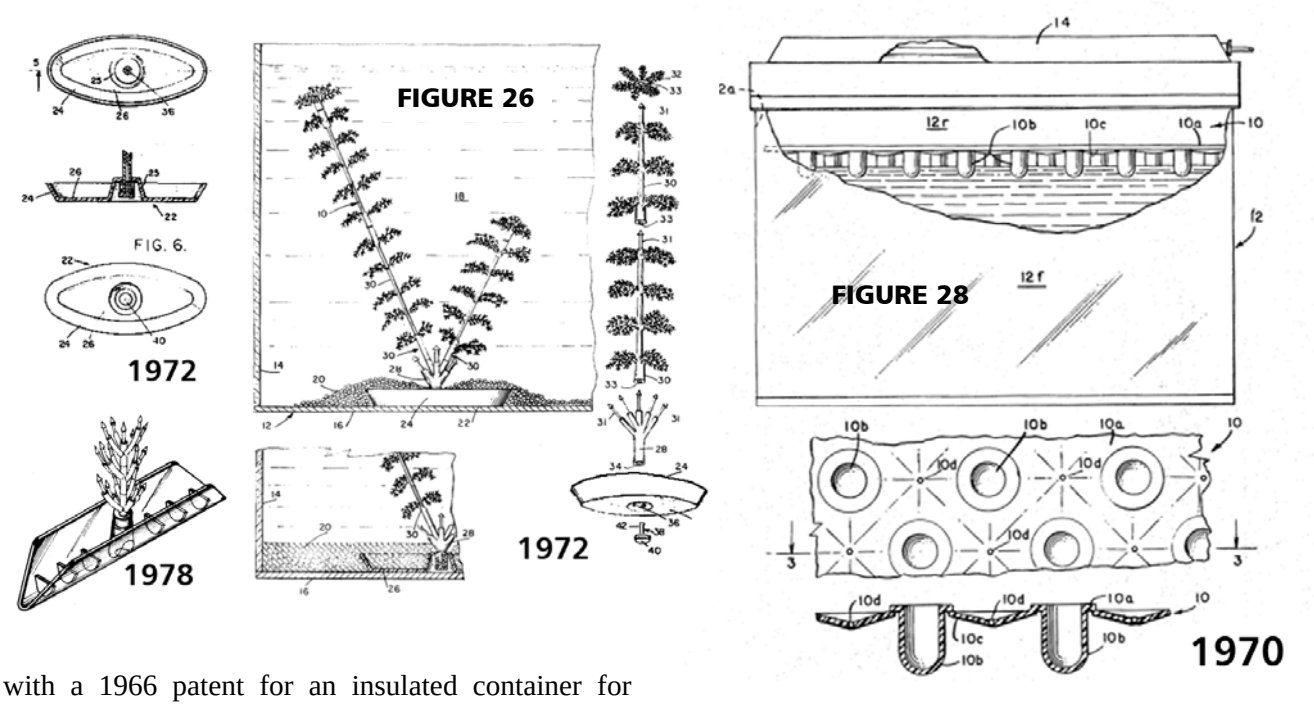
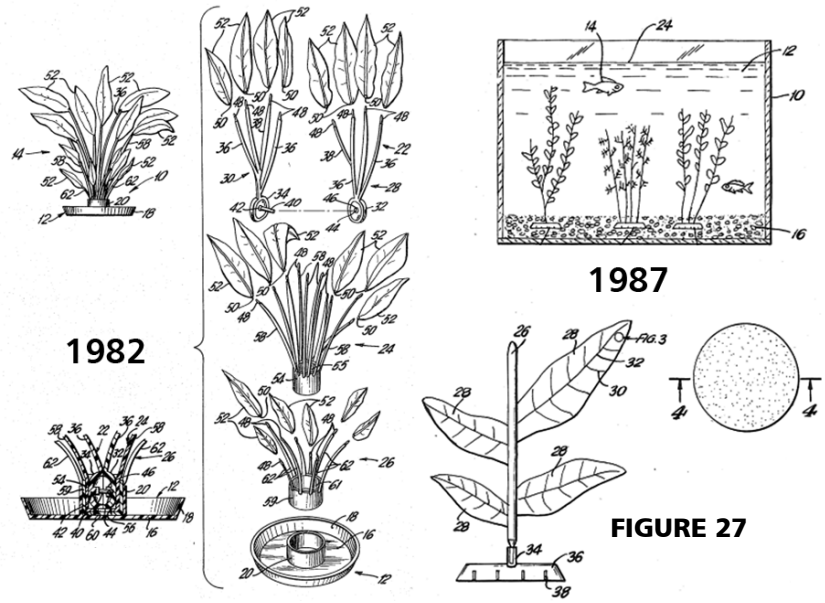


with a 1966 patent for an insulated container for shipping fish.

He also had numerous patents involving artificial aquarium plants. Figure 26 shows an oval dish-type anchor (1972) and a trough-like anchor (1978), both familiar to aquarists even today. The 1972 artificial plant to the right in the figure was designed to wave in the movement of the water returning from a filter. Figure 27 shows two additional artificial plant patents. The plant in the 1982 patent could stand upright on a shelf in a pet store, thus improving its display and sales appearance. The 1987 patent on the right in the figure featured a rough plastic surface that encouraged the growth of algae, thus providing a more natural appearance.

Willinger patented a number of small but useful devices, the thermometer (still widely used in the hobby today), fish feeder, and artificial gravel bed shown in figure 28. The fish feeder was designed to hold freeze dried foods such as tubifex, and cleverly packaged in one unit as a feeder and a container for the food. Re the artificial gravel bed, Willinger argued that gravel was heavy, thus inconvenient to purchase and carry home, and increased the overall weight of the aquarium; that it was difficult for beginners to estimate the amount of gravel needed; that gravel contained interstices that trapped food particles; and that the novice was uncertain as to the optimal placement of the rocks and gravel, and where to place the plants in a tank, i.e., "aquascaping." Note that characteristic of many of Willinger's patents, even when they were incremental or subtle, they were valuable improvements.



Finally, there were a number of patents that were quite inventive, showing a

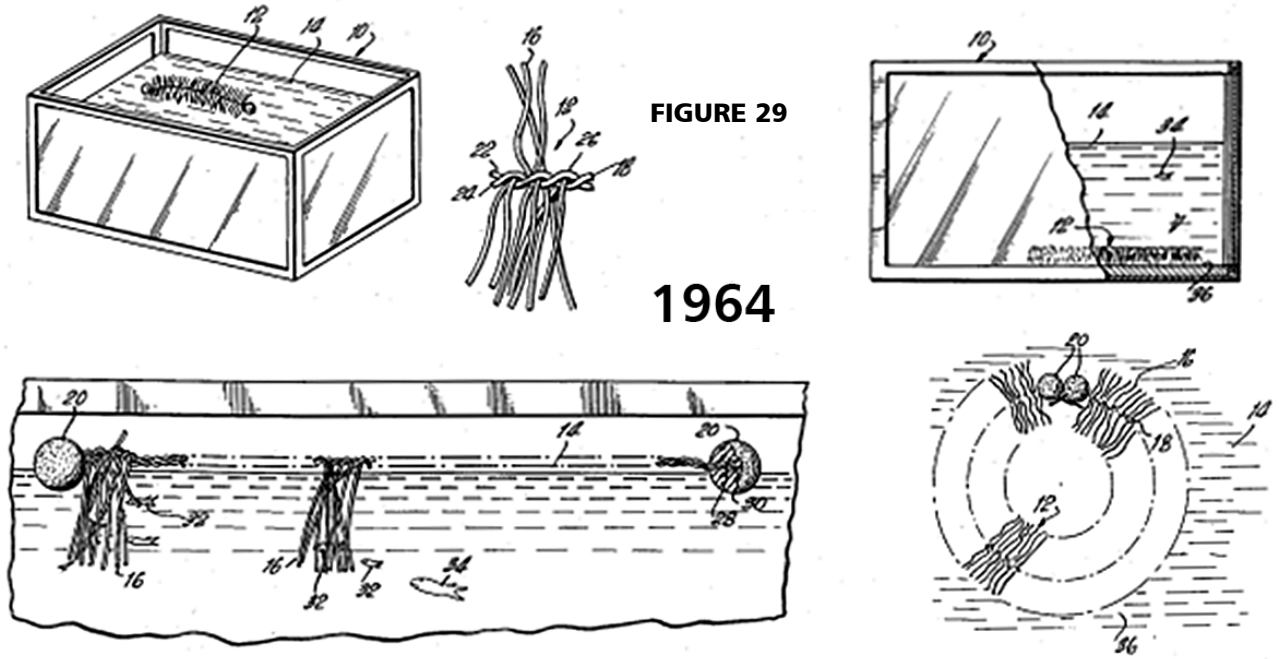


FIGURE 29

1964

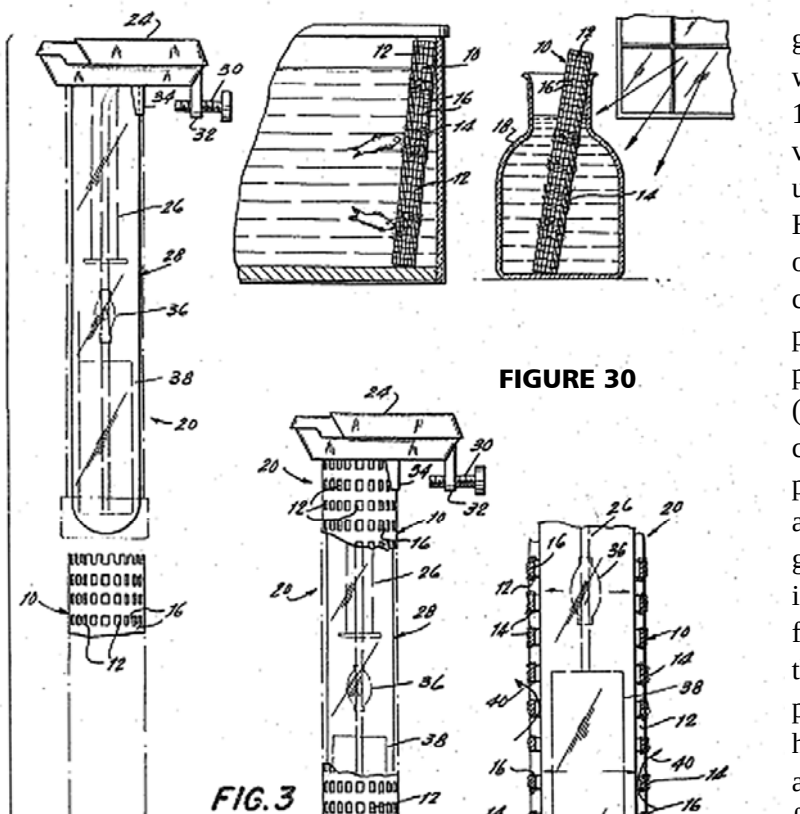

FIG. 3

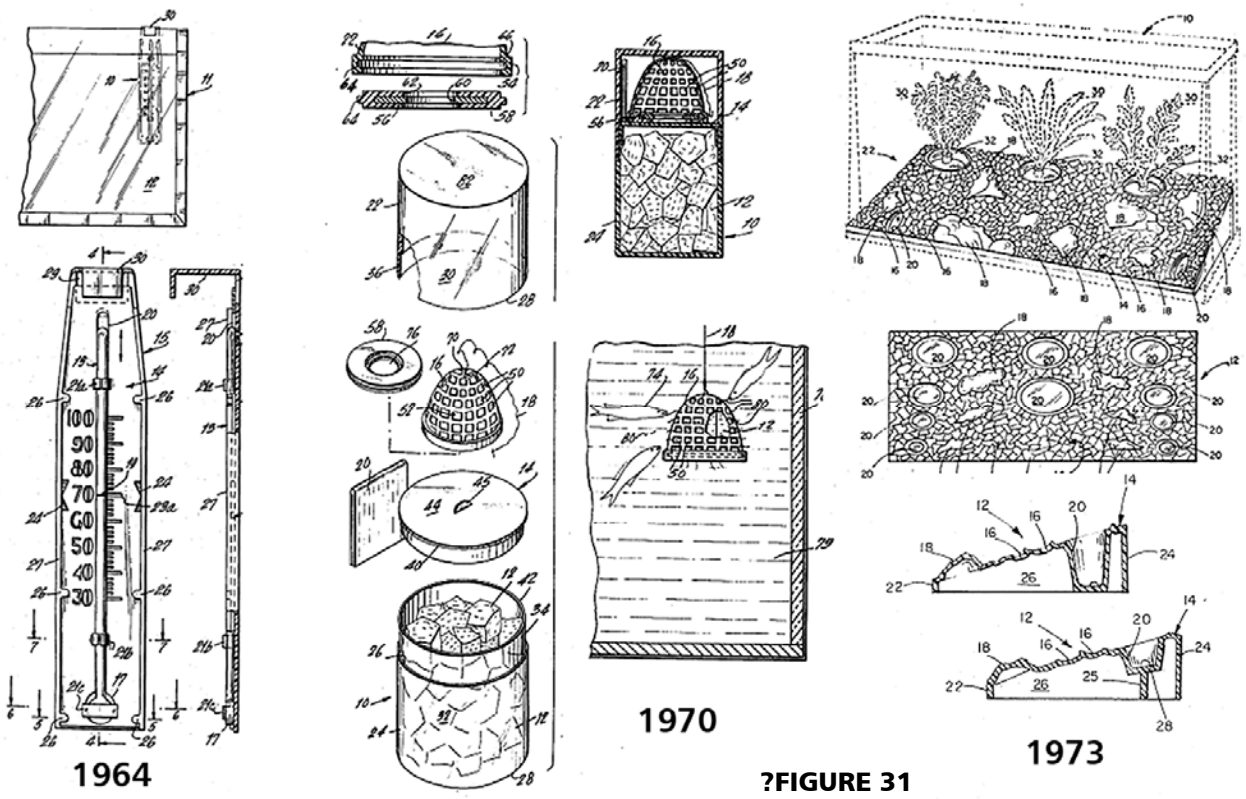
FIGURE 30

1967

great deal of imagination. An early one was that shown in Figure 29, patented in 1964, for a spawning device. This was a variation on the nylon spawning mop, used for many years by killifish fanciers. However, aquarists generally make their own mops so this patent was never commercially appealing. An interesting patent awarded in 1967 was for an algae propagating and fish feeding system (Figure 30). It consisted of a mesh tube, constructed of stainless steel or plastic, placed in a jar or water where the sun was allowed to shine on it, thus producing a growth of algae. The tube was then placed in an aquarium where the fish could then feed on the algae. A variation was to slide the tube over a heater containing a bright pilot light. The combination of light and heat then would spur the growth of algae and provide an algal browsing site for the fish. A patent awarded in 1970 for a floating cover was designed to prevent evaporation from an aquarium (Figure 31). The cover was molded from a thin sheet of plastic that could be cut with a pair of scissors to fit the in side of the



?FIGURE 31

tank. The tubes molded into the cover provided the floatation, sufficient that the top of the cover floated some distance above the surface of the water, proving airspace between the surface of the water and the cover for the interchange of oxygen and carbon dioxide. Small holes were provided between the flotation bodies to permit any condensation water from a reflector cover to drain back into the tank.

Thomas Alva Edison once said, “Genius is 1% inspiration, 99% perspiration,” and so many people have patents: Abraham Lincoln, Harry Houdini, and Hedy Lamarr are among some of the more famous (Lincoln received a patent for a device to lift boats over shoals, Houdini received a number of patents for diving suits, and Lamarr had the original idea and patent that led to cellular phone, i.e., the concept of “frequency hopping”). Inventiveness is closely related to the concept of entrepreneurship, particularly with regard to the idea that the freedom to succeed requires a corollary freedom to fail. The virtue of inventiveness is that it explores new territory, a task which requires challenging the status quo, and an aversion to failure is simply not consistent with the “1% inspiration, 99% perspiration” kind of genius that Edison embodied. Thus it was with Allan Willinger’s aquarium inventions. Some were fanciful or convoluted and therefore failed, some were simple but nevertheless productive, and some were invaluable additions to the equipment of the aquarium hobby. Success or failure, in the history of aquarium inventions, none really surpassed the creativity, ingenuity, or imaginative mind of Allan H. Willinger.

THE EARLY HISTORY OF AQUARIUM AERATION

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, February 2, 2013)

To describe the early development of aquarium aeration, we start in 1854 when Dr. Robert Ball introduced a novel mode of aeration at the newly opened Dublin Aquarium.

Ball (1802-1857) was born in County Cork, Ireland and ultimately became one of Ireland's most noted naturalists. After a career in the civil service, he became Director of the Dublin University Museum in 1844. He was a Member of the Royal Irish Academy and President of the Geological Society of Ireland. Dublin University conferred on him the degree of LL.D. He became Secretary of the newly founded Queen's University of Ireland in 1851, and was a Fellow of the Royal Zoological Society. About 1838 Ball devised a dredge net to collect marine organisms. It was used all over the world, and was so apt for its purpose that it was little modified later. It is known as Ball's dredge or more generally simply "the dredge," and it was commonly used by aquarists when collecting their own fishes from ponds or the seashore (Figure 1).

Of all the Dublin Societies of which Dr. Ball was a member, the Royal Zoological Society, founded in 1830, was that with which he was most pre-eminently associated. It was there that he acted, for more than twenty years, as an Honorary Secretary, devoting to it "a large portion of valuable time, and the energies of a strong and cultivated understanding." The Zoological Society was responsible for running the Dublin Zoo and Ball understandably was involved. He devised a method whereby all of the tanks in the aquarium were connected by a tube with a single pair of bellows. From this long tube, branches passed off and opened into each tank so that one puff of the bellows supplied air to the whole of the tanks (Figure 2).

The passing of the air into the tanks had a very pretty effect, and visitors were so fond of blowing the bellows, that Dr. Ball, who described this arrangement at a meeting of the British Association at Cheltenham, stated that the authorities of

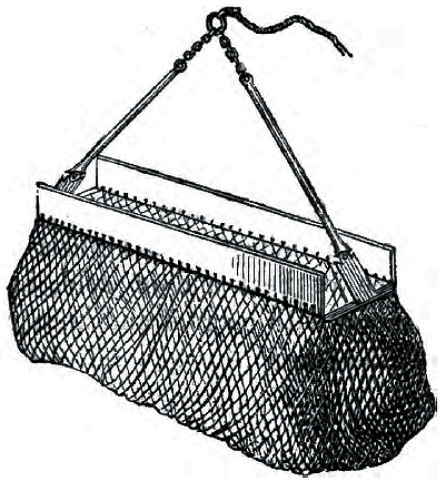

Figure 1: Ball's Dredge.

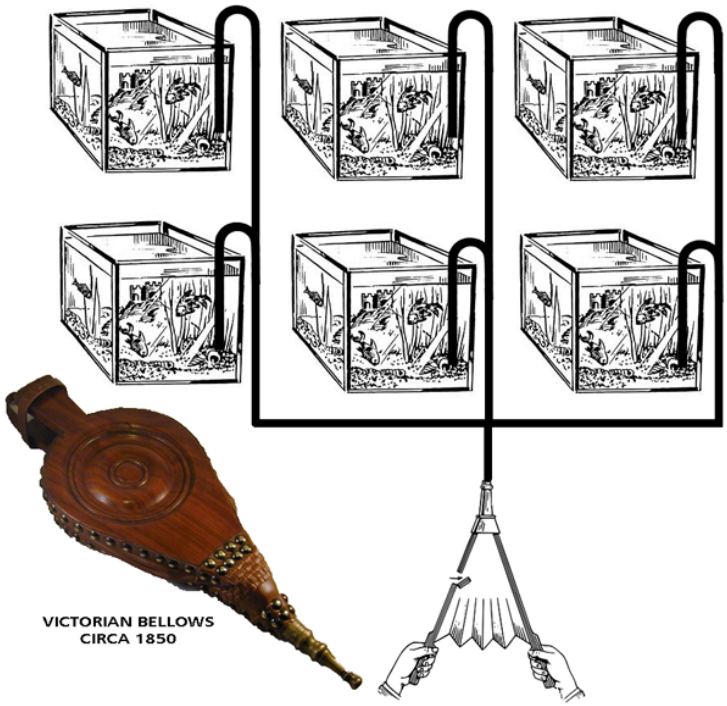

Figure 2: The Dublin Aquarium Bellows System.

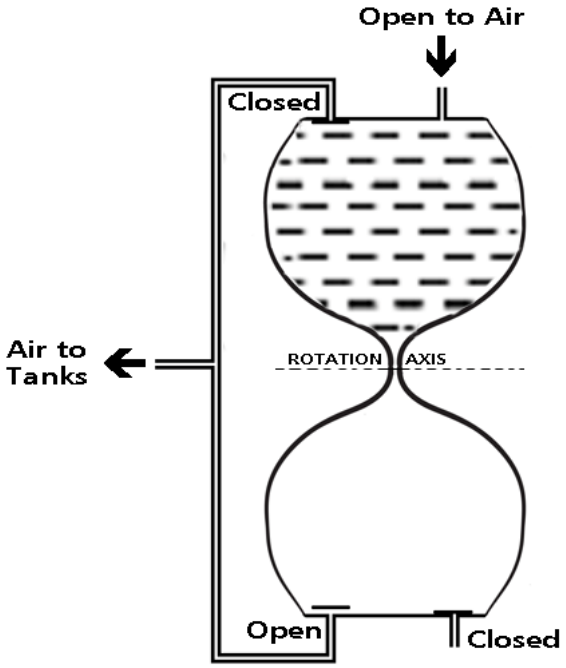

Figure 3: The "hourglass" aerator devised by Henri Milne-Edwards.

the Gardens had found it entirely unnecessary to employ any of the men in the Gardens to pump in the air. This worked well for this small public aquarium and for the one later established in Paris 1860, but it of course was not practical for larger public aquariums. (It should be noted that the early public aquariums, such as the ones in London, Dublin, Paris and Hamburg, actually had only a few on view, typically 12 to 14.) Ball's method of using a bellows to aerate private aquaria was recommended in by Edwin Lankester in his book, *The Aquavivarium, Fresh and Marine* (1856) so it was employed by hobbyists as well as public aquariums.

In 1856, Baron Jules Cloquet revived the use of bellows for the purpose of aeration. Cloquet (1778-1883), was "a prince of medical science in France" who died in Paris at the great age of 104, thus having known most of the great men of his day. He was given the rank of Baron by Napoleon III, and was a Commander of the Order of the Legion of Honor. Cloquet was the author of many works on anatomy and surgery, but it was through his great monograph in five volumes on descriptive anatomy that his fame chiefly survives.

Cloquet was a member of the Société zoologique d'acclimatation, established by Isidore Geoffroy Saint-Hilaire in 1854. Is name was later changed to the Société nationale d'acclimatation de France (i.e., The National Society for Nature Conservation) to better reflect its main objective of nature conservation against the increasing destruction of habitats by industrial development. Cloquet was an active member, and was responsible for the importation of exotic plants into France. He also took part in establishing the Paris aquarium, located in the Jardin d'Acclimatation de Paris (or the Jardin Zoologique d'Acclimatation as it was first called - essentially a zoo).

His instrument had a gutta-percha pipe fitted to its nozzle, and at the extremity of this was a lead tube that extended to the bottom of the aquarium. The innovation here was that the opening of the tube was covered with wire-gauze, which produced extremely fine bubbles and hence, enhanced aeration. (We are all familiar with this type of aeration, since the faucet aerators in our homes consist of a little wire mesh that fits over the ends.) Cloquet's innovation was the beginning of the air stone in its many incarnations and he deserves the credit for this now common aquarium device.

The next development was by Alphonse Milne-Edwards (1835-1900), the son of the great naturalist, Henri Milne-Edwards. He obtained a medical degree in 1859 and in 1876 became an assistant to his father at the Jardin des Plantes, the main botanical garden in France. In 1891, he became the director of the Muséum National d'Histoire Naturelle, devoting himself especially to fossil birds and deep-sea exploration.

His apparatus took the form of an hourglass (Figure 3), consisting of two chambers connected by a narrow passageway. The upper chamber was full of water, the lower full of air. The water descended by its own gravity from the upper

chamber into the lower, expelling the air and driving it via tubes into the tanks and thus aerating them. Because of its large size and the narrowness of the passageway, the operation of emptying the upper chamber took a long time, but when once this was accomplished the entire apparatus was rotated, reversing itself, during which time it closed one set of valves and opened another. Since the former air chamber now contained water and was uppermost, the water continued to be aerated as before. I have not been able to uncover any evidence, however, that the device was ever adopted either by any public aquarium or private aquarist. Figure 4, however, shows an adaptation of the idea to a fountain aquarium shown in a German aquarium book published in 1886.

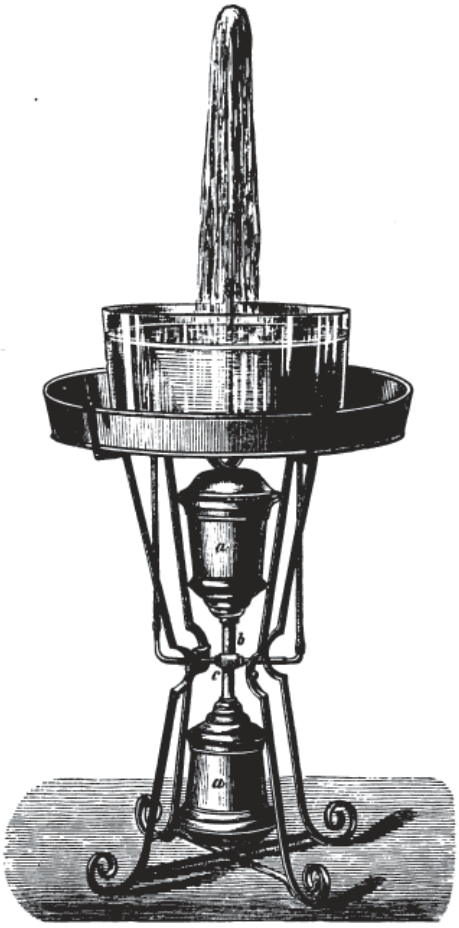

Figure 4: An aquarium based upon the Milne-Edwards aeration principle (from "Das Süßwasseraquarium und seine Bewohner: Ein Leitfaden für die Anlage und Pflege von Süßwasseraquarien," by Wihelm Heß, 1886.

In 1855, Mr. George Hurwood (1798-1864) of Ipswich, which is in Suffolk, England, used the pressure of a stream of water, either from the waterworks in towns or from the high cisterns that often existed in the dwellings of the day, to compress air that in turn forced a current of seawater into an aquarium.

Hurwood, a civil engineer, was at one period frequently employed by the Admiralty to conduct investigations on the probable effect upon tidal waters of projected railway and other works, and he invented and patented several ingenious and useful mechanical contrivances that were extensively employed. He was, for example, well known in farming circles for his invention of mills for grinding corn as well as other pieces of agricultural equipment. In 1861, the

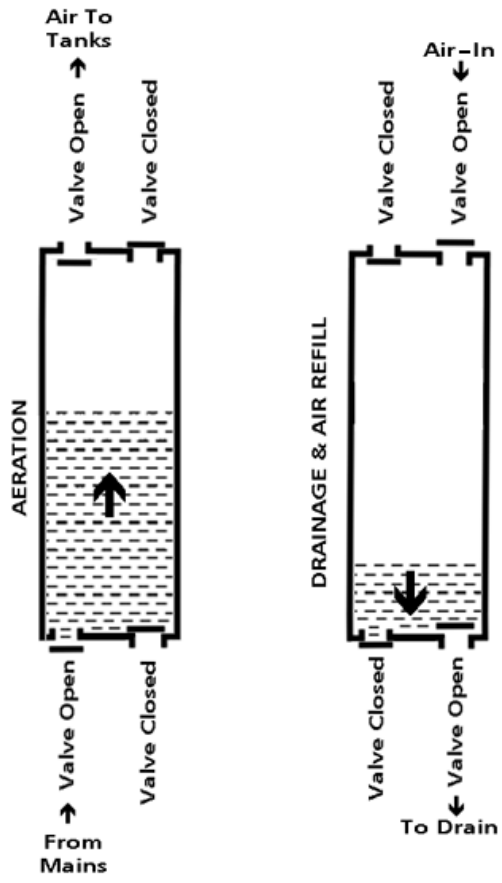

Figure 5: George Hurwood's Aerator.

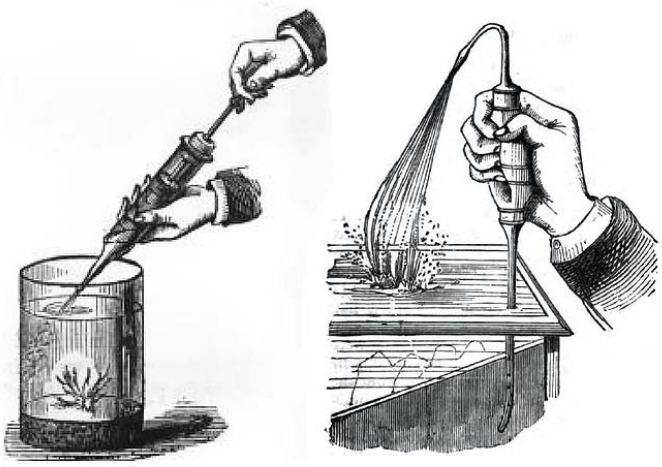

Figure 6: Lloyd's Simple Aeration Devices.

Council of the Institution of Civil Engineers awarded him a Telford medal for his paper "On the River Orwell and the Port of Ipswich." In Hurwood's device (Figure 5), as the water from the mains flowed upwards, the air above it would be compressed and driven out (where it could be used directly or else used to pump seawater). The motion was of necessity intermittent (unless the apparatus was in part doubled) since as the water neared the top of the tank, the drain and air-in valves were opened and the aeration ceased until the air was thus replenished. This arrangement was adopted by several private aquaria in England and therefore it was the first aquarium pump in the history of the hobby.

This arrangement was introduced by William Alford Lloyd into the Paris Aquarium in 1860; it was eminently successful and continued in operation for thirteen years. Hurwood's apparatus was also applied by Lloyd in the Hamburg Aquarium in 1864 where the air was used to drive a pair of water pumps as this kept the fresh water from being mixed in with the seawater.
For the purpose of occasional aeration in the home aquarium, a drip-glass was recommended by Philip Henry Gosse (1788-1854) in his 1856 book, *The Aquarium: An Unveiling of the Wonders of the Sea*.

"One of the simplest modes by which this object can be effected, is the drip-glass. I have been accustomed to suspend over the Aquarium, a perforated bell-glass (I think it is called a bee-glass) of suitable size, into the orifice of which a bit of sponge may be pushed, or a cork drilled with small holes. The cord which suspends the drip-glass passes over a pulley at the top of the window, so as to be raised or lowered at pleasure. Every morning sufficient water from the Tank is drawn or dipped off, to fill the drip-glass, which is then hoisted to its full height. The contents run out in slender streams, or in a rapid succession of drops, which, passing through some four or five feet of air before they reach the Tank, become effectually purified."

George Brettingham Southerby (1788-1854) in his 1857 book (published posthumously), *A Popular History of the Aquarium of Marine and Fresh-Water Animals and Plants*, suggested:

"A fountain-Aquarium, with apparatus for drawing the water up into the reservoir, would be a very good contrivance. This would save all the trouble of baling the water out of the tank, at the risk of disturbing the living organizations within it. A small pump, drawing the water through fine holes from near the bottom, would effect the purpose. The unsightliness of the apparatus could be disguised by rockwork, and the fountain, assuming the form of a cascade, might be so placed as to present an elegant object."

In his 1858 catalog (*A List, with Descriptions, Illustrations, and Prices of Whatever Relates to Aquaria*), William Alford Lloyd shows two aeration devices on sale in his store: (1) a syringe and a rubber squeeze bulb siphon starter (Figure 6).

A complicated arrangement of aquariums, aerated fountain style with its hoses cleverly concealed within the stand, is also pictured in Lloyd's catalog (Figure 7). His description of how the air was supplied was as follows:

"A slate cistern of 100 gallons capacity is placed

in any convenient and cool place, and at any convenient distance, either in the apartment containing the Tank, or elsewhere, and at such a height that the base of the cistern is not less than 12 inches above the summit of C. A second cistern of 100 gallons capacity is placed in any convenient and cool place, so that its top is at a not less depth than 24 inches below the surface of B. A feed-pipe of half-an-inch diameter is conducted down from near the bottom of the upper cistern, and, near the floor, at the points marked "entrance," it is divided into two branches, each of three-eighths of an inch in diameter, which (shown in dotted line, G) run up the stand, and are concealed in its legs. Then they are subdivided into four branch pipes of a quarter of an inch diameter each, and these pass through four holes in the base of A, and rise through C, at the top of which their orifices diverge outwardly, and they then discharge their contents equally over the rocks into the four divisions of A, overflowing which, the water falls into B through pipes inserted in four other holes in A, and finally run over the mouth of the exit pipe F, into the lower cistern, whence it is raised again once a day to the upper cistern, ready to perform another circuit, and thus the same water may be used continuously for years.

"The mode of raising the water from the lower cistern to the upper is either by a pump constructed so as not to be injuriously affected by the action of sea-water, or better, by employing the pressure of a column of fresh-water obtained from a main or from an upper cistern as a motive power to lift a somewhat shorter column of sea-water. The operation is then effected without labour, and the fresh-water (of course, unmixed with sea-water) may afterwards be used for ordinary household purposes."

Lloyd's reference to raising the water from the lower cistern is, of course, Hurwood's system. Oddly enough, the block print (Figure 8) of his store shows none of his aquaria being aerated.

In his book, *The Aquarium, its Inhabitants, Structure & Management* (1876), John Ellor Taylor (1837-1895) describes a number of schemes to aerate aquaria. The first involved taking the easy way out, i.e., a continuous stream of water from the household tap:

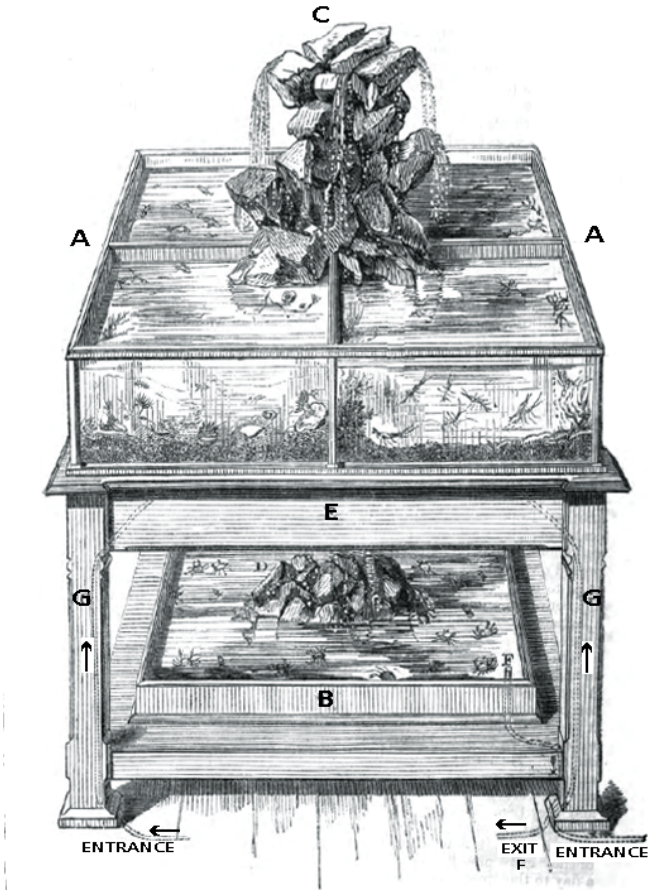

Figure 7: Lloyd's Tank with Fountain Aeration.

"It will be noted that all the foregoing directions apply only to streamless fresh-water aquaria. When opportunity affords (as it often may do) of constructing them so that the water may be conducted by a pipe from the usual household supply, and a constant circulation and aeration can be kept up, much labour will be saved, and the objects will appear more healthy and active."

This scheme, however, is not conducive to keeping tropical fish today where both water quality and temperature are critical factors.

His second method was simply to place water

Figure 8: Lloyd's Store.

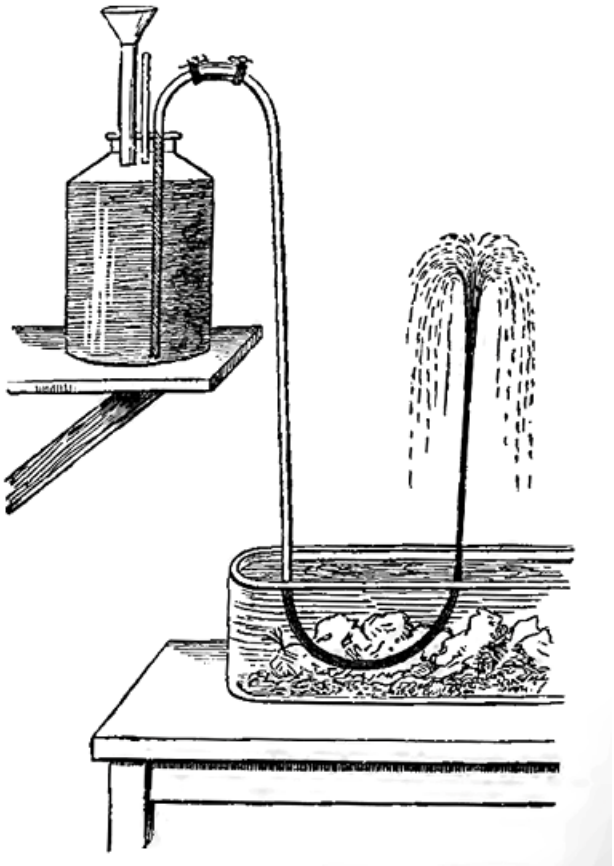

Figure 9: Taylor's Fountain Aerator.

taken from the tank into a jar situated higher than the tank, and then siphoning it back into the tank:

"Another means of promoting circulation is that of having syphons, which may be made to gently pour in the tank a fine stream of water from a jar placed above. If the current is made to flow a few inches through the air, it will mechanically entangle some of it and thus convey it to where it is required. But the ingenuity of a really careful aquarium-keeper will soon suggest to him various simple means of this kind, by which additional aeration can be obtained if required. The water referred to is of course taken from the tank into which it is made to run."

A variant on the second method placed the siphon tube down into the water in a U-shaped bend and then exiting some distance from the water surface. Depending upon the height of the jar, a fountain of some strength was produced, aerating the water as it fell back into the tank (Figure 9).

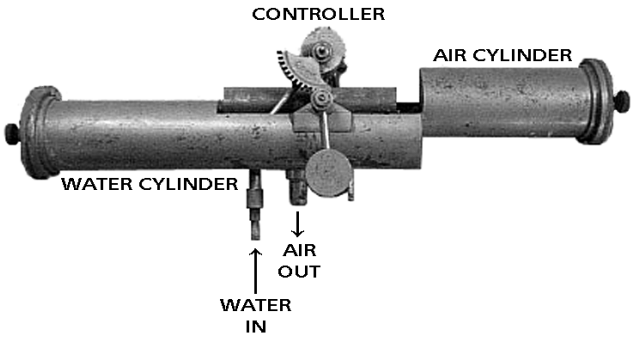

Figure 10: K.D.A Air Pump.

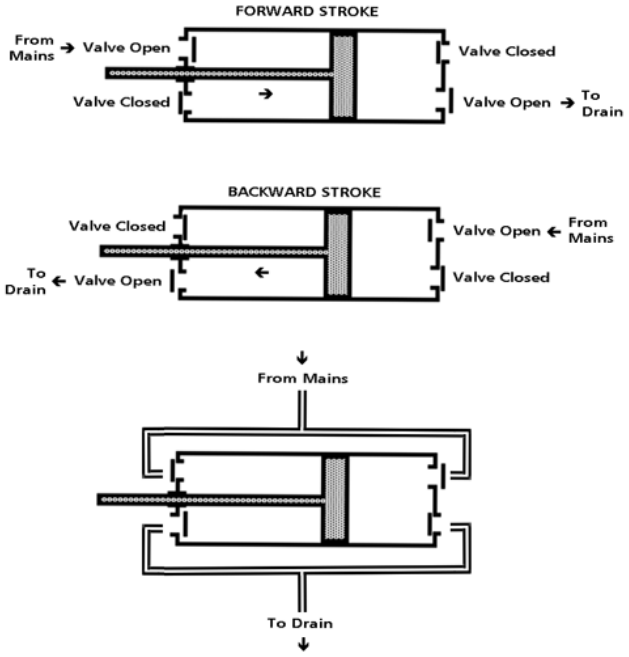

Figure 11: The Water-Driving Principle of the K.D.A. Pump.

The KDA (Kindelsche Durchlüftungs Apparat) air pump was introduced in 1908 (Figure 10). This device was a double piston water pump where both pump chambers were driven by water pressure through a common eccentric cam; this common drive allowed one piston to pump air while the other was refilling with air.

On the forward stroke, the entering water from the mains pushes the piston to the right, the water then going directly to the drain. On the backward stroke the procedure is reversed, this times the piston moving to the left (Figure 11). This, of course, accomplishes nothing more than moving the piston back and forth at the cost of the water usage. However, if one then connects an identical pump to the water pump - but one that uses air instead of water - then in effect we have an air pump feeding air to the tanks (Figure 12).

The device was characterized by an extremely low water consumption and high efficiency. The water consumption depended on the number of connected air outlets; only 1 liter of water in five hours was consumed using a single air outlet. Depending on the strength of the water pressure and the line resistance of the individual air outlets, at its fastest action it was claimed that a single KDA pump could power up to 60 air outlets.

The apparatus was relatively small, 13.8 inches in length, 4 inches high and 2 inches wide, and could be installed by anyone without needing any specialized knowledge. The only require-

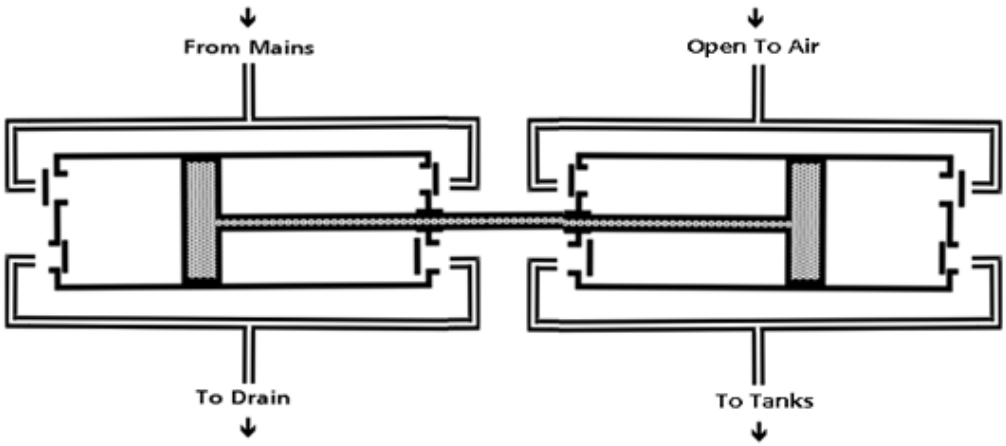

Figure 12: The K.D.A. Pump showing both pumps (water on the left and air on the right) connected.

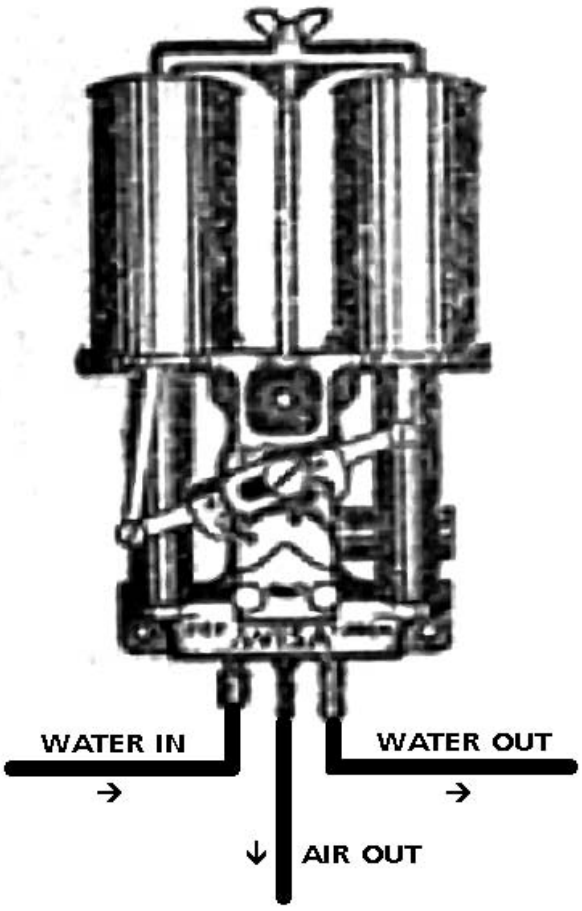

Figure 13: WISA Air Pump.

ment afterwards was that it had to be oiled from time to time. The device, moreover, had the advantage of shutting down automatically when the aeration had to be shut down or when there was an accidental obstruction to the aeration line; the operation of the pump automatically resumed when the problem was fixed, all this with great savings on water usage.

A very similar air pump to the K.D.A. was manufactured by Wisa (Figure 13). The principle was identical except in the case of the Wisa the two cylinders were situated vertically, side by side, rather than horizontally more or less in line. Whether one would choose the K.D.A. over the Wisa would probably depend upon the dimensions of the space available for installation.

Although the K.D.A. and Wisa pumps were decided improvements, being a double-acting pumps that provided air continuously where Harwood's pump was a single-acting pump in which no air was moved during the time the air chamber was replenished with outside air, Hurwood clearly gets the credit for inventing the first aquarium pump.

Lastly, it was very common for aquariums of the 1900's to be powered by air from an air tank, the air being replenished when necessary by a bicycle pump (Figure 14)

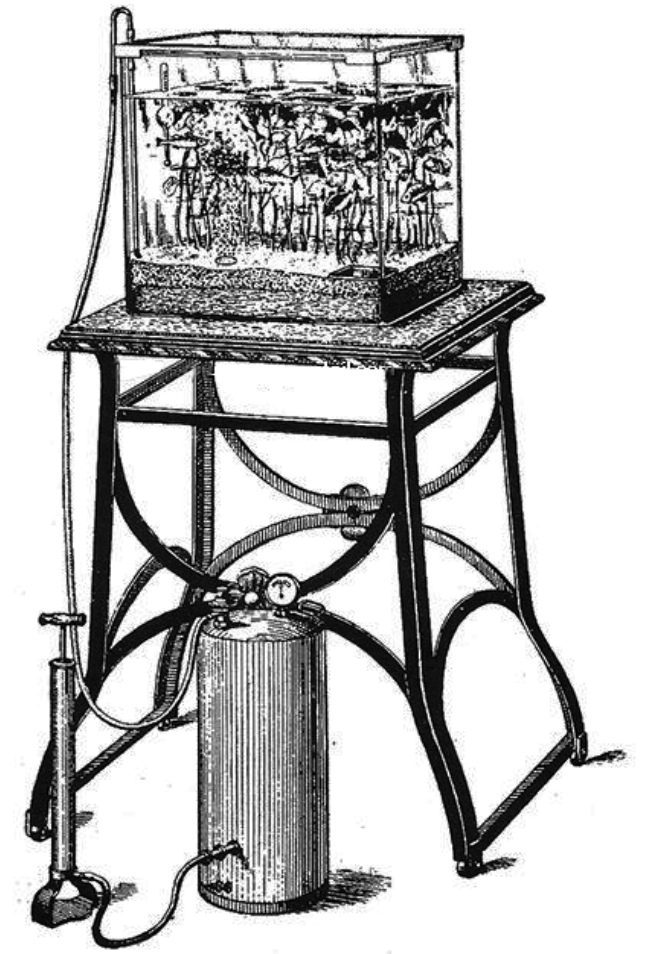

Figure 14: Air Tank with Bicycle-type Pump.

THE ORIGINS OF THE CICHLID HOBBY

By Albert J. Klee, Ph.D.

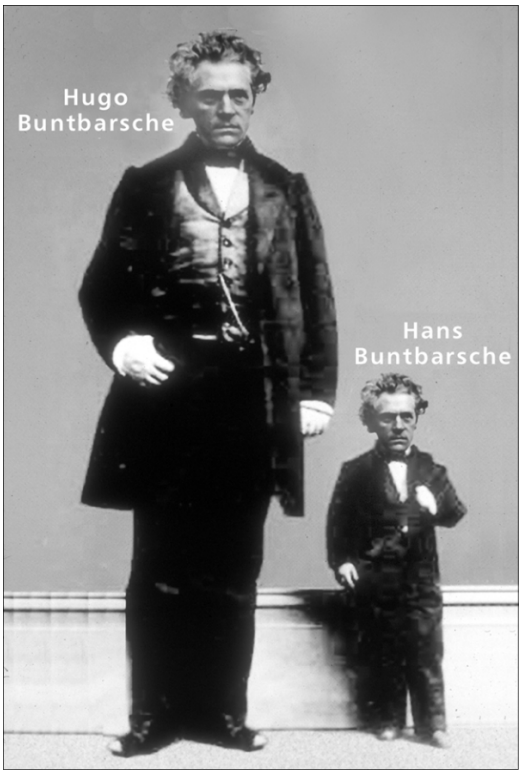
(Buntbarsche Bulletin, No. 227, pp. 28-33, April 2005)

The story starts in the year 1853 in the small Bavarian town of Buchstahude, Germany, when Fräulein Elise Eingemachte, an Editor's assistant who was carrying a box of umlauts to the printer, bumped into Emil Buntbarsche, a plumber doing maintenance work on the Flügelhorn that was played by a member of the Königliche Musik und Pumpernickel Gesellschaft, an organization that had a rehearsal hall in the same building. As a result of the collision, umlauts went flying all over the place and Emil, who was a real gentleman, helped Elise gather them up and return them to the box. Emil, who hadn't had a date since the fall of the Habsburg Monarchy (he was one of those German hippies known locally as a "flowerkraut"), chatted up Elise and soon they were holding hands regularly on the Liebestrasse.

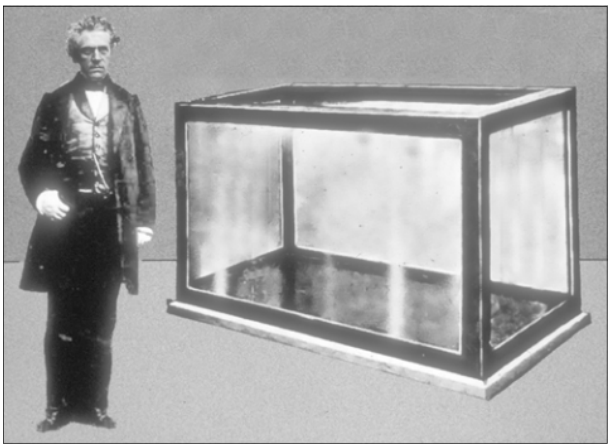
As a plumber, Emil had good connections so they were married a few months later and immediately tried to start a family. However, in their wisdom the Buchstahude Bürgermeisters had decided to make the sole road in town one-way only, so when Emil was finished with his day's work and tried to get home, he wound up in the next village located some forty kilometers away. Emil had to abandon his donkey and walk back, arriving home too late and too tired to do anything but have a quick supper of Krabbensalat, Schneckensuppe, and Schweinsmedallions. Fortunately, the Bürgermeisters reversed themselves and rescinded the law, and a year later the Buntbarsches were blessed by the arrival of twin boys whom they christened, Hugo and Hans.

Although the Buntbarsche brothers were rather undistinguished students (Hugo, for example, when asked why Buchstahude cows wear bells answered, "Because their horns don't work," and Hans thought that a Caesarean Section was a district in Rome), they did excel in natural history and even earned money after school by selling the rough bottom fish they found in the local river. For this they were paid daily, a remuneration known by the early Romans as "Karpe per diem." They devised a logo for their business consisting of two interlinked H's, and this was the very first Bismarck.

In addition to collecting carp, Hugo and Hans also netted smaller fishes such as Bitterlings, and also the complementary Dankelings, and



Hugo and Hans Buntbarsche. The brothers were identical twins, so the citizens of Buchstahude had great difficulty in telling them apart. The problem was solved when Hugo began to keep the larger cichlids, and his brother the smaller ones.



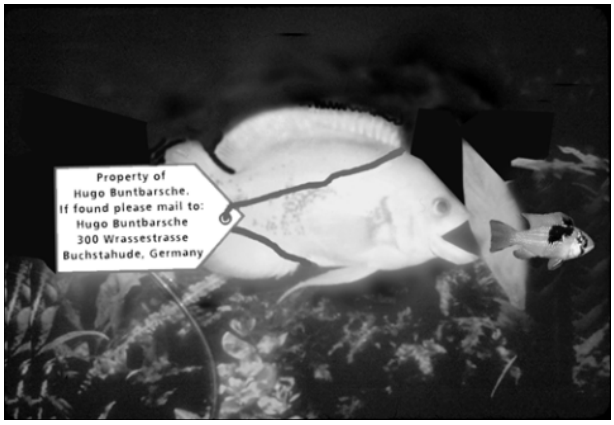
Hugo Buntbarsche and one of his smaller spawning tanks. When Hugo topped up his tanks, the water level in the Rhine dropped three feet.

this was the very beginning of the aquarium hobby for them. One of their uncles, Wolfgang Amadeus Buntbarsche, was an importer trading Hasenpfeffer and Kasespaetzle for items that were hard to come by in Buchstahude, such as frankincense and myrrh. Knowing that the boys were interested in keeping fishes, Wolfgang brought back a number of cichlids from Africa and South America, and from that day on the Buntbarsche brothers would keep no other fishes than those.

Their interest in cichlids, however, was quite different. Hugo, who stood 6 feet 7 inches in his Lederhosen, was only interested in the really big species. Hans, who only came up to Hugo's belt buckle, was interested solely in the dwarf species. (Since the brothers were identical twins, the only way the townspeople could tell them apart was by the size of the fish they kept.) Although Hans' equipment was, as befitting his charges, rather small, Hugo's on the other hand were immense. His filters, for example, were made to remove really large particles, such as gravel, dead sheep, and canoeists. Their enthusiasm for these fishes led them to establish, in 1889, the very first cichlid association in the world, the Deutsche Cichlid Gesellschaft (Author's Note: The Minutes of their first meeting are appended to this article).

On one occasion when he discovered some white spots on one of his Chanchitos, Hugo, who had some knowledge of English, exclaimed, "Ach, this is serious!" Hans misunderstood what his brother was saying and recorded it as "Ach, thee op thirius." Later, a Prussian microbiologist who had trouble with his vowels and thought that a diphthong was the lower part of an abbreviated bathing costume, changed it to "ichthyophthirius." Thus was born the first known aquarium fish disease. Savvy cichlid fanciers still refer to it as "Ach," rather than the more plebeian "Ich" favored by less enlightened aquarists such as guppy fanciers and, of course, killifish enthusi-

Hans Buntbarsche adjusting the pH in one of his dwarf cichlid aquariums. His tanks were so small that water changes involved eyedroppers and pipettes. Hans only used the finest Kölnisch Wasser (Cologne Water) for his fish. The fish shown here is the very rare *Apistogramma ottovonbismarcki*.



One of Hugo's large cichlids feeding on his brother's *Apistogramma*. Hugo was a careless aquarist and was forever losing his fish. As a consequence the local ASPCA required him to provide them with tags containing his return address. This happened so often that the local fishermen demanded that the postage was prepaid.

asts. This is not surprising, since the former chose that specialty because it was the only fish they could breed, and none of the latter have been known to respond to any external stimuli whatsoever without large doses of peat water in their morning coffee.

One day when Hans was out netting daphnia for his dwarf cichlids, Hugo set out to feed his own fish and discovered that he was plumb out of his own fish food, i.e., Bratwurst and Rotkraut. Glancing over at the biggest cichlid in his collection, *Boulengerochromis microlepis*, he noticed that it was heavy with eggs. As this was an emergency, he immediately fed it most of Hans' prized *Apistogramma* collection.

When Hans returned home and found out what Hugo had done, he completely lost it and grabbed his father's service revolver and shot Hugo right between the eyes. This created a hole from his forehead to the back of his head about three-quarters of an inch in diameter, but fortunately for Hugo did little harm since the brain is divided up into three parts: the left, the center, and the right and, as is well-known, cichlid fanciers do not use the center portion of the brain for anything of any consequence. Hugo, therefore, did not miss it in any way, the only aftereffect being that, when the wind blew in from the North it made a whooshing sound as it traveled through the hole, causing Hugo to ask if there was a polka band practicing in the vicinity.

Over the years the Buntbarsche brothers developed many new strains of cichlids, some of which are popular even to this day, such as the "Inherit the Earth Meeki," sundry genetic variants of *Pelmatochromosome*, *Chichlasomas* in

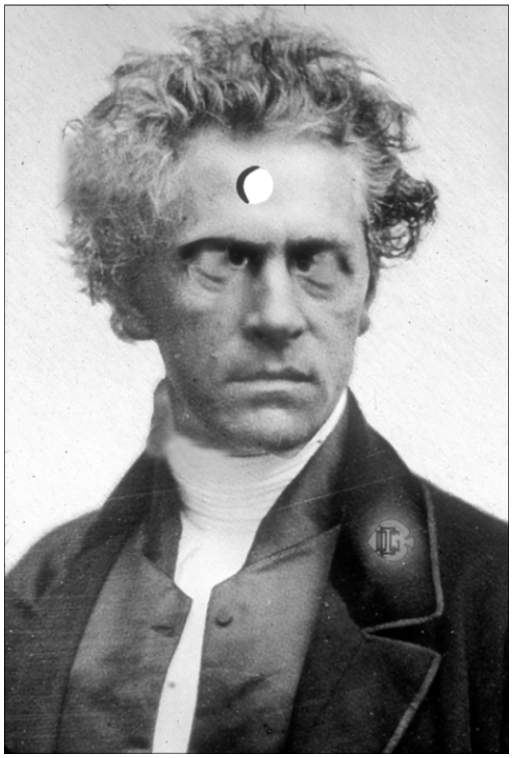


Figure 5: Hugo Buntbarsche after being treated at the Buchstahude Medizinisches Institut für Gestörte Liebhaber von Cichlids (Buchstahude Medical Institute for Disturbed Cichlid Fanciers) for the .44 caliber pistol wound inflicted by his brother.

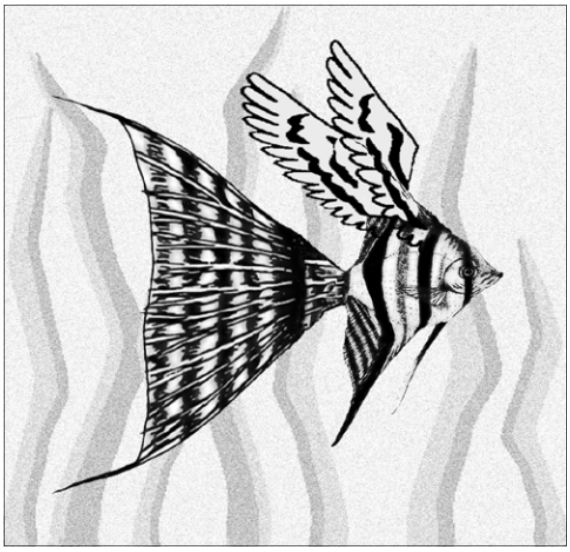


Hugo Buntbarsche developed many specialized strains of cichlids, the most famous being "Der Fliegende Engelfische." Hugo was not satisfied that his Angels were so slow moving, so he set out to remedy the situation. At the time, the "Fliegende Engelfische" could outswim any tetra known to the hobby by a margin of ten to one, and his cat went meshuga trying to catch one.

numerous, long-lasting flavors, and the very aggressive *Terrorphyllum scare*. They developed special foods for cichlids, such as the Apristograham cracker, and also developed an interest in their diseases, being the first to develop a vaccine against the dreaded, "Cichlid Cell Anemia."

(The following is from *Der Buntbarsche Tagesbericht*, Band 1, November 1889. The author hopes that readers may overlook any minor errors that may have occurred in translation. AJK)

Minutes of the first meeting of the Deutsche Cichlid Gesellschaft, Buchstahude, Germany, October 10, 1889.

Last Thursday evening, just after the conclusion of the featured program, "Convict Cichlids, Three Stripes and You're Out," a sudden storm knocked out all power to the meeting room, plunging it into darkness just as Hermann Groschnoz was admiring the latest trophy he won (and one more to hang with his other *Tropheus*), taking First Place in the South American Class for his "Bandido Chanchito." With the light suddenly extinguished, Herr Groschnoz inadvertently lost his grip on the trophy (a replica of a Valkyrie holding a spear in one hand and a Firemouth cichlid in the other), and the pointed end landed in the vicinity of Gertrude Gummiknüppel's more

Not to be outdone by his brother, Hans Buntbarsche developed a number of *ramirezi* strains, one of which was his "Alpen Ram." It proved to be a nuisance to other fish as it was always butting into their conversations. Moreover, the fish were hard to feed, as they would only eat fresh Edelweiss.

than ample backside or, more precisely as Herr Doktor Präsident Ottoclave described it, “Wo die Sonne nicht scheinen.”

Gertrude, our Refreshment Committee Chairman (known affectionately as “Strudels und Noodles”), was at the time bent over trying to extinguish an extensive field of candles on her 60th birthday cake, a double German chocolate with extra cream, that she had so thoughtfully brought to the meeting to share with all of us. Upon being struck by the trophy, Gertrude, whose hands were still fastened around the cake plate, cried out ”Ach, mein hinteres Ende!” and straightened up rapidly, tossing the cake onto the head of Gottfried Gansburger who, at the time, was attempting to light an eight-inch, Weimar Republic Commemorative cigar. Unfortunately, the cake was liberally laced with rum and promptly exploded upon coming into contact with Gottfried’s cigar lighter. His eyebrows were removed during the detonation and pieces of cake were scattered everywhere. One large piece bearing the legend, "Glücklicher Geburtstag, Gertrude," fell into the formidable frontage of Fräulein Katharina ("Die Cupcake") Kantilever, who, upon thinking that her brother-in-law was taking untoward liberties, hollered “Nehmen Sie Ihre Hände aus meinem Büstenhälter!” and lashed out with a half-filled bag of extra hard Pfeffernüsse.

However, in the dark her aim was off and she accidentally struck 97-year old Adolf Edelweiss, our resident expert on *Hemorrhoidichromis* and *Bananacara* species, on the back of his head. Herr Edelweiss's false teeth immediately flew out and upwards, fastening themselves onto Gustav Geschaftig, right in the middle of what can only be described with some delicacy as his “Frucht des Looms.” Gustav, who at the time thought the problem was only a burned out light bulb, was on a ladder screwing in a replacement. Yelling “Gott hilft mir!” he dropped the box of light bulbs he was holding and they exploded as they hit the floor. Oberbürgermeister and part time constable, Heinrich Haberdasher, a specialist in Kerosene *Lamprologus*, thought that Napoleon’s troops were once again invading peaceful Buchstahude and, drawing his weapon, fired several rounds from his 1873 Mauser pistol. Fortunately no one was injured, but a stray bullet passed through several of the 100-gallon tanks holding the larger cichlids entered in the show.

The floor of the meeting room quickly filled with aged, conditioned water to ankle level and Frieda Fratzsaddle, who had had been celebrating her recent divorce from her fourth husband with a fifth of Old Granddad (“Alte Grossvater”) became confused, thinking she was on a sinking ship. Her ecumenical cries convinced all present to join hands and sing the only Calvinist hymn she knew, “Näher mein Gott zu Ihnen” (“Nearer My God to Thee”). Although the lights came on shortly afterwards, it took some time before sundry indignities were forgotten. The fish thrashing on the floor were carefully sorted out from pieces of glass, false teeth, and birthday cake, and a motion to adjourn was made, seconded, and passed.

Respectively submitted,
Lotte Kasebier, Sekretär.

A SHORT HISTRIONICS OF THE AQUARIUM HOBBY

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Message 1046, July 21, 2003)

The earliest record of fish keeping is found in Egypt where, along with Mesopotamian graffiti and Hittite expletives, pictures of well-known African aquarium fishes are found carved on the sides of tombs. The instructions for keeping these fishes were written in a script based upon aquatic plants and known as Egyptian hyacinths. These earliest of all fish keepers lived in the Sahara desert, so although there was little water to be had, there was plenty of sand to cover the bottom, the middle, and the top thirds of their tanks. There was, in fact, only enough water to allow rubbing each fish once a month with a damp rag. Fish keeping at the time was fraught with many problems; the tombs leaked, it was hard to see through the marble sides, and the climate was such that the Egyptian aquarists had to live elsewhere, requiring a long commute from Nubia just to feed their fish.

The next record of the aquarium hobby is found in ancient Greece, where Socrates devised the first practical method for filtration, which involved poring aquarium water through discarded hosiery remove food particles. This was known as the "Sockratic Method." The members of his combined aquarium society and school of philosophy were called "Tetrahedonists," and they practiced their oratory by tossing Barbs at one another. Socrates' specialty was Discus, but his wife kept throwing them away.

Next on the scene were the Romans. The first killifish society was established by the brothers, Rivulus and Remiss, the latter so named because he forgot to put covers on the tanks and the Rivulus jumped out. Later, Neapolitan aquarists combined their hobby with their love of cooking and made famous such dishes as Brine Shrimp Scampi and Neon Tetrazzini. These early Italian aquarists were in the habit of drinking much vino when they were building their aquaria and their tanks invariably, especially those built in Pisa, leaned to one side.

A British publican, Fillup Gosh, actually invented the first straight-sided tank by first devising a rectangular commode for use under a Queen-size bed. The Queen, however, found the right-angled corners too uncomfortable to use so Gosh decided to offer his containers to aquarists. They were sold with a guarantee known as a "30-day Warrington." (It has sometimes been argued that Nathaniel Ward invented the aquarium; however, his was a sad case and he took a job with the British Civil Service and became a Ward of the State.) The hobby in England at that time was a favorite of female aquarists but was constrained by the strict moral codes of the day. Victorian ladies could not, for example, raise either their skirts or the water levels in their tanks without undergoing social opprobrium. Male aquarists, on the other hand, met nightly in local pubs and got tanked. After Gosh's death, his career suffered a dramatic decline.

Although Gutenberg had long since invented movable type and the bible, the world was now entering a time of great inventions and discoveries. With the advent of the Industrial Revolution, people stopped reproducing by hand and started reproducing by machine. Cyrus McCormick, for example, invented the McCormick raper, which did the work of a hundred men. Louis Pasteur discovered a cure for rabbits and, at the American Museum in New York City, Barnum displayed the famous musical insect known as the humbug

and also the first Beleaguered whale. Barnum was a very rich man and could afford a Butler. William Damon, who also worked for Barnum, circumcised the world, looking for new species of marine fishes for the Museum.

The greatest of the early American aquarists was Hugo Mullet, who was born in Germany in 1846, supposedly on his birthday. He had to leave Germany in a hurry when he was found defacing the currency, an offense known as "Deutschmarking." Mullet settled in Cincinnati and bred goldfish, a corruption of the German word for the then very expensive "geltfisch," itself derived from the Hadassic plankton feeder, "geltfilterfish." Unfortunately, Mullet could not spell Cincinnati properly, often leaving out one of the n's, a condition known as "enervation." He was therefore forced to move to Brooklyn where correct pronunciation was unheard of. Mullet was a snappy dresser and when he strolled by at the Packer Collegiate Institute where he was employed as an aquatic cosmetologist, the girls would say, "There goes that striped Mullet!"

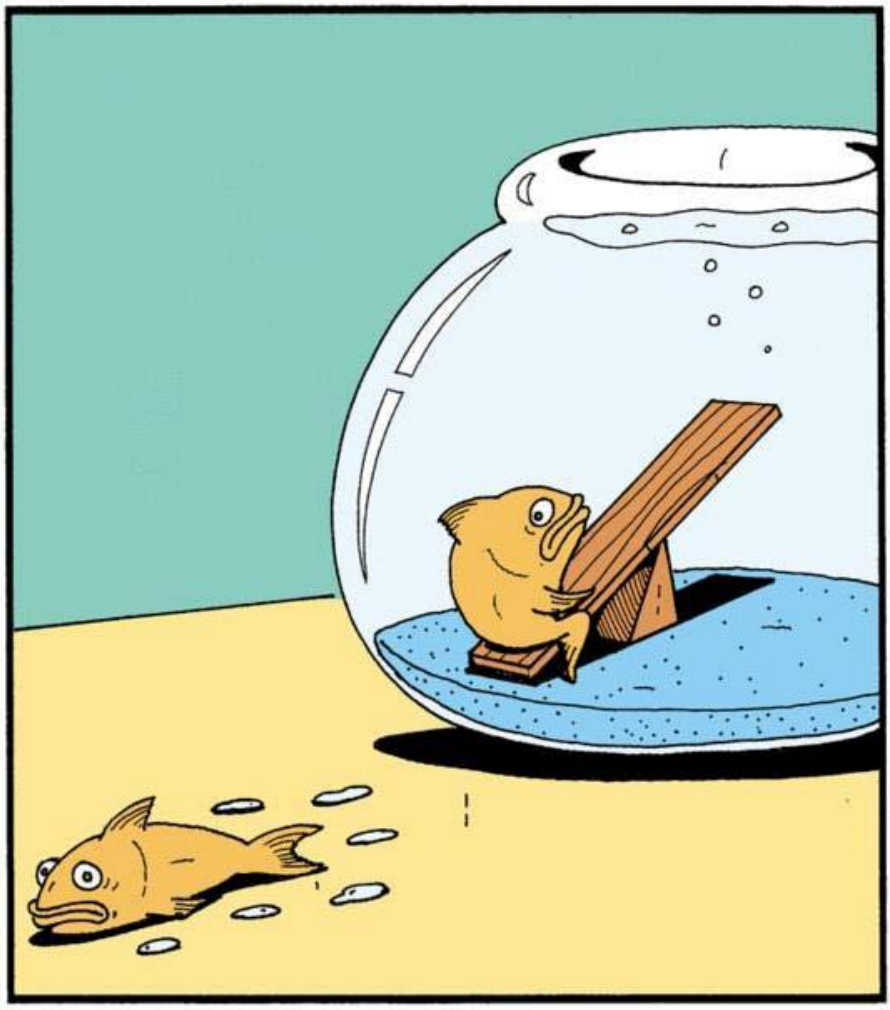
One of our first aquarium club organizers was Phosgene Smith who founded the New York Aquarium Society. Smith had a very poor understanding of geography, so the club actually met in New Jersey and held its monthly bowl shows in Omaha, Nebraska. He had a hard time on the road when checking into motels, as no one would believe a name like "Smith" on the register. What made it all the more difficult was his insistence on asking for three-hour rates. In any event, his book, The Home Aquarium…Wherever It Is Located," set down some of the basic principles of fish keeping that aquarists follow today, such as wearing rubber-soled shoes when transferring electric eels and eschewing pianos as aquarium stands regardless of the number of tanks they will hold. Smith, by the way, loved playing with his instruments and kept a spinster in his attic just for this purpose.

A famous aquarist of the day was Richard Dawn, who imported many of our most popular aquarium fishes. Two of his many catfish introductions included the Corydormouse, named for its prominent whiskers, and Lawncareria, prized for its ability to keep aquatic grasses under control. Other introductions included the unfortunate Hapless Chromis, the singing catfish Doras dayi, the predatory Belly Knee Sox, a number of Labeos whose names were on everyone's lips, and both Hemigramma and Hemigrampa species. Dawn was a very energetic aquarist, most likely stemming from his habit of eating overactivated charcoal. Dawn died in 1929 and is still dead.

One of the most influential pre-World War II aquarists was William T. Inners. Inners was half English, half Irish, and half Scotch, but he mostly drank the latter. Inners lived in Philadelphia, the home of Benjamin Franklin who in the early days of the American hobby discovered electricity by rubbing together two electric eels, one positive the other negative. (It is mistakenly thought that Franklin invented electricity "while flying a kite" but this was a transcription error, and as it is well known that he liked his ale, it should have read, "while high as a kite.") Inners was a printer, often typecasting most of the well-known aquarists of his day. The Neon tetra, Hyphenated Innersi, is named after him.

Inners was one of the earliest photographers of tropical fish, his most famous being of a Glue Bularis, which, unfortunately, stuck to his lens. He published a very popular magazine called "The Aquarium," but it was hard to read because of all the watermarks. Inners was also a prolific writer, his most famous book being "Erotic Aquarium Fishes," containing innovative ideas such as mentholated breath mints for Firemouth cichlids, Docksid-

ers for Walking catfish, tarnish removers for Silver Dollars, turn signals for Head-and-Tail -Light tetras housed in very short tanks, tiny pliers for removing the thorns from Rosy Barbs, and small waterproof microphones for Talking Catfish wanting to break into show business. After his death in 1969, however, he wrote very little.



THE ORIGIN OF THE PLASTIC BAG IN THE AQUARIUM HOBBY

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Message 4804, April 14, 2006 & Yahoo Message 4808, April 15, 2006

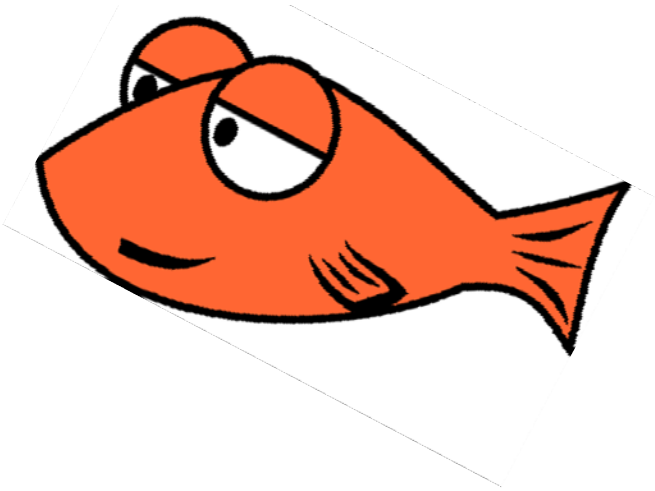
In the late 1940's a fellow by the name of Algernon Fiddle was getting married and picked up his Tuxedo at the rental store. On his way home he stopped off at a friend's house where he saw some broadtail guppies his friend had recently developed. Offered a number of pairs for the taking, the problem was that there was no suitable container available. The quick-thinking Fiddle took the plastic garment bag off his Tuxedo and tied off the slit end provided for the coat hanger hook. Voila! The transportation problem was solved and Fiddle made it home with his guppies intact, although the same could not be said for his Tuxedo since his friend kept white angora cats and, without the plastic garment bag for protection, the Tux was coated with white cat hair giving Algernon the appearance of a moldy prune at his wedding. (His normally wrinkled physiognomy unfortunately added to the effect.) Suffice to say that the honeymoon was not without some sharp words from the bride.

The idea was quickly taken up by a local pet shop who ordered a thousand bags from the garment bag supplier, the only stipulation being that the bags be only 12 inches long. The supplier at first thought that the bags were destined for a re-make of the Wizard of Oz but that misunderstanding was soon cleared up. Improvements soon followed, notably the removal of the legend, "Dry Clean Only" from the bag since customers who dutifully followed the instruction found that their fish shrank significantly and were hard to see.

P. S. I am surprised that you folks think this is just a "tale." Algernon Fiddle was an important figure in the history of the hobby. He was the first to invent a form of the undergravel filter, although he carelessly omitted the holes in the tubes that ran under the gravel so the filter didn't do very much. He also devised the very first frameless glass aquarium but the Elmer's glue he used made for a very short tank life span (a matter of a few seconds, actually). Sadly, Fiddle came to an untimely end when, standing in his bare feet in a puddle on the floor, he attempted to rearrange the inside filter in a tank containing his pet electric eel.

Fiddle's experiments with electric eels were legendary, by the way, as he ran all of his heaters, pumps, and lighting fixtures off that single tank although there were quite a lot of pyrotechnics in his fish room before he learned to use a step-down transformer to get the voltage nearer to 110. The first time Fiddle connected an incandescent lamp to the eel tank it was so bright that a passing steamer though it was the Barnegat lighthouse and it ran aground in Fiddle's front yard with a cargo of Vietnamese potbelly pigs.

In any event, use any of this material as you want. To quote from Jane Austin's Pride & Prejudice: "For what do we live, but make sport of our neighbors, and laugh at them in our turn?"



MINI-MEMOIRS of a FISH FANCIER

BY Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Message 784, March 26, 2003 & Yahoo Message 832, April 4, 2003)

The story starts in the mid-60's with two other people, Barry E. Franz and Samuel F. Wineberg. Barry was an industrial engineer at the Proctor & Gamble HQ in downtown Cincinnati, and Sam was a CPA residing in Fairfield, Ohio, a community a bit farther northeast. Both were avid aquarists and we three were old friends living within a 30-minute drive from each other. Barry was a little younger than I, Sam a bit older.

Barry was a marketing specialist and wanted to get into some aspect of the fish business where he could apply his talents without the restrictions imposed at work (P&G at the time was almost as fussy as IBM, i.e., dark suits, tie, no short sleeve shirts, and certainly never, never appear in the hallways sans jacket!). He tried to interest Sam and me in the hardware side of the fish business but both of us, having our own business qualifications (I, for example, at the time held the position of Adjunct Associate Professor of Information Sciences in the Graduate Business School at Xavier University in Cincinnati) thought it didn't have the proverbial snowball's chance in you know where to succeed.

However, about this time Jim Crawford (then Editor of *The Aquarium Journal*) told me that the San Francisco Aquarium Society (SFAS) was thinking of getting out of the publishing business. The IRS had questioned the tax-free status of their brine shrimp operations that was supporting the magazine since the *Journal* was operating at a loss. The SFAS, therefore, was willing to give the magazine away free to anyone they thought could sustain it as a viable operation. Barry jumped on this and suggested that we take up the SFAS on their offer.

Sam and I also liked the idea so in the summer of 1965 I went to San Francisco accompanied by my wife, Joy, and I made the pitch before a special committee of the Society. The SFAS was interested in one thing and one thing, only; the continuation of the AJ as a publication of quality content in the spirit of its long history. Consequently, they had three main criteria: (1) Did the applicants have the necessary knowledge of the aquarium hobby to carry on the AJ's traditions? (2) Did the applicants have the necessary business acumen to manage the magazine as a business, and (3) Did the applicants have sufficient capital to ensure that the magazine would survive financially?

Jim Crawford, who was pushing as hard as he could for me to take over the AJ, thought the decision was in the bag and even printed the cover of the August 1965 issue with the subtitle, "New AJ Publisher." I went back to Cincinnati and reported to Sam and Barry that it looked as if we were going to be in the magazine business. However, at the last minute, TFH Publications made a counteroffer and the SFAS decided to give the AJ to them.

With regard to the third criterion, there was no way Barry, Sam, and I could compete with a multimillion-dollar corporation. Jim was devastated but I was a bit more philosophic about it. After all, at least we had tried. (I am not going to discuss what TFH did with the AJ or what the members of the SFAS thought about it. You are all familiar with the former, and there are still those who were members of the SFAS at that time around to speak to the latter.)

Coincidentally, just after we were informed of the Society's decision, we learned that *Tropicals Magazine* also wanted out so Barry and I traveled to Chicago to discuss buying the magazine. Since Barry and I had not fallen off the turnip truck on the way to Dogpatch, we "examined the books" and quickly concluded that the stiff asking price wasn't worth the subscription base. We returned to Cincinnati and, after a lengthy deliberation, the three of us decided to start from scratch; we each ponied up some coin of the realm and formed a Subchapter-S corporation as a first step in the publication process. The first issue of *Aquarium Illustrated* appeared in January 1966 with me as Editor and Barry as Managing Editor. The duties were split three ways as follows: Sam was responsible for distribution, billing, payments and subscriptions; Barry was responsible for sales and advertising; and I was responsible for production. The first issue carried on its masthead such aquarists as Cook, Kelly, Maier, Schofield, Walker, Turner, Wolfsheimer, Nieuwenhuizen, and Stratton, and professionals including Miller, Rosen and Cohen. Others, like Loiselle, were added later on. (This issue also contained the first in a series some of you may heard of called, "A History of the Aquarium Hobby in America.")

This was a fun time in the hobby for me. I was the first aquarist since Roth and Innes to actually do the layout on a national fish magazine, the paste-ups and the preparation of artwork and prepress on the photographs. One of the first things I did was to build a table in my basement (right alongside 120 fish tanks!) 16 feet long where I laid out the assembling of each issue of the magazine on a production-like basis. Lordy, we had fun with that mag! Sam and I were happier than two guppies in a tank full of daphnia.

However, it is necessary for a little digression (mathematicians, as I told the AKA last year, are fond of tangents) since it is of some historical interest that will be new to the group. Those sixteen feet of table space with its hot waxer, light box, and other publishing paraphernalia of the time, was in use only every other month. One day I got the idea that we might also publish something to fill in the gap, and what I came up with was to be directed at fish hobbyists, a one-pager, printed on heavy stock and with spot color, that had some space at the bottom where a pet store could stamp its name, address, hours, etc., and hand out free to its customers to encourage them to keep coming back to the store.

I broached the idea to Barry and Sam. The latter was enthusiastic but Barry was dead set against it, maintaining that it would never work. Argue as we did, Barry was unmovable. Sam and I then asked Barry if it was OK with him if we embarked on the project as a joint venture that did not involve *Aquarium Illustrated*, and he agreed. Thus was born *The Aquarist's Notebook*. I put it together and got it printed, and Sam handled distribution and billing. As it turned out, it was highly profitable and involved relatively little work on our parts. We published it monthly for six years, producing 64 separate issues over its life. The first issue appeared in June of 1967, and the last in December of 1972. I mention this up because some of you may have copies of *The Aquarist's Notebook* in

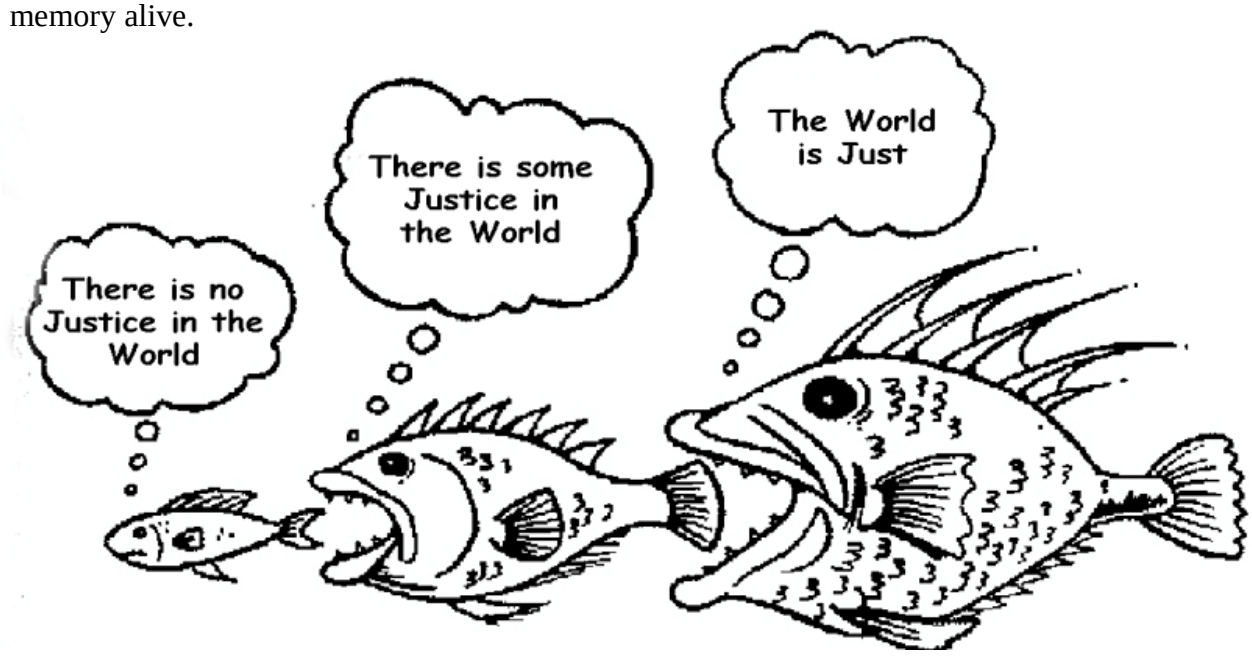
your possession and as it carried no publisher's identification other than its name and a post office box in Fairfield, Ohio, its origin remained a mystery until now. Just to keep the historical record up to date, in 1969 Sam and I also published a compilation of some the best material from *The Aquarist's Notebook* and it called *The Aquarist's Annual* (52 pages and again, no publisher's identification other than its name and a post office box). Although we didn't lose any money on the project there wasn't much interest in it among our pet shop clients, and so there were no repeat issues. So if you have a copy, that's another mystery solved!

By the way, Sam and I established a partnership that existed solely on a handshake. The only paperwork we ever did was the yearly partnership return to the IRS required for tax purposes. He was a remarkable man, so unassuming that no one would ever believe on first meeting him that he was a pilot on the Pacific front during World War II. Sam wrote the "About the Author" section to the revision of my history that Lee is publishing, and would not let me give him any credit in the book for it. He passed away a short time ago, but forty year's of friendship keep his memory alive.

By way of a quick review, the Pet Library series was conceived by Earl Schneider (and owned by Hartz Mountain, the pet conglomerate)) with the intention of breaking the hold TFH Publications had at the time on the low-priced end of the pet book market. To this end it was highly successful, and after the Pet Library series was introduced, TFH left this area of the pet publishing market.

I was asked by Earl, who was the editor of the series (a distinguished aquarist himself and writer par excellence who, by the way, should feature significantly in any post World War II history of the hobby in this country when it is written), to do three things: to participate in writing some of the titles, (2) to assist in finding and recommending authors, and (3) to lend my name and assistance in helping to promote the series. This I did, suggesting prospective authors, writing two or three of the booklets myself, and participating in two trade kickoff meetings, the first one being held in Chicago and the second shortly afterwards in New York City; for PR purposes, in each case I represented the fish authors.

Although it may seem strange perhaps that I did not write the killifish booklet, to me this



was an opportunity to open the field to young people with talent and Bruce (and John) filled the bill to the proverbial "T." (He also met the "young" criterion as well; it may surprise some, but Bruce was only seventeen years old when I invited him in 1961 to join the AKA Charter Committee. In those days, Bruce was like a younger brother to me and I often slept in a cot in his bedroom whenever I went to New York on business. This is as they say, however, another story.) In any event, this is why I wound up writing about guppies and catfishes instead of killies or any of the other fish groups I may have had a stronger interest in.

There is an amusing story concerning the Pet Library series sales campaign. Hartz Mountain provided racks to the pet shops to hold the booklet for display, and carefully designed the size of the booklets so that the competing TFH publications would not fit the racks. TFH countered this by sending thousands of their booklets back to the bindery and had them cut down so they could fit. However, after the trimming they looked positively awful and actually increased the sales of the Pet Library booklets!

Up to this time I had been the proverbial "babe in the woods" when it came to the ins and the outs of the tropical fish industry. Other than what I had gleaned by chatting with advertisers such as Alan Levy or a few industry-savvy friends like Earl Schneider, my contacts had always been almost exclusively hobbyists and/or ichthyologists, my interests being solely with the non-commercial side of things, although I did have a fair knowledge of, and many contacts in, the import/export business, both in this country and abroad. This was to change drastically with my editorship of *The Aquarium*, and I became acquainted with practices and personalities that considerably darkened my perspective on human nature.

I mention this in passing because there is an age-old paradox that has plagued historians ever since recorded time, that of separating a person's character from his or her achievements or abilities, We know, for example, that Coleridge was a drug addict, Poe was an alcoholic, and Byron was accused of incest. Furthermore, a part of a person's character may have a bearing on or connection with the subject at issue, while other parts may be totally irrelevant. Anyone writing about the post World War II history of the hobby will have to resolve such issues, but as this is meant to be a narrative dealing with events, not personalities, I'll move on.

Well it was time for me to fulfill my part of the bargain and endeavor to implement the operational model discussed previously. I was surprised both at the format change when I saw the first issue (I liked the old *The Aquarium* format much better) and how much I missed the control over the layout that I had in *Aquarium Illustrated*. One problem that cropped up right away was that, being a monthly, the deadlines for each issue were short and therefore there was no way I could be sent the galleys, check them for errors, and then return them to New Jersey in time to meet the printing deadline. Since neither John Hayes (nor later Sig Albert, who replaced John for a short while) knew very much about aquarium fishes, few of the errors that left my desk or those introduced in typesetting were caught in the galleys. Understanda-

bly, the appearance of these errors in the publication was a constant source of irritation to me.

It took a couple of issues to work out a reasonable modus operandi and to build up the staff. As with *Aquarium Illustrated*, I assembled a distinguished group of aquarists and professionals as specialist editors and consultants and won't bother to list them here. As for the content of the magazine, the Willingers were true to their word and pretty much left me to set tone, tenor and policy. Early in the game Alan Willinger suggested to me that the magazine was following the lines of *Aquarium Illustrated* and catering disproportionately to advanced hobbyists, so I did an analysis of content and came to the conclusion that he was absolutely right. TA was not AI, nor was it ever meant to be, so after identifying eight basic categories within the aquarium hobby and using a two-dimensional matrix taped to the wall of my office, I worked out a scheme whereby at least one article for each of the categories would appear in the magazine within any two-month publication period. This solved the problem.

By the end of the second year (1969), the history series had been completed and it was clear that the editing of the magazine was becoming more and more of a burden. In addition to editing, writing and dealing with the spate of author correspondence, I had a full-time job, was teaching graduate school part-time, was writing and producing *The Aquarist's Notebook* and traveling on a frequent basis between Cincinnati and New York in addition to the rather extensive travel my own professional life was demanding.

It is important to remember that at the time there were no home computers to assist with the editing nor was there an internet to facilitate communication. Today, of course, the situation would be vastly different but in 1969 things were still done the hard way. One wag once characterized writing in this way: "Writing is easy. All you have to do is stare at a blank sheet of paper until drops of blood form on your forehead." Well, there are many similarities here to editing part-time, long distance! Nevertheless, I had three more years to go.

Then in the Spring of 1970 an event occurred that further complicated the situation, i.e., I was offered the opportunity of returning to school in the Fall for my PhD, all tuition paid, on full salary, and sufficient time off to attend classes. Accordingly, I asked the Willingers if they would consider releasing me from the editorship of *The Aquarium* later in the year. While they were mulling that one over, other things were happening in New Jersey. The various TFH enterprises distributed products at this time that were in direct competition with those manufactured and sold by Metaframe, e.g., filters and other aquarium-related items. *The Aquarium* and TFH were competitors, therefore, in a much broader sense of the word, not just as magazines. In the Fall of 1970, just about when I was starting school, TFH attempted to initiate a new ploy, that of loading *The Aquarium* with advertising for these competitive products.

There was no way Metaframe could respond in kind. Aquariums, Metaframe's major product, were fast-becoming an undifferentiated commodity (like electricity) and thus the profits were small. Although there was considerable profit in items like filters, the competition was keen. If the introduction of a new filter bombed, then one suffered a loss for the year and had to wait until next year's trade show to try again. TFH, on the other hand had a steady income from its vast publishing empire, something Metaframe did not have.

The Willingers were aghast and tried to refuse the advertising. However, the lawyers told them that this was illegal - if you accepted advertising from one, you were bound by law to accept it from all. The Willingers were infuriated (and I couldn't much blame them) and decided to turn *The Aquarium* into a house organ where the only advertising that appeared was Metaframe's, which was legally permissible. This they did, starting with the February 1971 issue of *The Aquarium*. I was now the editor of a house organ, an intolerable situation for me. Few people want to read a national tropical fish magazine that mentions only one manufacturer's products. One reads a magazine for its editorial content, sure, but one also reads it to be informed of new products and to learn more about and to be able to locate existing ones. For me this was a deal-breaker, and the Willingers acknowledged it. However, they asked me to stay on for a "few months" longer as a favor, saying that something significant was going to happen in the near future.

The "something significant" turned out to be that the well-known toy maker, Mattel, was negotiating in secret to buy Metaframe. The Willingers had always treated me fairly so I agreed to continue as editor, although those "few months" dragged on to December 1971 when the last issue of *The Aquarium* was published. Because they had no need for a house organ, especially one devoted solely the aquarium hobby, immediately after Mattel purchased Metaframe they discontinued TA.

The announcement in the last issue stated that "Publication of *The Aquarium* magazine in its present format will be suspended with the December 1971 issue," suggesting that the magazine would reappear in the future in some other reincarnation ("...a novel, exciting, magazine for the hobby...") The subscribers were offered a choice; either a prorated share of their subscription returned or their subscription transferred to a planned, "novel, exciting, magazine for the hobby." Since I had no prior knowledge of the wording of this announcement, having seen it for the first time only after receiving the final printed issue myself, I was rather astonished.

It remains a mystery as to what was behind this wording and I can offer only one possible explanation. It might be that Mattel was considering publishing a new magazine that would deal not only with the aquarium hobby - which now they were part of - but also with other areas in which Mattel was involved. The powers behind Mattel at the time, Ruth Handler and her husband were fascinating and somewhat erratic characters in their own light, and it is not improbable they might have been considering such a project and were merely being careful not to burn any proverbial bridges.

Thus ended the final chapter in the long, thirty-nine year history of *The Aquarium* magazine.

"The Worldly Hope men set their Hearts upon Turns Ashes - or it prospers; and anon, Like Snow upon the Desert's dusty Face, Lighting a little hour or two - is gone."

(Rubáiyát of Omar Khayyám)

THE MEN WHO PRECEDED THE AQUARIUM HOBBY

BY Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, November 10, 2012)

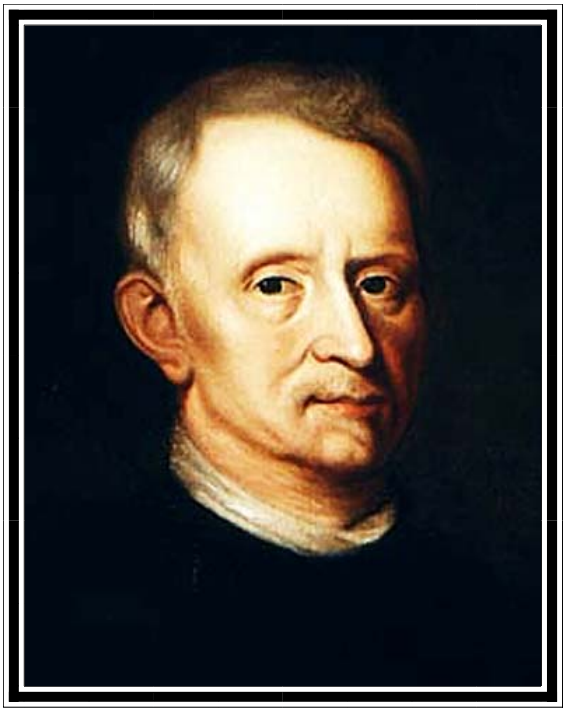
The Victorians were faced with a very formidable problem in their fish keeping, i.e., how to keep their animals alive in an aquarium without aerating or changing the water. In their search for a solution, they referred to the prior research that demonstrated that plants produced oxygen and absorbed carbon dioxide, while animals absorbed oxygen and produced carbon dioxide in a sort of counterpoise between the two kingdoms. Indeed, the requirement for plants was mandatory for the Victorians when determining who was first to "invent" the aquarium.

Aquarium historians, although alluding to some of these precursors to the aquarium hobby, have only provided sketchy information about their specific contributions or have not mentioned them at all. In this paper, I propose to fill this shortfall and to introduce some new names heretofore not previously acknowledged in aquarium hobby history.

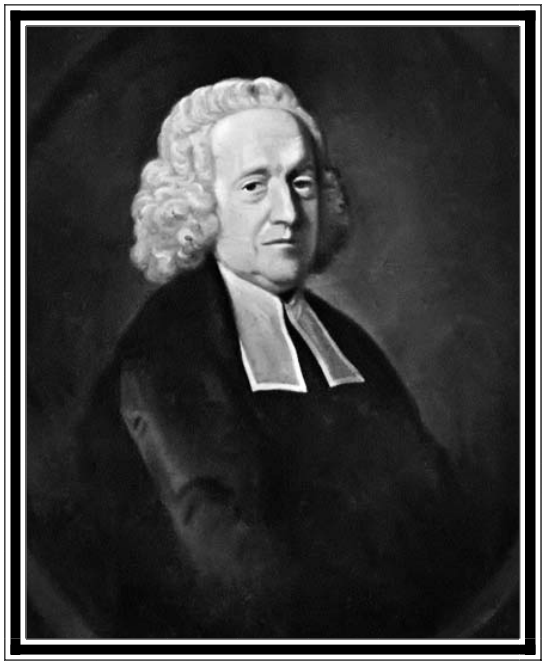
JAN BAPTIST VAN HELMONT (1580-1644)

Perhaps the first experiment designed to explore the nature of photosynthesis was that reported by the Jan van Helmont, a Flemish physician, philosopher, mystic, and chemist who introduced the word "gas" - from the Greek word chaos - into the vocabulary of scientists. Van Helmont lived and worked during a unique period of history - the dawn of the scientific revolution. As Europe began to shrug off the old-fashioned superstitions of the Middle Ages, scientists learned how to conduct experiments and make rational observations, rather than believing in religious phenomena to explain the world around them. However, the clash between science and faith eventually caused difficulty for van Helmont. He was interrogated by the notorious Spanish Inquisition for giving scientific explanations for supernatural events.

During the early 1600s, van Helmont was embroiled in a controversy over a pamphlet he had published on curative ointments. He was condemned for heresy by the General Inquisition of Spain, a special committee set up to punish those who contradicted the Catholic Church. Van Helmont was also denounced by the University of Louvain's medical and theological faculties. Eventually, he was detained and interrogated, then kept under house arrest for years. Perhaps because of this experience, van Helmont published little of his work. On his deathbed, he gave his writings to his son to edit and publish.



Jan Baptist van Helmont (1580-1644)



Stephen Hales (1677-1761)

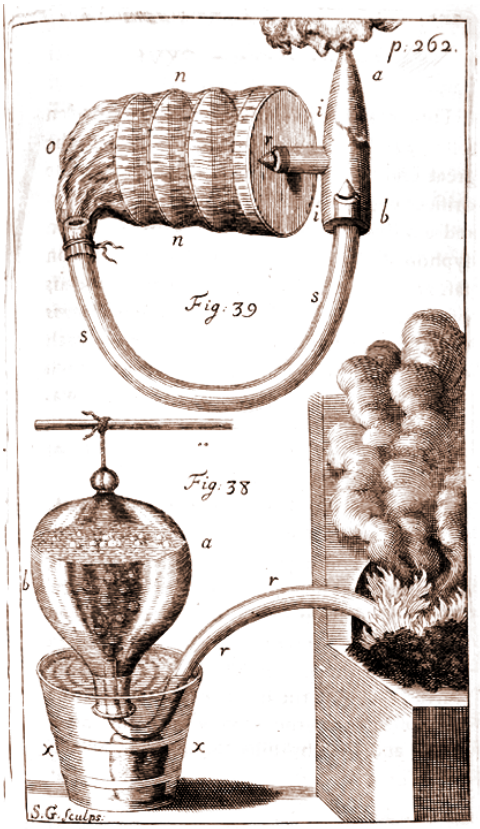
In 1643, van Helmont He performed an experiment to determine where plants get their mass. He grew a willow tree and measured the amount of soil, the weight of the tree and the water he added. After five years the plant had gained about 164 lbs. (74 kg). Since the amount of soil was basically the same as it had been when he started his experiment, he deduced that the tree's weight gain had come from water. Since it had received nothing but water and the soil weighed practically the same as at the beginning, he argued that the increased weight of wood, bark and roots had been formed from water alone. However, this "deduction" is incomplete, as a large proportion of the mass of the tree comes from atmospheric carbon dioxide, which, in conjunction with water, is turned into carbohydrates via photosynthesis.

Von Helmont did not discover photosynthesis, but this famous experiment with the willow tree provided a good hint for others to follow up. Van Helmont's experiments, by the way, were almost certainly inspired by Nicolaus of Cusa's 1450 book, "De Staticus Experimentis," in which he stated: "If a man should put an hundred weight of earth into a great earthen pot, and then should take some Herbs, and Seeds, and weigh them, and then plant or sow them in that pot, and then should let them grow there so long, untill hee had successively by little and little, gotten an hundred weight of them, hee would finde the earth but very little diminished, when he came to weigh it againe: by which he might gather, that all the aforesaid herbs, had their weight from the water."

STEPHEN HALES (1677-1761)

During the 1600s, naturalists made significant progress in describing and illustrating plant anatomy, but it is Stephen Hales - a British clergyman - who is generally considered to be the founder of plant physiology and a pioneer of quantitative physiology. He was born in Kent, England and studied theology at Cambridge, but also read mathematics, physics, and botany. He became a clergyman but also devoted much of his time in scientific pursuits particularly in the conduct of experiments in plant physiology. From his first experiments in 1724, he was soon recognized as England's foremost living scientist, Newton having died three years earlier. His most important work, "Vegetable Staticks," published in 1727, was in plant physiology. He suggested that plants derive something from the atmosphere, a guess that future researchers have proven correct and has become an essential component of the process of photosynthesis in plants.

He observed that the volume of air just above the water surface decreased when a plant was grown in a closed atmosphere and concluded that air was "being imbibed into the substance of the plant." He also noted that light enters leaf surfaces and flowers and may play a role in plant growth and development. In



Some of the equipment Hales constructed to perform his plant experiments.

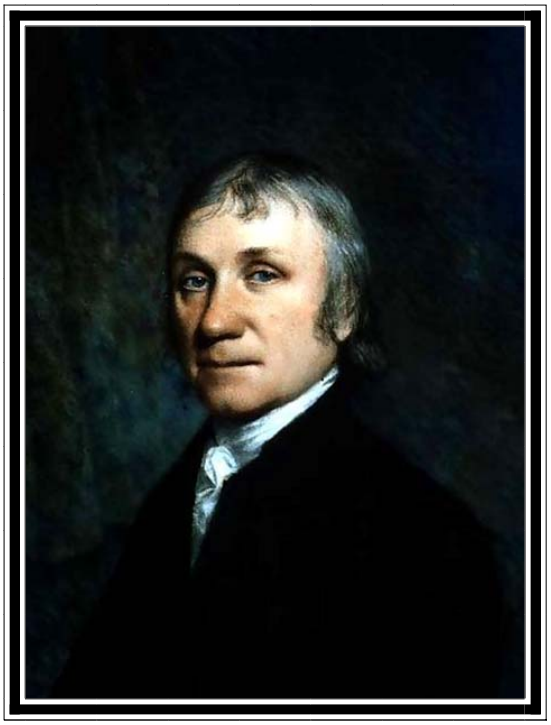
addition, Hales developed instruments and techniques for the quantification of plant processes.

JOSEPH PRIESTLEY (1733-1804)

The first evidence (1772) that gases participate in photosynthesis was reported by Joseph Priestley, an English theologian, Dissenting clergyman, natural philosopher, chemist, educator, and political theorist.

There is a historic dispute about who discovered oxygen. Most credit Priestly alone or both Priestly and Scheele. Oxygen was discovered for the first time by the Swedish chemist, Carl Wilhelm Scheele, in 1772. Joseph Priestly, an English chemist, independently discovered it in 1774 and published his findings the same year, three years before Scheele published. The French chemist, Antoine Lavoisier, also discovered oxygen in 1775. He, however, was the first to recognize it as an element and coined its name, “oxygen” - which comes from a Greek word that means “acid-former.”

Of all the achievements reported in Priestley’s great paper the most surprising was the discovery of the “restoration” of air by vegetation. Considering the “consumption of air by fires of all kinds, volcanoes, animals breathing, and so forth,” Priestley was convinced that there must be some provision, by God in nature, for remedying the injury which the atmosphere receives … “In what manner the process in nature operates, to produce so remarkable an effect,” Priestley wrote, “I do not pretend to have discovered”, but vegetation did restore bad air. He had not yet recognized the agency of light in the process; he didn’t understand that plants used the



Joseph Priestley (1733-1804)

Jan Ingen-Housz (1730-1799)

"fixed air" in the atmosphere in a complex process of photosynthesis. He had, however, started a program of investigation that would involve numbers of chemists and plant physiologists for a number of years.

Priestly knew that if a burning candle is placed in a sealed chamber, the candle soon goes out. If a mouse is then placed in the chamber, it soon suffocates because the process of combustion has used up all the oxygen in the air — the gas on which animal respiration depends. However, Priestley discovered that if a plant is placed in an atmosphere lacking oxygen, it soon replenishes the oxygen, and a mouse can survive in the resulting mixture. Priestley thought (erroneously) that it was simply the growth of the plant that accounted for this. He did, however, conclude that plants reverse the effects produced on the air and thus become the chief means by which the purity of the atmosphere is maintained.

JAN INGEN-HOUSZ (1730-1799)

Ingen-Housz was a Dutch physiologist, biologist and chemist. Ingen-Housz was also a proponent of inoculations as a means of inducing protective immunity and was the first to describe Brownian motion.

Jan Ingen-Housz discovered photosynthesis, the process by which plants utilize energy from sunlight and from atmospheric carbon dioxide to synthesize carbohydrates, although there is some controversy over whether the honor should go to Priestley. All life forms on Earth depend on photosynthesis, either directly or indirectly. In 1779 he discovered that the effect observed by Priestley occurred only when the plant was illuminated. Scientists knew that the flame of a candle in a sealed jar would eventually burn out; likewise, a living animal would die in a sealed container. They explained this as the "good air" being used up.

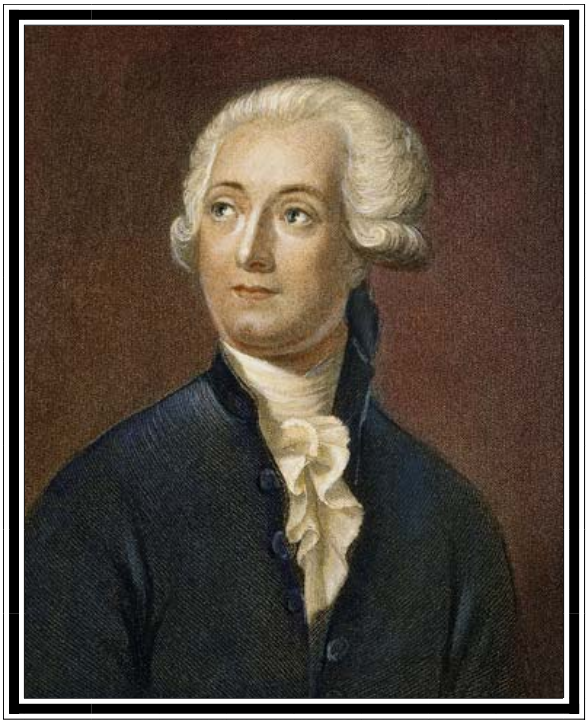
In the 1770s, while studying various gases, Priestley showed that plants could restore the fresh air in the containers by removing the "bad air" (now called carbon dioxide) and replacing it with "good air" (now called oxygen) such that the air could once again support a burning candle or the respiration of a living animal. Ingen-Housz extended these studies to show that the release of oxygen required light in the visible range of the spectrum and that only the green parts of plants possessed this capability of restoring the air. These findings laid the foundation or scientific understanding of the process now termed photosynthesis.

ANTOINE-LAURENT LAVOISIER (1743-1794)

As Ingen-Housz was performing his experiments, the celebrated French chemist (and

Revolutionary) Lavoisier disproved the phlogiston theory, first stated in 1667 by Johann Joachim Becher. The theory postulated the existence of a fire-like element called "phlogiston," which was contained within combustible bodies and released during combustion. The theory was an attempt to explain processes of burning such as combustion and the rusting of metals, which are now collectively known as oxidation. Lavoisier conclusively demonstrated that candles and animals both consume a gas in the air which he named oxygen. This implied that the plants in Priestley's and Ingen-Housz experiments produced oxygen when illuminated by sunlight.

Considered by many as the founder of modern chemistry, Lavoisier was a powerful figure in the deeply unpopular Ferme Générale, 28 feudal tax collectors who were known to profit immensely by exploiting their position. He was branded a traitor by the Assembly under Robespierre during the Reign of Terror in 1794. He had also intervened on behalf of a number of foreign-born scientists including mathematician Joseph Louis Lagrange, granting them exception to a mandate stripping all foreigners of possessions and freedom. Lavoisier was tried, convicted, and guillotined on 8 May in Paris, at the age of 50.



Antoine-Laurent Lavoisier (1743-1794)

Lavoisier's importance to science was expressed by Lagrange who lamented the beheading by saying: "Cela leur a pris seulement un instant pour lui couper la tête, mais la France pourrait ne pas en produire une autre pareille en un siècle." ("It took them only an instant to cut off his head, but France may not produce another such head in a century.") One and a half years following his death, Lavoisier was exonerated by the French government. When his private belongings were delivered to his widow, a brief note was included, reading "To the widow of Lavoisier, who was falsely convicted."

JEAN SENEBIER (1742-1809)

Jean Senebier was a Swiss pastor, botanist and naturalist who wrote many works on vegetable physiology. Though others had shown that a great part of the substance of plants must be obtained from the atmosphere, no progress was made until bubbles of gas were observed on leaves when they were submerged in water, which Joseph Priestley recognized as oxygen. Ingen-Housz proved the simultaneous disappearance of carbonic acid; but it was Senebier who clearly showed that this activity was confined to the green parts, and to these only in sunlight, and first gave a connected view of the whole process of vegetable nutrition in strictly chemical terms.

The growth of plants is accompanied by an increase in their carbon content and Senebier discovered in 1782 that the source of this carbon is carbon dioxide and that the release of

Jean Senebier (1742-1809)

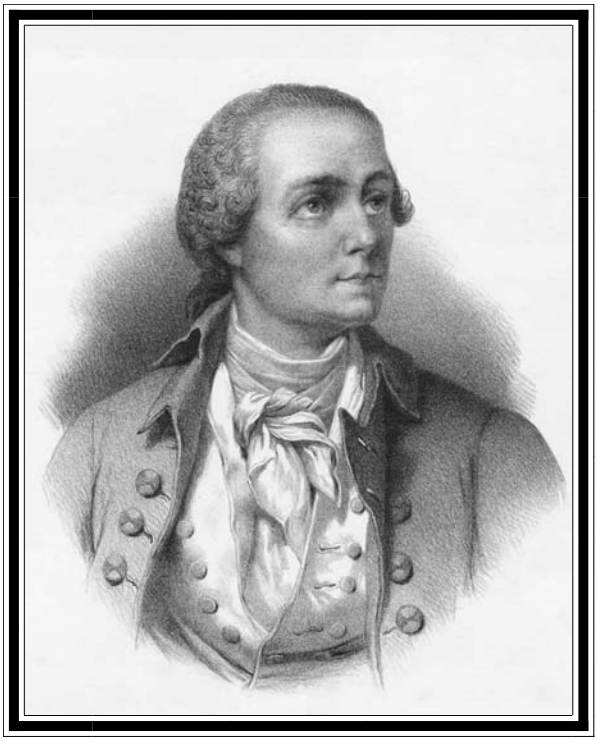
oxygen during photosynthesis accompanies the uptake of carbon dioxide. Senebier concluded (erroneously as it turned out) that in photosynthesis carbon dioxide is decomposed, with the carbon becoming incorporated in the organic matter of the plant and the oxygen being released.

Ingen-Housz considered Senebier's *Mémoires* to be "a copy of his own work from the evidence of the planning and sequence of the experiments performed, the eudiometric units used and the terminology." However, the acknowledged repetition of one scientist's experiments by another is not plagiarism.

NICOLAS-THÉODORE DE SAUSSURE (1767-1845)

De Saussure was a Swiss chemist, botanist and student of plant physiology who made seminal advances in phytochemistry. De Saussure sustained and added to the discoveries of Ingen-Housz and Senebier and proved that the green parts of plants take up and decompose a substance of the air at the same time that they assimilate water. His experiments on carbon assimilation are numerous and precise, and were presented with great perspicuity in his "Recherches Chimiques sur la Vegetation" published in 1804.

De Saussure found that the decomposition of carbon dioxide by green plant parts was a process necessary for the continued life and growth of the plant, but in addition he found that the carbon dioxide content of the atmosphere surrounding a plant might be increased, by artificial means, up to the point where it actually was injurious to the plant. Large quantities of carbon dioxide in the air were favorable adjuncts only if the plants were in condition to assimilate rapidly. After determining the amount of carbon appropriated by a plant, de Saussure found that the plant increased in weight by an amount out of proportion to the quantity of carbon fixed. Consequently, although he was of the opinion



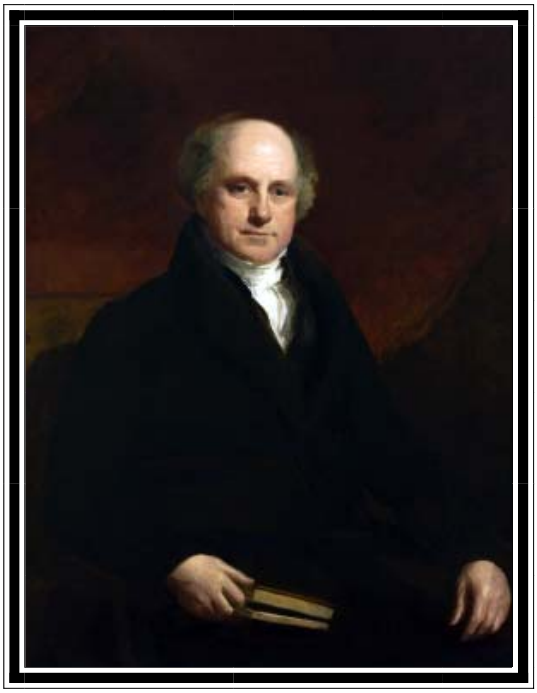
Nicolas-Théodore de Saussure (1767-1845)

that the great mass of the vegetative body was built up from the components of the atmosphere, it was clear that a part of the vegetable mass was derived from the fixation or utilization of the soil solution.

DANIEL ELLIS (1772?-1841)

Ellis - an army surgeon who later turned his career to a study of agriculture - was a contributor of articles on "Vegetable Anatomy" and "Vegetable Physiology" to the Encyclopaedia Britannica, 1815-24, In 1807 he published "An inquiry into the changes induced on atmospheric air by the germination of seeds, the vegetation of plants, and the respiration of animals," that summarized in some detail the prior work on photosynthesis and animals and discussed his own experiments on the changes in air from plants and animals. Ellis took issue with Priestley's conclusion that plants reverse the effects produced on the air: "However much, therefore, we may be disposed to admire the beautiful provision which this supposed reciprocity of action would establish between the functions of animal and vegetable life, we must suspend out belief in its truth until better proofs are brought forward than these experiments afford." Daubeny was later to prove that Ellis was wrong.

Ellis was one of the first to mention the requirement of oxygen in the water for the survival of fishes in a section of his book titled "Of the Changes induced on the Air by the Respiration of Insects, Worms, Fishes, and Amphibious Animals": "The same necessity of fresh air in the water in which they live, is required by aquatic animals. Zoophytes, according to Mr Davy, require the presence of air in the water in which they grow, and they act upon it like fishes The animalcules in pepper water remained *in vacuo* twenty-four hours and, being afterwards exposed a day or two to the open air, Mr Derham found some of them dead and some alive. Mr Ray remarked, that fishes cannot live in water without air: they will live in a vessel of water with a narrow mouth for months or years; but if the vessel be stopped, so as wholly to exclude the air, or interrupt its communication with the water, they will be suddenly suffocated. Dr Priestley confined several small fishes in a vessel, containing three pints of rain water, that had been previously well boiled to deprive it of its air, and they lived only between three and four hours. Mr Davy introduced a large thornback [i.e., a type of ray found in the coastal waters of Europe] into a jar containing three cubic inches of water, which had been deprived of its air by distillation through mercury: he was very quiet for four minutes and a half, but then began to move about, and, in seven minutes, had fallen on his back, but still continued to move his gills. In eleven minutes, he was motionless, and when taken out, after thirteen minutes, he did not recover."



Daniel Ellis (1772?-1841)

Charles Giles Bridle Daubeny (1795–1867)

CHARLES GILES BRIDLE DAUBENY (1795–1867)

Daubeny was a physician, chemist and botanist. One of his more important papers was published in 1836, "On the Action of Light upon Plants, and of Plants upon the Atmosphere," in which took a systematic survey of the leading facts ascertained by Priestley and Ingen-Housz, Senebier, Ellis, and especially Saussure's findings that the green color of plants - supposed to be connected with the decomposition of carbon dioxide - is produced most rapidly under the action of violet rays.

The careful series of experiments by Daubeny disproved the latter's findings. Where Priestley saw a counterpoise to the effects of animal respiration in the process of plants decomposing carbon dioxide and giving out oxygen, Ellis, however, did not and by a series of experiments attempted to establish his opinion. Daubeny showed that these experiments were flawed and agreed with Priestly. He also concluded that as a very small portion of a tree or shrub generates a very considerable quantity of oxygen, the action of plants in absorbing carbon dioxide and releasing oxygen serving as a complete compensation for reverse action of that of the animal kingdom.

Daubeny was a contemporary of Charles Darwin, a passionate scientist and a very wealthy man. In 1849, the Duke of Devonshire invited him to join a party of eminent botanists and horticulturists at Chatsworth House to come and see his *Victoria amazonica.* This was the first time that the Victoria water lily had flowered in England. As soon as Daubeny saw it he stated that he simply must have one and he returned to Oxford to build the Water Lily House and the tank (the building was 36 by 30 ft.; the tank, located in the center, was 27 by 21 ft. and was 12 ft. in depth). He suc-

Daubeny's study at the Daubeny Laboratory, Magdalen College, Oxford.

cessfully grew and flowered the Victoria in 1851 and then charged the people of Oxford a shilling to come and have a look. Unfortunately, the people of Oxford not only stayed away but also wrote aggrieved letters expressing their concern at paying to see just one single plant!

CONCLUSION

Based upon the work of these men who preceded the aquarium hobby, the goal finally was reached: "…the popular notion of an Aquarium being in all probability derived from those antiquated glass vessels of globular shape and narrowed upper extremity (upon which it would be well if the Legislature imposed a heavy tax as a prevention of cruelty to animals) in which gold and silver fish have been imprisoned, and the water has been changed at more or less irregular intervals! My present purpose is to show…what those experienced in these matters are perfectly well aware of, that the water of a well-managed Aquarium needs to be changed no more than does the soil of one's garden in which are grown vegetables and flowers" (Hughes, 1874).

SOME NOTES ON FÉLIX DUJARDIN

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, November 17, 2012)

If you Google the phrase "In 1838, Félix Dujardin noted owning a saltwater aquarium, though he did not use the term," you will come up with about 35,000 hits. You'll also come up with 239 hits in French containing the phrase, "En 1838, Félix Dujardin annonce détenir un aquarium d'eau de mer, bien qu'il n'utilise pas encore ce terme," which is simply a translation of the English term.

Whoever came up with the term apparently didn't know that much about the aquarium hobby, since the term "aquarium" (in the fish tank sense) didn't come into being until about 1852 (Klee, 2012), so of course Dujardin didn't use the term. Furthermore, although the remark is tantalizing to the aquarium hobby historian who is trying to pin down "firsts," it leaves one wanting. One does not know what sort of aquarium was used, what animals and plants were contained within or where the original reference might be found for the statement.

Félix Dujardin.

In my paper, "Who Invented the Aquarium" (Klee, 2012), I quoted from an article written by the director of the l'Aquarium du Jardin d'Acclimatation (Rufz de Lavison, 1863) who included verbatim a note sent to him by Jean Louis Armand de Quatrefages de Bréau (1810-1892), a well-known French naturalist who maintained that Dujardin should be credited with the discovery of the marine aquarium. Quatrefages briefly noted that starting in about 1838, Dujardin had kept marine animals alive in jars containing water lettuce (*Ulva*) for long periods of time without resorting to either aeration of water changes. He specifically mentioned that he had observed living jellyfish in Dujardin's jars.

At the time covered by my Invention article, the explicit definition of an aquarium was "animals + no aeration or water changes" or implicitly, "animals + aquatic plants" since without aeration or water changes, the only way to keep animals alive in a container of water was to use aquatic plants. The term "animals" was deliberately vague. It is important to note that one of the requirements for being "first" was publication, a requirement that holds even to this day in this and other fields.

Quatrefages's description of Dujardin's accomplishment, however, does not satisfy the publication requirement. To see whether the claim is valid, therefore, we must examine

Dujardin's publications. Life is made easier here since a complete set can be found in Joubin's lengthy (61 pages) biography of Dujardin (Joubin, 1901).

Joubin lists 96 papers and classifies them so it is necessary only to examine his zoological papers that I have listed in the accompanying table. I have added the last column to identify what animals were being discussed in each.

Since it is Johnston's paper of 1842 that currently is the basis for the title of the first marine aquarium, sans fishes, it is necessary only to examine the six papers whose number I have boldfaced in the table. However, I did examine papers 42 and 43 since they relate to the jellyfish mentioned by Quatrefages.

Regarding the first paper (42), the following is my translation of some relevant parts:

"For several years I kept in a large number of jars of algae and marine animals from different localities, each of which is the subject in a series of carefully recorded observations.

"In July of 1841, in jars of seawater from the Mediterranean that I maintained since March 1840, I saw for the first time on the walls of a small neighboring zoophyte, Syncoryne, the formation of a filamentous stem, its thickness one-fifth of a millimeter and covered with a horny envelope, throwing off a few branches here and there, each terminating in a small club-shaped head. Around the bulge of the head were four arms arranged in a cross with perfect regularity and it is these that I propose to use the name of Stauridie for to designate the larva of the jellyfish."

Regarding the second paper (43), the following is my translation of the relevant part:

"As I related in a previous paper, in 1843 I was led to the comparative study of polyps and jellyfish by observing them kept alive for several years in a small jar filled with seawater. I dealt with any excessive evaporation and maintained the same specific gravity. The walls of these bottles were gradually entirely covered with small algae, infusorians, protozoa, annelids and polyps, and these animals became acclimatized, adapting themselves to these changes in the environment; under these conditions I have observed very young mussels keep the same size for three years."

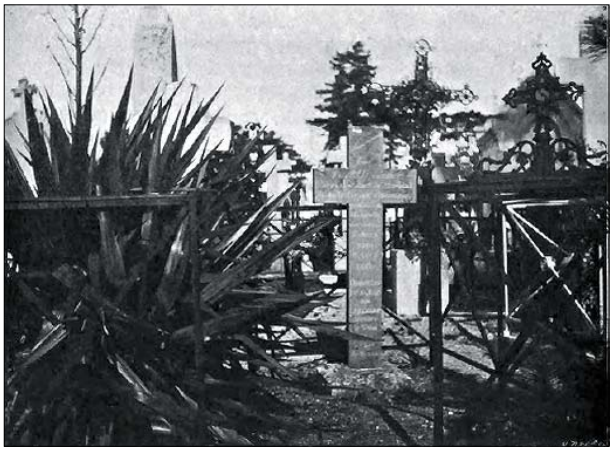
Thus we have from Dujardin himself the fact that he kept marine aquaria (sans fishes), but since both of these papers were published after 1842 it is necessary to example the six boldfaced papers in order to determine priority.

Publication 40 is quickly dealt with since it is a short note stating "…that these ambiguous beings [i.e., sponges] that wandered far from the plant kingdom to the animal kingdom, are actually groups of animals…" No reference is made to keeping them in aquaria.

Publication 41 can also be discarded since it deals with freshwater, but I'll take a detour here because it is interesting in a historical sense. By way of background, Spongilla is a genus of freshwater sponges found in lakes and slow streams. They attach themselves to rocks and logs, and filter the water for various small aquatic organisms such as protozoa, bacteria, and other free-floating pond life. The also tend to cover the cases of caddis-fly larvae. The following is my translation of the relevant portion of the paper:

"The Spongilles gathered from the Seine in the following October exhibited the same phenomena, especially in that the filaments were more clearly flagelliform. In May, as the water began to deteriorate by putrefaction, I developed doubts about the existence of these filaments in very fresh Spongilles. I thought there could have been monads producing filaments or at least altered sponges so I resolved to wait until spring to study Spongilles again since I was sure to find nascent cases on the larvae in the caddis fly pond. One should be aware how quickly sponges corrupt the water in their jars and the difficulties I encountered in keeping them alive for even five or six days, so I could not help but be surprised hearing Mr. Gervais announce that he revived dried Spongilles by placing them in water. I often saw all my Spongilles dead within twenty-four hours, thereby losing the opportunity to observe them. I finally was

Dujardin's home (left), next to the church of Saint Helier.



The tomb of Félix Dujardin.

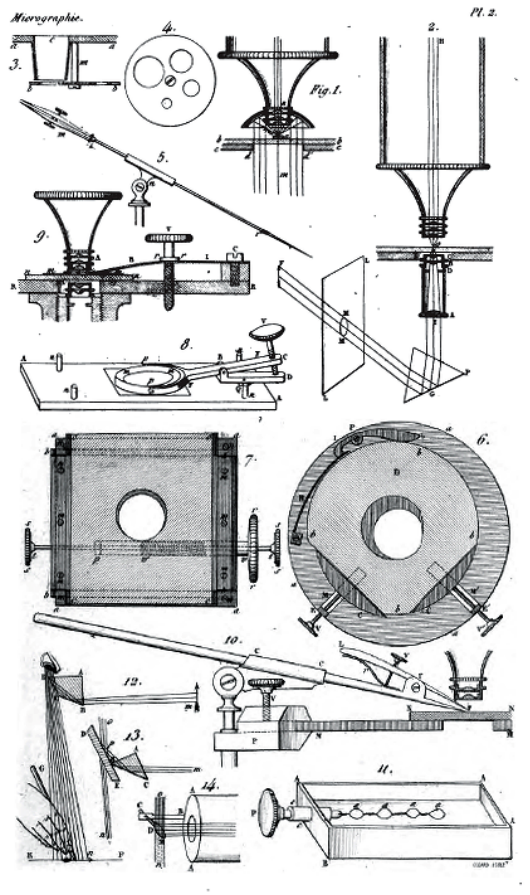
able to keep them using only two or three caddis fly cases that hosted the Spongilles. The Spongilles would them emerge in each jar filled with water and lots of aquatic weeds, They were placed in shallow bottles at home because in the pond where they live, they always chose their habitation site on the cases of the caddis fly larvae that were near the surface."

I find this interesting since this shows that Dujardin was one of the first who kept a freshwater aquarium (sans fishes). However, as I have shown in my "Who invented the aquarium?" paper, des Moulins preceded him by eight years for this honor. This leaves papers 45 to 47. Paper 45 can be ignored since Quatrefages states that Dujardin didn't start his aquaria until 1838 and Quatrefages should know as he was a close friend; indeed, Quatrefages, Dujardin and Louis Michel Français Doyère (a French zoologist, 1811-1863) formed a small group in which they discussed their scientific observations, exchanged information about their current work and discussed their future projects. Curiously, in every one of their letters they included in large print a sort of password for authentication, i.e., "we will see"! Unfortunately, Doyère fell out of favor with Quatrefages, whose relations with Dujardin then chilled and later was further stressed by a dispute over priority in later years. Quatrefages, however, always defended Dujardin when it came to considering who was the first to maintain a marine aquarium.

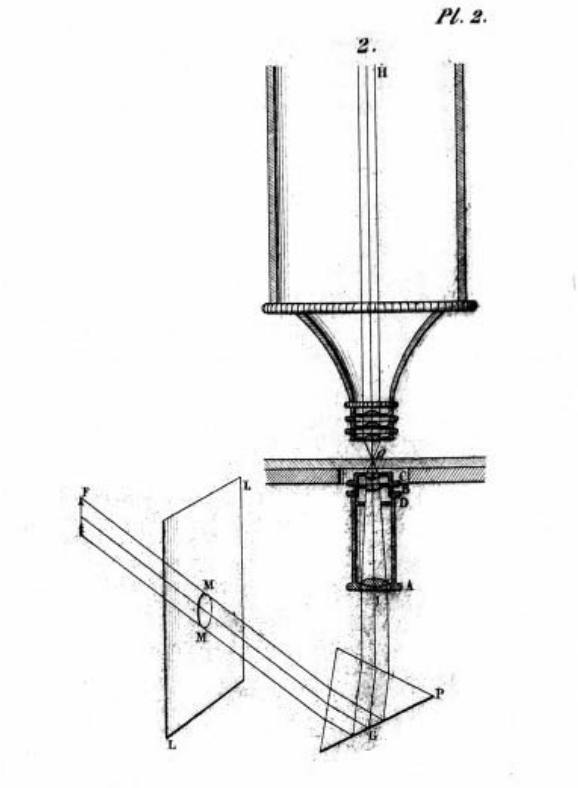
I have examined papers 45, 46 and 47 but find no discussion of keeping the animals concerned in aquaria; their contents generally describe new species, document anatomical details or devise new classifications.

Dujardin is primarily known for his work with microscopic animal life, and in 1834 proposed that a new group of one-celled organisms be called Rhizopoda (meaning "root-foot"). This name was later changed to Protozoa. In 1835, he disproved Christian Gottfried Ehrenberg's hypothesis that microorganisms have the same organs as the more complex animals. Also in 1835, he was the first to describe protoplasm, the jellylike material in animal cells which he called "sarcode," from the Greek word meaning "flesh" (Hugo von Mohl is credited with introducing the name protoplasm for it in 1846). This substance, now called cytoplasm, was later found in living plant cells. Although the term protoplasm is rarely used any more in a strictly scientific sense, many of the notions associated with the term have survived. He also considered the then disputed question whether sponges were animals or plants, and concluded in 1838 that they were animals, which is what they are considered today.

It is interesting to note that both Dujardin and Warington were interested in microscopes and made improvements to them, Warington even inventing a microscope that bears his name. Among his improvements to the microscope, Dujardin was the first to use an achromatic substage condenser and in 1843 wrote a book, "Nouveau manuel complet de l'observateur au microscope" [New Complete Manual for the Microscope Observer]. Warington's object was to provide an arrangement whereby the compound microscope could be brought to bear upon living objects in an aquarium, when these might be either in contact with one of the glass sides or be not far removed from it. This he accomplished by making use of the body of a Student's microscope, with the grooved limb in which it slides, and attaching the latter by a strong cradle-joint to a tubular stem that could be fixed at any height upon the edge of the table that supports the aquarium, by means of a clamp with a binding screw.

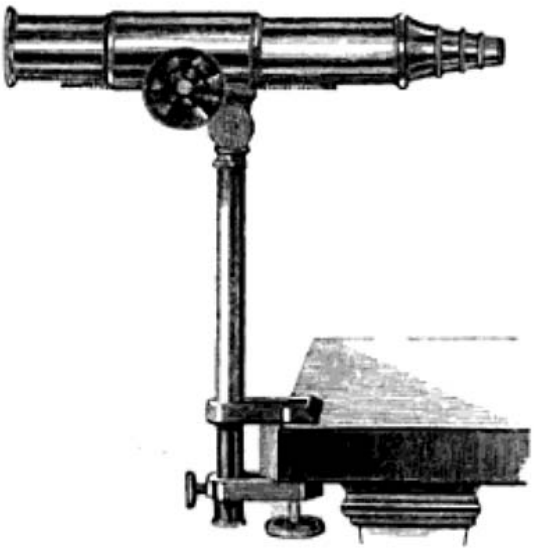


A page from Dujardin's "Nouveau manuel complet de l'observateur au microscope."



Dujardin's achromatic substage condenser.

Dujardin's education at the École Polytechnique was in mathematics, not zoology, a subject that was later self-taught. His criticism of Ehrenberg's theory earned him many insults and the disdain of famous men in the field who objected to this unknown young man who attacked the universally accepted and officially taught ideas of the day. The fact that he was proven right only added to the discomfort of this ménage of self-centered and pompous academics. Having neither an important academic position nor fortune, he was forced to write in journals in order to implement his small salary to support his family and raise his two children.



Universal Microscope, arranged for viewing objects in an aquarium.

For about nine months in 1849, Dujardin spent the time away from his family in order to complete some of his research in peace and quiet. His biographer (Joubin) writes:
"Seeking quiet and not to be disturbed by any annoyances, he settled on the outskirts of Rennes in a little old house, then in the countryside, one rather more like a farmhouse than a dwelling for a scientist. He had a fairly large garden, a large room on the ground floor and a fairly large kitchen. Living there as a hermit, he probably felt that the kitchen and its dishes were completely useless, so he transformed the ground floor into an aquarium; plates, glassware and jugs used to contain cultures where he had (the word is his) infusorians and rotifers, were sorted out so as to have each species in its own tank. All of this was in admirable order; his notes, veritable journals of the aquarium that unfortunately I found only in fragments, attest to the meticulous care with which these vessels were numbered and the experiments conducted. Nevertheless, Dujardin, jealous guardian of the sanctuary, sometimes consented to let in a few neophytes; the Canon Hodé [a vicar of the parish of Saint Helier, frequented by Dujardin; he also had a passion for the natural sciences] was among them and it is from him that I have these details. He was not alone. I have already stated that Dujardin held a deep place of affection for his family in his heart. A niece told me that when she was six or seven years old, she sometimes was allowed to accompany her uncle into the mysterious kitchen when she was a good girl, but could not let go of the hand of the scientist who ensured that an indiscreet finger, dipped in one plate and then another, never came to affect the purity of these so painstakingly selected cultures."

During his entire life, Dujardin endured the greatest of difficulties - jealousy and injustice. The construction of experimental apparatus, the purchase of books and the publication costs of his work absorbed most of his income. Nevertheless, when at a distance of century and a half we take a detailed look at his work, one recognizes all the scientific progress for which we are indebted to him. He not only was one of the greatest scholars of his century, but a man in the highest sense of the word.

AQUARIST EXTRORDINAIRE—PIERRE CARBONNIER

by Albert J. Klee, Ph.D.

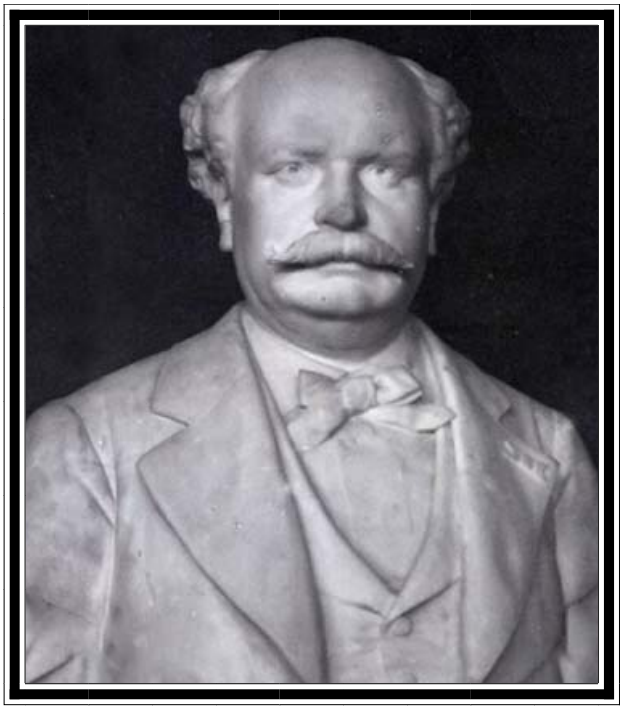
(Aquarium Hobby Historical Society, Yahoo Files, December 15, 2012)

Pierre Carbonnier was born on August 7, 1828 in Bergerac, the son of Pierre and Marie Andrieu. The third child in a family of 12, he married Josephine Flusin Zelie in Paris in 1857. He began his career in Marseille where he occupied himself with fish farming, befriending some well-known naturalists along the way. His "Guide Pratique du Pisciculteur" ("Practical Guide to Fish Culture") was published in 1866 and soon he acquired a respected name of his own.

He settled in Paris in 1855 and founded one of the oldest retail houses in Paris marketing fish, aquarium plants, aquariums and outdoor pools. He also built a fish farm on the Quai de Mégisserie. In 1869, Carbonnier began raising exotic fish, notably the Paradise Fish (*Macropodus opercularis*) brought from China in 1869. In 1874 he imported all sorts of anabantids including different species of gouramis such as the giant gourami (*Osphronemus goramy*) and the banded gourami (*Trichogaster fasciata),* the betta (known in France as the poisson combatant), the Climbing Fish (*Anabas scandens*) and the Spanish Killifish (*Valencia hispanica*), breeding most of them and writing about his experiences, mostly in the *Comptes rendus de académie des Sciences* (*Proceedings of the Academy of Sciences*) and the *Bulletin de la Société d'Acclimatation* (*Bulletin of the Society of Acclimation*). The latter was formed for the purpose of acclimatizing, domesticating and breeding newly introduced exotic animal species, either useful or ornamental, and later the goal of protecting these exotic species and their habitats was added as well. It is considered the oldest association for nature conservation in France.

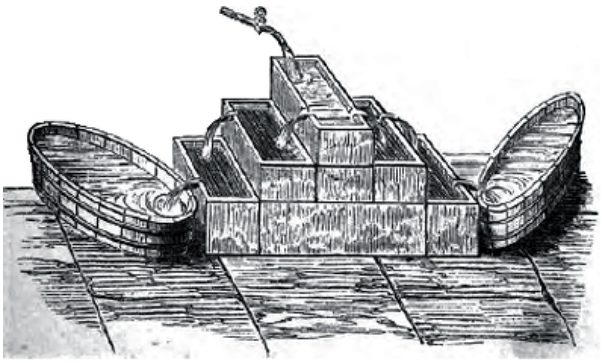
He also bred sunfish and blue gills imported from New York, the catfish *Corydoras paleatus* imported from Argentina, the Canadian Silver Bass [i.e., the freshwater drum, *Aplodinotus grunniens*] and goldfish such as the telescope.

For his work in improving the fish population in Spain, he was awarded the Order of the Knight's Cross in 1870 and becames the "Chevalier de l'Ordre de Charles III d'Espagne." At the International Exhibition of



Pierre Carbonnier (1828-1883).

Note: Any text in square brackets, whether in the text, bibliography or appendices are explanatory notes or updated scientific names provided by the author, not Carbonnier. Fish names and identifications have changed radically since the 1800's, and customs, terminology and situations might not be easily understood today.



An illustration from Carbonnier's 1864 book, "Guide Pratique du Pisciculteur."

river and maritime industries opened at the Palais de l'Industrie in Paris in 1875, he won the Gold Medal for his studies of freshwater aquariums and introduction of exotic fish species. In 1878 he directed the Aquarium du Trocadero, which was one of the main draws of the Exposition Universelle (the Third Paris World's Fair), which celebrated the recovery of France after the 1870 Franco-Prussian War. As a result, he was made a Chevalier of the Legion of Honor.

Carbonnier was an avid naturalist and a good man, noted for his kindness and dedication and who treated his fish with fatherly tenderness. His articles - models of keen observation and judgment - on the transport of live fish and on the reproduction and development of the nest-building fishes have repeatedly drawn the attention of aquarists, naturalists and scientists alike.

CARBONNIER'S HOME AQUARIUM

The last chapter in his Guide Pratique du Pisciculteur concerns the home aquarium. As it is quite lengthy, I have reproduced it (translated) in Appendix I. It is interesting to note that Carbonnier was aware of the origin of the word "aquarium" from the world of gardening (for further details on this subject see my article,

The "Maison Carbonnier" from a wood engraving by E. Chevalier in an article in *La Chasse Illustrée*, 1874.

Carbonnier (center) and two Russian aquarium pioneers, Solotnizki and Merschinski.

"Who Invented the Aquarium?" in Klee, 2012). He also advocated partial water changes and provided information about aquarium construction and their costs in his time, how many gallons of water were required per fish, what fish to include in the community tank and what to avoid.

Carbonnier claims the credit for inventing the flat-sided aquarium, pointing out that he built the first flat-sided tank ten years before the book was published, which was in 1864. Even allowing that he actually wrote the text two years prior to its publication in 1862, this would mean that he built the first such aquarium in 1852. However, Warrington provided a sketch of his flat-sided aquarium in a January 1852 gardening publication (Klee, 2012) and so clearly has publication priority. This was a somewhat obscure publication, so I conclude that Carbonnier was not aware of it at the time.

BREEDING FISHES

Carbonnier is probably best known in the aquarium hobby for his work on breeding the Paradise fish and the South American catfish, *Corydoras paleatus*. Because this is seminal material, I have placed his first articles on both in Appendixes II and III, respectively.

In the course of doing the research for this article I frequently came across the following two quotes (or modifications of them): **"The paradise fish is a true aquarium staple, having famously been introduced to the hobby by a French soldier named Gerault way back in 1869. Of the initial 100 specimens shipped, 22 survived and were successfully bred later that same year by another Frenchman, the Parisian Pierre Carbonnier,"** and **"First European import: 1869, France, by Gerault, a French officer. He was ordered to bring 100 *Macropodus opercularis* to France by the French consul in Ning-Po, Simon. 22 fish survived the trip, and 17 were delivered to the famous breeder Pierre Carbonnier in Paris, who bred them in the same year."**

The problem with these statements is that Géraud was not a French soldier but an officer aboard the steamship *Empress*; 22 fish were shipped, not 100, and all 22 survived the trip. Only 17 of the fish were *Macropodus opercularis*, however; among the other five included two types of anabantoids, (including the betta) and a loach; and it was Eugène Simon, the French consul, who was responsible for bringing the fish to Paris (Géraud was not "ordered to bring 100 fish to France"; he only assisted Simon during the trip). The true account of how the Paradise fish got to France can be found in Appendix II.

Another error I came across involved Paul Carbonnier, who assisted Pierre Carbonnier in the importation of many of his fish species. Paul Carbonnier has often been described in the British and American scientific literature

as Pierre Carbonnier's "father." The problem is that someone (or more than one and it was copied) translated the French word "parent" as the English word "parent" (in his article, "Nidification du poisson arc-en-ciel de l'inde," for example, Carbonnier refers to "mon parent, M. Paul Carbonnier") and since it is clear that Carbonnier's mother was not involved in this assistance, "parent" was reduced to "father."

However, "parent" in French can also mean family member, relative, relation or kinsman as well. In point of fact, Paul Carbonnier was really Carbonnier's nephew; indeed the term, "mon neveu" ("my nephew"), was used later in the cited article.

In any event, Carbonnier reported additional observations on the spawning of the Paradise fish the following year in "Nouvelle note sur un poisson de Chine appartenant au genre Macropode" ("A new note on a Chinese fish belonging to the genus *Macropodus*").

One species he bred might just be one of the earliest of the exotic killifishes bred in the hobby, i.e., *Valencia hispanica*, and since it is short I reproduce here (translated) his observations in their entirety from his 1881 paper, "Reproductions de poissons exotiques":

"A few years ago, one of our colleagues in the Société d'Acclimatation, Mr. Graells, a Spanish naturalist, notified me of the existence north of Barcelona, in freshwater pools where sometimes the Mediterranean ebbs, small fish from 2 to 2-1/2 inches long of the genus *Cyprinodon*, and I thought its study could offer a great scientific interest.

Valencia letourneuxi

"I then wrote to Mr. Ventrillon, the French designer attached to the great industrial firm, l'Espagne of Spain, directed by our colleague, Dr. Joseph Muntadas, if he would be so kind as to bring me some of these small fish on his next trip to France.

"In September of 1878, Mr. Ventrillon arrived in Paris with eight Cyprinodons but three died shortly afterwards. I had only four males and one female fish, which during the summer of 1879 provided me with fourteen small fry. These in turn have reproduced a few months ago and my group of fish now is thus increased by fifty new specimens similar to those which I have the honor to place before your eyes.
"I reserve for a future communication, to acquaint you with the singular mode of reproduction of this interesting species, until I have followed up and observed them again."

Unfortunately, Carbonnier died less than two years later before he was able to provide the promised details.

Another article I have added to the Appendices (Appendix IV) is Carbonnier's account of the importation and breeding of the Giant Gourami, *Osphronemus goramy* ("Le Gourami et son nid"). I do this because its spawning differs somewhat from that of the Paradise fish and Carbonnier describes it in minute detail; also, it is an example of the interest the *Société d'Acclimatation* had in importing tropical fish and exploring the possibility of adapting them to the climate of France and/or its colonies. Carbonnier discusses this issue and offers his opinion on the probability of success.

Anabas testudineous

Lastly I include a portion of the note Carbonnier sent to the Society ("Importation de poissons exotiques: Anabas, poissons combatants [i.e., bettas], gouramis") regarding two of three shipments made to him of *Anabas*, the Climbing Perch:

"The first shipment consisted of forty-four Anabas collected in the waters of Calcutta by Monsieur Paul Carbonnier, and he reported no loss during its journey to Wales. Having been entrusted then to the care of Mr. Ozias, the second engineer aboard the *Hoogly*, forty-two of these fish arrived alive and I have not had a single death since. In his letter, Monsieur Paul Carbonnier writes that he often encountered these fish in numerous groups, several hundred meters from the river, crawling on the ground and doing well in overland travel.

"Some travelers have even claimed that these fish climbed up trees, but this needs to be confirmed. Nevertheless, on the ground they employ some very singular motions; the posterior part of the body and tail follow a sequence of movements, the consequence of which is to propel the body forward. Its huge gill covers, open at this time, are armed at their base with strong sharp serrations firmly inserted into the ground to prevent any movement backwards. It uses both pectoral fins to maintain its balance; seals do not crawl better on the ground than this fish. But what is most remarkable about them is their method of breathing, in which they seem to take only atmospheric air. In water, its mouth is always closed except to eat and the gill covers, which have a thin membrane lining the inside of the body, move only slightly. Every few moments the fish rushes to the surface to renew the air bubbles that are transported to its pharyngeal cells; in this it behaves like the Gourami, Macropode and the Arc-en-Ciel [i.e., *Trichogaster fasciata*], a breathing pattern I described to the Academy of Science in a note of February 1874. The Anabas reaches a weight of 14 to 17-1/2 ounces and is very good to eat. In India, the natives give the flesh of this fish high marks.

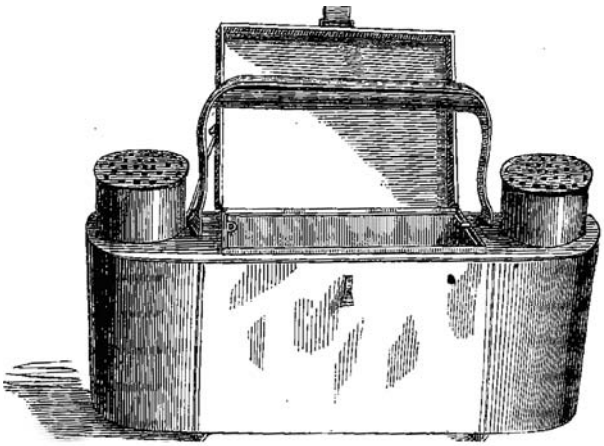
"The third introduction was an experiment. Twenty-two Anabas and six Gouramis were sent from Calcutta to Wales by Monsieur Paul Carbonnier to me in a transparent container; the water was not changed en route and no one cared for the fish during transport. Ten Anabas and three Gouramis arrived live in Marseille on August 1 and in the same container were the skeletons of those who died en route. This is important since it provides evidence that all fish belonging to the labyrinthiforme group can take in oxygen for breathing directly from the atmosphere. Those who died on route from Wales to Marseille probably died of hunger. What makes me certain that this is the explanation of what happened on the way to Marseille is that it corresponds to that of our valued friend, Monsieur Chevalier."

TRANSPORTING FISHES

Early on Carbonnier was not only receiving shipments of fish from contacts in China and India, but was importing the as well. The following is his note to the Société d'Acclimatation ("Du transport des poissons," 1871):

"I take this opportunity to let you know of the promising success I have achieved in sending freshwater fish of our country to America, Egypt, and Algeria.

"A few weeks ago, the two sons of the President of Republic of Peru told me that of a hundred fish that I had sent the previous year, thirty-eight had arrived alive and had



Carbonnier's apparatus for Shipboard transportation.

been bred in quantity. In exchange for this activity an hoping to bring to France a new species of fish, I always look for some kind of reciprocity.

"For a long time I did not receive anything in return. However, three months ago, Mr. Godillot, a merchant in New York to whom I had sent some of the interesting Macropodus that I'll take the opportunity to report on soon, promised to try shipping fish from North America.

"Finding in Mr. Godillot a Frenchman devoted to his country, I sent him transport instructions together with a special device. This device left Le Havre on the transatlantic liner St. Lawrence on August 8th, and was sent back to me on the same ship a month later.
"Starting out from America with about fifty fish, twenty-eight arrived alive. I still have all of them, and I must add, that under the influence of a lot of suitable food, the abdomen of a number of females is inflated, which makes me hope that I will be able to breed them.

"You can count on this species Messieurs, as the climate of New York differs little from that of our country, What is unfortunate is that these new minnows are not likely to exceed the size of that of a gudgeon, but judging by appearances, they should make excellent fries. I have just been advised by Monsieur Godillot that he will be sending me a new species in the same device. [Note: The "minnows" sent from New York were *Fundulus* (probably *heteroclitus*). In France, it was common for the local minnows to be fried up as a meal.]

"The issue of transport of live fish is quite complex. When it comes to sending them over large distances, there have been so many failures proceeding by trial and error. Nevertheless, the results can help point us to the correct way to ship fish. Here are some of the conclusions that can be made.

"If one keeps fish used to living in strong light for several weeks in dark containers, fungal threads grow and cover their scales and fins, killing them in a few days.

"On the other hand, fish living in deeper waters, or living mostly hidden under stones, transport very well in the dark, especially when the water is changed twice a week. This change of water is most necessary because without light, it becomes polluted in a few days. At 68 to 77 degrees, microorganisms abound in forty-eight hours in less well-lit waters.

"Well nourished, healthy specimens, 2 to 2-1/2 inches in length should be selected for transporting. Prior to this, keep them in pure water so that they finish digesting all their food (twenty-four hours is usually enough time). If the travel does not exceed one month, withhold any food during this time. Each fish must have at least a quarter of a gallon of water, renewed when possible. Lacking special equipment, glass and terracotta vases with large openings covered with a cloth that permits air to pass through are preferred for the air breathing fish; for the others any container may be used.

"There are cases, in long voyages, for example, when feeding becomes necessary, and one is sometimes advised to provide farina or hard egg yolk. One must be careful using these materials, since I am sure was the main cause of our failures. A fish in such a greasy container from the flour and egg yolk, will died asphyxiated in less than a day.

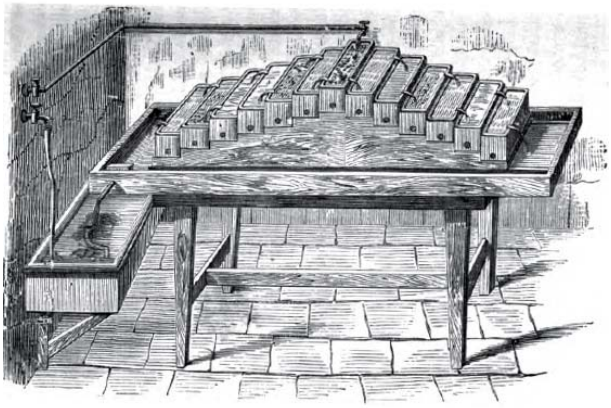
"Despite the restrictions aboard ship, there are always resources that can be taken advantage of, e.g., flies, mites, cheese, small bits of meat; this is the kind of food that should be given. It is essential that all food uneaten by the fish is removed a few hours later.

"It is through these means and these special precautions, such as my instructions, that I have succeeded and have the honor to provide you with an example of the arrival of an American fish in France.

"The device I built for the transportation of live fish over long distances is made of tin in the form of a basket slightly compressed on its two lateral faces, It is 16 inches long, 6-1/4 inches wide and 6 inches high, and contains about 2.6 gallons of water. A hinged handle placed in the upper part allows easy handling. It is very portable and one person can easily carry it around.
"On the upper side there is a frame 8 inches long by 6 inches wide, containing a pane of glass. The glass is held in place by pins and can be removed to allow cleaning of the insides or extra ventilation for the fish. A hinged, polished tin lid covers the whole transparent portion of the device; when open it serves as a reflector and can be tilted at different angles to provide varying amounts of light to shine on the surface of the water.

"At each end of the apparatus there is a wide-mouth bottle with a lid pierced with ventilation holes. One of these openings is used to introduce water and fish; in the lid of the second neck is welded a cylinder wire mesh, 5 inches long, with a hole at its base. This cylinder is designed to hold charcoal, immersed in the water, to maintain it in a good state of purity. To protect the fish from the rough surface of the wire, a perforated partition was established in the interior.

"A small zinc armature, fixed to one side of the device, prevents rusting of the tin, and at the same time neutralizing or considerably slowing the production of microorganisms. The physiological cause of the slowdown that



Another illustration from Carbonnier's 1864 book, "Guide Pratique du Pisciculteur."

I have often seen in the growth of microorganisms in an environment where there is a low emission of electricity and a little hydrogen production, deserves the attention of qualified specialists.

"These are the basic details of the conveyance; it facilitates continuous monitoring of the fish and provides the necessary hygienic conditions that they require during the transport."

Carbonnier provided much practical advice in this short note regarding preparation of the fish before shipping, feeding them (or not) during transit and how much water was needed per fish. His observations on the differences in transporting fishes that lived in well-illuminated waters versus those that preferred darker were unique. Carbonnier was innovative at the time in the use of charcoal to purify the water when artificial aeration was not available, and although the purpose of the zinc in his device was primarily to stave off the rusting of the tin, he observed that it also reduced the population of harmful microorganisms. He was also careful in protecting the fish from the rough wire mesh used to hold the charcoal. In the long run, of course, it was the so-called "German shipping can" (so-called because the original concept was developed by Frank Buckland) that won out over Carbonnier's design.

Carbonnier's table showing the preferred water depth of various species of fishes as a function of water temperature.

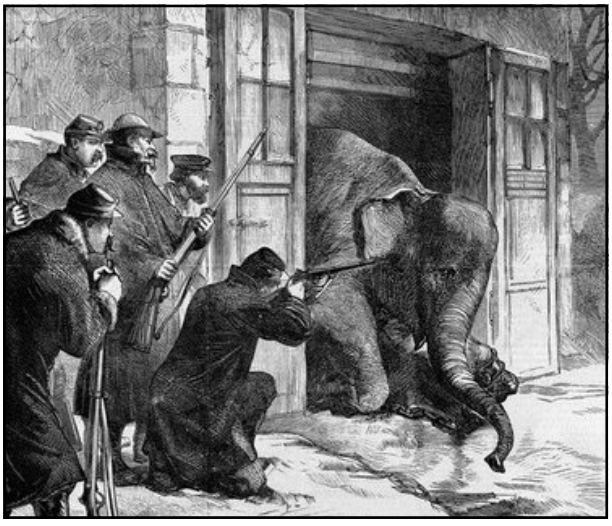
THE EXPERIMENTER

Over the years, Carbonnier put together a table showing the range of depth a particular species of French fish would be found as a function of the temperature of the water. He used this information to explain the spawning and post-spawning behavior of fish in his 1873 article, "De l'influence de la pression extérieure sur la vie des poissons" ("The influence of external pressure on the life of fishes"). This was also published in the Danish journal, *Nordisk Tidsskrift Fiskeri*, a year later ("Om det ydre tryks inflydelse paa fiskens," 1874).

THE FRANCO-PRUSSIAN WAR

In his "Le Macropode de Chine" ("The Macropode of China"), published in 1872, Carbonnier describes the terrible times he experienced during the Franco-Prussian War. Often referred to in France as the War of 1870 (actually July 1870-May 1871), it was a significant conflict between the Second French Empire and the Kingdom of Prussia aided by various German states. The war and its resulting German victory brought about the unification of Germany and the shifting of the balance of power in Europe. In France it led to the downfall of Napoleon III and the end of the Second French Empire, followed by the French Third Republic, which continued resistance in the war with newly formed armies, and ended with the Paris Commune uprising of 1871.

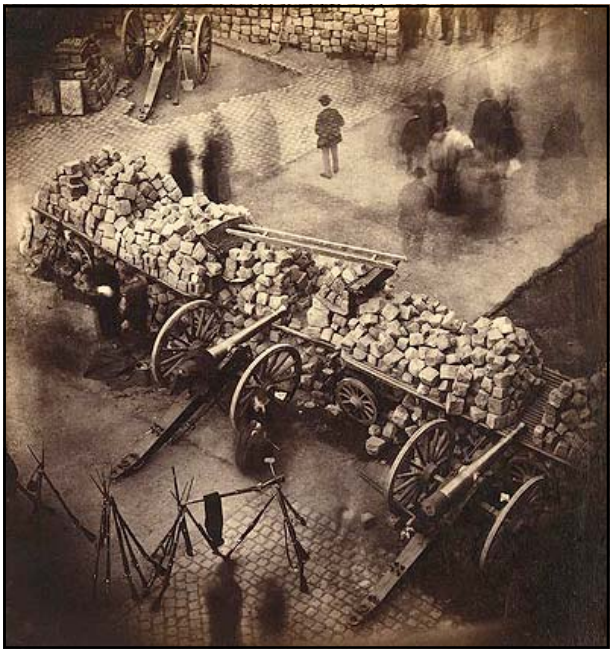
The Siege of Paris (19 September 1870 – 28 January 1871) brought about the final defeat of the French Army. The bombardment lasted 23 days, usually two to five hours each night. Dogs, cats and rats were frequently eaten. The animals of the zoo were added to this diet, including Castor and Pollux, the two elephants that



Parisians shooting an elephant for food at the Jardin des Plates, Paris, in 1871

were the pride of Paris. Only the lions, tigers, and monkeys were spared; the big cats for the difficulty of approaching them, and the monkeys because of "some vague Darwinian notion that they were the relatives of the people of Paris and eating them would be tantamount to cannibalism." On 18 January, with Paris starving, German troops occupied the city and the new German Empire was proclaimed at the Palace of Versailles.

The Paris Commune was a government that briefly ruled Paris from March 18 to May 28, 1871 and included a high proportion of skilled workers and several professionals, but also anarchists, socialists and Marxists. It was not surprising therefore that many of its decrees were controversial. Carbonnier, of course, was certainly not a fan of the Prussians, but he wasn't particularly fond of the Commune, either. The following are excerpts from his article:



Barricades set up by the French during the siege of Paris, 1871.

"When the bad times came and the Prussians enclosed us in their circle of iron and fire, I had in my possession, in addition to my twenty adult pairs, about seven to eight thousand fry of various ages. But, alas, this unexpected success came with terrible worry and suffering! I will not attempt to tell you the whole story; suffice it to say that water was more essential for me than any other element, followed by gas since in my shop all the lighting and heating was supplied by gas. Soon both the water and gas supply was cut off and all winter long I had to send my students to the Seine to bring back water for fish. I had to burn everything in sight to revive and save them from freezing. In the seven days of the week, four days was spent in this ceaseless work; the other three I spent on the ramparts when I was called to duty.

"But despite all my efforts, I could not supply the fish with sufficient food; in vain I shared my meager portion of horse meat with them. My losses were large and the mortality struck both the slow and the young mercilessly, but the strongest of them resisted everything and

The Rue de Rivoli after the Siege of Paris, 1871.

Pierre Carbonnier, 1828-1883

when the day of deliverance came - when I was finally able to feed them sufficiently - they were, so to speak, resurrected and I wound up with about two thousand strong and healthy fry.

"Along came the Commune, this time to satisfy their dual desire of ordering me to comply with the orders of the insurgent government, and to take away my students, exposing them to the dangers of a new siege, I left Paris, and taking with me my aquatic family, I settled in Champigny, where I have, or rather had, a property.

"Alas! The Prussians had passed through there. My fish farm was destroyed and the trenches of my formerly flowing fish ponds were all dry. In addition to the loss of fish and fences, the house was riddled with shell fire. I saw shell pits and mounds of rubble at every step. It was gloomy evidence of the furious struggle that took place within this narrow valley; this now was my new surroundings.

"However, here in solitude and among ruins is where I settled down. My fish were my only companions. I devoted four and half months in rearing and breeding them, and I went back to Paris in August, this time with six hundred adult pairs, all similar to these I have honor to show you, and six thousand youngsters of various ages. You see, gentlemen, when I persevere, I am sufficiently well rewarded with success.

EPILOGUE

My examination of the life of Pierre Carbonnier proved valuable in that it filled the gap in the early history of the hobby that started with the abatement of the aquarium fever in England that started in the 1860's and ended near the turn of the Nineteenth Century. Not only did he breed a host of anabantids, such as *Colisa lalia*, but he also bred very dissimilar fish, including *Corydoras*, *Umbria* and *Valencia*, describing in detail what he did and what he observed. He also imported the Glass fish *Pseudambassis ranga* and the cyprinid *Nuria danrica* (formerly *Esomus dandricus*). He described in detail the construction of an octagonal aquarium and devised a successful method whereby fish were transported over great distances by ship. He was an experimenter and amassed data that was of great interest to, and much in demand by, his colleagues. He won medals for his studies of freshwater aquariums and introduction of exotic fish species and for the direction of a public aquarium that was the main draw at the Third Paris World's Fair in 1878.

Pierre Carbonnier died in 1883. His life was an interesting and fascinating one, deserving of more than just a few words about his work with *Macropodus* and *Corydoras*. He did exciting things in his day and I very much would have liked to have met him. I would, however, have pleaded "prior engagements" in 1870 and 1871!

BIBLIOGRAPHY

Note: I haven't dwelt on Carbonnier's involvement in fish farming because aquarists are generally more interested in what goes on in the aquarium than in the pond. For similar reasons I haven't elaborated on the succession of owners of Carbonnier's shop in Paris. For greater detail on both of these matters consult Pechauf's 2011 article. Be forewarned, however, it is written in German.

APPENDIX I: THE APARTMENT AQUARIUM, FROM THE "GUIDE PRATIQUE DU PISCICULTEUR" ("PRACTICAL GUIDE TO FISH CULTURE") 1864.

"An aquarium is the name given to a tank or basin, a kind of breeding ground of small dimensions, in which plants and aquatic animals such as fish live and thrive.

"The aquarium is specially designed to place before the eyes of the observer the phenomena of vegetation in water, the reproduction and development of fish, their manners and their habits. Its shape, therefore, must not be distorted if the many details useful to know about the animal and plant life that grow within are not to escape these observations. For the same reason, it must be constructed of transparent sides and contain a sufficient amount water.

"It is no longer just a heated greenhouse where horticulturists or amateur gardeners cultivate their flowers, or something designed to grow a profusion of the beautiful tropical plants known as the water lily. The lily, in these conditions, is at once a welcome surprise for the visitor's eyes, and escaping from the water surface of the basins from which it grows is beneficent moisture that cools the air in a greenhouse that is too dry. It is undoubtedly through this that the aquarium has become a piece of luxurious, leisure time furniture, taking its place next to the elegant plant stands in the living rooms in the apartments of the rich.

"For a long time now, those who study the habits of fish are increasingly attracted to observe them directly, and looking for a different or unusual kind of recreation they have in their possession spherical glass vases filled with water containing a few goldfish that pass their lives in a continuous and tiring circular motion. The shapes of these vases do not lend themselves to making these observations either easy or comfortable. It can easily be imagined then, according to the fish or plants they contained, that they were seen in unreal ways, their shape shortened to view or contorted unpleasantly. Without running the risk of comparison one could say that what was seen was only a caricature of the plant or fish.

"Aquariums today have flat surfaces; consequently they depict an accurate view of what they contain from the outside. It was about ten years ago that we built the first flat-sided aquarium for Baron Heurteloup, and without wanting to suggest that the English have copied us, since they have constructed similar aquaria, we claim the honor of this modest and useful invention, an honor probably very small, but not a frivolous one.

"Allow us to point out that our work in pisciculture on occasion led to improvements, principles that today are recognized throughout the practice, and that never, not even in the course of this little book, have we ever claimed anyone else's' legitimately acquired priority. We remind our readers that we have never neglected the opportunity to give credit to these humble scholars, skilled illustrious practitioners or modest researchers. However, that we claim our rights to take credit for the invention of flat-sided aquaria, both with regard to the idea and for the details of its construction, is a small matter of pride that when the claim is examined it will be found in our favor because we are truly the inventor of these aquariums.

"Although the Chinese had a lot of time to learn about and use these kinds of vessels, they did not use them for the study of aquatic plants or fish; the dimensions and shapes of their aquariums were in no way suitable for this purpose. They were used instead to enhance the decoration of their strange architecture, both outdoors and indoors. This is, without doubt, because the goldfish, which comes from these distant countries, is so easy to breed in almost any container.

"Aquariums that are built today vary in the form and details of the arrangement of their component parts, but first and foremost they all have straight and transparent sides. Those established in the zoological garden in the Bois de Boulogne present to the curious observer the most beautiful of these designs.

The octagonal aquarium constructed in Carbonnier's Paris shop.

People who visit there for the first time are amazed by this little miniature sea, populated by small aquatic meadows and forests that appear to be unconcerned being the subject of this intense curiosity. For many people the desire to have such an object of their own in their home for recreation is natural. We will soon show that to carry out this desire is neither difficult nor expensive. The only problem we might face in the installation of the aquariums in question is the lack of an exposure to direct sunlight, because without this warmth the underwater plants will not grow or multiply.

"The most widely adopted shape for aquaria is the rectangular one, the octagonal shape being preferred by those who desire more elegance and richness of detail.

"The figure shows the aquarium model built by us, which is located in the center of our store. Its dimensions and capacity are as follows:

Diameter, 39 inches;
Height 24 inches;
Weight of the tank with the rock and water, 1280 pounds;
Tank capacity, 130 gallons.

"The base is formed of a thick slate plate with eight small copper columns attached. They form the sides of the octagon and hold the thick glass that is the walls. They are held in place to the bottom plate and to the glass panes all the way up to the height of the columns using water-proof putty. A circle of polished copper provides a strong and elegant border at the upper part, strengthening the whole construction. A rock rises from the middle of the basin, forming a sort of cave where the fish can seek shelter from any bright light or other stimuli that affects their behavior. Various aquatic plants grow in small cavities outside the rock cave. The whole is supported by a strong wooden table.

"Most aquariums are much less elaborate than the model described above, and their capacity varies from 2-1/2 to 50 gallons. If the buyer doesn't find anything to his liking among those that we have in our store, at his request we custom manufacture one. The bottoms are cast iron, slate or glass, depending on its use. In those designed to contain sea water, contact of the water with metals such as iron or copper must be avoided since their oxidation has the most serious consequences on plants, fish and other marine organisms. The means of production that we use allows us to price these tanks at 1 to 1-1/5 francs per liter of capacity [about $3.4 to $5 per gallon in today's currency].

"It remains now to provide some background before stocking the aquarium with plants and fish, and to discuss the care required to achieve the desired results. They will pertain especially to fresh water, for which we believe hold no secrets.

"Those who prefer a show of flowering aquatic plants rather than that provided by moving creatures, no doubt have in their possession an aquarium used only for such culti-

vation, oblivious to the pleasure experienced by others who contemplate and follow the development of living beings that can also live in the same environment. It seems that nature does not separate two major relationships from each other, that is to say, that of aquatic plant life and aquatic animal life. In fact, these two provide essential elements for each other, and if this balance is not maintained, they both suffer.

"Air, as everyone knows, is necessary both for animals and plants. Animals consume oxygen and release carbon dioxide; plants, on the other hand, absorb carbon dioxide and give off oxygen. What happens in our atmosphere has its equivalent in the aquarium so it is necessary therefore to establish and maintain an environment that caters to both plants and living creatures.

"The number of living creatures we introduce must be proportionate to the capacity of the aquarium; one can, on the other hand, never introduce too many plants. When the water doesn't contain what is needed for the plants, they just borrow it from the atmosphere. It is not the same for fish; their makeup does not allow them to utilize the air we breathe. From time to time, during storms or when the atmospheric pressure decreases, we see them move up to the surface in the layer that has more oxygen, but this only happens when there are too many in the aquarium, or when they are not accustomed to living in stagnant waters. In the latter case, it is not necessary to keep plants in the tank.

"We have found that to live and thrive in an aquarium, a fish 1.2 to 1.7 inches in length needs 0.26 gallons of water. An aquarium of 26 gallons capacity, therefore, can hold a sizeable population of fish, permitting us to observe the differences in the customs and habits of many different species, along with studying the reproduction of our freshwater snails.

"It would be unwise to mix fish in the aquarium whose manners or habits differ widely. Some are too aggressive, such as pike, perch, eels and sticklebacks. They should always be separated from the more harmless species or they will pursue them continuously and when they can't kill and eat them, they will maim them by biting their tails and fins. In this latter state, the unfortunate victims are no longer a object of study or recreation as their means of moving about are taken away; they are condemned to remain motionless, a pity.

"Among the fish that thrive in the aquarium and one easiest to maintain is the goldfish from China which, by its diversity of coloration, provides a most pleasing look at a single glance; others include the minnows, which like our birds, have the most beautiful colors during breeding and take the food presented to them from your fingertips just a few centimeters below the surface of the water; tench, which plow through the gravel, providing an opportunity for other fish to grab various organic materials that are trapped there as food; dace and bleak, who delight us in their rush to show how nature has been lavish in their favor, giving them very developed fins and an overall shape that allows them to go twenty times around the aquarium in a single leap; and bream, roach, bitterling, carp, loach, all fish of different forms and habits that live in perfect harmony and help to provide a varied and continuous interest in the aquarium. Regarding the stickleback and its mode of reproduction in the aquarium, we refer the reader to what we said on page 148.

"The introduction of plants in the aquarium can be done in several ways: the most common is to leave them in the pots in which they were grown and set them on the bottom of the tank, covering and filling the gaps between them with coarse sand or gravel, thus forming a single united dome from which new growth emerges.

"Another is to place a bed of peat a few centimeters thick at the bottom of the tank, and cover it with a thick layer of gravel 2 or 3 centimeters deep in order to prevent the earth mixing with the water and disturbing its transparency.

"Plants that can be grown in the aquarium are numerous: we recommend preferably the water lily, iris, reeds, water sensitive (which floats on the surface), water crowfoot whose many branches provide a most beautiful effect, umbrella palm, *Valisneria* and rosoli (also called the flycatcher because it asphyxiates flying insects that land on the flower, then closing and reopening after the insect moves no longer; fish frequent the vicinity of the plant, in the hope that it will give them the opportunity to grab an easy prey). [Carbonnier is talking here about semi-aquatic plants in aquariums that are half-filled, permitting then to grow out of the water and to flower.]

"The presence of various snails in the aquarium is necessary. They feed on the plant detritus that may corrupt the water and thus serve to maintain its purity. Most of them constantly crawl on the walls of glass and scrape off the algae that develop there; in this way, through the tireless work of these scavengers, the glass retains its transparency.

"In a well populated aquarium, the show is very entertaining. We can see water beetles walking during the day at the water surface in an inverted position to hunt small animalcules; the snails coming up from time to time to the surface to breathe, then dropping to the bottom; the clams in which you can try making fake pearls, as is done in China; and to vary the show already so varied, we can easily add Lilliputian freshwater shrimp, salamanders and turtles to this population, and many other animals it would be too long to list.

"To sustain life in such a large population does it require continuous and meticulous care? No. We can find no evidence that this is needed.

"A bird raised in a cage often flies around terrified, colliding against the bars of its prison, scattering the millet and hemp which is their food over the furniture of the apartment. It requires more care and presents more liabilities than the many residents of an aquarium. In an aquarium the animals live calm and quiet lives satisfied with little, almost nothing, and can be maintained without food for several months.

"In an aquarium where the fish have sufficient space and where the vegetation is abundant, it is necessary to renew the water only partly, once a week. As do the majority of animals, fish react badly when there is a large change in temperature or in their environment, and the entire renewal of the water where they lived for eight days would lead to these changes most of the time. The tank can be emptied easily, in whole or in part, by means of a small rubber tube used as a siphon and, in the latter case, it has the advantage of sucking out the water from the depth deemed best, that is to say, depending upon how far down in the aquarium the tube is placed we can siphon out water from the bottom, middle or top. During cold weather, the fish are in a kind of torpor, so a water change is not necessary more than once a month.

"Many people feed the fish in an aquarium with bread or bread crumbs or even bits of unleavened bread or wafer; this, however, has dire consequences. Some of this food remains in the water and sooner or later decomposition takes place, imparting a sour taste to the water and clouding it. Food ingested by fish and then discarded in its droppings have the same effect, but to a lesser degree. Experience has taught us that meat, especially cooked, minced beef, is the most suitable food in all respects. Furthermore, it does not disturb the water before or after it has been digested by the fish. They eat better and require smaller amounts, and their droppings provide food for the snails. Be assured that this is what happens. When an excess of droppings accumulate on the bottom of the tank and cannot be removed by siphoning out with the rubber tube, one must use the curved pipette curve shown. A few pinches of ground beef thrown on the surface of water is enough food for all of the inmates for a week. A good routine precaution to take is to avoid feeding the fish the day before a partial water change.

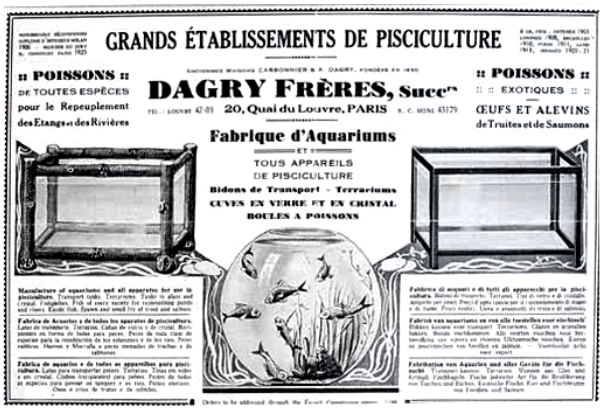
The photographs on this page are of the Dagry House, the successor to Carbonnier's establishment. In 1930, the year shown, it manufactured home aquariums, terrariums and fish farming equipment, and it also sold exotic fish, fish for stocking fish ponds, and reptiles. The store still exists to this day.

(Photographs were taken by A. Lemaitre, courtesy of Association d'aquariophilie et de terrariophilie at aquarium32.com and Jacques Teton.)

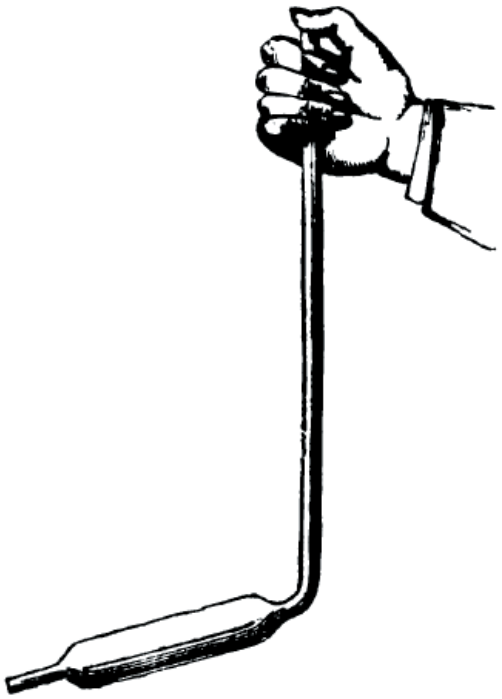
In the foreground is the Proprietor at the time, Henri Leveaux.

The same shop inside. Various models of aquariums line the shelves. Below these are tropical fish and at the bottom are cold water fish. At the right is a circular aquarium with a fountain.

Examining a new importation of fish. Shipments at this time were carried out in large tin cans wrapped in wicker.



The shop's outdoor display.



The device used by Carbonnier to siphon uneaten food and detritus from the bottom of a tank.

"Small bloodworms that the fishermen use as bait, such as flies and the red worms found in lettuce are much sought after food for fish. Indeed, they snap up and digest all kinds of vegetable and animal material that can pass through their mouths; our only decisions are in the choice of the quality and quantity of their food.

"The last tip that we have to offer in the installation and maintenance of aquariums in an apartment is that you do not expose them to bright light. Most freshwater fish avoid bright light and moreover, it tints the water greenish, masking problems inside the tank and preventing seeing what is going on. The recess of a curtained window exposed to the light for a half-day is the best location in an apartment for an aquarium. You can enjoy the enchanting spectacle of an animated world amidst picturesque vegetation. The learning gleaned and the entertainment experienced goes on without ceasing."

APPENDIX II: "RAPPORT ET OBSERVATIONS SUR L'ACCOUPLEMENT D'UNE ESPÈCE DE POISSON DE CHINE" ("REPORT AND OBSERVATIONS ON THE BREEDING OF A SPECIES OF FISH FROM CHINA"), 1869.

"On July 8, our indefatigable colleague, Monsieur Simon, Consul of France in Ningpo, arrived in Paris, bringing from these distant lands a number of fish still unknown to most of our naturalists. It is, however, not the first time Monsieur Simon showed his devotion to science and to our Société d'Acclimatation, and for this he certainly has earned his award of the title of Honorary Member.

"It is necessary to appreciate how much greater the difficulties are when transporting fish as opposed to plants and terrestrial animals; suffice it to remind one on this subject of the numerous persistent and almost fruitless attempts made in recent times to transport the Gourami from the island of Réunion to France.

"It is only fair to say that Monsieur Simon had in this difficult task Monsieur Géraud, an officer aboard the Empress who was bright and eager to help. It is to them that we owe two of the new acquisitions that have enriched the science of ichthyology and from the following facts I have every reason to believe that the domestication of the fish is now a reality.

"Starting on July 9, Monsieur Simon, building upon my practical knowledge as a pisciculturist and as an observer, had been kind enough to collect some of these fish for me. Of the about one hundred that he had taken at the beginning, there remained only twenty-two. Enclosed in glass jars with a capacity a bit over one and a half liters, Monsieur Simon provided them during the voyage with crushed vermicelli, which resulted in making the water a milky white.

"As such a regime would certainly be sufficient to kill the most robust fish of our country within a quarter of an hour, the possibility

of returning them to health by placing them in a suitable medium seemed good.

"From July to August I kept seventeen individuals of 7 to 8 centimeters in length, all belonging to the same genus, that of *Macropodus*, but they are a species completely unknown so far. The dorsal and anal fins are very long and tinted with the most vivid of colors. The scales, of all shades of the rainbow, provide vertical stripes of yellow, red and blue, and they are streaked from head to tail with stripes that change color. Added to this is a graceful, softly rounded, long forked caudal fin, that expands like that of a peacock's tail, so it is not surprising that I thought it should be given the name of Paradise Fish because it is among fishes what the Bird of Paradise is to birds.

"Of this group there are twelve males and five females; the latter are smaller and less brightly colored. Two other fish belong to the same genus but are different species, identified as fighting fish or bettas [at this time the betta was known as *Macropodus pugnax*].

"Their size is about that of our Epinoche [i.e., stickleback]. They are a pale gray, unremarkable at rest, but when something excites or irritates them they expand their fins, straighten up and instantly become an iridescent color. The eye is like a green azure fire, all fin rays become purple-red mixed with blue and green, and each scale is a small shining pearl. Its appearance is really indescribable; it must be seen to get an adequate idea.

"I still have another pair of fish from the same source, but like our Misgurn or grand eloche [a loach, i.e., the weatherfish, *Misgurnus fossilis*] it offers nothing of interest in particular; also included is a number of goldfish with a double caudal fin, an anomaly I frequently encounter and quite common in our country. I have recently given three specimens to the Zoological Gardens.

"The seventeen in the first group of fish came from rice fields in Guangzhou. When they were handed to me on July 10, most had clipped, worn fins, and their bodies were covered with fat, dirty pustules that would have inevitably killed them before long, and so the first order of business was to get rid of them. The task was not easy, but here's how I did it.

"In an aquarium containing about 70 liters of water, I placed clumps of aquatic plants, choosing a sedge with rough foliage, i.e., *Carex*, mixed with filamentous plants. I put in my fish and gave them food from the red worm jar. To get to the worms that were located at the bottom of the aquarium, the fish were forced again and again to pass through the aquatic plants, which in three or four days stripped by rubbing all of the material with which their bodies were contaminated, and I soon had the satisfaction of seeing their colors reappear and their fins reforming and growing rapidly.

"Ten days passed thus, during which my fish swelled visibly. The females especially took on an extreme amount of weight, which I attributed first to the abundance of food, but it was only the prelude to spawning. In fact, the morning of the eleventh day I noticed, not without surprise, a big change in the appearance and behavior of my fish. In the males, the edges of the fins were yellowish blue, and the extended spines of each pectoral fin were saffron yellow. Their fins spread like a wheel similar to the peacocks and pea hens of India, and with their vivacity, jerky leaps and display of their bright colors they tried to attract the attention of the females. The latter did not seem indifferent to this display and they swam slowly to the males and seemed to take pleasure being near them.

"Noting that the males and females were fighting and guessing that spawning would take place soon, I choose the strongest male and placed a female in a special aquarium with slate on three sides, illuminated by only a single glass pane and containing 40 liters of water.

"Ignorant of how spawning and fertilization would take place, I tried to ensure that the environment in their new would ensure success. I filled the bottom with sand, placed clumps of aquatic plants in the tank, and

placed a piece of slate leaned on one side of the tank to provide them with some shelter. "This all occurred on the morning of July 21; the water temperature was 72 degrees Fahrenheit.

"After taking ten minutes to explore their new home, the male came to rest against the transparent side of the tank, and at the surface of the water relentlessly absorbing and expelling air bubbles, he formed a kind of floating foam with a diameter first of 2 inches, then increasing to an area of 16 square inches. This was maintained without any absorption of tank water as a result of the secretion of a greasy mucus - the envelope of each bubble - produced in the mouth of the male.

"Then the male approached the female. I saw it expand its fins and bend them in an arc-like hoop. Then the female, who stood vertically with her head above the water, oscillated the lower part of her body in the semi-circle of the male who, bending and contracting his long fins, fastened to her side and, with obvious effort for at least half a minute, tried overturn her. Nothing is more graceful than the movements of these animals, dressed in their bright colors, dropping 15 to 20 inches down from the surface and then returning to the nest every ten minutes from 11:30 am to 3 pm. During the resting intervals, the male kept working on his foam nest, which at one point was a half inch thick at the center.

"However, until three o'clock this had, in fact, been nothing but a preliminary coupling. No doubt that the eggs in the female and the sperm in the males were not yet in a state that would induce any egglaying, but after 3 pm there were effective couplings. The male, pressing more forcefully against the shaking female, induced her first spawning. As the eggs were leaving they made almost immediate contact with the genitals of the male, who passed on his sperm to them. The actual coupling is in the middle of the water; the operation begins at the surface and ends before the fish have reached the bottom. They then separate and the eggs float up into the next.

"Starting with the first egg, I saw the male trying to eat all he encountered so, eager to save some, I collected one hundred to one hundred and fifty with a pipette and placed them in a bowl. Then seeing them still spawning, I left the eggs in the tank to see what would happen. Then, to my surprise, I found that far from devouring the eggs, the male harvested them in his mouth and placed then in the foam. Up to seven o'clock, I saw the same actions repeated: mating, spawning and egg collection by the male.

The Paradise Fish, *Macropodus opercularis.*

"When all was finished the male chased the female, who was pale and discolored, to a corner of the tank where she remained motionless. He then undertook the care necessary for the successful incubation of eggs, restoring the gaps in the foam that oc-

curred now and then, and taking a few eggs in his mouth where they accumulated in large numbers and placing them in less populated places. When the foam layer seemed too tight, he broke it up and immediately filled the new voids with new bubbles. He labored thusly for ten days without ceasing, without rest and without food.

"As for the eggs I had collected, they were stored in water whose temperature was maintained between 70 and 73 degrees. I examined them under a microscope twenty-four hours after spawning, finding they were transparent on one side; the other had two small spheres, nested one inside the other, and of a different color.

"Re-examined forty-eight hours after spawning, I saw the heart beat of the embryo, so they had indeed been fertilized. Finally, after sixty to sixty-five hours, the hatching began. What happens in this case is that the embryo undergoes two transformations before reaching the perfect state. Immediately after hatching, it is a true tadpole. The tail is well formed, but the head, trunk and yolk sac are enclosed in a sphere. It swims in this state and the eyes are visible, but there is no distinct mouth. It does not form until the second or third day. Five days later, eight days after birth that is, what was in the remainder of the sphere is reabsorbed, and the little animal is fully formed.

"Throughout these transformations, the male continues to provide the embryos with the same care he has given to the eggs. He swims in pursuit of those who escape from the foam, inhales them into his mouth and brings them back into the protective shelter. I saw him, most likely saving his strength, collect eight or ten in a single hunt and saw no injuries or any damage to the fry. This lasts until the number of repairs to the nest tries his patience, and he signals the end of his task and abandons his offspring to themselves.

"This transport of eggs to a foam floating on the surface and the mode of incubation is quite different from that of he fish in our climates, and may be shared by several other Chinese species. It is said that the ability to collect the sperm in great abundance by damming steams with weirs and mats is the means implemented by the Chinese who make a trade of stocking rivers and lakes with these fishes. So far I find this somewhat difficult to believe.

"My seventeen Chinese fish, reduced to sixteen by the death of a female and in which consists of twelve males and four females, provided me with six broods in three weeks. Some of them even started for the third time eight days apart, an astounding fertility. In five days the abdomen of the female, flat and compressed after spawning, bulges again; spawning seems to be intermittent in this species and is repeated every eight days during the summer.

"My difficulty slowing me down now is the kind of food to give these 6 to 8 mm in length fry, since they refuse all food not moving. In vain I tried flour, egg yolk powder, crushed meat, flesh, fish, beef liver; nothing worked. They would eat live prey, but newly-born Daphnia are four times too large for them.

"This caused me to lose a thousand fry, but I still have many that are strong and I count on the fertility of my females. I am experimenting with patience and courage and do not despair of success in breeding them. The rearing of this fish may not be easy but. be that as it may, it is quite remarkable."

APPENDIX III: "MŒURS D'UN POISSON DE LA FAMILLE DES SILURES, LE *Callichthys fasciatus, CUV.*" ("CUSTOMS OF A FISH FROM THE CATFISH FAMILY, *Callichthys fasciatus, CUV.*"

"I have in my possession a number of individuals of the species from the river Plate called Callichthys fasciatus, Cuv. [*Corydoras paleatus*]. This species is characterized by two barbels at each angle of the upper lip, two rows of broad and strong scaly plates that

cover the flanks and intercept the lateral line, and two dorsal fins, of which the second (adipose) is furnished like the first with an osseous ray. These fishes, as I have ascertained, frequently take in a provision of air at the surface of the water; but their most interesting peculiarity consists in their mode of copulation and reproduction.

"At the moment of fertilization, the female brings together her ventral fins, after the fashion of two open fans united by their edges, and thus forms a sort of cul-de-sac, at the bottom of which the aperture of the ovaries opens. The male sperm is contained in a sort of membranous sac, and a few moments afterwards it arrives at the female's opening where the eggs find themselves bathed in a liquid very rich in spermatozoids.

"Each such union consists of five or six eggs, which the female retains for a few minutes in the pouch thus described; then she quits the bottom to search for a favorable spot for their development, her choice leading her in preference to a well-illuminated part, such as the glass wall of the aquarium, or a stone submerged in the water. With her mouth, she cleans a place at least 4-6 inches below the level of the water; then, applying her abdomen to this substrate, she opens her sac and the eggs, which are adhesive, are attached.

"All the eggs being deposited, contact with the male recommences; the positioning of the eggs follows one another forty or fifty times in the course of the day. I estimate the total number of eggs released at about two hundred and fifty. I should note that the spawnings I have observed always started between 9 and 10 am, and terminated about 2 pm.

"At the moment of deposition the eggs, arranged in groups of from three to five, are of a milky white coloration but slightly transparent. Afterwards they become yellowish, and at the moment of hatching, i.e. from the eighth to the tenth day of incubation, they become blackish; this latter coloration is due to the pigment spots which cover the body of the embryo.

"At the moment of their birth the fry are globular in shape. At first one can only distinguish the four barbels; the umbilical vesicle, which is semitransparent, is not very large. The fry holds itself in a normal position, not lying upon its side like that of most other fishes. The tail and the other fins appear quickly. These latter developments last on the average three days, during which time the fry lead an independent and isolated life. When this period is past, i.e. from twelve to thirteen days after egg deposition, the youngsters collect together and move about the bottom of the aquarium. The growth of this fish is not very rapid; it does not become adult until two years after its birth.

Corydoras paleatus

"An interesting fact is the variation in the month of reproduction in our Callichthys. At La Mata it breeds during October and November. After arriving in Europe, a year passed without them producing young. In 1878, the spawning took place in August and September. This year (1880) they spawned in the month of June. Evidently there has been an adaptation

to our climate, the temperatures of which are the reverse of those of South America."

APPENDIX IV: "LE GOURAMI ET SON NID."

"In recent years, I have had the pleasure of describing for the Société d'acclimatation the curious and interesting habits of certain species of fish of the air-breathing order, labyrinthiformes.

"During breeding, the males use their bright colors to attract females, build a nest to house the eggs and provide attentive and efficient protection to their offspring during their embryonic development as well as after hatching. These facts indicate an instinct in these fish that is developed to the highest degree, revealing faculties hitherto believed only possessed by animals higher in the animal kingdom. These are the Macropodes [*Macropodus*] of China and Colises [*Colisa* species] of India.

"The study of a fish of the same family, the Gourami (*Osphronenus olfax*) [*Osphronemus goramy*], whose name has often been mentioned in this forum and in the Bulletin of the Society and that has made known to those who were unable to attend our meetings, gave me no less profound astonishment and admiration, and comparing my present observations with those I have already made with regard to the behavior of the Macropodes and the Colises, I am tempted to conclude that in all fish of this remarkable air -breathing order, nest-building is essentially based on the formation of an aggregate of air bubbles in which the male deposits or provides for the arrival of the eggs.

"I will not attempt to give you an analysis of what has been said and written about the Gourami or refute the many theories issued thereon by various authors; my role is more modest. They based upon observations with my own eyes and I will endeavor to give you the most accurate information. The five hundred hatched in my establishment in July last and whose current size varies from 1 to 2-1/2 inches, is convincing testimony as you can see from the specimens I now have the honor to present to you.

"The Gourami is a freshwater fish of India, remarkable for the uniqueness of its physiology, its size and the taste of its flesh. Many travelers report having seen them weight twenty pounds and more, and that their flesh was delicious. From recent and reliable information I have learned that in the markets of Calcutta where fish is sold live, its weight rarely exceeds 9 pounds. Gouramis are found in freshwater in the Netherlands East Indies, China, Réunion - where it was naturalized in the last century - and in French Guiana, where it was imported later.

"The body of the Gourami is slightly discoid, that is to say high and laterally compressed; the snout is at an angle exceeding 90 degrees, the mouth is thrust outward; the lower jaw extends a little more than the upper and in the male becomes thicker with age. In the course of the first year, the latter is pointed and the lips project slightly.

"At birth the dorsal and anal fins extend beyond the caudal fin, the latter being short and rounded. The rays of the dorsal fin can fold into and disappear entirely in a furrow that extends over the entire length of the back, which allows the fish to pass easily through the branches of aquatic plants. This character is less apparent in the anal fin.

"The ventral fins are reduced to the first ray, which develop into a long filament that extends the length of the body, and is endowed with an extreme flexibility. The fish can position them forward, backward and sideways, an organ certainly of touch and of great sensitivity.

"Metaphorically speaking, for me the Gourami is a great coliseum, whose development changes according to the areas inhabited. As for color, I never saw a more variable fish. The bottom of its dress is brown, the fins are darker. Greenish blue stripes crisscross his body transversely, but in winter they are not seen. Ordinarily this fish is dull and earthy,

but with the approach of the warm season and the time comes for spawning, it takes on a wedding dress that is second to nothing, including that the Macropodes of China.

"Cuvier assumed that the pharyngeal cells observed in the fish from this family were designed to store water, dripping it on the gills to keep them in a state of moisture favorable to the oxygenation of the blood coming from the heart. I was able to demonstrate that out of water, these fish do not live longer than the carp and tench of our country, and that the cells in question are reservoirs of air that the animal is obliged to renew at the surface to maintain its respiration in stagnant waters. (See the *Proceedings of the Academy*, February 16, 1874.)

"When the oxygen in the air contained in these reservoirs is absorbed, the Macropode expels the old bubble and immediately takes in another at the surface. The Gourami and Anabas reject the old air bubble before taking in another; Colise Arc-en-Ciel [*Trichogaster fasciata*] sometimes expel the old bubble through the mouth and sometimes through the gills.

"It is now amply demonstrated that all fish air-breathing labyrinthiformes can draw on the oxygen they need to breathe either from the external air or from the water.

"This has greatest importance in relation to the ease of transportation of these animals. Indeed, one simply puts them in a large container filled two-thirds and it need not be renewed. It is this knowledge that allowed us to transport them successfully in the same water for more than five weeks; without this ability, they never would have survived crossing the tropics. Forty-four Gouramis arrived in Paris in the same water (the Ganges), and only two were dead.

"But why is it that the many attempts that have been made over the last century to introduce the Gourami in France did not succeed? The reason seems to me very simple. Importers, believing that they were doing the right thing, completely filled their water jars and stretched a canvas or something similar over the surface of the water in order to prevent a fish that sometimes leaps more than 10 inches high from jumping out; also, any abrupt replacement of a large part of the water where there is a large difference in temperature can also contribute to any failure to bring them back alive.

"This method of breathing is, I believe, an insurmountable obstacle to the acclimatization of the Gourami in waters that may freeze over.

"In 1873, the first two shipments of these fish were sent to me from India by Paul Carbonnier; the individuals shipped being too large, however, they died during the crossing of the Red Sea.

"On December 11th the same year, Dr. Danion, a doctor on one of the Messengers ships, brought me seventeen live fish that had been entrusted to him by my nephew [i.e., Paul Carbonnier]. I introduced them at the next meeting on the 12th [i.e., a meeting of the Société d'Acclimatation], without providing a name since I wanted make sure in advance that I actually had Gouramis [Gourami was the common name given at the time to *Osphronemus goramy*, named by Lacepede in 1802; we sometimes refer to it today as the "Giant Gourami"].

"Monsieur Autard Bragard, who a few months ago brought back several specimens of this species that were deposited in the Museum, recognized mine to be young Gouramis. Drawings that Monsieur Mesnel had made of this fish for the magazine *Pittoresque* [*Picturesque]*, and illustrated in the work of M. Millet in *les Merveilles des fleuves el des ruisseaux* [*The Wonders of Rivers and Streams*], reduced my suspicions to certainties, and at the next session in December 1870 I had the pleasure to announce that we had seventeen Gouramis living in Paris.

"Therefore, I made every effort to acquire new shipments. Our illustrious President, Mr. Drouyn Lhuys, arranged for me to travel by express on the Paris-Lyon-Méditerranée route with all of the containers I had designed for

transport and, with the help of many engineers on the ship the *Courier*, the Company was rewarded for their dedicated efforts since one hundred and eleven Gouramis were alive in Paris in 1874.

"Now, gentlemen, I found it difficult to keep these fish alive in our relatively cold climate and to breed. This part of my work will, I hope, be less boring. If I have put three years of tireless study and breeding into this species, I have been richly rewarded: first by finally achieving success, and then by the opportinity to describe the scientific discoveries that allowed me to do so.

"In the spring of 1874, I noticed that the shape of my fish had changed; the body elongated a bit as did the height proportionally. The head ended in a blunt tip and the lips – especially that of the males – swelled significantly. Some of them had become almost completely discoid. Finally, as regards their coloration, these younger fish were quite different. I did not think that at this size they would breed, but after reading the memoire of Baron Roujoux in the Bulletin of August 1801 where he said that the Gourami can reproduce while being small, and noting that those of Guadeloupe [a small French island in the Caribbean] resulting in a degenerate race whose individuals became become smaller and smaller with time, the thought of a possible breeding scheme came to me with the aim of improving the species by careful selection. To this end, I isolated several pairs of fish in different aquariums, but the results were negative.

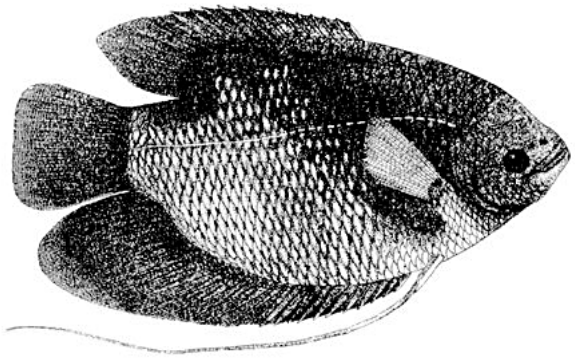
"In the spring of 1875, I placed them all in a 13 foot diameter pool where the water was maintained during the summer at a temperature of 68-72 degrees Fahrenheit; the fish broadened out a bit, but did not spawn.

"I had known that whenever a young fish is starved for about three or four weeks, the skeleton is formed and it cannot grow any larger no matter what food regime is then offered. Such was the case of my Gouramis who had gone without food during the long trip.

"Finally, in October 1875, the temperature fell significantly so I decided to collect my fish and bring them back to Paris. I found more than twenty-two alive, the others dead from causes that I could not determine, and last spring, no more than fourteen individuals were left. This time, if I were not to lose the species, I needed to try an experiment, i.e., to raise the water temperature to a level favorable for breeding. In the month of June, I placed my fourteen Gouramis in a 53-gallon aquarium and, using a gas heating system, I maintained it at a constant temperature of 77 degrees Fahrenheit.

"Within a short time the fins of male fish were the most vivid of iridescent colors; the throat became blue, the stripes took on a green tint and the anal fin took on a blue-steel coloration bordered by an orange line throughout all the twists of its serrations. The

THE GIANT GOURAMI (*Osphronemus goramy*)



dorsal fin, blue-steel like the anal fin, and had a border across its length of a white stripe. The two ventral fins, black at their base, were the most beautiful reddish orange along the rest of their length.

"The males, nine in number and adorned with bright colors, pointed their ventral fins forward, constantly copying each other and flaunting their beautiful costumes.

"It was a combat zone in the rivalry for the possession of a female. The females, five in number, nestled in the bottom of the aquarium, watching the fight and waiting impatiently for the final result. If one of them dared to enter this arena, she returned bruised.

"The females had nothing in common at this time with the males who leapt out of the water; if one of them picked up air at the surface, the others would simultaneously rush to the spot.

"On June 27, the lips of the most beautiful male were swollen beyond measure. I also noticed that all the other males seemed to recognize defeat because no one dared approach him. The iridescence colors had disappeared in the losers, and he alone, by his brightness and vivacity of movements, seemed to assert his supremacy. All the females now had recognized their master, because they did not take their eyes from him and sought his company from the rest. Among this group of females it was not difficult to distinguish his favorite, although at first glance her abdomen did not seem more swollen than that of the others. I saw the male pay her more attention, bending around her with more elegant curves of his body.

"On June 28, the male began constructing a foam nest in one corner at the surface of the water. Ready for anything, I had prepared a variety of materials which I suspected he might need. In a few hours the nest reached a considerable size, 6 to 7 inches in diameter and 4 to 5 inches in height. The next day the nest was scattered about, the froth floating to and fro over the surface of the water. I suspected that during the night a great struggle took place and I immediately took the opportunity to remove all but the two breeders. My idea paid off and soon a new nest was built, constructed partly with materials from the old nest and with new bubbles produced by the male.

"In the Chinese Macropode the male takes in the air bubbles and ejects them directly under the nest of foam; being impregnated with mucus supplied by the buccal membrane, they maintain their shape. The Gourami's mouth, however, does not appear to secrete as much mucus. It is part of the male's job to find the construction materials that may be at hand and then to collect those that seem to fulfill the requirements and bring them to the nest.

"To this end, he goes to the surface of the water, turning his back to the nest, and takes in atmospheric air, ejecting it in the form of gas bubbles. During this activity, any poorly constructed bubbles are destroyed; only those whose envelope has adequate strength are collected and deposited in the nest. By this time, the mucous secretion seems to be more plentiful and if the male is not successful in finding materials with which to bind the nest, then it descends to the bottom of the water in search of some aquatic plants, preferably confervae. This he takes in and chews for a few moments. These plants undoubtedly stimulate the buccal membrane that excites secretion, like in humans where the secretion of saliva and gastric juices is initiated by spices.

"By the evening of July 4th, a very large globular nest was floating in my aquarium. The male positioned himself below and watched attentively; he would not allow one finger to touch the glass and risked killing himself by rushing furiously headlong into it. Whenever the female approached, the male showed his satisfaction in his position below the nest by his display of splendor and bright colors. At one point, his body had acquired sufficient flexibility to clasp the female and lead her to the nest for the first spawning; other egg releases soon followed and were repeated nearly forty times in three hours.

"A colisa Macropode would have no trouble in collecting the eggs and put them in order in the nest. The Gourami, however, does not seem to know how to take them into his mouth and bring them to the surface. It uses an odder ploy, facilitated by the arrangement of its branchial (gill) lamellae.

"After each release of eggs, which are nearly the same density as water, they float to and fro in the aquarium. The male rises to the surface to obtain a goodly quantity of air and then lowers himself well below the eggs. Suddenly, by a violent contraction of the membranes of the mouth and pharynx, it forces the air within the mouth to escape through the branchial gaps, divided into tiny bubbles by the lamellae and fringes of the gills as it is sprayed out. The violence of the expulsion is such that it produces two jets of a blast of air that envelopes the eggs and carries them to the surface.

"Nothing is more curious than to see this maneuver of the Gourami male as it almost completely disappears in the middle of a veritable fog of air and when at last this is dissipated, air bubbles resembling thousands of tiny beads reappear, clinging to the rough scales and rays of his fins.

"I estimated the number of eggs that were deposited in the nest to be two or three thousand, from which I did not obtain more that 600 fry, most eggs being infertile.

"The initial incubation period is three days; after this period, a series of changes begin similar to those I have already reported for other species. The tadpole swims belly up and has the shape of a ball ending with a small tail. After an additional three days, that is to say six days after hatching, the embryonic period is now completed and a number of the bolder fry venture out and attempt to escape the paternal eye. The male pursues these fugitives and some are even sprayed by the jets of air because of their boldness. This brings them to the surface and back into the cradle of the family.

"The first appearance of young Gouramis takes place at the surface of the water, and at this age they already draw atmospheric air, the element indispensable to the existence of all the fish of this family.

"The father gives up his parental responsibilities after ten days after birth, letting them wander to suit their whim.

"Observing the development of the young Gouramis, one is struck by their rapid growth; in sixty days, mine reached an average length of 2 inches. It is true that in July and August this year the temperature in Paris was very high, but it is also due to the action of light on the development of the fish of this family, a fact to which I call the attention of naturalists.

"In their country of origin, where the length of the day is roughly equal to that of the night, it is normal and customary that fish growth occurs throughout the twelve months of the year. In our country, these lengths are not the same. When the length of night exceeds that of the day, there seems to be a complete cessation in their development.

"Those of you, gentlemen, who have raised Macropodes have observed this fact. During the winter days no progress is made in growth even though the water temperature is maintained at the same level as in the summer. But when March 15th approaches, a sort of awakening occurs and these fish grow more rapidly, continuing as the length of the

day increases and number of night hours decreases.

"After removing all of the fry and providing the necessary care for them, I soon saw the male get back to work. He build a new nest at four-week intervals but unfortunately, after an accident that caused the death of the female, the male suddenly abandoned his job and lost his breeding colors overnight. Fish of this family of air-breathers seem to feel strong ties to each other.

"I have observed several male Macropodes, whose females were jumping out of the aquarium, lose all their colors in a few hours; the same behavior seems to occur in the Gourami.

"Perhaps I have spent too much time in relating all these facts relating to the breeding and spawning of the Gourami, the hatching of the eggs and the various phases that follow. These facts, as I have reported them, have at the same time prompted the question that I now ask. Can these laboratory studies, as I may call them, be turned into practice. Is the Gourami likely to acclimate in our temperate countries?

"I hardly dare to share with you some thoughts about this question that came to me during the long and painstaking observations I made with this fish. I do not believe in the possibility of its acclimatization in our country. Regarding its necessity to breathe atmospheric air, it would be impossible to do so in our ponds or streams whose surfaces are likely to freeze in the winter. Together with the kind of asphyxia that I have seen in my aquarium experience when, during cold weather, air at a much lower temperature than the water in which it lived was taken in, these facts seem to discourage any attempt in this direction.

"Over time I have been able to observe the Gourami in the summer and in the beginning of inhospitable times. I saw that the fish can live, in a mild winter, in water of a temperature not lower than 50 degrees Fahrenheit. In one case, which unfortunately I cannot state is an exception, when a sudden lowering of the temperature brought the water down to 43 degrees, many fish died but others survived. Added to this is the fact that when the cold season arrives, the breathing of the Gourami slows down, as indeed happens in other fish. I have even observed several specimens that wound up in the mud remain there for several weeks in a state bordering on suspended animation.

"One word more, Messieurs, to describe the conditions under which I think breeding of the Gourami should be attempted: shallow water, but with a large surface area that is exposed to sunlight in the warm season and is therefore heated; a very active aquatic vegetation, giving rise to an abundant amount of oxygen adhering to its leaves that the Gourami eagerly takes up (and it is worth noting that, even under these conditions with access to oxygen of a high state of purity, the fish still goes up to the surface of the water to renew its oxygen reserves); and a bottom of mud or clay that allows it to sink into, providing a shelter against the adverse effects of temperature changes. Such conditions are those I think will be useful in testing out the Gourami set free in nature.

"About its food, it consists of plant debris and the various insects and small animals that live and grow in the water.

"It is here, gentlemen and honored colleagues, that I depart from my humble role of observer; it is now up to you who have given us so many examples of the practical sense you have made from the application of the general observations and results that our research and laboratory studies have provided. If my predictions are correct, one day is not far off when perhaps where we reach a goal most hotly pursued by our Company: the Gourami, a tropical fish living and thriving in the freshwaters of southern France and Algeria."

Emil Adolf Rossmässler, Father of the Aquarium Hobby in Germany

by Albert J. Klee, Ph.D.,

Aquarium Hobby Historical Society, Yahoo Files, January 5, 2013

Emil Adolf Rossmässler was born in Leipzig in 1806. His family, like many others, was struggling economically due to the Napoleonic wars. At an early age he developed an interest in science and a skill in drawing that was passed on from his father, an engraver. From his school days at St. Nicholas, the school of his native town, he acquired friends who had similar interests, among them Theodore Velcro, the son of a wealthy copper works merchant, who had a Herbarium and a Mollusk collection at his disposal. Theodore was his constant companion when they collected snails, mussels and plants. Emil lost his parents early on and was thus partly dependent on the altruism of relatives and partly on his own unskilled labor, such as the copying of correspondence, lessons and books.

On Easter of 1825 he entered the University of Leipzig. He would have preferred studying medicine but his uncle, who then was in *loco parentis*, found this to be too expensive and so Emil fulfilled a wish of his deceased mother and became a Protestant theologian. Finding his theological studies rather dry, being based mostly on the study of manuscripts and letters, he spent a great deal of his spare time studying botany, the tuition for which was supplied by a sympathetic professor. He was so successful in this field that by his second year he was teaching botany to pharmacy students.

In 1827 Rossmässler went to the Thuringian town of Weida to accept a teaching position, and happily remained there for 2-1/2 years. One fruit of this stay was some work with plants. In 1830 his treatise, "Contribution to the knowledge of the flora in Weida's Gross-herzoglich-Sächsische Neustädter circles," appeared in the journal *Flora*, and a year later in the same journal, "Plantae Lipsienses, Weidanae et Tharandtinae." He also provided input to H.G.L. Reichenbach's "Flora of Germany in dried specimens." The latter work was done so well that he was offered the post of professor of zoology at the Royal Academy of Forestry and Agriculture in Tharand (a town in Saxony), although he was asked to first acquire the necessary qualifications for the post.

Thus Rossmässler left Weida on Easter 1830 for his home town to prepare for his new teaching position, moving in June of the same

Figure 1: Emil Adolf Rossmässler (1806-1867).

Figure 2: The Four Seasons, by Emil Adolph Rossmässler, 1856

year to Tharand. His thesis was on the zoological spruce weevil that had just devastated Tharand's pine plantations. In 1882 he published his "Systematic survey of the animal kingdom" containing a collection of his drawings. In 1834 he did another on the insects of Tharand's forests. He prepared teaching guides for his students that contained drawings that lent clarity to the texts and afforded an opportunity to examine the extent of his knowledge. With particular zeal but also with great success, he took up the study of land and freshwater mollusks that he had started in his boyhood.

In September 1832 he spent several weeks in Vienna and there conducted research, collected, and recorded with untiring zeal. He returned with a storehouse of rich material that spurred him to a fruitful literary activity in the field of mollusks. "Diagnoses conchyliorum terrestrium et fluviatilium (in two volumes)" appeared in 1834, followed in 1835 by the first volume of his obra maestra, "Iconography of the land and freshwater mollusks," an outstanding feature of which was its many high quality drawings of hitherto un-illustrated European species. In the last plate of this volume he made his first attempt at lithography. Only the first plate of the second issue showed his drawings; all subsequent illustrations were his lithographs. He made progress in this art from issue to issue; thus the images of the last volume are the most beautiful.

In 1835 Rossmässler led an expedition to Trieste in the Karst Mountains, and afterwards went on to Carinthia in the Alps. In early 1837 he arrived in Berlin where he met the most important living naturalists such as Alexander von Humboldt, Von Buch, Ehrenberg, the brothers Gustav and Heinrich Rose and other well-known men who inspired him to think along new lines. After the uninterrupted publication from 1835-39 of the Iconography, the professor of mineralogy in Tharand retired due to age and illness and Rossmässler took over his position, including leading the mineralogical excursions of his pupils. This caused him to deal with geology in detail, processing the plant imprints of the Altsattel lignite basin from the rich fossil collections of the Heinrich Cotta.

Under the title: "Contributions to Fossilization," Issue 1 with 12 plates appeared in print in 1840. After the death of Prof. Raumer in the summer of the same year, he delivered lectures on plant physiology and therefore now felt once again stimulated to literary production in this field, an example of which was "The Main Things About the Internal Structure and Life of Plants," which was published in 1843 and that presented the most important scientific

knowledge in this area in a way understandable by the practical farmer. Despite this heterogeneous activity, in 1842 the eleventh and in 1842 the twelfth issues of Iconography appeared.

Politically, Rossmässler was quite active. In 1848, he belonged to the Funfzigerausschuss, a committee to set up a permanent committee of the Frankfurt pre-Parliament [the Frankfurt parliament was the first democratic one in Prussia, existing from 1848 to 1849 when the King took over again]. From May 1848 to June 1849 he was a deputy for Pirna in the Frankfurt National Assembly. He belonged to the moderate left factions, first with the German court, and later with the Nurnberger court.

In 1845 Rossmässler had converted from the Protestant to the Catholic faith and by 1846 his inclination towards the creation of the Ronge'schen Deutschkatholicismus - a schismatic sect formed in December 1844 by German dissidents from the Roman Catholic Church, under the leadership of Johannes Ronge - had been adopted formally. For religious reasons, he heavily criticized what was evil in the government at the time, in particular as a member of the Frankfurt Parliament where he was particularly active in the School Committees, and this made him unpopular with the Government. He was among a group of deputies who fled to Stuttgart in 1849 to establish a Rump Parliament until they had to give way because of the violence they encountered. Accused of treason, he was found not guilty. Therefore, in the summer of 1849 he retired at his own request with a little less than half of his previous income. Compelled now to write for money, he became a science writer for the people.

Besides his writings for the popular press, Rossmässler was advocate in supporting educational opportunities in the form of local galleries and museums, the formation of natural history societies in the form of "Humboldt associations," and to the creation of Workers' Education Associations. He was a founding member in 1861 of the Industrial Educational Association in Leipzig, and founded the German Workers Union convention which, after his death, became the Social Democratic Party. In 1865 he brought in the first woman member in his local Education Association. After a prolonged bout with kidney and bladder disease, Rossmässler died, surrounded by his family, on April 8, 1867.

ROSSMÄSSLER'S WORKS

In Tables 1 and 2 I have listed Rossmässler's most important works and also his contributions to the *Die Gartenlaube* (*The Arbor*) to

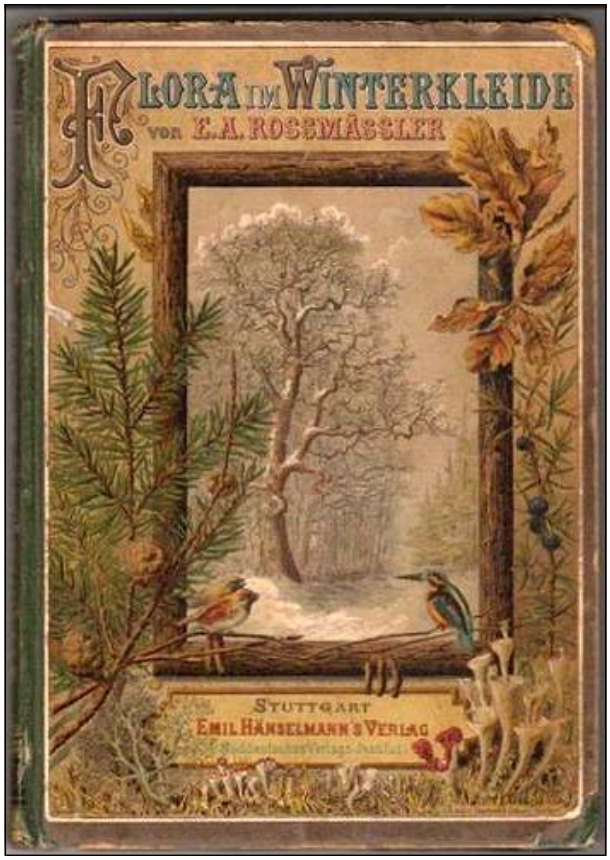


Figure 3: Flora in Winter Dress, by Emil Adolph Rossmässler, 1856

TABLE 1: PUBLISHED WORKS	
1832	Systematic Overview of the Animal Kingdom.
1833	Iconography of the Land And Freshwater Mollusks (3 volumes).
1840	Contributions to the Study of Fossils.
1843	The Main Things About the Internal Structure and Life of Plants.
1847	A Study of The Anatomical Characteristics of the Woody Parts of the More Important German Trees and Shrubs.
1850-1853	Man in the Mirror of Nature. (5 volumes).
1852	Popular Lectures in the Field of Nature. (2 volumes).
1854	Travel Memories from Spain. (2 volumes).
1856	Flora in Winter Dress.
1856	The Four Seasons.
1856	The History of the Earth.
1857	**The Freshwater Aquarium.**
1858	Water. Second reproduction edition in 1860.
1859	Man and the World of the Sea.
1860	Natural History Lessons.
1862	The Forest.
1860	The Natural History Lesson - thoughts and suggestions on a reorganization of the same.
1863-1868	The Animals of the Forest. (2 volumes, together with Alfred Brehm).
1856-1859	*Nature* (Journal published by Otto Ule and Karl Mueller).
1859-1866	*From the Home* (Rossmässler's own magazine).
1868	For Free Hours.
1868	Microscopic Views. (Collection of Rossmässler's lectures).
1874	My Life and Ambition. (Autobiography, published posthumously by Karl Russ).

show how his writing and his audience changed after leaving public office. I have also bold-faced the two entries that had a significant effect on the aquarium hobby in Germany. First, a few words about *Die Gartenlaube*, since Rossmässler published a great many of his popular articles there.

TABLE 2: ARTICLES in the *GARTENLAUBE* (*THE ARBOR*)	
1853	Spanish Travel Letters, I-VIII.
1856	Botanical Lectures for Women. First the Plant System.
	The Lake in the Glass.
	A Note.
1857	Hard and Brown Coal and Peat. First article.
	Hard and Brown Coal and Peat. Second article.
1858	The Avalanche.
	Hard and Brown Coal and Peat. Third Article. The Appearance of Coal.
	The Blackthorn.
	A Ruin of the House [an article about snail shells].
	Hard and Brown Coal and Peat. How was coal created?
1859	Pearls. First half - Interior construction and development of the pearl.
	Second half - Pearl luxury, pearl fishing, pearl trade.
	An International Congress of the future [on preserving the world's forests].
1860	On the marble deposits of Rübeland [noted for its caves, grottos and rock masses].
1862	The Rosenlaui glacier [located in the Swiss Alps].

Die Gartenlaube - Illustrirtes Familienblatt was the first successful mass-circulation German newspaper and a forerunner of all modern magazines. Its complete title translates into English as *The Garden Arbor - Illustrated Family Journal*, but throughout its history it was known simply as *Die Gartenlaube*. It was started in Leipzig, Germany in 1853 and although Brunner (Brunner, 2003) credits Rossmässler as being a co-founder of the magazine, the founders actually were Ernst Keil as publisher and Ferdinand Stolle as editor. The objective was to reach and enlighten the whole family, especially the German middle classes, with a mixture of current events, essays on the natural sciences, biographical

sketches, short stories, poetry and full-page illustrations. Between 1853 and 1880, works by prominent German writers, such as Goethe and Schiller, dominated its pages and at one time it claimed to have the largest readership of any publication in the world. Although its publication has long since ceased, Die Gartenlaube remains important for comprehensive historical analysis in many fields and is regarded as an essential source for the understanding of German cultural history.

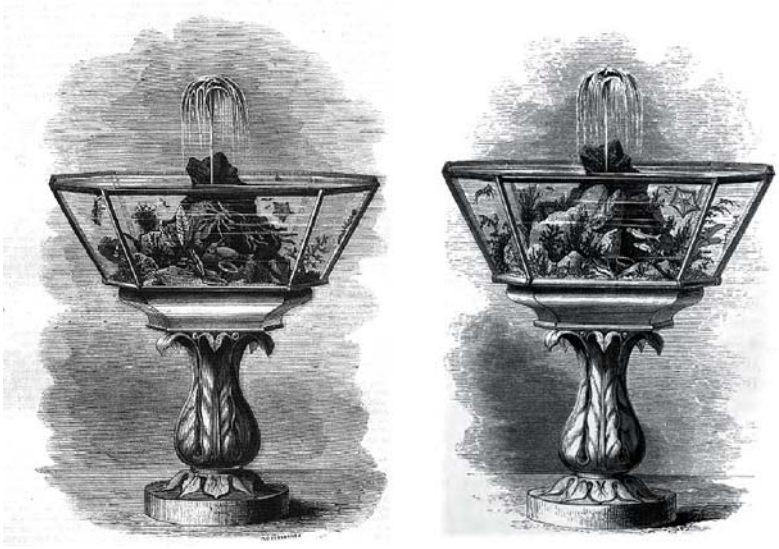

Figure 4: The left image is taken from the 1854 article, "Den Ocean auf dem Tische"; the one on the right is taken from Gosse's 1854 book, "The Aquarium."

In August of 1854 in Issue 33 of a monthly section called "Blätter und Blüthen" ("Leaves and Flowers) in *Die Gartenlaube*, an unsigned three-page article appeared titled, "Wie er- und Behält man den Ocean auf dem Tische, oder das Marine-Aquarium" ("How one keeps the Ocean on the Table, or the Marine-Aquarium"). This essentially parroted information about the marine aquarium derived from British sources. Indeed, Figure 4 shows a side-by-side comparison of the lone figure in the article with one taken from Gosse's book, "The Aquarium: an unveiling of the wonders of the deep sea;" the images are, barring a few minor details, identical.

In May of 1856 in Issue 19 of *Die Gartenlaube*, Rossmässler's first article on aquarium fishes appeared, "Der See im Glase" (the Lake in the Glass"), with the following introduction:

"Besides the "Ocean on the Table," which is now so widely acclaimed in English coastal towns, we should add "the Lake in the Glass" in which inland residents have a special interest. Both are encouraging signs of the daily increasing taste for nature, and following the description of the former in No. 33 of *Die Gartenlaube* last year by another author - the first article about the aquarium to appear in Germany - we present here now a description

Figure 5: A cover from *Die Gartenlaube*.

Figure 6: The image from "Der See im Glase," 1856.

of the "Lake in the Glass" and a comprehensive guide to its furnishing and care.

"When the Ocean on the Table - or whatever one calls this decorative and instructive artifact also referred to as the aquarium - first became known from England, I could have kicked myself when I realized that, as a student of nature dedicated to the popularization of this wonderful science, it was my usual habit for many years to make scientific observations of aquatic animals and plants in large glass containers, but I overlooked the possibility of using it as a new way to awaken and nurture its scientific sense among the people. The recent events that have led to the production of glass containers and stands after many unsuccessful attempts have only just now led to the desired results, and now as spring has returned after a long and hard winter, we eagerly fill these vessels with life."

That Rossmässler saw the aquarium as a tool to advance the cause of popular science, especially with children, is shown in the following taken from his article:

"An aquarium in the home is an effective way to introduce an intimacy with nature into a child's world. Kindergartens and schools – yes, even the best of schools - should make use of it. It sharpens the eye and focuses it within a circle of serenity previously unnoticed. For the child with an inquisitive mind, the story of the development of snails and that of many insects and frog-like amphibians provide not only something interesting to talk about, but useful knowledge as well."

The three champions of the aquarium in its early development were Gosse in England, Carbonnier in France and Rossmässler in Germany, but the three were motivated quite differently. "Des Menschen Wille ist sein Himmelreich" ("His own desire leads every man") is an old German proverb, and thus Gosse used the aquarium to extol the glory of God, Carbonnier viewed it as an opportunity to increase the population of new fishes introduced into France and its possessions, and Rossmässler saw it as a means of educating the masses in the natural sciences.

Rossmässler advances a rather weak argument for the freshwater aquarium when he states, **"For its part, the freshwater aquarium has the decided advantage of the combination of animal life cavorting about below the water level and green plants rising joyfully above them, while in the marine aquarium, everything must stay under water,"** referring to the type of aquarium pictured in his article of a small girl watching the creatures moving about (Figure 6). In this tank the plants emerge from the water and tower over the tank, leaving very little room within the tank for the fish.

Brunner (loc. cit.) spends some time asking why there was this sudden change in interest from saltwater to freshwater aquariums and offers some metaphysical explanations based upon the serenity of the latter. I think his first answer is closest to the real reason, i.e., **"… had the handling and maintaining of saltwa-**

ter aquariums already come up against too many limitations?" It is true that in the matter of interest on the part of the public, the marine aquarium has always won hands down. In a public aquarium, visitors flock to the marine exhibits while the freshwater tanks are quickly passed by. However, these institutions have the resources and the trained staff to maintain saltwater collections, whereas the average person of the time did not. Marine tanks were difficult to maintain even with easy access to salt water, and artificial salts were never a success in the Nineteenth Century. Carbonnier had it right when he stated in his "Practical Guide to Pisciculture" (Carbonnier, 1864), **"It remains now to provide some background before stocking the aquarium with plants and fish, and to discuss the care required to achieve the desired results. They will pertain especially to fresh water, for which we believe holds no secrets."**

There were no secrets – at least no insurmountable ones - to maintaining the freshwater aquarium; the success of the marine aquarium, on the other hand, had to wait until the Twentieth Century when technology came to its rescue, albeit at a much higher cost than its freshwater cousin.

Table 3 shows the amount of space Rossmässler devoted to the different topics he discussed in "Der See im Glase." Not surprisingly, plants and snails – his early interests - account for over 60 percent, whereas fish took up only five percent. With regard to plants, Rossmässler described 51 different kinds but these were to be decided by the kind of aquarium it was designed to be:

"Before I describe them, readers will have to deal first with the question of whether they want their plants to be just part of the landscape or whether the aquarium should have more the appearance of a thicket of plants." The latter Rossmässler referred to as **"…a small botanical island …with only a limited space for the fish…"**

The entire fish section is as follows:

"Turning now to the fish, keep the aquarium free of predatory types such as trout, pike and perch. Small herbivorous fish of any kind are suitable, since in this small living space their growth is restricted and they remain small. This is demonstrated by the goldfish (actually a carp, *Cyprinus auratus*), which in a pond grows to about one foot but in an aquarium reaches no more than 4-5 inches in ten years. Incidentally, the origin of the goldfish is China, the only aquarium fish imported from other parts of the world. Feed our little fish sparingly with dried ant eggs (if it is not a sacrilege for a scientist to describe ant pupae as eggs!), white wafers, bread crumbs and the like. The many little plants and animals that show up over time - this occurs also in the wild – and that can be found at the bottom of the tank, can also serve as food. As they romp blithely about in the vessels of square form and size specified on page 256 [i.e., about 20 gallons], these small minnows must imagine they are an audience for the languid fish of China dressed in gold. Let's introduce the weather fish, *Cobitis fossilis*, into the aquarium as weather forecasters, but first we must make a place for him where the sandy bottom is free of stones so that he can dig through it."

Figure 7: The cover of "The Aquarium: Instruction and Guidance for its Creation and Maintenance," by Ludwig Müller.

Regarding maintenance, Rossmässler did not advocate water changes, but relied upon the plants to remove the detritus:

"This then is only about life in our aquarium. But will it remain alive? Do we need a lot of care and effort to achieve it? How often do we need to change the water? The answer is Never. If the plants are happily thriving they will, with their roots, take up all the decaying waste materials that the animals add to the water. At this moment, standing next to the desk at which this was written, is a large aquarium whose water has not been renewed once in six months. Sometimes one just needs to top up what is lost by evaporation. Note that because the water can become overheated, the place for the Freshwater Aquarium is not at a window that is illuminated by strong sunlight for long periods. Dead fish do not escape one's attention because they lie on their sides and float on top of the water, so these larger bodies can be removed easily before they rot. Nevertheless, in those six months at least ten larger snails died and rotted in my aquarium, their empty shells now lying on the bottom, although no fish has died. That which could have endangered the animal life was immediately taken up by plants as nutrients."

LUDWIG MÜLLER
(IMPORTANT NOTE: See my essay, "A Case of Piracy and Plagiarism" on pages 631-635.)

Before turning our attention to Rossmässler's most important work, "Das Süsswasser-Aquarium," it is necessary to discuss "The Aquarium: Instruction and Guidance for its Creation and Maintenance," written by Ludwig Müller and published in 1856, a year after the debut of "Der See im Glase" and a year before "Das Süsswasser-Aquarium" appeared on the scene.

Until recently, no one was aware of the existence of this book until a German aquarist discovered a reference to it (Barford, 1902) in a short review titled, "Das Aquarienbüchlein aus dem Jahre 1856. Ein Beitrag zur Geschichte unserer Aquarienliebhaberei" ("The aquarium booklet from 1856. A contribution to the history of our aquarium hobby"). A further search found mention of it in numerous bibliographies, paperback lists and catalogs (some containing commentary on the book) dating from 1856 to the turn of the century. However, no library in Germany had a copy and it was considered a "long lost" book. Only one was known to have survived until a copy was discovered in the Harvard College Library and subsequently digitized by Google. It is more a booklet than a book, however, since it only consists of 38 pages.

The Harvard Library copy is bound but the original had only a paper cover, so it is not surprising that so few copies survived these 150 years or so.

If the book was a mystery, however, its author is even more so but more on that later.

Unlike "Der See in Glase," which contained only one image, Müller's book had 24 illustrations. There were striking differences between the two as well (see Tables 3 and 4), notably that there was much more emphasis on fish and other living creatures and much less on plants in Müller's little book. In setting up the tank and maintenance, they were about equal.

TABLE 4: BREAKDOWN OF "THE AQUARIUM. INSTRUCTION AND GUIDANCE FOR ITS CREATION AND MAINTENANCE"

SECTION	PERCENT
Introduction	5
Setting up the tank	5
Fish	10
Water insects and snails	34
Amphibians	15
Aquatic Plants	17
Maintenance	14
TOTALS	**1.00**

The following is the introduction in the book:

"As it involves little effort and without a significant expenditure of time, the display of aquariums or water tanks for marsh and aquatic animals in our living rooms has awakened in many the desire to devote a portion of their attention and observation to natural history, as a representation for which the aquarium must be considered.

"A great deal of interest has always been paid to Gold- and silver fish. The less common species of fish, however, are overlooked and the amphibians and aquatic insects that are found in our lakes and rivers are barely noticed. Through the aquarium you will get to know them better, for their basic nature and way of life, just as their exterior appearance, is a rich and interesting source of knowledge for many.

"With their characteristic discernment, the best equipped among those whose desire it is to better know the residents of our ponds and streams, are observed in women. The aquarium is both appealing and praise-worthy, and provides us with food for thought. In viewing an aquarium, a new, previously unknown world unfolds for us.

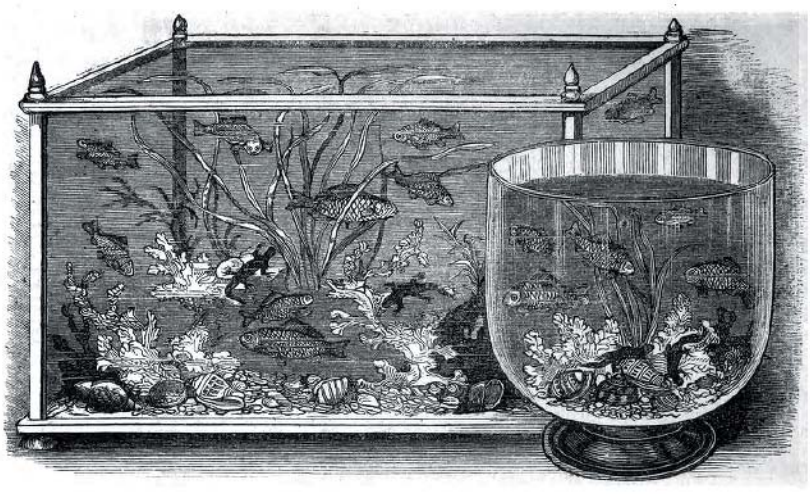

Figure 8: From "The Aquarium: Instruction and Guidance for its Creation and Maintenance," by Ludwig Müller.

"As unworthy of our attention as many of these animals may appear to us, we must keep assuring ourselves that they all, like every one of us, fill and assume an important place in God's Creation and Establishment. In nature, there are things that we do not know, and even the simplest of their virtues has some

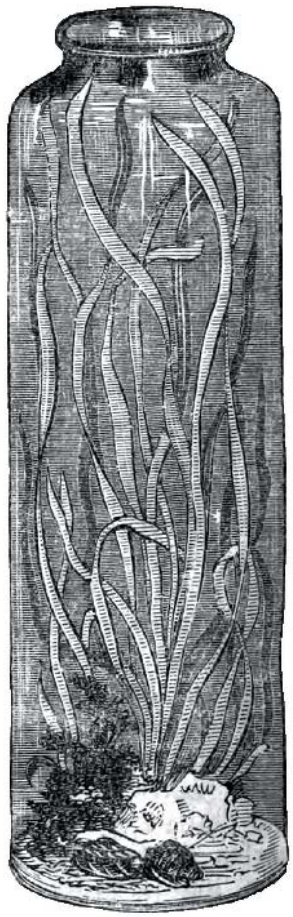

Figure 8: Vallisneria aquarium from "The Aquarium: Instruction and Guidance for its Creation and Maintenance," by Ludwig Müller.

natural and important purpose worthy of observation, for the Creator made us receptive to the beauties and mysteries of nature and instilled in us a desire for spiritual enlightenment.

"They say that to make discoveries is one of the most satisfying pleasures of the human mind, and this sentence acknowledges that we must stand firm in the truth that besides the natural history itself, this scientific field beckons to the energetic explorer, attracting him with its large depository of instructive and interesting facts. Nature is inexhaustible, and we can never stop learning. Increasingly and at every opportunity we can learn from it. The more this happens, the more thoroughly we appreciate that Divine Providence has created this wealth of resources for all of us. We proceed now to the care of the creatures that concern us."

What may surprise some is his comments on women, the first such in the history of the aquarium hobby. In addition to the above is the following taken from the fish section:

"It has long since been a favorite activity among women to keep goldfish in round bowls, and yet few have acquired a more detailed knowledge of the habits and customs of their pets required to keep them healthy for the duration of their confinement."

As for the religious references, they suggest that the author might be a clergyman. The special attraction of natural history for the clergy at the time was explained by John C. Loudon, writing in the *Magazine of Natural History* (Loudon, 1835)

"Compared even with a taste for classical studies, for drawing, painting, or any other branch of the Fine Arts; or for amateur turning, or any other kind of a mechanical employment; a taste for Natural History in a clergyman has great advantages, both as respects himself and others. It is superior, in a social point of view, even to a taste for gardening. The sportsman often follows his amusements to the great annoyance of his parishioners; the horticulturist exercises his gentler pursuit within his garden; and the classical or indoor student of any kind secludes himself in his closet or his laboratory; but the naturalist is abroad in the fields, investigating the habits and searching out the habitats of birds, insects, or plants, not only invigorating his health, but affording ample opportunity for frequent intercourse with his parishioners. In this way their reciprocal acquaintance is cultivated, and the clergyman at last becomes an adviser and friend, as well as a spiritual teacher."

Other than his book, however, nothing is really known about Ludwig Müller. There is a "Doktor" in front of his name but in light of a number of minor errors in his book, such as including two lizards and a snake in the section entitled "Amphibians," I doubt that he had a scientific education at that level, further

suggesting that his doctorate was in theology or perhaps was honorary. There is speculation that he was the author of the 24-page aquarium section in the 1857 *Naturgeschichte der Amphibien und Fische* (*Natural history of amphibians and fish*), since the illustrations in the two publications are the same, but this has not been proven. In any case, this does not shed any light on the author himself.

In the plant section Müller shows a really odd, extremely elongated aquarium (Figure 8) containing *Vallisneria spiralis (misspelled as "Valisneria," another example of one of the minor errors that anyone versed in "Naturwissenschraft" or Nature Science would not have made) and a few snails.*

In the section entitled "General remarks on the establishment and maintenance of an aquarium," Müller shows two pieces of equipment (Figure 9), a net and a method of changing water in a goldfish bowl. Rossmässler, I note, failed to provide any illustrations on this subject either in "Der See im Glase" or "Das Süsswasser-Aquarium."

At the end of Müller's book there is an interesting half-page advertisement for aquariums built by Ernst Häckel, a metal fabrication and plating factory located in Wurzen near Leipzig. Their standard sizes ranged from 26 inches to 43 inches in length and from 11-1/5 to 21 inches in height. Their prices, in terms of today's currency, were 15 gallons, $77; 25 gallons, $95; 40 gallons, $113; and 60 gallons, $140. The firm would build aquariums to order, and they boasted that the **"…biggest so far made in our factory had a circumference of 19 feet and a height of 2-3/4 feet…"**

"The Aquarium: Instruction and Guidance for its Creation and Maintenance" was fairly well-written and must have been widely available in its day since it was included in so many references and, as a paperback, it must have been inexpensive. In my view, the relative emphasis placed on the individual areas was, in my view, superior to that of Rossmässler's "Der See im Glase." However, a comparison of the two was summed up nicely in a review that appeared in the *Botanische Zeiting* for October 1856, a review in which I heartily concur:

"Its [i.e., "Der See im Glase"] scientific value strikes one as far higher than the first [i.e., "The Aquarium: Instruction and Guidance for its Creation and Maintenance."] This is further vouched for by the fact that the author is already known as a real naturalist. To this can also be added the jewelry of a truly attractive presentation, a characteristic of Rossmässler's works."

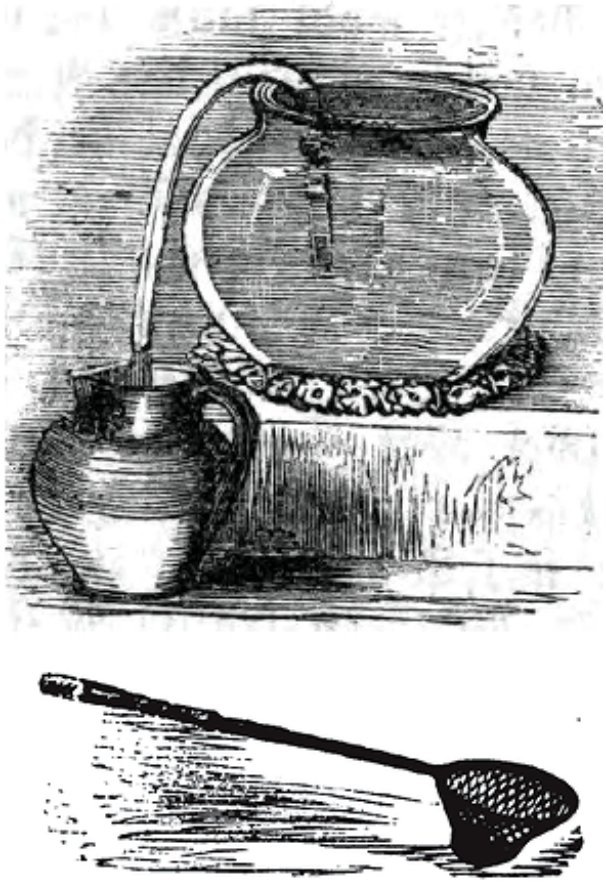

Figure 9: Images from "The Aquarium: Instruction and Guidance for its Creation and Maintenance," by Ludwig Müller.

Although Müller's book arrived on the scene before "Das Süsswasser-Aquarium," it apparently had little effect - if any - on the aquarium hobby in Germany. Not only had Rossmässler already paved the way with his "Der See im Glase," but because of his numerous articles on nature topics he was very well-known where Müller was not. In any event, the matter was settled upon the arrival of "Das Süsswasser-Aquarium."

DAS SÜSSWASSER-AQUARIUM

In 1857 Rossmässler published his famous book, "Das Süsswasser-Aquarium, Eine Anleitung zur Herstellung und Pflege desselben" ("The Freshwater Aquarium, A guide for its Establishment and Maintenance")." Depending upon how ones does the count, it contained 88 pages and 81 figures, over half of which of the latter were of aquatic plants. Table 5 presents a breakdown of the sections of the book, which may be compared to Tables 3 and 4. A quick comparison shows the close similarities with his "Der See im Glase" and the differences with the Müller book (i.e., the greater emphasis on fish and other living creatures and a lesser emphasis on plants in the latter).

Rossmässler dismisses the marine aquarium, partly because he had no experience with them but also because he believed that they would never succeed because of their cost. For the times, he certainly was right. Not only were aquarium heaters, filters and aeration unavailable to freshwater aquarists, saltwater aquarium technology such as marine salts, ultraviolet sterilizers, filters, protein skimmers, deionizers, reverse osmosis and the like were unavailable to the would-be marine aquarist. Only after World War II would marine aquariums be feasible – albeit still expensive – for the homeowner.

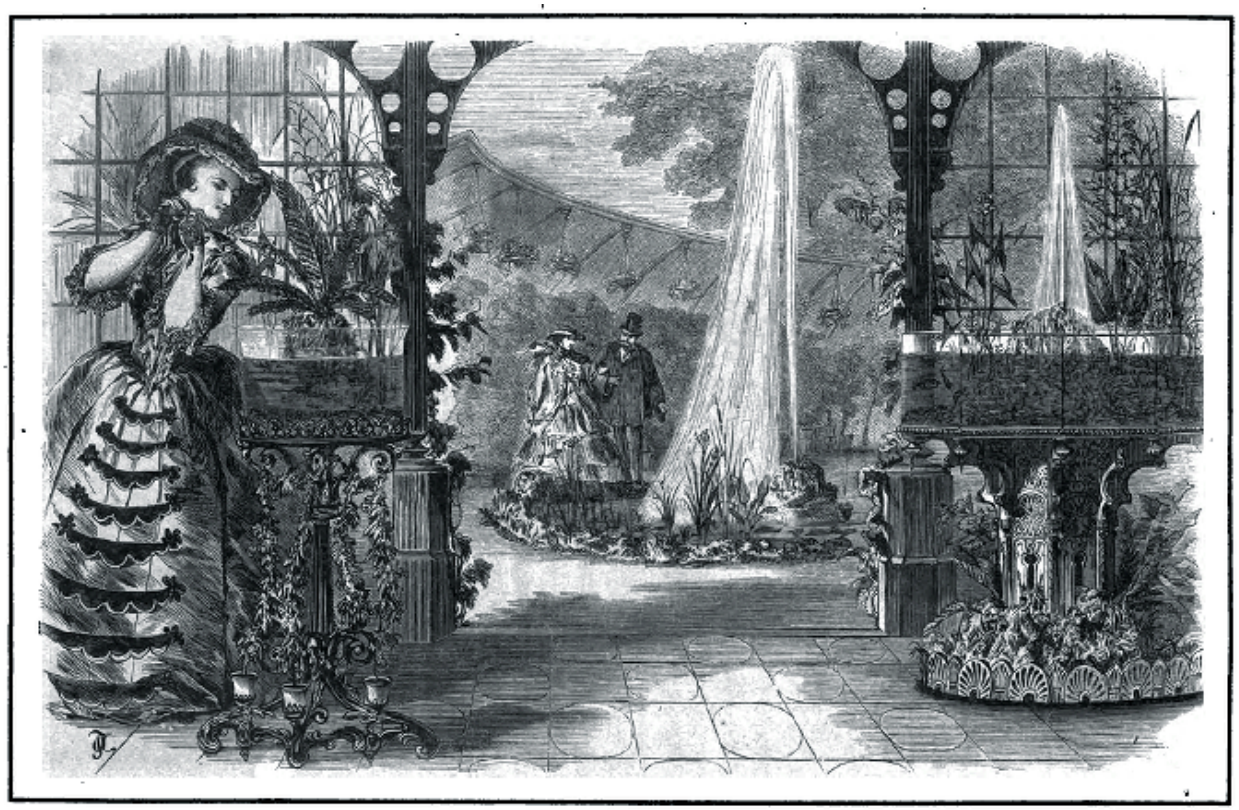

Figure 10: From "Das Süsswasser-Aquarium," by Emil Adolph Rossmässler.

Rossmässler discusses three types of aquariums:

"At the top of the list, and at least until now almost alone in its use, we have the vase-like aquariums as I will call them for brevity, i.e., those which consist of large, wide, cup-shaped glass vessels. The cover picture shows one on the left side.

"Then comes the box aquariums, in which glass panels are set in a cast-iron framework (see the right side of the picture). [Author's note: One has to look hard to see the differences between the two depictions. The one on the left has a flared top and is all-glass; the one on the left has straight sides and distinct panels.]

"The third type I call the basin aquariums. You find these only in attached greenhouses and garden living rooms, and are constructed of stone with a clay bottom."

The last type is the aquarium of the gardener (and the origin of our word for a fish tank), essentially a vessel used to grow aquatic plants, hence the clay on the bottom for the plant roots, but since it contains water, there is no reason why fish and/or other aquatic animals may not be added. A more detailed history of what Rossmässler terms the basin aquarium can be found in my monograph, "Who Invented the Aquarium?" (Klee, 2012).

The section of the book dealing with the living creatures of the aquarium is most unusual, and its introduction follows:

"The goldfish defines the theme of this chapter. We obtained it from the Chinese, the only species that has ever been introduced over a wide range in Europe.

"But even if the goldfish (*Cyprinus auratus*, thus a generic brother to our carp, *Cyprinus carpio*) will always appear more aristocratic in its official Mandarin dress alongside the simple dress of our native fishes, the latter shall still remain our compatriots and have a priority claim to our favor.

TABLE 5: BREAKDOWN OF "DAS SÜSSWASSER-AQUARIUM"

SECTION	PERCENT
Foreword	2
History of the freshwater aquarium	2
Of the various types of aquariums	1
What is an aquarium an•d what should it be?	2
General rules for the aquarium	3
Introduction to the plants	1
a. water plants	20
b. marsh plants	17
Plants for the pond aquarium	12
Fish and other creatures for the aquarium	
a. Fish	1
b. Water insects and snails	18

"But almost every class of animals provides creatures to enliven our aquarium; for example, if you bother to provide the necessary means to prevent the water shrew from escaping, you can certainly keep it at home. I hereby introduce the creatures of the aquarium, one after another, starting from the low-

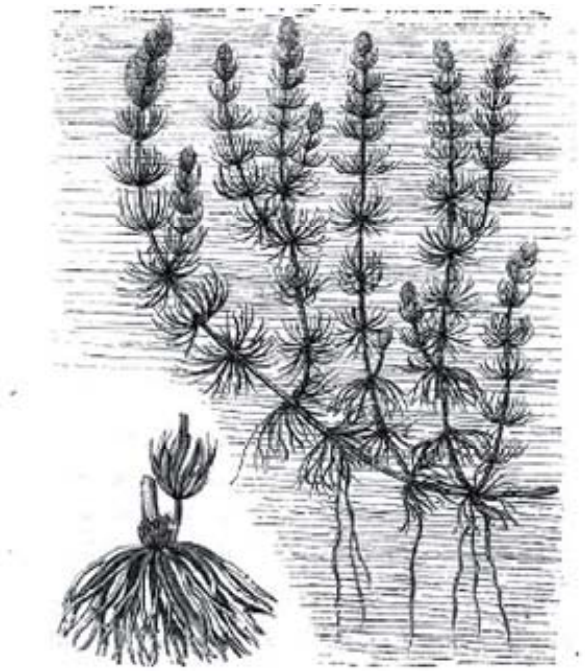

Figure 11: *Ceratophyllum demersum*, from "Das Süsswasser-Aquarium," by Emil Adolph Rossmässler.

est and then ending with those that stand on the highest rung of the animal kingdom."

The second paragraph shows Rossmässler's predilection towards native animals and the third signals his intention to describe these animals from the lowest to the highest in the animal kingdom. To do this, he divides the chapter into eight sections; Section I infusorians, Section II polyps, Section III worms (e.g., tubifex), Section IV insects, Section V crabs (e.g., *Gammarus*), Section VI mollusks, Section VII fishes, and Section VIII amphibians.

The other chapters of the book that deal with the types of aquariums and their construction, aquascaping, care, feeding and collecting are all well-written and comprise the basics of the aquarium hobby even as practiced today. However, other than plants and animals, the book is devoid of any illustrations whatsoever; drawings and diagrams would have been helpful in all of these areas. As I have mentioned, even Müller's small book contained two illustrations of this sort. Considering Rossmässler's background and skill in illustration, this deficiency is difficult to explain.

Rossmässler's last chapter expands on the basin aquarium, but as this form is a transition between the aquarium of the gardener and the "parlour aquarium" of the day, this is understandable. Except for the lack of illustrations in the areas mentioned and fish diseases (very little was known then about the latter), Rossmässler overlooked very little for the fledging aquarist when he wrote his book.

ROSSMÄSSLER'S LEGACY

The credit to Rossmässler for the development of the aquarium in Germany is based upon the fact that after the launch of the marine aquarium before the large audience of *Die Gartenlaube*, he recognized the great opportunities for the masses in the observation of aquatic animals in glass jars, an activity that for him and other scientists was not new. Because freshwater plants and animals were procured nearer at home much more easily and cheaply, he replaced the aristocratic "Ocean on the Table" with the more democratic "Lake in the Glass." In this he was helped by the technological development in the production of flat or sheet glass that made the aquarium affordable for many people. It is worth noting that 1880 marked the date of the 4th Revised edition of "Das Süsswasser-Aquarium" (edited by Otto Hermes, Director of the Berlin Aquarium), published 14 years after his death.

Rossmässler is not only regarded as the Father of the aquarium hobby in Germany, but also as the champion and sometimes founder of natural history museums, in particular the one in Leipzig, an early representative of the movement for nature conservation, a fighter

for environmental protection and a reformer of scientific education in schools.

Rossmässler would most likely not have welcomed certain elements in the future development of the aquarium because he wanted to encourage people to monitor nature close to home. He would have been critical of the introduction of tropical fish and plants, apart from the excesses of the aquarium accessories industry such as “burping clams” and the like, and I have no doubt that he would be turning over in his grave if he saw the brisk business done today in plastic plants. Then again, perhaps the intensive study of ichthyology and ecology that has been pursued by many aquarists, resulting in the development of new knowledge of what would have otherwise remained just a group of non-economic small fishes, might have reconciled him to a great extent.

EPILOGUE

The German revolution of 1848 turned the interplay of science, politics and religion into a public affair. Many of Rossmässler’s contemporaries shared his fundamental belief that any sound societal order had to be grounded in a scientific view of the world. According to this conviction, religious devotion had to be channeled away from the institutionalized churches and - through the mediation of science teachers - directed toward the admiration of the natural world. Consequently, freethinking and politically engaged scientists such as Rossmässler tried to create democratic political structures by cultivating nature studies. Their hero was a man whose affinities for democratic and liberal ideas were already well known, but whose close affiliation with leading circles of established scientists in Europe and with the royal court of the Prussian king made him, on first view, a rather surprising model to emulate: Alexander von Humboldt, cosmopolite, traveler, and Germany’s towering figure in the field of natural sciences.

Imbued with the spirit of Humboldtian thinking, Rossmässler and those sympathetic to his ideas left a remarkable imprint on post-revolutionary cultural and intellectual life in Germany, despite numerous obstacles and even open resistance by state and church authorities. They helped launch a broad movement to make science popular among the German population, although the legitimacy and potential intellectual authority of this field remained highly contested.

Unfortunately, in Germany, unlike in other Western countries, a gap widened over the course of the nineteenth century between rapid economic modernization and political democratization, which allowed state authorities, the military and old elites to dominate the political arena and deny the claims for

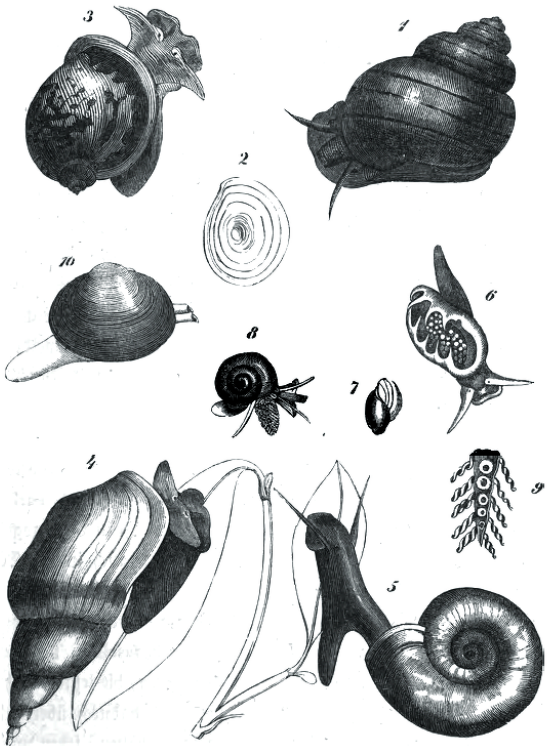

Figure 12 : Snails for the Aquarium. from Das Süsswasser-Aquarium, 1857.

Figure 13: Emil Adolf Rossmässler (1806-1867) later in his life.

participation raised by the middle classes and the workers.

When Otto Ule and Karl Müller decided to publish the journal *Die Natur: zeitung zur verbreitung naturwissenschaftlicher kenntniss und naturanschauung für leser aller staände* (*Nature: A Newspaper for the dissemination of scientific knowledge and views of nature for readers of all levels*), they heard that Rossmässler was interested in publishing a similar magazine and, knowing that he could attract staff and provide quality illustrations, added his name along with theirs to the masthead in the first two years of publication. Towards the end of his association with the magazine, however, Rossmässler wanted Ule and Müller to lower the price of the magazine and to set its level closer to the people.

Rossmässler got along quite well with Ule, a vicar's son who had also been involved as a Democrat in the revolutionary events of 1848/49. Ule had been fined and imprisoned for several weeks for insulting a Prussian minister so, like Rossmässler, a career at a Prussian university was impossible and he was forced to work as a journalist and writer. On the other hand, Müller, a pharmacist, couldn't suppress his resentment at being criticized for the price of the magazine when the price of Rossmässler's own book, *Das Süsswasser-Aquarium*, was set so high. Nevertheless, Rossmässler left on an amicable basis and Ule and Müller continued to publish the magazine. It turned out that they were the better businessmen since it had a 50-year run, a respectable showing for the time. I tell this story because it shows how dedicated Rossmässler was in striving to introduce and encourage the study of nature among the common folk.

At the Natural Science Association of Saxony and Thuringia in 1871, a speaker gave Rossmässler a posthumous but involuntary compliment. After a presentation on the Darwinian theory of evolution, which then of course, was still very controversial - Ule was for and Müller was against - the rapporteur noted that **"Archdeacon Schmidt from Aschersleben followed up on the previous lecture by explaining that he was a staunch opponent of Darwinism, his malacologic experience contrasting with that of Rossmässler who has been a pronounced Darwinian long before the appearance of Darwinism…"** Better the Archdeacon could recognize a little of Rossmässler's work, even if this man of the church had certainly meant something quite different!

The Development of the Aquarium Hobby in Germany, 1852-1890

by Albert J. Klee, Ph.D.,
Aquarium Hobby Historical Society, Yahoo Files Section, February 9, 2013

American aquarists as a rule know little about the very early development of the aquarium hobby in Germany. What is generally known are mostly Ernst Bade's books from the turn of the century, i.e., "Süßwasser Aquarium" (1896) and "Praxis der Aquarienkunde" (1899), and two post World War I books, Christian Brüning's "Ichthyologischer Bilderatlas" (1932) and Arnold and Ahl's "Fremdländische Süßwasserfische" (1936).

To this end, I explore here the development of the aquarium hobby in Germany from 1852 to 1890, viewed through the literature of this period. Since I will proceed chronologically, these references are arranged in order of year of publication and are identified by number. All other references are identified by author and year and are placed in an "Additional Bibliography." When referring to the title of a book or article I present both the original German title (so you can find it in the references) as well as a translation into English.

LIEBIG'S WORLD IN A GLASS

Reference 1 (1852), an anonymous review titled, "Liebig's Welt in einem Glase" ["Liebig's world in a glass"], requires the following introduction.

In 1849, Robert Warington devised an ecologically balanced system using a 12-gallon aquarium in which he placed two small goldfish. Also placed in this container was a small *Vallisneria spiralis* plant and five or six water snails, *Himnaea stagnalis*. The container was then more or less sealed (he used muslin). The plants produced oxygen and took up the carbon dioxide produced by the fish, the pond snails served as garbage disposers and their young were eaten by the fish. In daylight, this biological balance held for years. A replica of this system in the form of about a meter wide water-filled glass sphere is in the Natural History museum of Vienna and is shown in Figure 1.

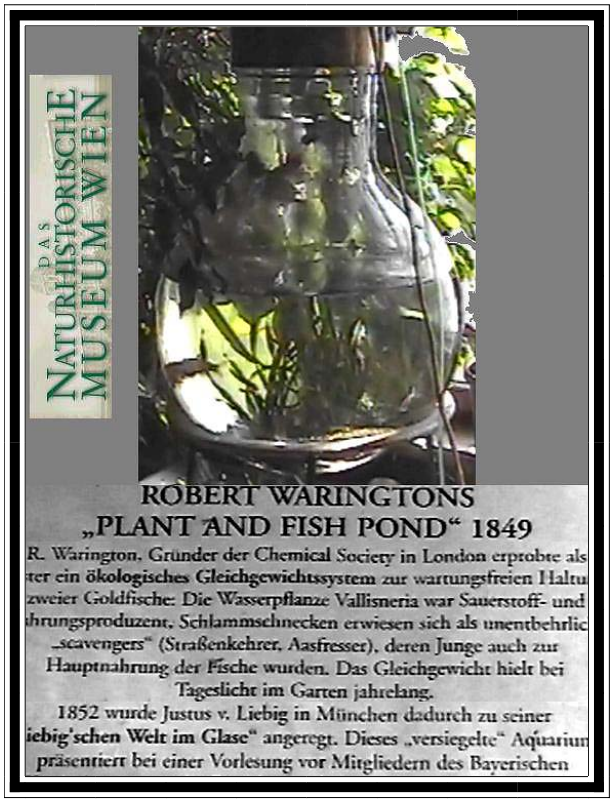

Figure 1: A replica of Warington's sealed, balanced aquarium in the Natural History Museum of Vienna. The last line of the legend reads, "Inspired by this, in 1852 Justus von Liebig created in Munich his "Liebig's world in the glass." This "sealed" Aquarium, presented at a lecture to members of the Bavarian Royal House, was the introduction of the aquarium into Germany."

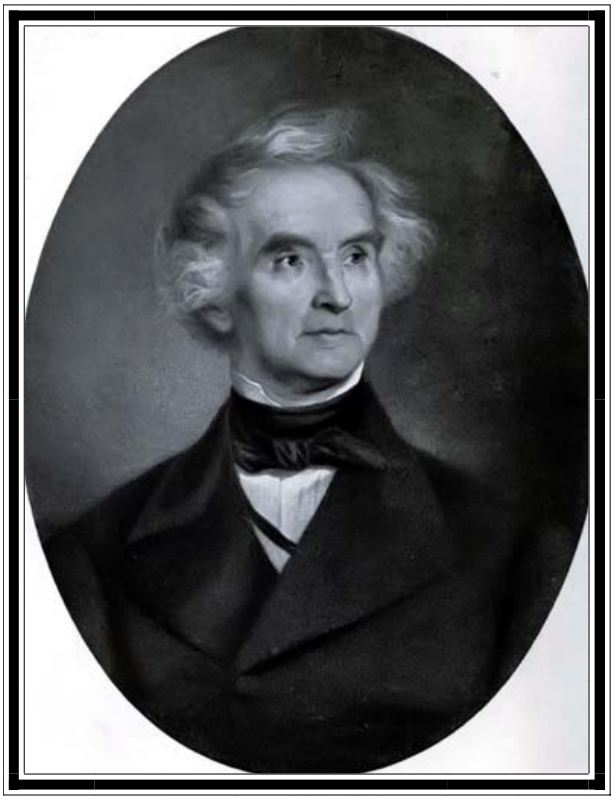

Figure 2:
Justus Freiherr von Liebig (1803-1873).

Justus Freiherr von Liebig (1803-1873) was a German chemist (Figure 2) who made major contributions to agricultural and biological chemistry, and worked on the organization of organic chemistry. As a professor (he received an appointment from the King of Bavaria to the University of Munich in 1852), he devised the modern laboratory-oriented teaching method, and for such innovations, he is regarded as one of the greatest chemistry teachers of all time. He is known as the "father of the fertilizer industry" for his discovery of nitrogen as an essential plant nutrient, and for his formulation of the "Law of the Minimum," often simply called "Liebig's Law." The principle actually was developed in agricultural science in 1828 by Carl Sprengel, a German Botanist, but was later popularized by Liebig. It states that growth is controlled not by the total amount of resources available, but by the scarcest resource, i.e., the limiting factor. An image of a barrel - often called Liebig's barrel (Figure 3) – is sometimes used to explain Liebig's law. Just as the capacity of a barrel with staves of unequal length is limited by the length of the shortest stave (say phosphorus) and can only be increased by lengthening that stave, when that stave is lengthened, another one becomes the limiting factor.

During a visit to England he was shocked to observe the sewage of Britain being sent out to sea and subsequently delivered a tremendous tirade against the British for their practice of importing bones from Europe instead of using their sewage as a fertilizer. In later years his reputation became so great that he was regarded as the final authority in chemical matters, and he was often involved in scientific controversies. In the field of biochemistry, for example, Liebig became involved in a famous dispute with Louis Pasteur. As a supporter of Berzelius (a famous Swedish chemist), he claimed that all chemical changes were

Figure 3: Liebig's Barrel.

brought about by catalysts and that no organisms were involved; thus in 1869 he argued that there was nothing biological about fermentation. Pasteur, however, managed to demonstrate that the vinegar produced by wine souring on contact with air resulted from the action of yeast.

While at the University of Munich, Liebig became fascinated with Warington's work and made his own replica that quickly became known as "Liebig's world in a glass." The article is a summary of both Liebig's and Warington's observations and is important because it marks the beginning of the aquarium in Germany.

The next on the scene was an article (Reference 2) titled, "Kasten für die Wasserpflanzen, oder das Zimmer-Aquarium" ["Cases for aquatic plants or the Parlour Aquarium"] but this was merely a translation of Ward's "The Aquatic Plant Case, or Parlour Aquarium" that appeared in The Garden Companion, and Florists' Guide of 1852, a copy of which appears in my monograph, "Who Invented the Aquarium?" (Klee, 2012). This was followed in 1854 with "Blumengestell mit Fischbehälter" ["A flower stand with a fish tank"] (Reference 3), a picture of which is shown in Figure 4. This, however, was nothing more than the traditional gardener's aquarium, albeit a very elaborate one, containing fish. At the end of this reference, under the title of "artistic garnish," was the drawing of the aquarium shown in Figure 5.

DR. HEINRICH BETTZIECH-BETA

In 1854 and 1855 there appeared four articles in the weekly magazine, *Die Gartenlaube* (a magazine also discussed in my Roßmäßler monograph), all containing the phrase, "Der Ocean auf dem Tisch" ["The Ocean on the Table"]. Until recently, the author of these articles was unknown until Mathias Pechauf, in an article titled "Wer war der Verfasser des 'Ocean auf dem Tische'?" ["Who was the author of the 'Ocean on the table'?"] identified him as Dr. Heinrich Bettziech-Beta.

Bettziech-Beta was born in 1813, the son of a farmer in a small village in Saxony, Werben by Delitzsch. Of Slavic/Serbian ancestry, his birth name was Johann Heinrich Bettziech but as he was a follower of Hegel's philosophical views, he took the pseudonym "Beta" to get around the "taint of foreign birth."

He attended the Latin School of the Francke'schen Foundation in Halle, and then studied philology, philosophy and science at the University of Halle. After earning his

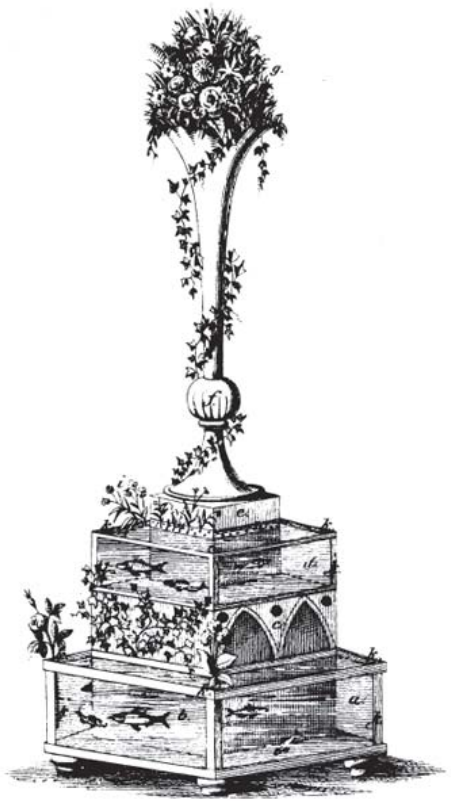

Figure 4: "A flower stand with a fish tank," from Reference 3, 1854.

Figure 5: "Artistic Garnish," from Reference 3,1854.

Ph.D. in 1838, he moved to Berlin. Although he did not participate directly in the revolution of 1848, he edited the *Berliner Krakehler*, a satirical political magazine which was banned in 1849. In addition, he wrote numerous pamphlets on current topics that criticized the Prussian justice system and so was investigated for "incitement to treason" with a possible sentence of two to nine years in prison.

A fugitive warrant was issued for him but he escaped in 1851 by boarding an emigrant ship in Bremen and went to London where he married his first wife. Here he made his living by writing for English, German and Russian newspapers and magazines. As the London correspondent for *Die Gartenlaube*, he made many interesting contributions about all aspects of social life in London and throughout the United Kingdom and thus significantly contributed to the great success of this magazine in Germany. Bettziech-Beta knew Karl Marx but there was no love lost between them, Marx terming him a "hack." He held an open house for all emigrants from Germany and supported many of them. After the general amnesty on the occasion of the inauguration of King William I of Prussia (later Emperor William I of Germany), he returned to Berlin in 1861 to continue his writing, dying there in 1876 after a long illness.

Returning now to Bettziech-Beta's articles previously mentioned, the first one (Reference 4) discussed Philip Henry Gosse's 1854 book, "The Aquarium: an unveiling of the wonders of the deep sea"; the next two (References 5 and 6) discussed artificial sea water and Reference 7 provided instructions on the establishment of marine aquaria and their maintenance. This last article, "Wie erund behält man den Ocean auf dem Tische, oder das Marine-Aquarium" ["How one keeps the Ocean on the Table, or the Marine-Aquarium"] is the one that prompted Roßmäßler to write his famous article on freshwater aquariums (Reference 8), "Der See im Glase" [The Lake in the Glass"].

Reference 9 (1856) was based upon an article that appeared in an 1854 issue of *The Gartenlaube* that discussed the principle of the balanced aquarium, and Reference 10 was Ludwig Müller's "Das Aquarienbüchlein aus dem Jahre 1856. Ein Beitrag zur Geschichte unserer Aquarienliebhaberei" ["The Aquarium Booklet from 1856. A contribution to the history of our aquarium hobby"]. However, References 7, 8 and 10 have been discussed in detail in my article on Roßmäßler, so I won't describe them again here.

Georg Ritter von Frauenfeld (1807-1873) was an Austrian naturalist and zoologist (Figure 6), specializing in entomology and malacolo-

Figure 6:
Georg Ritter von Frauenfeld (1807-1873) .

gy, and was curator of the mollusk collection in the former Kaiserlich-Königliche Zoological Court Cabinet in Vienna (now the Museum of Natural History). In 1851 he founded the Zoological and Botanical Society in Vienna and from 1857 to 1859 took part in the Novara expedition. In 1860 he was awarded the Austro-Imperial Order of Leopold III. Class, and elevated to the hereditary knighthood. In 1868 he became vice president and editor of the Association for the Dissemination of Scientific Knowledge, published in Vienna.

Reference 11, "Ueber Aquarien" ["About Aquariums"], was written in 1856 by Frauenfeld and discussed both salt and freshwater aquariums with about one third of the text taken from translated English sources. As it was with everything that Frauenfeld wrote, however, it was of high quality compared to some of its predecessors.

A little different in approach was Reference 12 (1857) "Naturwissenschaftlicher Seehandel, oder: Der Ocean auf dem Tische noch einmal" ["The maritime trade in nature science, or: The Ocean on the table once more"] where the author (anonymous) discussed the commercial side of the marine aquarium hobby and included material about Lloyd's establishment in London. Figures 7 and 8 show illustrations taken from the article.

Reference 13 (1857) is a two-part article in four sections, the first one written under H. Heinrich-Beta's own name: "Die Natur als Hausfreundin: I. Blumenfenster, II. Flora's Krystall-Palast in Zimmer, III. Blumenfenster

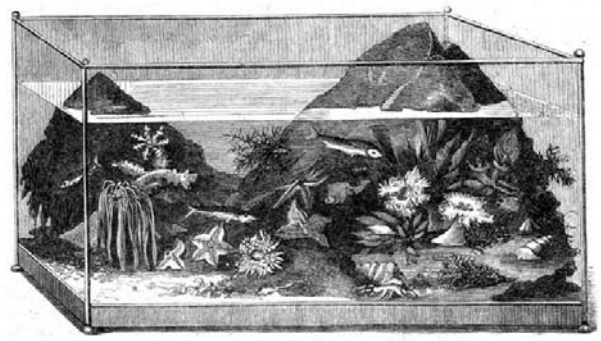

Figure 7: From "The maritime trade in nature science, or: The Ocean on the table once more," Reference 12,1857.

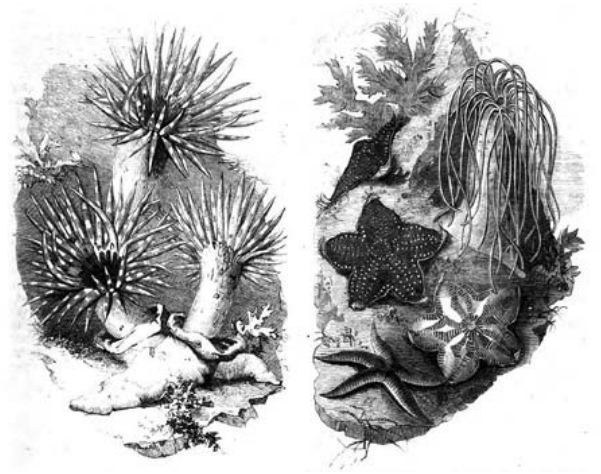

Figure 8: From "The maritime trade in nature science, or: The Ocean on the table once more," Reference 12,1857.

Figure 9: "The Flower and Aquarium Window," from Reference 13, 1857.

mit Aquarium, IV. Blumenvasen und Gartenhäuser" ["Nature as a Friend of the Family: I. Flower Window, II. The Crystal Palace of Flowers in the Room, III. Flower & Aquarium Window, IV. Vases & Garden Sheds"]. The only part of this article that is relevant to the aquarium, however, is Section III, "The Flower and Aquarium Window," an illustration of which is shown in Figure 9. Reference 14 is Roßmäßler's book "Das Süßwasser-Aquarium" which, like references 7, 8 and 10, has also been discussed in detail in my article on Roßmäßler, so I won't describe it again here either.

Another of those short articles that appeared in the garden magazines of the time, - Reference 15 (1857) - was titled "Ueber Zimmer Aquarien" ["About Room Aquariums"]; Figure 10 shows the aquarium described in the article.

Reference 16 (1858), "Ueber Aquarien" ["About Aquariums"], which appeared in a weekly magazine of horticulture and botany, was written by Frauenfeld and to be expected was a cut above the last, dealing with both marine and freshwater aquaria. Frauenfeld discussed light, temperature and feeding for both marine and freshwater aquaria, and also artificial marine water for the former. Regarding the vessel itself, the author was not sanguine about all-glass types such as the typical bell jar since they were usually not cooled properly and broke easily when jarred. They often burst, seemingly without any cause, flooding the room and trapping the animals in the broken glass where they quickly died. The author recommended pentagonal and octagonal aquaria

Figure 10: From "About Room Aquariums" Reference 15, 1857.

made with zinc or iron frames where the sides flared outward progressing to the top.
Published in 1858, Reference 17, "Aquarien zur Belustigung" ["Aquariums for Amusement"], is interesting because of where it appeared, i.e., in "Der ärztliche Hausfreund: Zur Förderung der Gesundheitspflege und Kenntniß des menschlichen Körpers und der Natur: Aerzten und Nichtärzten gewidmet" ["The Medical Family Friend: For the promotion of the health care and knowledge of the human body and nature. Dedicated to Physicians and Laymen"].This was a weekly magazine, edited by a medical doctor and somewhat similar to the health care newsletters of today, although nature subjects that had a bearing on health were at times included. The article itself dealt essentially with the carbon dioxide/oxygen relationship between plants and animals and gave no details about how one was to set up and maintain an aquarium, referring the reader instead to Müller's 1856 aquarium book, which apparently was more fairly wide-read than previously realized.

The decade of the 1850's ushered the aquarium hobby into Germany and produced two of its most important early books, Müller's "Aquarium. Belehrung und Anleitung solche anzulegen und zu Unterhalten and Roßmäßler's "Das Süßwasser-Aquarium. Eine Anleitung zur Herstellung und Pflege desselben. It was off to a good start.

THE DECADE OF THE 1860'S

Karl August Möbius (1825- 1908) was a German zoologist and pioneer (Figure 11) in the field of ecology. In 1863 he opened in Hamburg the first German marine public aquarium exhibit. In 1868, shortly after passing his doctoral examination at the University of Halle, he was appointed Professor of Zoology at the University of Kiel and the director of the Zoological Museum. Marine animals were among his main research interests and his first comprehensive work on the fauna of the Kiel Bay emphasized its ecological aspects ("Die Fauna der Kieler Bucht," co-authored with Heinrich Adolph Meyer, and published in two volumes in 1865 and 1872, respectively). In 1888 Möbius became the director of the Zoological Collections of the Museum für Naturkunde in Berlin, and Professor of Systematic and Geographical Zoology at the Kaiser Wilhelm University, Berlin, where he taught until 1905, retiring at the age of 80.

This decade began with Reference 18, "Einrichtung und Erhaltung der Aquarien, mit Berücksichtigung der Aquarien des naturhistorischen Museums in Hamburg" ["Establishment and Maintenance of Aquariums, with regard to the Aquariums of the Museum of Natural History in Hamburg"], written by Möbius and published in a magazine for "gardening and flower enthusiasts," but being authored by Möbius it was more informative than most such articles. He described some of the fish kept at the Hamburg Natural History Museum and, for the first time, fish imported from India and Java,

Figure 11:
Karl August Möbius (1825- 1908).

including the marine Butterfly fish, *Chelmon rostratus* and the Archer fish, *Toxotes jaculator*. The article went on to mention the development of the aquarium citing Ward, Priestly, Ingenhaus and Sennebier, followed by a discussion of the carbon dioxide/oxygen cycle in the aquarium. The Museum had three aquariums of various sizes in the 40 to 50 gallon range for the two marine tanks, smaller for the lone freshwater tank; these and their contents were described in detail.

Reference 19 (1860) had the usual garden magazine content so I'll quote the author's introduction to the article, **"Parlor aquariums been written about many times in various magazines, so much so that we have always shied away from augmenting its literature. Today, however we want to devote a few words to the same,"** and move on!

The third book on the freshwater aquarium appeared in Germany in 1861 (Reference 20), "Das Süßwasser-Aquarium: Kurze Anleitung zur besten Construction der Aquarien und Instandhaltung derselben, sowie Schilderung der Süßwasserthiere" ["The Freshwater Aquarium: Short guide to the best construction of aquariums and their maintenance thereof, and a description of its freshwater animals"], written by Dr. Eduard Heinrich Graeffe. Although Graeffe was Swiss, not German, his book is in German and was published in Hamburg where he was living at the time.

Graeffe (1833-1916) specialized in Hymenoptera, Diptera and Hemiptera. He was hired by Johann Godeffroy, a wealthy shipping magnate with a private museum in Hamburg where he was employed in order to arrange the collection as a scientific exhibit. The museum, which contained insects from Australia, Samoa, Fiji, Tonga and the Phoenix Islands, also functioned as a dealership in natural history material and lasted from 1861 to 1885. Earlier he had worked at the Zoological Station in Trieste where there were a number of aquariums in its basement and where Graeffe most likely obtained his interest in the subject.

Table 1 shows how the Graeffe broke down the various sections in his book. When one compares this with Roßmäßler's Süsswasser-Aquarium (Klee, 2013a) the main difference noted is the reversal of emphasis on plants versus animals, i.e., Roßmäßler spent 40 percent on plants and Graeffe spent 39.5 percent. Indeed, in his introduction to his book Graeffe wrote: **"There have been various writings about the aquarium, of which the best known is by that writer of popular science, Mr. Roßmäßler. However, the latest experiences of our English aquarium friends were excluded and in addition he takes the plant kingdom into account more than anything else, whereas here it is the animal kingdom that takes precedence. Therefore, my work might not be entirely superfluous."**

Although Graeffe's book did have some illustrations that were not of plants or animals

(Figure 12), they were, however, more or less copies from previous literature. In short, this book is just an extension of Mueller's with some added illustrations copied from English sources.

Reference 21 (1863) - "Das Aquarium" - by an anonymous author appeared in a publication that contained essays on cultural and historical topics of the times. It was, in essence, a fairly lengthy historical essay on the development of the aquarium, both public and private, and included among other things Dujardin's work in France and Barnum and Cutter's in America. It was very well done and was the first of this type to appear in the German literature.

Reference 22 (1863) was a short but concise article, "Einige Bemerkungen über Aquarien" ["Some remarks about aquariums"], by Dr. Karl Möbius that appeared in a zoo journal. It presented a comparison of the advantages and disadvantages slope-back versus flat-sided tanks with regard to substrates and aeration. He followed this two years later (1865) with another article in the same journal (Reference 23), "Einige Fingerzeige für die Bevölkerung und Erhaltung der Aquarien" ["Some tips for the population and conservation of aquariums"]. Anything written by Möbius deserves careful reading and this article is no exception. He sets the theme of his article as follows: **"We demand more from aquatic animals than nature provides. We catch fish in rivers, crabs in streams, snails in bogs, mussels in ponds and put them all in one and the same limited water space. Is not similar to when we placed mammals, birds, reptiles and insects from hot and cold zones, from dry deserts and from damp shady woods into the same room? And yet we expect them to move happily, eat and reproduce. We need to connect to nature if we want to learn the scientific principles of the aquarium so that we are able to achieve the greatest possible perfection under artificial conditions."**

He goes on to cite as an example the advice that **"...a newly setup aquarium should contain only pure-washed sand, pure stones, pure river or lake water is erroneous. No water is pure; the water in streams with a gravel base is different from the water of a pond with a calcareous bottom, and the water in a marshy ditch contains substances other than river water, no matter that they may all look alike in a clear-glass aquarium. There are animals that live in muddy water over a muddy bottom, those that live in water over a sandy bottom, those that live in water over a stony base and there are those that thrive on all soil types."**

"I myself have had to overcome with effort the abhorrence of a mud bottom in an aquarium. In the tanks that were set up for Mr. H.A. Meyer and me when we were hired to study the fauna of Kiel Bay, the animals would only thrive when, in addition to the live ones, decaying plants were also in them. Only when we finally decided to place a layer, three to four fingers high, of dark mud from the port of Kiel in two aquariums, did we manage to get the mud inhabitants healthy."

The editor also chimed in with the following comment: **"We have had the same experience**

Figure 13:
Prof. Dr. Gustav Jäger (1832-1917).

with tadpoles. All the feeding and changing of water came to naught when the mud bottom in which they dig to find wholesome food was missing; only one must be careful not to disturb it and muddy the water."

Georg Frauenfeld wrote an article in 1869 (Reference 24) that dealt with the problems of supplying marine water to aquariums situated inland, "Beschreibung eines einfachen Seeaquariums für Aktinien" ["Description of a simple marine aquarium for Actinia"]. Frauenfeld reduced evaporation and kept his tank from becoming contaminated with dust by the use of a tight glass cover and maintained the water level almost to the top. Every six to eight weeks he ran the water through a clean towel and removed the secretions that settled on the glass interior. In this manner he kept anemones alive for over a year without any water changes.

"Das Leben im Wasser und das Aquarium" ["Life in the Water and in the Aquarium"] is a 360-page book (Reference 25) written by Prof. Dr. Gustav Jäger (1832-1917) in 1868 (Figure 13). Jäger was a German natu-

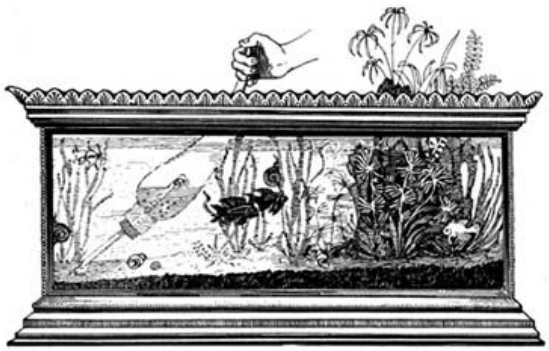

Figure 14: From "Life in the Water and in the Aquarium," Reference 25, 1868.

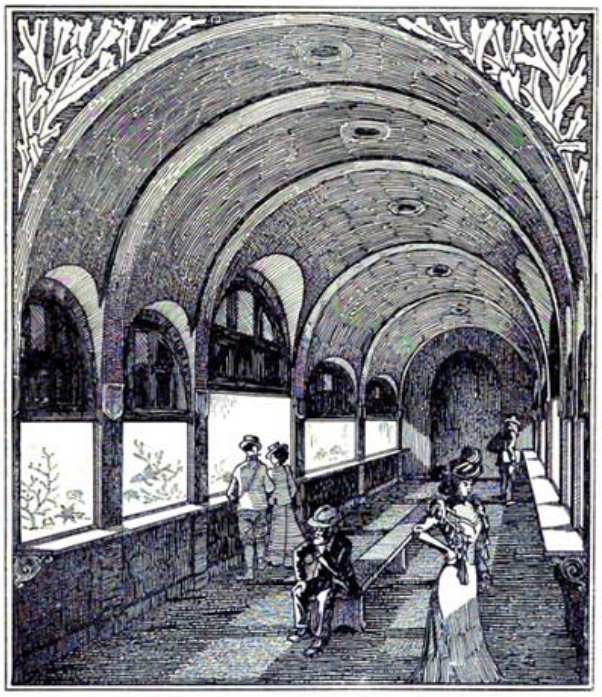

Figure 15: From "Life in the Water and in the Aquarium," Reference 25, 1868.

ralist and hygienist. After studying medicine at Tübingen he became a teacher of zoology at Vienna and in 1868 he was appointed professor of zoology at the academy of Hohenheim. Subsequently he became teacher of zoology and anthropology at Stuttgart polytechnic and professor of physiology at the veterinary school. In 1878 Jäger advanced the first crude version of the pheromone concept. His postulated skin "anthropines," popularly dubbed "lust compounds," came astoundingly close to reality but the idea was too far ahead of the possibilities of chemistry and the life sciences at this time to be corroborated by experiments. In 1884 he abandoned teaching and started practice as a physician in Stuttgart. Unfortunately, although the information was sound, very little in his book was concerned with aquariums per se; the freshwater aquarium section was only 6 pages, the marine aquarium only 8-1/2 pages. Figure 14 shows the only freshwater illustration in the book and Figure 15 shows the only one for marine water, a woodcut of the Hamburg Aquarium.

We return now to Dr. Heinrich Bettziech-Beta (Reference 26) with three of his articles, "Aquariumscultur, Der Ocean auf dem Tische and Die Aquariums-Marine" ["Aquarium Culture, The Ocean on the Table and The Marine Aquarium"] in his 1868 book, "Die Bewirthschaftung des Wassers und die Ernten daraus" ["Water, its Management and the Crops from it"]. The first described public aquaria, the second described the private aquarium (including tank construction, water changes, artificial salt water, maintenance, etc.) and the third described animals suitable for the marine aquarium. These three topics took up a total of 45 pages but there was only a single illustration (Figure 16), that of a private marine aquarium.

Reference 27 (1868) brings us back to the freshwater aquarium with a 17 page article titled "Das Aquarium" in a journal called (translated), "Nature and Revelation, for the Mediation between nature research and Faith for all levels of education," published by a Munich synod and popular with some religious establishments (the copy Google digitized was from the Batz Memorial Library of the Abbey of Gethsemani, Kentucky). In it the author (anonymous) boils down Roßmäßler's book to 17 pages with no illustrations but he does refer the reader to his book for those seeking more details.

Speaking of Roßmäßler, Reference 28 is the

Figure 16: From "Water, its Management and the Crops from it," Reference 26, 1868.

Figure 17: From "The Room Aquarium," Reference 29, 1870.

Figure 18: From "The Room Aquarium," Reference 29, 1870.

second edition of his book, published in 1969 and edited after his death by his friend, Alfred E. Brehm. Brehm changed almost nothing in the book, but some illustrations of fish such as the stickleback, the bitterling, three minnows (*Phoxinus laevis*, *Alburnus licidus* and *Leuciscus rutilis*) and three loaches (*Cobitis fossilis*, *Cobitis barbatula* and *Cobitus taenia*) were added (the scientific names of some cited here have been changed since then).

The decade of the 1860's had its share of competent writers who added material rather than simply repeating what had preceded them or what had been imported from Great Britain, notably, Karl Mobius, Georg Frauenfeld and Heinrich Bettziech-Beta. It also saw the publication of Eduard Graeffe's, "Das Süßwasser-Aquarium: Kurze Anleitung zur besten Construction der Aquarien und Instandhaltung derselben, sowie Schilderung der Süßwasserthiere" and the second edition of Roßmäßler's "Das Süßwasser-Aquarium."

THE DECADE OF THE 1870'S

The decade of the 1870's started off with Hermann Jäger's book, "Das Zimmer-Aquarium" ["The Room Aquarium"] in (translated) "The Room and House Nursery. Instructions for growth, maintenance and use of ornamental plants in the living areas with accessories along with descriptions of the most beautiful ornamental plants" (Reference 29). This was a short, 7-page article discussing the basic requirements for the living room aquarium, including the vessel, plants (as might be expected in a book of this sort, this took up the major portion of the article), fish and maintenance operations such as water changes. The reader was referred to Roßmässlers's Second Edition of "Süßwasser -Aquarium" for further details. Two illustrations were included, Figure 17 showing an ornate double-glass vase aquarium and Figure 18 depicting a framed window box aquarium.

An anonymous 1873 article in *Die Gardenlaube* (Reference 30), "Mein Stuben-Aquarium" ["My Parlor Aquarium"], provided details of the construction of the author's aquarium (Figure 19). In addition to fish, tadpoles, frogs and lizards, the author added diving beetles, dragonfly larva and other aquatic insects but fed them well enough with raw meat, earthworms and snail meat so that the fish and tadpoles were not attacked. As with the previous author, the reader was referred to the second edition of Roßmäßler's book for further information.

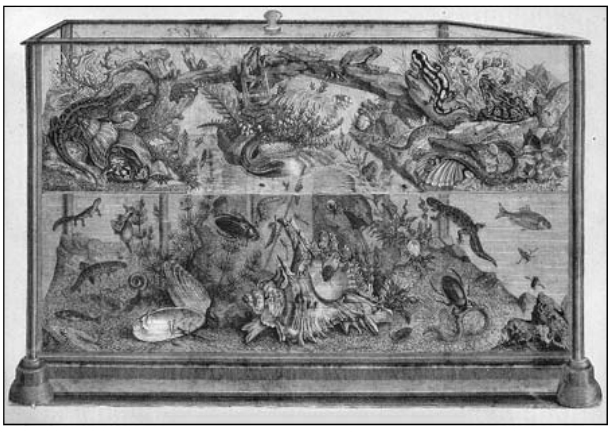

Figure 19: From "My Parlor Aquarium," Reference 30, 1873.

Figure 20: From "Images from the aquarium, the invertebrates of freshwater," Reference 33, 1878

In a well-written article (Reference 31), Friedrich Rossbach discussed the basic principles of the salt and freshwater aquarium including some of its history, lighting and heating. He also described a number of public aquariums and provided some details of the tanks used by them.

Michael Bach in his 1876 18-page article, "Aquarium" (Reference 32) in "Studien und Lesefrüchte aus dem Buche der Natur" ["Studies and gleanings from the book of nature"], didn't add anything new and it was clear that he relied heavily on Roßmäßler's work.

CARL FRIEDRICH WILHELM HEß

Dr. Carl Friedrich Wilhelm Heß (1841-1918) was a Professor of Botany and Zoology at the Technical University of Hanover. His Ph.D. thesis (1865) was on eastern Australian decapod crustaceans. In 1874 he wrote "Bilder aus dem Leben schädlicher und nützlicher Insekten: Die Hymenopteren" ["Pictures from the life of harmful and beneficial insects: The Hymenoptera"] and in 1892 "Die Feinde des Obstbaues aus dem Thierreiche: eine Anleitung zu ihrer Erkennung und Vertilgung für Obstzüchter, Gärtner, Landwirthe u.s.w." ["The enemies of fruit growing in the animal kingdom: a guide to their recognition and destruction for fruit breeders, gardeners, agriculturists etc."].

Reference 33 is a two-part book written by him in 1878, "Bilder aus dem Aquarium, die wirbellosen Thiere des Meeres" and "Bilder aus dem Aquarium, die wirbellosen Thiere des Süßwassers" ["Images from the aquarium, the invertebrates of the sea" and "Images from the aquarium, the invertebrates of freshwater"]. They were available separately or as two single books. The first book discussed and illustrated all kinds of marine animals except fishes; the only reference to fish was in discussing the formulas for marine water and in the commercial aspects of fishing. The second book was pretty much the same, Heß pointing out in his introduction that the book was designed to provide an overview of the lower freshwater animals. He does discuss the tanks themselves and one is shown in Figure 20.

Heß remarked that when there are a lot of plants and animals in the aquarium one can blow air into the water with a bellows, although he preferred a water fountain driven by gravity flow. However, this posed a problem

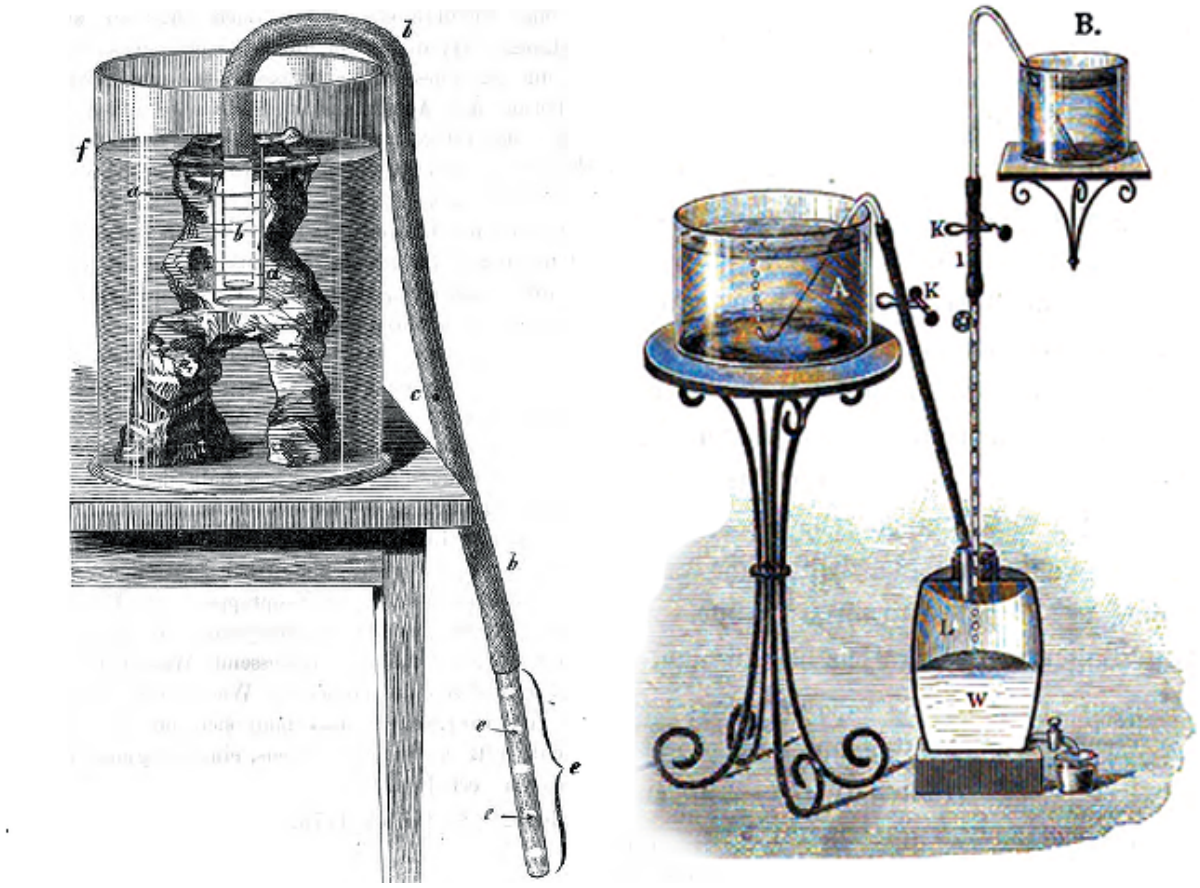

Figure 21: From "Images from the aquarium, the invertebrates of freshwater," Reference 33, 1878

with vase aquaria since no drainage pipe can be attached to them physically because they shatter easily. Thus, if not attended to, the water often flows over the edge of the tank and onto the floor. This problem could be solved a special type of airlift called a "Heber, the word for "Lift" in German (Figure 21, left). After priming the airlift tube, it is led to a short glass cylinder, closed at the bottom, where the water flows from the bottom of the tube into the cylinder while the air stays in the tube and continues to build up. However, above the top of the glass cylinder the excess water is removed so the pressure of the water contained in it is too low to force down the water retained by the air column and the lift stops working.

Figure 21, right is interesting in that it shows a variant on the familiar gravity aeration system. In the figure on the right an open container filled with water is connected to a closed container containing air. As the water flows from the top container to the bottom it displaces the air in the lower container and sends it to aquarium. When the upper container is empty, the water in the lower one is released, poured back into the upper one and the process repeated. Heß remarks that even using large containers, the process lasts but a short time.

Finally, Figure 22 shows a paddlewheel, the lower part of which is immersed in the aquarium so that the water is stirred and hence aerated. The driving mechanism is a clockwork motor.

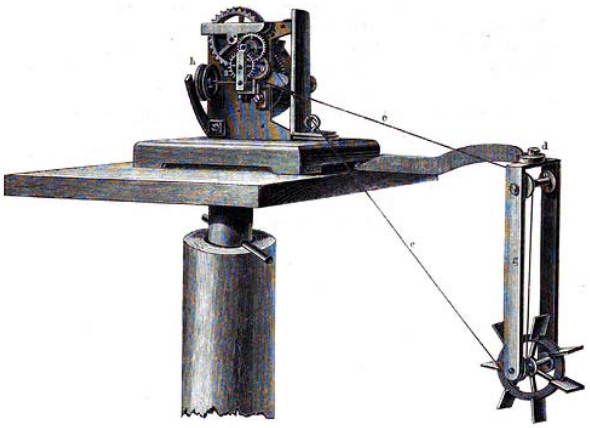

Figure 22: From "Images from the aquarium, the invertebrates of freshwater," Reference 33, 1878

With regard to fish diseases, there was much scientific research taking place at the time and aquarists borrowed freely from scientific publications to use in their own. Since this is a specialized area I won't pursue it further here except to quote one such scientist of the day, the Baron de la Valette St. George, Professor of Anatomy and Director of the Anatomical Institute at Bonn. The following was taken from an article he wrote for the German Fishery Association in Berlin (Reference 34):

"War is the watch-word of the whole of organic nature; there is a constant war of all organisms against outward unfavorable circumstances, and there is constant war among the different individuals. The feed- grain which falls into the ground, the worm crawling on the earth, the butterfly hovering over the flower, the eagle soaring high among the clouds, they all have their enemies - outward enemies threatening their existence, and inward enemies eating their life and strength.

"Even fish, which claim our special attention, are by no means permitted to spend their life in peace. Plants and animals endanger their very life, and when they have been fortunate enough to escape these, man comes and seeks to catch and destroy them with numberless arts and tricks.

"Confined to a special sphere of life, the water, they frequently do not find in it the necessary conditions of existence. In their very cradle, so to speak, that is, in the egg, the tender germs, scarcely awakened to life, are threatened by a dangerous enemy belonging to the lowest grades of the vegetable kingdom. This is the much-dreaded *Saprolegnia ferax* in an incredibly short time its long threads envelop the egg, choke it and destroy it."

The decade of the 1870's was most noted for the publication of Wilhelm Heß's two books, "Bilder aus dem Aquarium, die wirbellosen Thiere des Meeres," and "Bilder aus dem Aquarium, die wirbellosen Thiere des Süßwassers." These books of themselves were not especially important to the aquarium hobby, but they did pave the way for a more important book by Heß that would appear in the next decade. However, this decade also signaled an interest in aquarium fish diseases, spurred on by the research conducted on the diseases of native and commercial fishes by a number of scientists such as La Valette St. George.

THE DECADE OF THE 1880's

In 1886 Heß published his "Das Süßwasseraquarium und seine Bewohner: Ein Leitfaden für die Anlage und Pflege von Süßwasseraquarien" ["The Freshwater Aquarium and its Inhabitants: A Guide to the installation and maintenance of freshwater aquariums"] (Reference 35). This book, however, was a vast improvement over his 1878 freshwater aquarium book. A breakdown of the book's contents is shown in Table 2. Here the amount of space devoted to equipment, installation, filling and maintenance is almost equal to that of plants, and that devoted to animals is three times that of plants. In the table I have broken down the contents within the animal section and the fish predominate. Indeed, as a percentage of the whole book, fish account for 19.4%, essentially equal to

that devoted to plants. Furthermore, there were 105 illustrations in this 255-page book, and at the end of the book he listed 22 suppliers throughout Germany of aquarium animals and equipment.

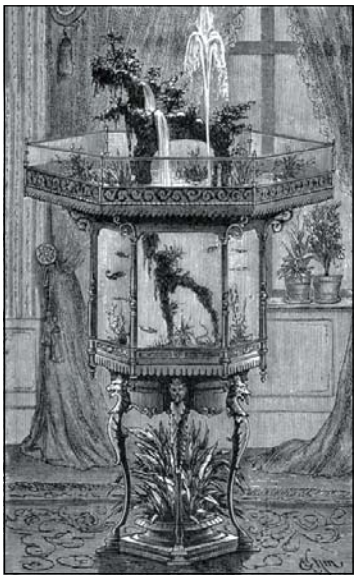

Figure 24: From "The freshwater aquarium and its inhabitants," Reference 35, 1886.

Heß described the construction of aquariums in great detail (Figure 23) and some of the more interesting types are shown in Figures 24 and 25, the former showing a very ornate combination aquarium/terrarium. One always wonders, however, if any of the aquariums such as the one shown in Figure 24 were ever

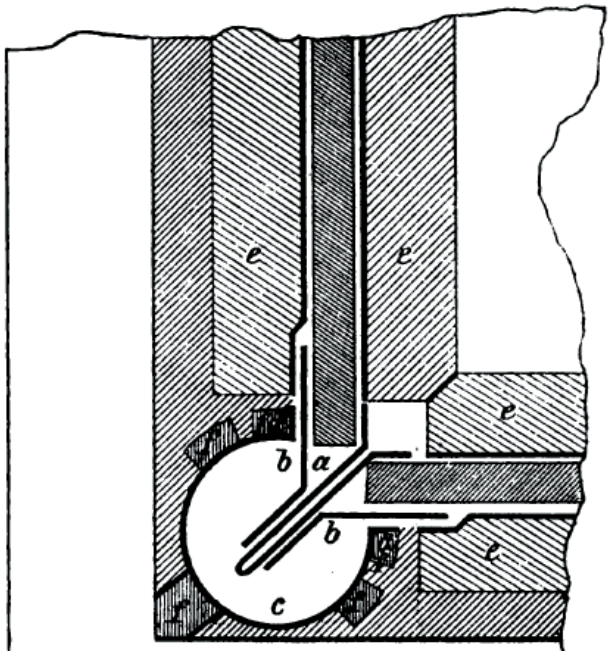

Figure 23: From "The freshwater aquarium and its inhabitants," Reference 35, 1886.

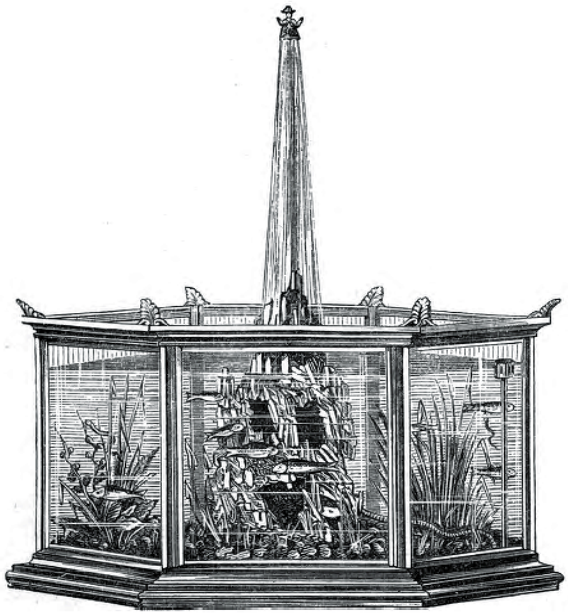

Figure 25: From "The freshwater aquarium and its inhabitants," Reference 35, 1886.

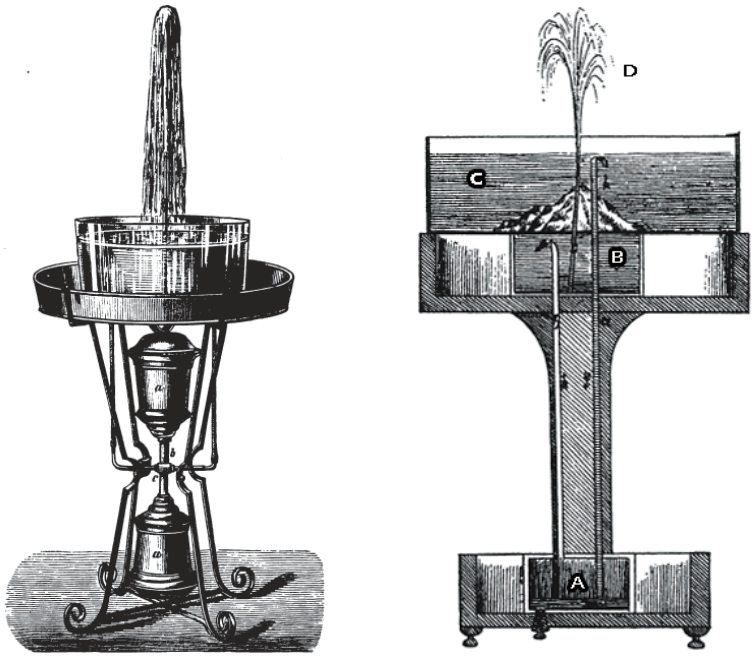
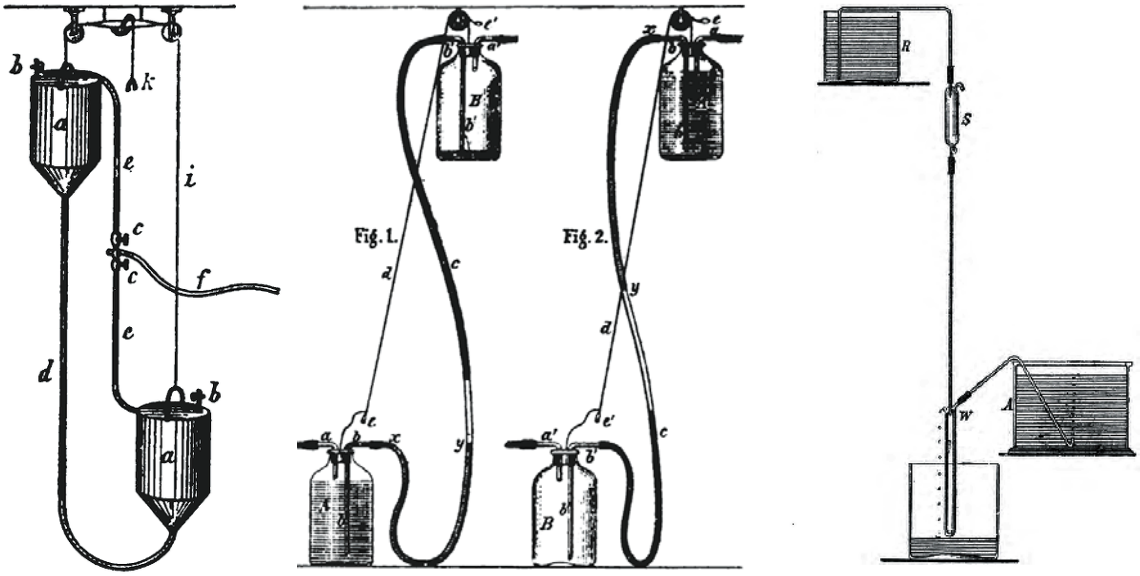


Figures 26 and 27: From "The freshwater aquarium and its inhabitants," Reference 35, 1886.

constructed. For one thing, how was access to the fish provided for (feeding, maintenance, etc.) when there was a terrarium on top of it? The woodcut shows a fountain and a waterfall, presumable driven by air (we'll get to how fountain aquarium were made soon), but where were the containers for the air and water and the conduits for them? Behind the curtain for the former and under the rug for the latter?

Heß shows a number of fountain aquariums, two of which are shown in Figures 26 and 27. Both of them are based upon the principle of water displacing air. The one in Figure 26, however, rotates the two reservoirs so that when the one filled with water is on top, the water flows down and displaces the air which is used to produce the fountain flow. Heß remarked that, depending upon the size of the reservoirs and the size of the tubing, the air flow could be sustained for two to ten hours before the reservoirs needed to be rotated. The principle is further explained in my article, "The Early History of Aquarium Aeration" (Klee, 2013b). In Figure 27, at the start



Figures 28, 29 and 30: From "The freshwater aquarium and its inhabitants," Reference 35, 1886.

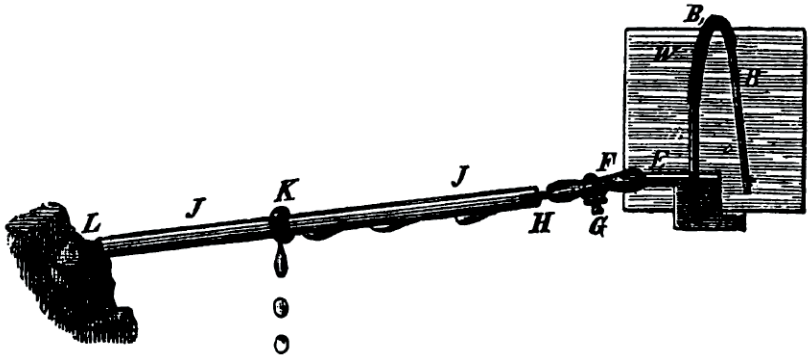


Figure 31: From "The freshwater aquarium and its inhabitants," Reference 35, 1886.

A is a reservoir containing air and B is a reservoir containing water. On the top of reservoir B is a fish tank, C. Water flowing from C into A compresses the air above it, forcing the air up into B where it pushes the water into the nozzle D where it then falls back into C replenishing the fish tank water. After a while B is empty and the process stops. Excess water is removed from C via a valve and the process is started over again.

A number of free-standing aeration devices based upon the displacement principle are discussed in Heß's book and I show two of them in Figures 28 and 29. Instead of rotating the air and water reservoirs as in Figure 25, the reservoirs were simply raised and lowered simultaneously using a pulley system.

Figure 30 is an interesting variation using the air lift principle. Water is drawn from reservoir R into a glass tube S that is open to the air at its top. This acts as a Venturi and as water passes through, air is mixed with the water. It passes through a U-tube and then, because now it is an air-lift, rises through the left portion of the tube to a chamber, W, where the water separates from the mixture and falls into the collection reservoir while the air continues into Aquarium A.

Figure 31 is based upon the drip or drop method. Water is drawn off from the reservoir on the right via a narrow tube that fits loosely into a larger tube, J, which is closed at its end, L. Tube J is positioned slightly downward (the author mentioned that it can be held in place by leaning end L against a rock in the aquarium to be so aerated). The flow of water is adjusted by the pinch clamp G. Water will back up in J and run back to point H where it forms droplets that run along its lower part. A rubber ring slides along J and its position determines where the water droplets will be released (presumably into an aquarium that, because of the buildup of water, must be emptied of excess water at times).

Figure 32, left shows a device using the Venturi principle to add air to the column of water leading from the aquarium. A smaller tube (a) from the aquarium is inserted into a larger one (c), the water running through picking up air as it moves downward into the pipe-

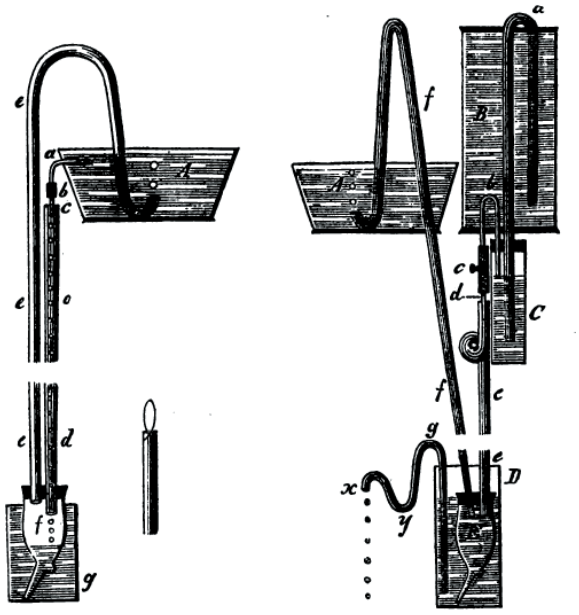

Figure 32: From "The freshwater aquarium and its inhabitants," Reference 35, 1886.

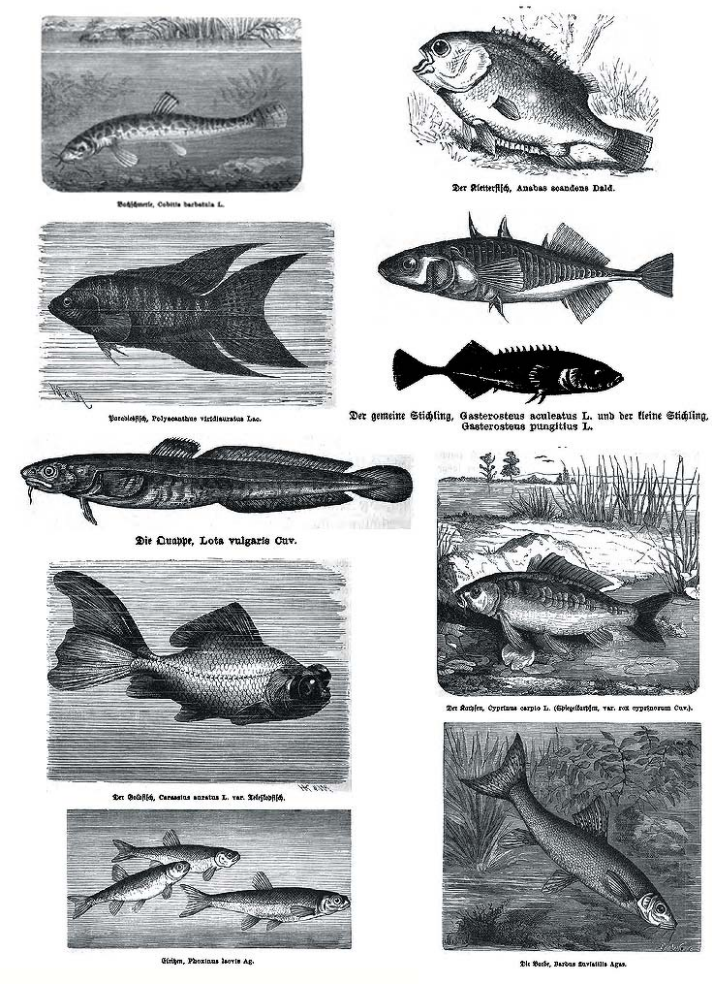

Figure 33: From "The freshwater aquarium and its inhabitants," Reference 35, 1886.

shaped container f (whose point is open) that is set in a sealed reservoir g. A short rubber tube fitted with a screw clamp (b) is used to control the flow. The air/water mixture separates in f and the air travels via a second tube to the aquarium. Following Pascal's Rule, in order to produce the necessary counter-pressure the deeper the water in the aquarium, the higher must be the glass (g). As a general guideline, one set the height of g the same as the height of the water in the aquarium.

Figure 32, right shows a modification of the system. A very wide and high earthenware pot (B) filled with fresh water is set on the table that holds the aquarium. Tube a carries the water into the bottle (C) where any sediment collects in the bottom. From C the water flows through the siphon (b) and from there on uses the same Venturi principle to pick up air as described in the preceding device. Tube (g) is a self-working lift that drains water from the open vessel (D) into a separate container.

Heß described a number of aquarium fishes, both native and exotic, and a number of these are shown in Figure 33.

A number of booklets of varying lengths end this decade. References 37 (72 pages), 39 (23 pages) and 40 (30 pages) were authored by Guido Findeis, an Austrian who was also a publisher of books and magazines on many subjects, including nature. Reference 38 (57 pages) was written by

Figure 34: "The saltwater aquarium and its inhabitants," Reference 38, 1886.

Figure 35: Bruno Dürigen (1853-1930.

Alexander Orleb and his brother, Gustav (Figure 34), and differs from the others in that it was intended for young readers.

Only the following, however, merits further discussion, i.e., the 52-page booklet (Reference 36) by Bruno Dürigen (Figure 35, "Fremdländische Zierfische: Ein handbuch für die naturgeschichte, pflege und zucht der bisher eingeführten aquarienfische" ("Exotic ornamental fish: Tips for the observation care and breeding of the paradise fish, gouramies, goldfish, telescope fish, dog fish [i.e., *Umbra*] etc.").

Dürigen (1853–1930) was interested in natural sciences in general, especially in the broad field of zoology. Although he wrote "Germany's amphibians and reptiles: a description and depiction of all the amphibians and reptiles occurring in Germany and adjacent areas"], he is most famous for his "The poultry farming manual and textbook of racial science, breeding, care and management of domestic, farm and ornamental fowl," consisting of 1082 pages in two volumes. Initially self-educated, as a guest student he completed his studies at the Berlin University, obtained an honorary doctorate and became an honorary professor for poultry science at the Agricultural Academy, Berlin. As we shall shortly see, Dürigen was also the first editor of the *Blätter für Aquarien und Terrarienfreunde*.

His "Exotic Ornamental Fish" book was published in 1886 by Paul Matte, the latter a famous breeder of exotic fishes. Based upon both Matte's and Dürigen's experiences, it was the first publication devoted solely to exotic aquarium fishes. Figure 36 shows the cover of the booklet and some of the fishes discussed.

Figure 36: "Exotic Ornamental fish: Tips for the observation care and breeding of the paradise fish, gouramies, goldfish, telescope fish, dog fish etc.," Reference 36, 1886.

DR. EMIL BUCK

Many of the devices shown and discussed in Heß's books were the brainchild of Dr. Emil Buck (e.g., Figures 19, 20, 29 and 30) and published, along with other articles concerning the aquarium, in the Zoologische Garten over the years 1874-1897 and in the *Blätter für Aquarien und Terrarienfreunde* (which we will get to shortly) over the years 1894-1895. Excepting when his material was reprinted from other publications, Buck's articles always were the lead in the *Blätter*. Figure 37 shows a grav-

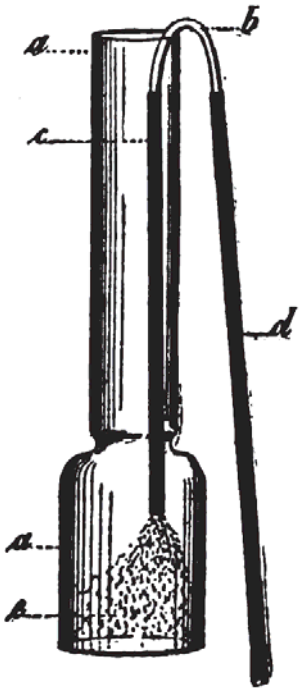

Figure 37: A gravel cleaner designed by Emil Buck, from the *Blätter für Aquarien und Terrarienfreunde,* No. 10, 1854.

el cleaner he made from a cylinder taken from an oil lamp and discussed in issue No. 10 of the *Blätter* for 1854 and Table III lists some of hid articles on fishes and equipment.

Emil Buck, the youngest son of wealthy parents, was born in 1840 in Metz. In 1845the family moved to Frankfort, where the family had roots since 1745. Although his mental development was strong, his health was somewhat delicate. Despite this handicap he developed an interest in the lower animal world in a significant way, crawling around on all fours in the garden for worms, insects, etc. seeking to look and observe them. He was not strong enough for the family's agricultural trade, and so in 1856 accompanied his elder brother, Victor, to Rotterdam to teach. The business administration department, however, was of no interest to him so Buck left in 1863 when, by the death of his parents, he had become independent wealthy and devoted himself exclusively to scientific study, particularly those related to his cherished biological studies of the lower freshwater animals.

He always sought to fill the gaps that existed in the state of affairs of his education, especially his knowledge of ancient and modern languages. He was tireless in the enrichment of his scientific knowledge, and in 1869 he joined the Senckenberggischen Naturforschenden Gesellschaft (Senckenberg Natural History Society). In 1873 he became its corresponding secretary and member of the management, and in 1879 took over the management of the herpetological section at the Senckenberg Museum. In 1875 he left for Zurich to attend the University of Zurich and in 1877 he received his Ph.D., his thesis titled, "Some Rhizopodenstudien." In the December 1876 issue of the *Journal of Microscopy*, this thesis work received a very favorable review.

His special interests were of two kinds, both of which were pursued in the minutest detail. The first was research on the world in miniature. The other was to provide environments in which the microcosm of fresh water could thrive. He was an authority in the establishment and maintenance of aquariums.

He was an avid aquarist and made his own tanks from cement and, with pumice, created miniature landscapes. There were no missing bays, ledges or terraces. Miniature heights, sometimes steep, sometimes gently sloped, went down to the water level of the "lake" to a small moss-covered island. The lower riverside areas provided swampy places and the rock bed was a sunken pool of water. All the living conditions of the nature of a lake were

№ 1 u. 2. Schriftleitung: Bruno Dürigen in Berlin S.W., Friesenstr. 25. I. Band.

Inhalt:

An die Leser! — W. Geyer: Wünsche und Ziele der Aquarien-Liebhaberei. — W. Hartwig: Verbessertes Aquarium. — Beliebte Wasserpflanzen. — W. Hartwig: Züchtung des kleinen Blattfuß, Lep. productus (mit Abbildung). — Die Schleimfäden des Seefichling-Nestes; nach Prof. K. Möbius' Untersuchungen (mit Abbildung). — P. Matte: Aufzucht von Blaufelchen. — P. Jung: Unsere Schlangen. — B. Dürigen: Die vierzehige Fußschleiche (Sepa monoecton). — Vereins-Nachrichten. — Ausstellung von Aquarien und Terrarien. — Kleine Mittheilungen. — Fragekasten. — Bitte. — Anzeigen.

An die Leser!

Mit Schluß des Jahres 1889 hat die Wochenschrift „Isis", welche ihrer Bestimmung gemäß in ihren Spalten auch der Aquarien- und Terrarien-Liebhaberei Raum geben sollte, aufgehört zu erscheinen. Da nun aber jene Liebhaberei während der letzten Jahrzehnte einen solchen Aufschwung genommen, daß sogar eigene Vereine sich gebildet haben, so faßte die mitunterzeichnete Verlagshandlung den Plan, eine Zeitschrift ins Leben zu rufen, welche ausschließlich den Zwecken der Aquarien- und Terrarien-Freunde dienen, ihnen Fingerzeige für die Einrichtung und Instandhaltung von Süßwasser- und Seewasser-Aquarien und Terrarien geben, sie bei Erwerb, Pflege und Züchtung der in denselben zu beherbergenden Thiere und Pflanzen durch Winke und Unterweisungen wissenschaftlicher und praktischer Art unterstützen sollte. Nachdem auch das inzwischen unter dem Titel „Aquarium und Terrarium" entstandene Organ des Vereins für Aquarien- und Terrarien-Liebhaber zu Berlin in ihren Verlag übergegangen, legt sie hiermit die 1. Nummer des neuen Blattes, dessen Leitung der mitunterzeichnete B. Dürigen übernommen, den Lesern vor.

Der Zweck unserer „Blätter" ist schon oben in wenigen Strichen gekennzeichnet. Sie sehen ihre Aufgabe darin, den Liebhabern von Zimmer-Aquarien und -Terrarien, den Pflegern empfehlens- und begehrenswerther Wasser- und Glashaus-Pflanzen, den Freunden der so ungemein anziehenden und so unerschöpflichen Stoff zur Unterhaltung und Belehrung bietenden, leider aber erst

Figure 38: The first issue of the *Blätter für Aquarien und Terrarienfreunde,* No. 1 & 2 combined, 1890.

so created, that the animals, some of them very rare, lived and multiplied. Highly inventive, he devised devices for aeration and was intent on improving them, as witnessed by his numerous publications. In 1866, worried for the survival of his animals, he was producing a flow of water and aeration in his aquarium by a device powered by strong spring work.

Emil Buck died in 1889 and in his obituary dedicated to him, Oskar Boettger (a German zoologist associated with the Senckenberg Museum in Frankfurt) stated: **"Biology owes the deceased an abundance of subtle and detailed observations, the aquarist loses one of its founders and most indefatigable apostle.**"

THE BLÄTTER FÜR AQUARIEN UND TERRARIENFREUNDE

The first issue of this magazine – 24 issues a year - appeared in 1890 under the editorship of Bruno Dürigen in Berlin (Figure 38). Very little on aquariums appeared in this issue, but in issue 22 Paul Nitsche discussed and described the fountain aeration devices shown in Figure 39. In an article by Wilhelm Geyer titled "Wünsche und Ziele der Aquarien-Liebhaberei" ["Desires and goals of the aquarium hobby"], the author discusses various groups of fishes, including the Cyprinodonts or "Zahnkarpfen" as the Germans termed them, a direct translation of the scientific name, i.e., tooth carps. In this section the author states: "Among them here included in the genus Fundulus are 20 species, informally known as "killi-fishes," making it the first time that the term killifish appeared in an aquarium hobby periodical. However, the Germans persisted in their use of Zahnkarpfen for these fishes, just as the Americans persisted in their use of Panchax until the advent of the American Killifish Association in 1962 when the whole world switched to using the term, killifish.

There were three pages of advertisements in the combined, No. 1 No. 2 issue but unfortunately, advertisements dropped off to only one page (and even less) in subsequent issues and continued on in this way for the remainder of the year. Each subsequent issue had about 10 pages, including advertisements

Paul Matte, Lankwitz,
Post- und Bahnstation Südende, Berlin-Anhalter Bahn.
— Anerkannt größte Züchterei fremdländ. Zierfische. —
Aquarien, Terrarien, Zimmer-Fontainen, Transportgefässe.

Aquarien-Pflanzen, Bodenfüllungen ꝛc. auf Wunsch gratis und franco.

Figure 40: Paul Matte's advertisement in the *Blätter*, 1890.

The advertisements, however, provide us with a good idea of the stage of development of the commercial side of the hobby in Germany at this time. Aquatic plants such as *Vallisneria spiralis* and *Aponogeton distachyon* (the latter originally from South Africa) were offered, as were aquariums of all shapes and kinds including ornate vases, four- and six-sided flat aquaria and fountain aquaria. Paul Matte's ad is shown in Figure 40 and reads, "The acknowledged biggest breeder of Exotic ornamental fish."

The fourth edition of Roßmäßler's book was available in two different bindings. A longer book – 213 pages – on marine aquaria, "Seewasser-Aquarien im Zimmer" ["Marine Aquaria in the Living Room"], written by Reinhold Eduard Hoffmann was also advertised. A third book (198 pages), written by Wilhelm Geyer, "Katechismus für Aquarienliebhaber: Fragen und Antworten über die Einrichtung, Besetzung und Pflege des Süsswasser-Aquariums, sowie über Krankheiten und Züchtung der Fische" ["Catechism for aquarium lovers: Questions and Answers on the establishment, staffing and maintenance of the freshwater aquarium, as well as diseases and breeding of fish"], was also advertised.

By 1890 then, the aquarium hobby, both freshwater and marine, was thriving and well on its way into the pioneering efforts on the part of German aquarists to explore foreign lands and to introduce new exotic species into the hobby.

ENDLER'S GUPPY: A SPECIES OR NOT A SPECIES?

By Albert J. Klee, Ph.D.

Aquarium Hobby Historical Society, Yahoo Files Section, March 16, 2013

One of the most divisive controversies in the aquarium world, one that has also spilled over into the professional world of ichthyology, is the naming of Endler's Guppy as a new species. The description of a new species and its ultimate disposition involves certain steps that must be taken by the author of the species and also actions by other ichthyologists that may arise along the way. A basic knowledge of the process is helpful in explaining controversies such as this one; it may also heal old wounds or, at the very least, reduce the level of acrimony in the dispute.

THE NAME

The name of the new species is admittedly not the first thing that comes to mind to its describer but there is no getting around it since there are rules that govern how one names a species. These rules are those put down by the International Commission on Zoological Nomenclature (ICZN), which acts as the adviser and arbiter for the zoological community by generating and disseminating information on the correct use of the scientific names of animals. The ICZN is responsible for producing the International Code of Zoological Nomenclature - a set of rules for the naming of animals and the resolution of nomenclatural problems. The essentials of this Code can be summed up in two words: bookkeeping, i.e., the rules for the construction of a name, and priority, i.e., the adjudication of instances where two ichthyologists for whatever reason have described the same species under two different names. For further discussion of these matters and examples of each I refer the reader to my monograph, "The Name Game?" (Klee, 2009).

Consequently, in addition to following the rules in deciding the name of the new species, an author must also do his homework to make sure that he or she is not, in a sense, "reinventing the wheel," since all that would accomplish is to present the world with one more synonym and we certainly have enough of those already. In any event, the name is not really much of a concern of aquarists, although it does annoy the aquarium community no end when a name has to be changed because an author was careless in following the rules of name construction or when priority deemed it necessary under the Code. However, since neither bookkeeping nor priority is an issue with Endler's guppy, we'll proceed to more important matters.

THE CRITERIA

What really comes first is the establishment of the reasons why the author thinks the fish in question is a new species. Oddly enough, except in very rare cases the International Commission on Zoological Nomenclature plays no substantive role here since it does not attempt to second-guess ichthyologists in this regard. The ichthyological community, however, does play an important role since if it doesn't accept the reasons given for the describing of a new species then it is simply ignored, although the name remains valid and cannot be used again by another ichthyologist. If there is no consensus about the new species then a controversy is generated, and this is what happened when Poeser, Kempkes and Isbrücker named *Poecilia wingei* in 2005 (Poeser *et al.*, 2005).

Historically, attributes (e.g., a forked tail), counts (e.g., the number of scales along the lateral line) or measurements (e.g., the ratio of the height to length) were used to describe a fish and were generally accepted as valid criteria. As time went by other characteristics

were added to this list of commonly acceptable criteria, such as the shape of bones or (if it was a livebearer to be described) the construction of the gonopodium . The Poeser paper, however, used color and breeding behavior as their criteria, thus unloosing an avalanche of objections.

With regard to color, the Poeser paper stated: "Its closest relative is the common guppy, *P. reticulata*, sharing identical meristic data, but differing by its enhanced metallic body pigmentation. This brightness in body pigmentation is also noticed in the females of *P. wingei*. Moreover, in the zone adjacent to the distribution area of the common guppy, *P. wingei* males exhibit a unique melanophore pattern, viz., a large band in the midsection of its body. The importance of this feature, i.e., the spatial distribution of melanophore patterns, is decisive for its recognition as a valid species."

With regard to breeding behavior, the Poeser paper stated: "The behaviour of *P. wingei* is new to science and is therefore extensively described." This is followed by 858 words of detailed description, a bit involved for a criterion of this sort.

Dr. Felix Breden, who has done extensive work with Endler' guppy at both at the morphological and DNA levels, outlined the reasons for Poeser being wrong at the April 2007 meeting of the American Livebearer Association (ALA) and these were summarized in the September issue of the *Tropical Fish Hobbyist* (Coletti, 2007). The six main reasons that he maintained Poeser was in error were as follows:

1. Behavioral differences can only be classified if a companion group is compared and done so over many generations.
2. Melanophore patterns are not criteria for speciation.
3. Coloration differences are not criteria for speciation. *Poecilia* are polymorphic by nature.
4. No real gonopodial differences between Cumana Endler's and guppy populations exist. This is necessary for taxonomic speciation among livebearers.
5. Endler's guppy hybridizes with other guppy populations frequently. Indeed there is little to no natural barrier to hybridization in the wild.
6. He found no DNA differences when comparing the Cumaná Endler's guppy to *Poecilia reticulata* populations to warrant a new species.

If the ichthyological community agreed with Breden, then Poeser's "new" species would be ignored and confined to the trash heap.

THE GENETICS OF THE GUPPY: AN INCIPIENT SPECIES?

For a long time the guppy was considered a taxonomic group with only one biological type, *Poecilia reticulata.* However, DNA sequence based studies revealed a marked genetic differentiation among guppy populations (Alexander and Breden, 2004; Carvalho *et al.*, 1991; Russell and Magurran, 2006; Shaw *et al.*, 1991). In particular, this phenomenon was especially true for fish from the Caroni vs. the Oropuche drainages of Northern Trinidad and for the Endler guppies from Cumaná vs. other populations from Venezuela. This genetic differentiation was interpreted as being the consequences of independent cases of incipient speciation in *P. reticulata.*

Guppy populations evolve rapidly, within 10 to 102 generations, as a response to changes in selection exerted by predators. The rates of evolution involved can be up to seven orders of magnitude greater than those seen in the fossil record. In 1998 Magurran reviewed the work on the Trinidadian guppy, *Poecilia reticulata*, a species that is renowned for its capac-

ity for population differentiation. Sexual selection, particularly female choice, appeared to reinforce the divergence that natural selection had generated. Perplexingly, however, there were no reproductive barriers that prevented interbreeding between these populations, even those that had been separated for at least 106 generations. Magurran postulated that sexual conflict may be the key to explaining this absence of speciation. Male reproductive behavior, particularly the high incidence of sneaky mating (a situation where if the female is not receptive, males frequently employ a form of coercive mating: the male approaches the female without any display, swings his gonopodium forward and tries to insert it into the genital pore of the unwilling female), may be instrumental in producing sufficient gene flow to prevent reproductive isolation.

Sneaky mating has the potential to undermine female choice, and is known to be an important means of sperm transfer in wild populations. Sexual dimorphism, also a result of sexual conflict in guppies, may inhibit speciation in another way. Morphological differences between the sexes, which have arisen for reproductive reasons, mean that males and females are pre–adapted for different foraging niches. This, in turn, reduces the opportunity for the development of different feeding behaviors, a mechanism that seems to have been important in sympatric speciation, the process through which new species evolve from a single ancestral species while inhabiting the same geographic region, of other fish species. Magurran concluded that the observed population differentiation in Trinidad was an instance of “evolution in action” where population differentiation has not led to the formation of species.

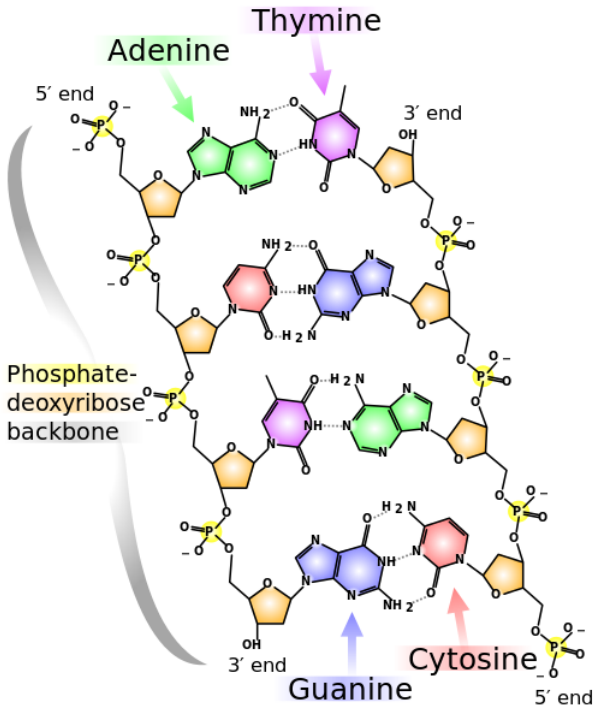
AUTOMATED DNA SEQUENCING: A PRIMER

Automated DNA sequencing is a research tool used by many ichthyologists to determine the sequence of DNA or genetic code that serves as the blueprint of life for every organism on earth. The process of DNA sequencing translates the DNA of a specific organism into a format that is decipherable by researchers and scientists.

DNA (which stands for Deoxyribonucleic acid) is made of chemical building blocks called nucleotides. These building blocks are made of three parts: a phosphate group, a sugar group (not the same as 'table sugar', however) and one of four types of nitrogen bases. To form a strand of DNA, nucleotides are linked into chains, with the phosphate and sugar groups alternating. There are four different bases in the DNA, namely adenine, guanine, cytosine and thymine but for convenience they are simply called “A”, “G”, “C” and “T.” These four are all that's necessary to write a code that describes our entire body plan. Sounds too simple? Keep in mind that the Morse code uses only four symbols (dot, dash, short spaces and long spaces), and you could spell out entire encyclopedias of knowledge with that simple code!

Double-stranded DNA is simply two chains of single-stranded DNA, positioned so their bases can interact with each other. Importantly, the two strands travel in opposite directions and the bases in the middle "pair up" with the bases on the opposite strand, so that a type 'A' nucleotide is always opposite a type 'T', and 'G' is always opposite 'C' (Figure 1). The dotted lines in Figure 1 are the weak nitrogen bonds that hold the two strands together. This has some critically important consequences: (1) If those two strands are separated, they still "recognize" their opposite strand, and (2) If one strand is lost or damaged, it is possible to build its exact duplicate just by examining the remaining intact strand.

FIGURE 1:
Double-Stranded DNA



In DNA sequencing, overlapping sequence data from many clones is analyzed by computers that re-generate the full length sequence by piecing the short sequences together like a puzzle (Figure 2).

The first step is to break open the cells taken from the fish in question to access the DNA, which can be done either by mechanical methods, such as grinding, or by chemicals methods. This is followed up by separating the DNA from the cell debris (Figure 3).

The next step involves separating the double-stranded DNA segment into its two strands, a

FIGURE 2: The Goal of DNA Sequencing

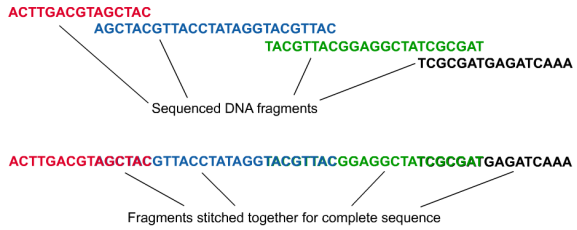


FIGURE 3: DNA Isolation and Purification

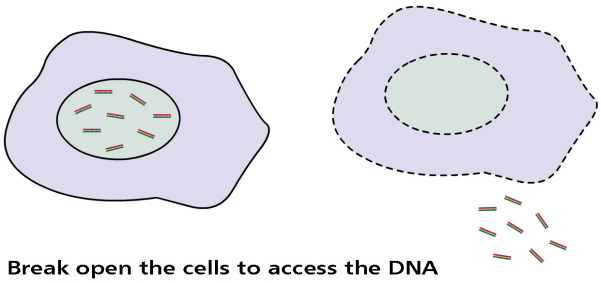

Break open the cells to access the DNA
a. Mechanical methods
b. Chemical methods
Purify DNA from the cell debris

process known as "denaturing." This is accomplished by heating the DNA mixture (there's a critical temperature at which this happens), which disrupts the weak forces holding the strands together (Figure 4). In Figure 4 the strands are represented by the dark green and dark red colored bars, the smaller projections representing the four (hence the four colors) different bases. One strand is designated the "template strand," and other the "complementary strand."

In the next step a small strand of DNA consisting of about twenty bases called a "primer" is annealed to the denatured template strand Figure 5). This is needed to prime the next step, DNA extension. In theory the two DNA

FIGURE 4: Strand Separation or "Denaturing"

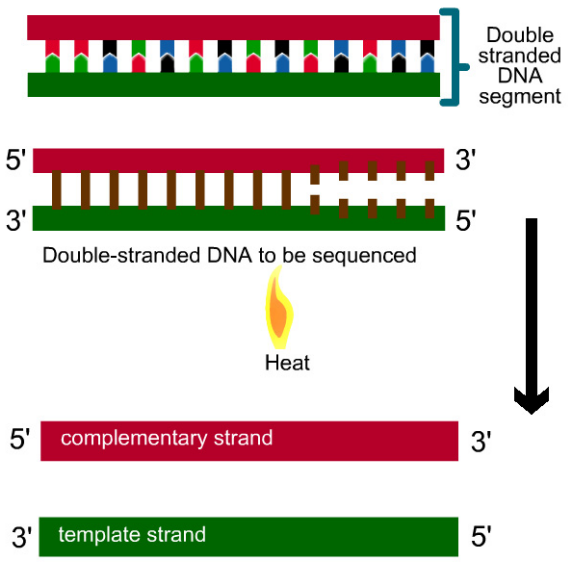

FIGURE 5: Primer Annealing

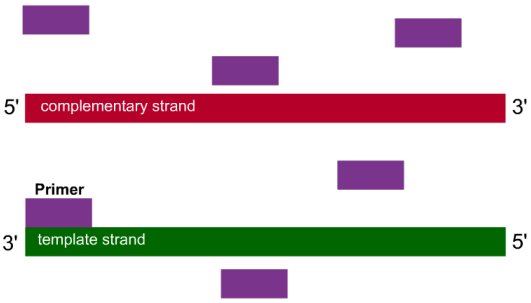
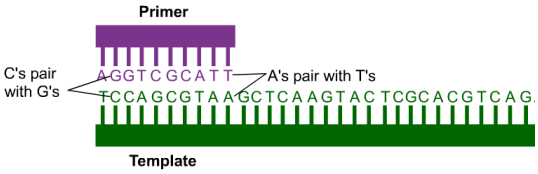


HOW THE PRIMER ATTACHES TO THE TEMPLATE

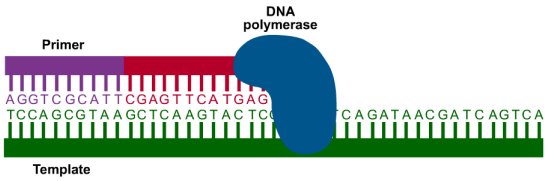


strands that were separated in the preceding step could snap back together but this is avoided by using a rapid cooling process which gives the small primer an advantage over the larger nucleotide. Also a large number of primers are added to make sure they will out-compete the complementary DNA strands for attaching to the template strands.

In the next step a DNA polymerase, an enzyme that synthesizes DNA molecules from the nucleotide building blocks or bases, is added (Figure 6).

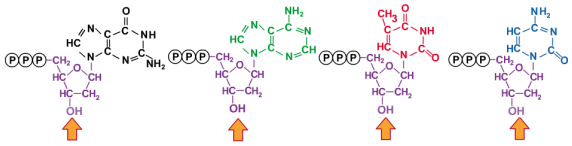
In the termination step (Figure 7) special bases that are missing certain OH groups stop the DNA strand assembly. Each of these modified bases is dyed different colors so they can be read by lasers in the computer.

FIGURE 6: Annealing

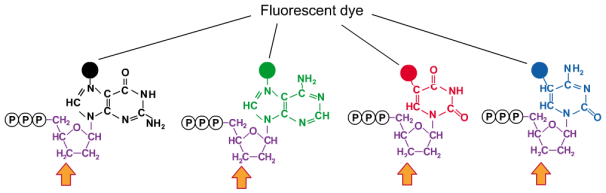


As the DNA polymerase moves down the template, it assembles new DNA chains using the 4 DNA building blocks, i.e., the four bases.

FIGURE 7: Termination

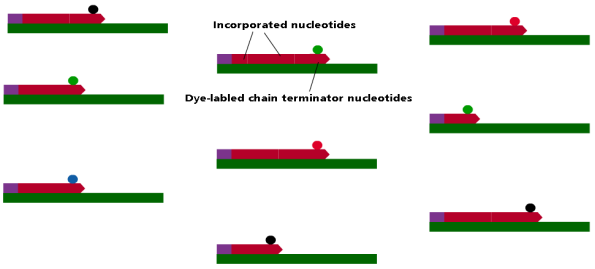


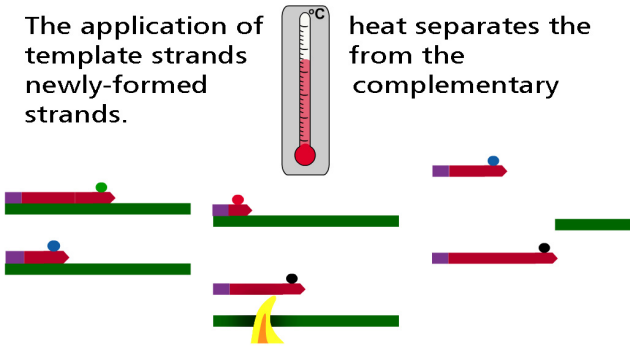
Special dye-labeled bases that are missing certain OH groups stop the DNA strand assembly.



The newly synthesized DNA strands each labeled with one of four dyes are now sorted by length using capillary electrophoresis. First the reaction mixture is heated to keep the newly synthesized strands from annealing with the template DNA strands (Figure 8).

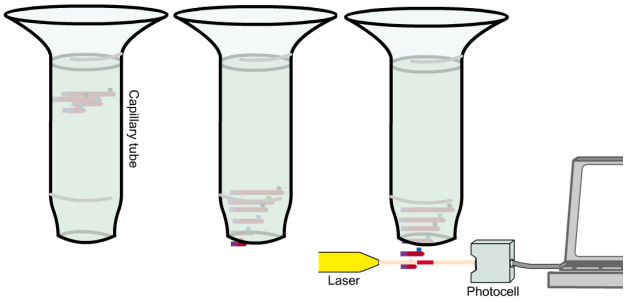
FIGURE 8: Sorting by Capillary Electrophoresis





The dye-labeled single strands are then loaded onto a tiny capillary tube containing a viscous gel-like material (Figure 9). A negative current pulls the electrically-charged DNA

FIGURE 9: Gel Electrophoresis



strands through the capillary. This tube is not much thicker than a human hair and is one to three feet long sufficient to separate strands that differ from only one base. Shorter DNA strands migrate through the gel more quickly and come out of the capillary at the bottom first. As the strands emerge at the bottom of the capillary they pass through a laser beam that excites the fluorescent dye attached to end of each strand. This causes the dye to fluoresce or glow at a different wavelength or color. This color is then detected by a photocell which feeds the information to the computer.

Figure 10 shows an example where the color of the strands, from the shortage to the longest, is red, blue, green, black, green and black. The computer receives this information as TCAGAG.

The computer also receives the information from the photocell as an electropherogram

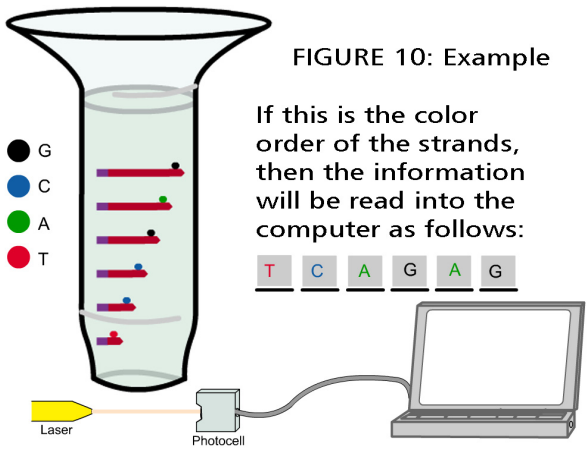


FIGURE 10: Example

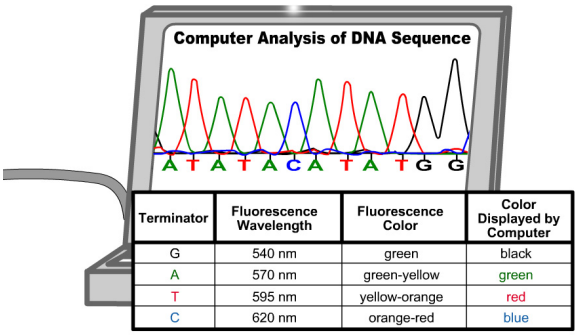
If this is the color order of the strands, then the information will be read into the computer as follows:

T C A G A G

which is a tracing of the signals received by the photodetector in each of the four wavelengths (Figure 11). Although the real colors received by the photodetector are closer to green yellow, orange and red, the computer assigns false colors to each of the four the tracings to make it easier to tell them apart. It also prints the letter of the appropriate base below each of the signal peaks. Because successive peaks correspond to DNA segments that differ in length by one nucleotide, the sequence of peaks reveals the sequence of bases in the original DNA sample.

FIGURE 11: Computer Analysis



Terminator	Fluorescence Wavelength	Fluorescence Color	Color Displayed by Computer
G	540 nm	green	black
A	570 nm	green-yellow	green
T	595 nm	yellow-orange	red
C	620 nm	orange-red	blue

ENTER THE PHYLOGRAM

In 2009 Schories *et al.* described a third species, *Poecilia obscura*, and showed by molecular phylogenetic analysis that *Poecilia reticulata, P. wingei* and *P. obscura* form a cryptic species complex (i.e., where the fish appear identical but are genetically quite distinct) are old species that arose by parallel evolution rather than being emerging new species.

The team used mitochondrial DNA, mitochondria being structures within cells that convert the energy from food into a form that cells can use. Although most DNA is packaged in chromosomes within the nucleus, mitochondria also have a small amount of their own DNA. This genetic material is known as mitochondrial DNA or mtDNA. Unlike nucle-

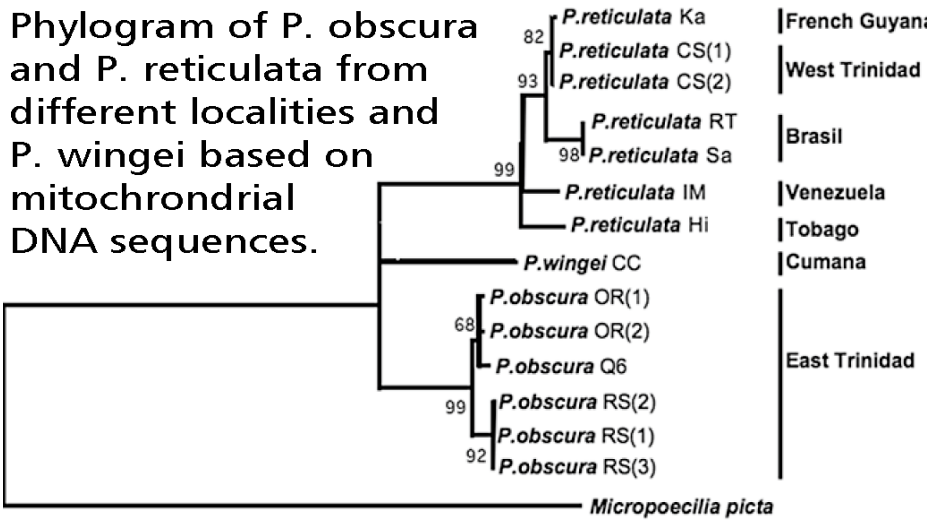
Phylogram of P. obscura and P. reticulata from different localities and P. wingei based on mitochrondrial DNA sequences.

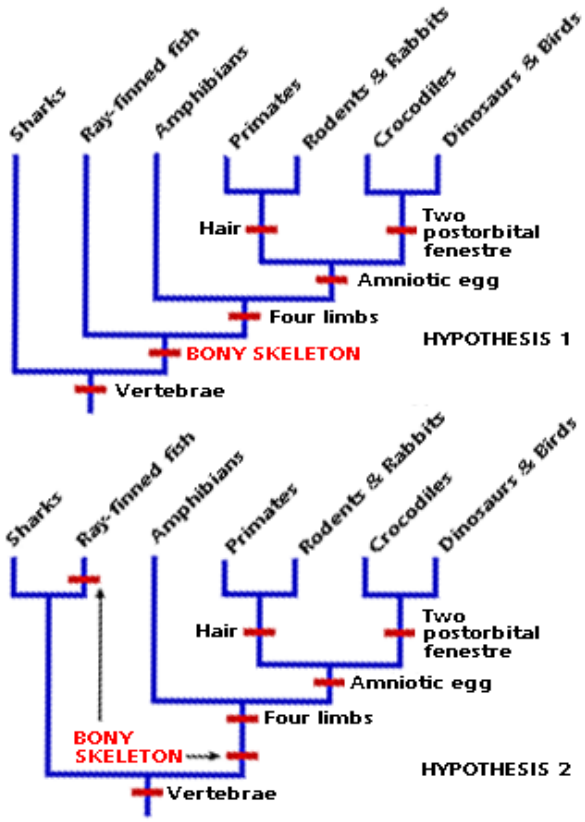


chondrion. Because of this and because the mutation rate of animal mtDNA is higher than that of nuclear DNA, mitochrondrial DNA sequencing represents a mainstay of phylogenetics, in that it allows biologists to elucidate the evolutionary relationships among species and also permits an examination of the relatedness of populations.

ar DNA, which is inherited from both parents and in which genes are rearranged in the process of recombination, there is usually no change in mtDNA from parent to offspring. Although mtDNA also recombines, it does so with copies of itself within the same mito-

Their phylogram (a phylogenetic tree whose branch lengths are proportional to the amount of change) is shown in Figure 12. Note that they did not show that *Poecilia wingei* was a valid species by DNA sequencing directly, since guppy DNA is too variable to distinguish species by DNA sequencing alone. Instead, they used the results of the sequencing as input to the heuristic and branch-and-bound tree searches shown in their paper.

FIGURE 13: Parsimony



In my monograph, "How Cladists Work," I described one heuristic method, i.e., maximum likelihood, but Schories et al. constructed their trees using both parsimony and distance (minimum evolution) criteria. Parsimony scores the number of changes between different character states that at minimum are necessary to explain the observed data given the tree. The best hypothesis is the tree requiring the fewest changes. This score, often referred to as the tree's length, is the minimum number of changes for the tree. Parsimony uses the observations without any attempt to use an explicit model to estimate the total number of changes. In Figure 13, Hypothesis 1 requires six evolutionary changes and Hypothesis 2 requires seven evolutionary changes, with a bony skeleton evolving inde-

pendently, twice. Although both fit the available data, the parsimony principle says that Hypothesis 1 is better - since it does not hypothesize unnecessarily complicated changes.

The Minimum Evolution criterion is a subclass of Parsimony and differs in that the observations are not used directly to calculate the tree score. Instead the data are transformed to pair-wise distances, and the score is calculated from those. Using pair-wise distances is an advantage for some kinds of data such as DNA-DNA hybridization where the data from the experiments are pair-wise differences. Bear in mind, however, that whatever the criterion used, the output from a phylogenetic analysis is nothing more than a hypothesis of relationship of different taxa.

THE ARGUMENT AGAINST HEURISTIC METHODS

Since this is the case, there can be legitimate disagreements on the determination of phylograms or phylogenetic trees. First of all, note that with respect to the Schories *et al.* paper I used the term "heuristic" because the trees are determined by heuristic methods. Heuristics are strategies using readily accessible, though loosely applicable, information to solve problems. For a variety of reasons, the finding of an optimal phylogenetic solution in ichthyology is impractical. For one thing, no one was around over the millennia to observe the evolution of species. A common way of overcoming this unhappy state of affairs, however, is the development of heuristic (approximate) methods.

A method is deemed to be scientific if it performs empirical tests, i.e., if it applies empirical data that could potentially refute the hypothesis of interest, so you can easily see that we are out of luck here. Methods such as heuristics that do not perform tests and therefore are not scientific may nonetheless point to more weakly or ambiguously corroborated hypotheses, such propositions being more easily refuted than those that have been more severely tested and are more strongly corroborated. Based on common usage, data exploration in phylogenetics is accomplished by any method that conducts sensitivity or quality analysis and this includes heuristical methods.

THE ARGUMENT FOR HEURISTIC METHODS

There are some that denigrate heuristic methods as "guesswork," but there are guesses and there are guesses. When I was teaching decision theory I would pose the following problem to my students: If you pull out a single card from a well-shuffled deck of 52 cards, what is the probably of it being an ace? They had no problem in ascertaining the correct answer, i.e., 4 out of 52 or about 7.7 percent.

To my next question, however, there was no equanimity: From a well-shuffled deck of 52 cards I pick one at random and throw it out the window without looking at it. I now pick a single card at random from the remaining 51-card deck. What is the probability that the card is an ace?

Now this can be calculated precisely but my students were not at that stage in the course just yet so I offered the following heuristic argument: The discarding of the card does not add to or subtract from your knowledge. Therefore you have no reason to change your estimate of 4/52. After this statement there were usually still some blank stares from the class so I continued with a variation of the same question: I now pick another single card at random from the remaining deck and toss it out the window. Again, what is the probability that the card is an ace?

I do this until 51 cards have been tossed out the window and a single card remains. Now

the answer is obvious. The situation is identical to picking a card from a deck of 52. It makes no difference whether the remaining deck of 51 still sits on the table or whether it has been tossed out the window. In this case the heuristic argument is as precise as the scientific technique that calculates the true probability.

Returning now to the original problem of throwing out a single card, I devise the following heuristic technique. I write a computer program that simulates the 52-card deck, the random discard of one card and the random drawing of a card from the remaining 51. The computer "looks at" the card and determines whether it is an ace or not and records the information. It starts over with the 52-card deck and repeats the process. It does this 50,000 times and prints out the number of aces it found divided by 50,000. The answer will be so close to the true answer of 4/52 that it makes no practical difference; in other words, for all useful purposes the method is as good as the scientific one.

The method I used was a heuristic one called Monte Carlo sampling. It was invented in the late 1940s by Stanislaw Ulam while he was working on nuclear weapon projects at the Los Alamos National Laboratory. Immediately after Ulam's breakthrough, John von Neumann understood its importance and programmed the ENIAC computer to carry out Monte Carlo calculations. (Being secret, the work of von Neumann and Ulam required a code name and Von Neumann chose the name Monte Carlo, a reference to the Monte Carlo Casino in Monaco where Ulam's uncle would borrow money from him to gamble.) It has been used to solve problems in physical sciences, engineering, computational biology, computer graphics, applied statistics, design and visuals, finance, business, telecommunications and mathematics, to name just some areas. The point is, don't throw out the heuristic baby with the bath water. Heuristic methods do have their uses and at times, very important ones.

SO, IS IT A SPECIES OR NOT?

Speciation in the guppy and its close relatives is complicated by interbreeding, introduction by aquarists and others of guppy populations into locations around the word and habitat disturbances (Rosen 1957, Endler 2011 and Klee 2013). As I pointed out early in this monograph, the ichthyological community plays an important role in this matter in three different ways: (1) If it accepts the reasons given for the describing of a new species, then that is that; (2) If on the other hand it doesn't accept the reasons then it is simply ignored; and (3) if there is no consensus about accepting the new species then a controversy is generated.

Prior to the publication of the paper by Schories et al. there wasn't much acceptance of the new species. Although their paper did not refute Breden's six objections, it added information on a molecular scale that supported Poeser's new species, information that was sufficient for many to change their minds.

Molecular systematics is an essentially cladistic approach: it assumes that classification must correspond to phylogenetic descent, and that all valid taxa must be monophyletic, meaning that each consists of a species and all its descendants.

Molecular phylogenies are sensitive to the assumptions and models that go into making them. They face problems like long-branch attraction (a phenomenon in phylogenetic analyses when highly dissimilar nodes, i.e., those with long branches, cluster together), saturation (where the phylogenetic signal is overwhelmed by multiple changes at each site, a sort of phylogenetic "noise") and taxon sampling problems (e.g., three-taxon trees can be very difficult to estimate correctly if the rates

of evolution are high). This means that strikingly different results can be obtained by applying different models to the same dataset. Only time will tell, therefore, if this is the majority opinion.

THE BITTERLING TEST FOR PREGNANCY

by Albert J. Klee

(Aquarium Hobby Historical Society, Yahoo Files, July 21, 2013)

Although I have discussed the use of pregnancy urine and the results of a number of experiments therewith, including some of my own, I have not previously looked into the details of the origin of the method, i.e., the use of the European bitterling (*Rhodeus amarus*) in a test for human pregnancy, which, simply put, the fish possesses an ovipositor that is supposed to elongate when the animal is exposed to pregnancy urine.

The procedure was essentially as follows. A mature fish was placed in a quart of water at a temperature of 75 degrees F. The fish was first observed to determine whether the oviduct was beyond normal limits, i.e., about 2 mm. If so, the specimen was rejected and another one selected. Four c.c. of the urine to be tested was added and the fish observed at 24 hour intervals for 72 hours. In a positive reaction the ovipositor reached a length of from 15 to 25 mm. Most of these occurred within the first 24 hours, and so the test was discontinued as soon as it was positive. A negative reaction could only be reported after 72 hours. After the test was completed the fish was placed in a tank with fresh water for recovery. The regression of the ovipositor following a positive reaction took about two weeks, and after three weeks the fish was able to be used again.

The history behind this is as follows: In 1934 Kanter et al. [1] reported successful experiments with the fish, their work being based upon that of Tozawa [2] in 1924, followed by Fleischman and Kann in 1932 [3] and Szusz [4] in 1935. However, when Kleiner et al. [5] repeated their work in 1935 they found it impossible to standardize the fish as Kanter and his colleagues did, i.e., to be able to select specimens that would respond in a like manner, and concluded that the biological reaction obtained was not a specific test for pregnancy.

In 1936 Gottlieb [6] attempted to repeat the experiments of these researchers. His attempts to standardize the fish were only partially successful, however. Fourteen out of 17 fish responded to the pregnancy urine, while 3 did not respond to any kind of urine and were therefore excluded from the test. However, it was impossible to find any of the fish which would not respond to certain urines from non-pregnant women. Urine from non-pregnant women or from males which gave a positive reaction in one fish would regularly give a positive reaction in all other fish. Standardization as required by Kanter and his colleagues, therefore, was found by Gottlieb to be only partially possible.

Gottlieb performed seven sets of experiments, the descriptions and results being as follows (the experiments were carried out during the months of May to September; the fish, therefore, responded to the test outside the breeding season just as well as during it):

1. Twenty-eight urines of women known to be pregnant were tested. Of these, 26 gave a positive reaction within 24 hours, while 2 gave a positive reaction within 48 hours. All the reactions were definitely positive.
2. Fourteen urines of women normally menstruating and definitely not pregnant were tested. Three gave definitely positive reactions within 24 hours, while 1 gave a slightly positive reaction, the ovipositor reaching a length of about 10 mm. within 24 hours. Ten samples gave definitely negative reactions.
3. Fourteen urines of normal males were test-

ed. Three gave a positive reaction within 24 hours. These three cases were tried again on several other fish, all giving a positive reaction.
4. Fourteen urines of female children, aged 6 to 8 years, were tested. Two gave a definitely positive reaction in 24 hours. These were tested over again, each on several fish, and gave positive reactions in 24 hours.
5. Twelve urines of women for at least five years in the post-climacteric period were tested. Three showed a, positive reaction in 24 hours and 1 a positive reaction in 48 hours.
6. Ten urines obtained of women while menstruating were tested. One gave a definitely positive reaction in 24 hours and 1 a definitely positive reaction in 48 hours.
7. Eight urines of women pregnant only two months or less (pregnancy is definitely ascertained now) gave definitely positive reactions in 24 hours.

From Gottlieb's experiments it can be seen that a positive reaction to the test can by no means be considered as reliable. However, none of the urine samples obtained from women who definitely were pregnant gave a negative reaction. The fact that some male urines and some urines from women definitely not pregnant are capable of giving the same reaction, proves that it was not a specific test for pregnancy.

In 1938, Fleischmann and Kann determined that in addition to the estrogen found in pregnant women, a specific non-pregnant adrenal hormone, corticosterone, could cause the observed bitterling ovipositor reaction [7]. This is what made the bitterling test not useful for its originally announced purpose.

ADDENDUM

One of the earliest written records of a urine-based pregnancy test can be found in an ancient Egyptian document circa 1350 BC. A papyrus described a test in which a woman who might be pregnant could urinate on wheat and barley seeds over the course of several days: "If the barley grows, it means a male child. If the wheat grows, it means a female child. If both do not grow, she will not bear at all." Testing of this theory in 1963 [8] found that 70 percent of the time, the urine of pregnant women did promote growth, while the urine of non-pregnant women and men did not. Scholars have identified this as perhaps the first test to detect a unique substance in the urine of pregnant women, and have speculated that elevated levels of estrogens in pregnant women's urine may have been the key to its success.

Hormone research blossomed in the 1930's. Scientists recognized that there is a specific hormone (now known as human chorionic gonadotropin (hCG) that is only found in pregnant women. A number of tests were developed to identify hCG by injecting samples to induce ovulation in rabbits, frogs, toads, and rats. These tests were expensive, required the sacrifice of several animals, and slow, often taking days to get results.

In the Aschheim and Zondek test, an infantile female mouse was injected subcutaneously with urine of the person to be tested, and the mouse later was killed and dissected. Presence of ovulation indicated that the urine contained hCG and meant that the person was pregnant. A similar test was developed using immature rabbits. It was a common misconception that the injected rabbit would die only if the woman was pregnant. This led to the phrase "the rabbit died" being used as a euphemism for a positive pregnancy test. In fact, all rabbits used for the test died, because they had to be surgically opened in order to examine the ovaries. While it was possible to do this without killing the rabbit, it was generally deemed not worth the trouble and expense.

An improvement arrived with the frog test, introduced by Lancelot Hogben, which still was used in the 1950s and allowed the frog to remain alive and be used repeatedly: a female frog was injected with serum or urine of the patient; if the frog produced eggs within the next 24 hours, the test was positive. This was called the Bufo test, named after the toad genus *Bufo*, which was originally used for the test. Other species of toads and frogs have been used later on.

THE MYTH of the ROMAN AQUARIUM: Reflections on Aquarium Hobby History Research

by Albert J. Klee

(Aquarium Hobby Historical Society, Yahoo Files, January 4, 2014)

In Bernd Brunner's "The Ocean at Home," we find the following paragraph:

> **"These fish were kept in opaque tanks, often made of marble, in front of the house. The first fish to enter the interior of a house in imperial Rome was the sea barbel, a much cherished and expensive breed. Allegedly, they were kept in small tanks underneath the cushions of the guest beds. Around 50 AD, panes of glass were brought to Rome, Herculanaeum, and Pompeii, to replace one wall of the marble tanks; now it was possible to actually see the hustle and bustle of the fish without having to guess their schematic movements from above."**

Because this statement has now been included in Wikipedia (re-phrased as: **"Introduction of glass panes around the year 50 AD allowed Romans to replace one wall of marble tanks, improving their view of the fish."**), it is now widely quoted in various versions on the Internet. If true, this would mark the Romans as the inventor of the flat-sided aquarium, not the British centuries later.

As Allan Nevins puts it in his "The Gateway to History," **"Mankind dearly loves a good story, and dearly loves to believe it true. Before any tale can greatly please the hearer thereof, it must have some degree of verisimilitude; it must conquer part of our faith."** Nevins illustrates this with the story of H. L. Mencken who, early in his career, wrote an article on the bathtub in which he asserted with plausible historical detail that it had been invented in the 1840's, that Millard Fillmore had been the first to install one in the White House, that the medical profession and the public long regarded it with deep suspicion, and that laws had been passed against the perilous contraption by Virginia, Pennsylvania and Massachusetts.

Mencken was astonished that his witty composition was accepted by most readers at face value. He was still more astonished to find newspapers and magazines copying these "facts" in ever-widening circles as they cropped up year after year in the most dignified of periodicals. As Nevins puts it, **"This naiveté of humankind has its humorous side. But to Historians, it is not quite so amusing."**

Although Brunner copied this material from Herrmann Mostar's "Die Arche Mostar ("Mostar's Ark"), the fault lies mainly with Brunner as he did not validate Mostar's statement and simply assumed that what he wrote was true. It should have been clear to Brunner that the assertion was unsubstantiated as Mostar provided no in-text references for any of his statements re the Romans save for one by Conrad Gesner and another by Seneca, both dealing only with the custom of wealthy Romans observing the colors in the death throes of the mullet. Mostar did not provide a bibliography, either. Brunner deserves some credit, however, for replacing Mostar's **"They put a small tank for them under the cushions of the guest bed..."** with **"Allegedly, they were kept in small tanks underneath the cushions of the guest beds."** Even Brunner was not going to buy that myth.

Mostar (1901- 1973), for those not familiar with the name, was a German writer, poet, columnist and, at times, a narrator, playwright and comedian. He also became Germany's most famous critical court reporter. This particular book deals with animals that have lived together with man, including dogs, cats, cocks, hens, doves, songbirds and fish, but also with the quite undesirable such as flies, spiders, bugs, lice, fleas and rats.

Although Mostar asserts that the Romans kept fish in marble aquaria containing glass panes, one in theory cannot disprove it, since one cannot prove a negative, i.e., that the Romans did not do so. In the same manner, if I make the statement that I saw two *Tyrannosaurus rex* copulating in my backyard, there is no way that anyone can disprove it. With regard to such statements we must insist that the assertor provides some evidence that can be assessed by those who are *compos mentis* and who respond with raised eyebrows to reports like little green men traveling through outer space to annoy earthlings with bright lights.

More seriously, such assessors must also have an understanding of how men in other eras lived and behaved. If one is writing about the first century AD, one relies upon (1) the authors of the time and (2) later authors who have done research of this time period and whose work is generally considered of the highest scholarship. For the first I have read the ten Roman authors in the bibliography and for the second the two modern-day authors listed below them.

Ludwig Heinrich Friedländer (1824 - 1909), by the way, was a philologist and historian noted for his comprehensive survey of Roman social and cultural history. His masterpiece was the "Darstellungen aus des Sittengeschichte Roms" ("Representations from Roman Cultural History"), a detailed and vivid portrait of the social life, customs, art and manners of the first two centuries of the Roman Empire. The work remains one of the most complete surveys of Roman life and society. It was translated into many languages, including English under the title, "Roman Life and Manners under the Early Empire."

In point of fact, none of the authors I cite who lived at the time mentioned aquaria with glass sides. If such existed they would most likely have been owned by Romans of wealth and these authors wrote thousands upon thousands of words about this stratum of Roman society. If such tanks had existed, surely at least one of them would have mentioned it. It would have been too good to pass up! Furthermore, neither Higginbotham nor Friedländer uncovered the existence of such aquaria either.

We can also examine the archeological evidence and here also one cannot prove a negative since we cannot state that some future excavation might not unearth a slew of such aquaria (or even a spaceship containing mummified bodies of a greenish hue). Nonetheless, the recent excavations at Pompeii and Herculaneum, which have provided the most detailed information to date of how the Romans of the day lived, have not unearthed any remains of aquaria with glass sides.

According to Higginbotham, Pompeii supplies the most accessible and best-documented group of piscinae built within an urban and, specifically, a domestic setting (the explanatory notes have been supplied by the author):

"The garden pond could be enjoyed and appreciated from different points of vantage, both public and private. The locations of many ponds within Pompeian houses permit the general or remote glimpse suitable for the casual acquaintance or client. Apertures or windows in the atrium and, specifically, in the tablinum (Note: A tablinum is the main room in a Roman house, later used as the formal reception or living room and study or office by the head of the household.) **allowed a more public audience to see the pond. Many of these same piscinae and others could be enjoyed from much more intimate surroundings. The location of dining areas and reception rooms around the garden often took into account the location of the fishpond. Triclinia** (Note: Triclinia are formal dining rooms in a Roman building.)**, set within rooms or shaded by pergolas afforded selected visitors or guests front-row seats to the splendors of the gardens and their ponds. At Pompeii, over twenty examples of piscinae are situated in close proximity to dining facilities with approxi-**

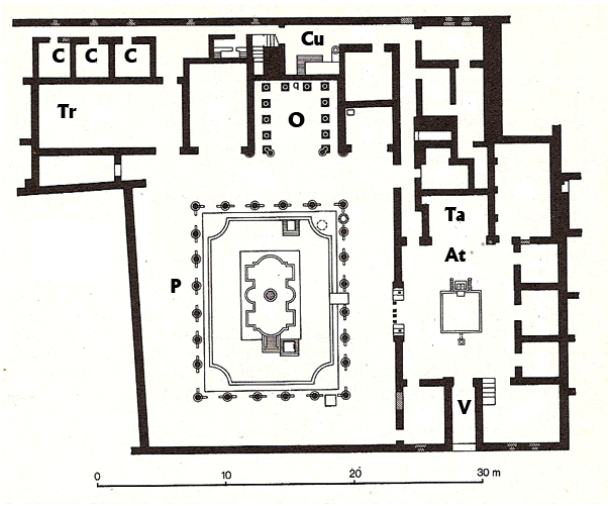

Figure 1: The Casa di Meleagro, Pompeii with a fishpond in the peristyle. Key: C = bedrooms; Cu = kitchen; Tr = triclinium; Ta = tablinum; At = atrium; V = entrance; O = oecus; P = peristyle. A peristyle is an open colonnade in a building surrounding a court that usually contains an internal garden, in this case, however, it is a fishpond. Note the oecus, the principal salon in a Roman house used occasionally as a triclinium for banquets, faces the fishpond.

mately an equal number located where they can be seen easily from reception rooms and garden exedrae (Note: An exedrae was a semi-circular recess or plinth sometimes set into a building's façade.). **The connection between ponds and dining areas is not solely aesthetic but has a gastronomic component as well. Fish or eels fresh from the piscina would make an impressive addition to private meals among friends and honored guests."**

Figure 3: The opposite view of the fishpond. Water cascaded down the six small stairs at the rear, Water also issued forth from a columnar fountain in the center of the pond. The semi-circular niches provided shade for the fish and protection for the smaller fry.

None of the fish receptacles discussed here by Higginbotham, however, are located within buildings and none have glass sides. An example of what Higgenbotham was describing is shown in Figures 1, 2 and 3.

Actually, the only known Roman tanks that contained live fishes are holding tanks associated with transporting fish by boat, fishmonger shops and kitchens. Athenaeus of Naucratis, a Greek historian circa 200 AD, describes

Figure 2: The fishpond in the Casa di Meleagro peristyle. The small square tank in the foreground, which was topped with marble revetment and painted blue, was linked to the larger pond by a single pipe. Higginbotham suggests that it probably served as an enclosure for special fish or to hold the fish while the larger pond was being cleaned.

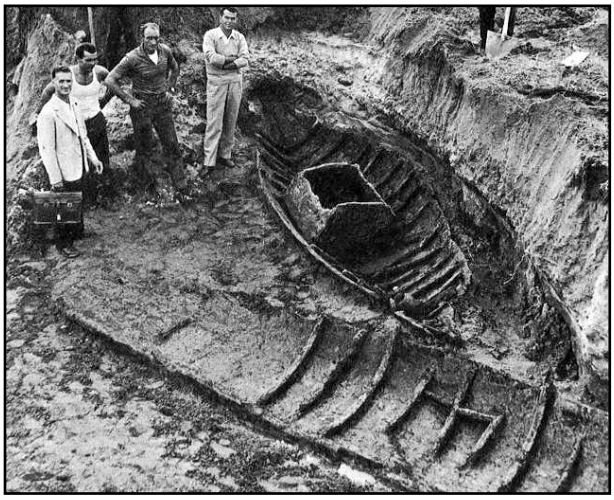

Figure 4: Boat with a fish holding tank (circa late second or early third century AD) found at Fiumicino (a coastal town in the central Italy), near what was the entrance to the Claudian harbor. It was constructed with wooden boards and coated with lead.

a ship built by Archimedes at the behest of the tyrant Hiero II, which had a live tank built into the bow and was constructed of lead and wood. During the construction of the airport at Fiumicino in 1958-59, a boat with a live tank (*navis vivaria*) built with wooden boards and coated with lead was unearthed near what was the entrance to the Claudian harbor (see Figure 4). The presence of holding tanks at some fishmonger's shops have been found in the market of Ostia and also at private houses in or near the kitchens. None of these, however, were made of marble or constructed with glass sides.

Mostar made other statements that are questionable, to say the least. In the following, Mostar is referring to eels, carp and bream: **"Well, all these fish live in water basins that were made from the most precious marble. However, they were still housed outside of the home; the eel had already made it to the fountain."**

Higginbotham, however, states that seaside fishponds were either excavated in rock or constructed of concrete. Inland ponds were usually built of concrete walls with masonry facings. The earliest fishponds built with a datable building method employed concrete faced with *opus incertum*. *Opus incertum* was an ancient Roman construction technique, using irregular shaped and random placed uncut stones or fist-sized tuff blocks inserted in a core of Roman concrete called *opus caementicium*. The *opus incertum* used in these fishponds appears to date to the last years of the second century BC or, more probably, the early years of the first century BC. *Opus reticulatum* was a construction technique using small pyramid shaped blocks of tufa set in a core of *opus caementicium*. The tufa blocks cover the surface, with the pointed end into the cement, so the square bases form a diagonal pattern that resembles a net, hence the name. The masonry facings were often of marble but the fishponds themselves were made of concrete.

Mostar also claimed that, with the arrival of aquaria with glass sides, guests could now also see the mullets breeding during their demise (**"Und nun erblickten die Damen und ihre Kavaliere die Seebarben beim Liebesspiel…"**), a patently ridiculous claim.

Because of erroneous statements such as these and because he provides no references for his assertion that the Romans had glass-sided aquaria, Mostar cannot be taken seriously and, by extension, neither can Brunner in this instance. For an assertion having this degree of consequence to aquarium hobby history, whoever wrote the Wikipedia piece should have done the required research, refuted the assertion out of hand or, better still, not mentioned it at all.

The Perils of Aquarium Hobby History Research: A Case History

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, January 11, 2014)

In my research into matters involving mullets (*Mullus barbatus*, and *Mullus surmuletus*), food fishes esteemed in Roman times, I came across several references to Hortensius (i.e., Quintus Hortensius Hortalis, 114 BC - 50 BC), one of the foremost Roman orators (Figure 1). He dominated the courts by using a florid style and by resorting to shameless bribery. Despite his best efforts at legal trickery and intimidation, he was defeated by Cicero in the Verres case, where Cicero was prosecuting Caius Verres for gross misgovernment in Sicily. Cicero's success in this case won him great acclaim and considerably helped his political career. Hortensius later joined Cicero in several *causes célèbres*, with Cicero always speaking last.

Hortensius gradually withdrew from politics into cultivated luxury. The vast wealth he had accumulated was spent on splendid villas, parks, fishponds and costly entertainments. He was the first to introduce peacocks as a table delicacy at Rome, and Cicero puts him among the aristocrats solely concerned about their fishponds. Lucius Licinius Lucullus, for example, a friend of Hortensius, was well-known for having cut a channel through a mountain near Naples to allow the sea to enter his fishponds and stir the water within to prevent stagnation, for which feat he earned the nickname, "Xerxes in a toga," after the Persian general who cut a channel through the isthmus of Mount Athos for this fleet to pass through. Hortensius also constructed similar fishponds at vast expense, so designed that the tide caused sea water to flow into them.

Hortensius used to water his plane trees with wine, and in a certain case in which he and Cicero had both to speak, he asked Cicero as a favor to change with him, as he was obliged to go home to water with his own hands a plane tree which he had planted on his Tusculum estate. Hortensius was noted for the pains he took in arranging his toga, folding it just so before a mirror. It is said that he once prosecuted a colleague for assault and battery because the latter, meeting him on a narrow footpath, had jostled him and disordered the folds!

One of the references to Hortensius I came across was an 1868 translation of *The Ocean World* by Louis Figuier. Figuier (1819-1894) was a French chemist and writer on occult subjects (Figure 2). After taking his doctorate in medicine and completing his postgraduate study in chemistry, he was made professor of chemistry at the school of Pharmacy in Montpellier and later exchanged this post for a similar one in the School of Pharmacy of Paris. Many honorary degrees in science and medicine were conferred upon him by various faculties during his career. However, in his research he found himself opposed by Claude Bernard, a French physiologist whom historian I.

Figure 1:
Quintus Hortensius Hortalis (114 BC - 50 BC).

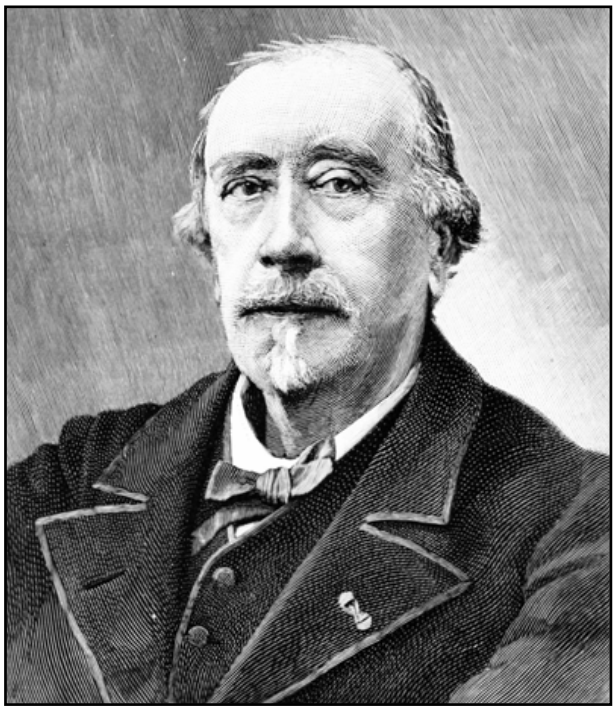

Figure 2: Louis Figuier (1819-1894).

Bernard Cohen of Harvard University called "one of the greatest of all men of science." As a result of this conflict, Figuier abandoned his research to devote himself to popular science. Much of the scientific information in the novels of Jules Verne, by the way, was taken from his works.

In any event, in *The Ocean World* I came across this statement in the section under mullets:

The great rival of Cicero, the advocate Hortensius, who attracted crowds of people to the Forum by his eloquent and elegant discourses, had an inordinate passion for this kind of enjoyment. These little inhabitants of the waters were led by a small canal which was carried under the festive table, and his great enjoyment was to witness the agonies of the unhappy fish just taken from its native element and carried to the table, palpitating with its dying convulsions, as it perished beneath his eyes, he in the meanwhile enjoying a sumptuous banquet.

This was accompanied by an artist's representation of what this might look like (see Figure 3). David W. Cheever, by the way, attributed to Martial (he cites Book X, Epigram XXX) the claim that Roman **"Pisciculture was carried so far that fishponds were constructed on the roofs of houses. More practical persons conducted a stream of river-water through their dining-rooms, so that the fish swam under the table, and it was only necessary to stoop and pick them out the moment before eating them; and as they were often cooked on the table, their perfect freshness was thus insured."**

Martial, however, said no such thing. The epigram actually reads, **"The line seeks not its prey in the distant sea, but the fish, descried from above, draws down the cord cast from bed or couch. If ever Nereus feels the power of Aeolus, the table, safe-supplied from its own store, laughs at the storm; the fishpond feeds turbot and home-reared bass; to its master's call swims the dainty lamprey; the usher summons a favorite gurnard, and, bidden to appear, aged mullets put forth their heads."**

Martial mentions nothing about fishponds on the roof or fishing under the table. On occasion, a rod and line was thrust out of a window from a bed-

Figure 3: "Agony of a Red Mullet at the Feast of Hortensius." From Figuier's "The Ocean World."

room to dangle over an outdoor fishpond (this is discussed thoroughly in the Fourth Edition of my "The Toy Fish," and this is what Martial was alluding to.

However, I was somewhat dubious about the claim and set out to see if I could find any validation of it in the writings of the authors of the day, such as Cicero, Pliny, Varro and others. In this endeavor, I was unsuccessful.

My next thought was that perhaps the translator had made an error so I started a search for the original French version. Alas, there was no such version. Unfortunately, Figuier provided no in-text references nor did he provide a bibliography. On the Title page, however, was the statement, "Chiefly translated from "La Vie et les Mœurs des Animaux," but when I examined that document I found nothing in it about fish. In the introduction by the translator, on the other hand, I found the following:

It is stated on the Title-page that "The Ocean World is chiefly translated from M. Louis Figuier's two most recent works. The History of the Ocean is to a large extent, but not wholly, compiled from 'La Terre et les Mers,' one of the volumes of M. Figuier's 'Tableau de la Nature'; but the larger portion of the work is a free translation of that author's latest work, 'La Vie et les Mœurs des Animaux'; other chapters, such as 'Life in the Ocean,' the chapter on Crustaceans, and some others, are compiled from various sources; they will not be found in either of M. Figuier's volumes; but in other respects his text has been pretty closely followed."

One misstatement was immediately apparent, i.e., only one such work was mentioned on the title page. What the remainder of this bibliographic gobbledygook meant was a mystery to me (and, as I shall later point out, I was not alone) but slogging on I examined *Les Poissons, les Reptiles et les Oiseaux* in Figuier's *La Vie et les Mœurs des Animaux* from his *Tableau de la Nature* and found what I was looking for:

Le rival de Ciceron, l'avocat Hortensius, qui attirait tout le peuple au forum par la beauté de ses harangues, avait une passion désordonnée pour ce petit habitant des eaux. Il faisait venir les rougets dans de petites rigoles jusque sous la table du festin; et il se délectait, assis devant un somptueux banquet, du plaisir de voir un de ces malheureux poissons retiré du bassin et apporté sur sa table, palpitant et agité des convulsions de l'agonie, périr sous ses yeux, en se colorant de mille nuances irrisées.

Keeping in mind that I needed here a more literal translation than an artistic one, I translated it as follows:

The rival of Cicero, the lawyer Hortensius, who attracted all the people in the forum by the beauty of his harangues, had a wild passion for these little inhabitants of water. The mullets were led into a small canal that was carried under the festive table, and he enjoyed sitting in front of his sumptuous banquet, the pleasure of seeing one of those unfortunate fish removed from the pond and brought to the table, and in agonizing convulsions, die before his eyes in iridescent colors of a thousand shades.

Although this didn't differ much from that of Figuier's translator, it did make clear that Figuier was saying that Hortensius brought his fish to the dining room by some sort of water conduit connected to one of his fishponds. The translator's **"... just taken from his native element..."** is not the same as my **"... removed from the pond..."** In any event, Figuier's statement could not possibly be true. For proof of this I refer to Marcus Terentius Varro (116 BC - 27 BC), Rome's greatest scholar and a satirist of stature, whose vast and varied erudition in almost every department of literature earned for him the title of the "most learned of the Romans" (Figure 4).

He was a man of immense learning and a prolific author. Inspired by a deep patriotism, he intended his work, by its moral and educational quality, to further Roman greatness. Seeking to link Rome's future with its glorious past, his works exerted great influence before and after the founding of the Roman Empire in 27 BC. Though not attracted to a political career, he played some part in the public life of the Roman Republic. Politically, he supported Pompey and during the civil war he commanded one of Pompey's armies. He escaped the penalties of being on the losing side in the civil war through two pardons granted by Julius Caesar, and Caesar later appointed him to oversee the public library of Rome in 47 BC.

Figure 4:
Marcus Terentius Varro (116 BC - 27 BC).

His only complete work extant, *Rerum Rusticarum Libri Tres*, has been described as "the well digested system of an experienced and successful farmer who has seen and practiced all that he records." One noteworthy aspect of the work is his anticipation of microbiology and epidemiology. Varro warned his contemporaries to avoid swamps and marshland, since such areas "breed certain minute creatures which cannot be seen by the eyes, but which float in the air and enter the body through the mouth and nose and cause serious diseases." The following is taken from this book. Appius Claudius Pulcher (97 BC - 49 BC), was a consul of the Roman Republic and a good friend of Varro's. This is he, talking to Varro:

Our common friend Quintus Hortensius had fishponds near Bauli which had cost him a great sum to build, and I know, for I often used to stay with him at his country-house, that he used always to send to Puteoli to buy the fish for dinner. And it was not enough that his fish-ponds didn't feed him, but he must needs, if you please, with his own hands feed them, being more anxious lest his mullets should feel the pangs of starvation than I do lest my asses at Rosea should go hungry. He spent, too, a good deal more on the former than I do on the latter in the matter of both food and drink. For all I need for the feeding of my costly asses is one little slave, a trifle of barley, and water found on the estate, while Hortensius in the first place kept an army of fishermen to feed the fish, who used constantly to bring him masses of tiny fishes which were destined to serve as food for the big ones. He would buy, besides, salt-fish, and throw it into his ponds, when the sea was stormy, and when, owing to the weather, the market that supplies the fish-ponds (the sea, that is) refused its food, and the live food, the fish eaten by the common people for supper, could not be got to shore with a net. You would sooner, said I, have got Hortensius's consent to your taking his carriage-mules from the stable and keeping them for your own, than a bearded mullet from his fish-pond.

This fanaticism and concern for his bearded mullets became a standing joke throughout Roman society but the point here is that Hortensius was so devoted to his fish that he could not stand to send them off to the banquet table, opting instead to purchase them from the market in Puteoli. He would not have constructed such a conduit from one of his fishponds to his dining table any more than a present-day fish fancier would serve up his pet arowana to dinner guests. Thus, Figuier's account is a myth, nothing more. The coup d'etat was provided by the following review that appeared in 1868 in *The Contemporary Review*:

The title-page of this lavishly-illustrated volume informs us that it is "*chiefly* translated from 'La vie et les moeurs des animaux' of L. Figuier." Monsieur Figuier is well known as a popular compiler, holding about the same position, as a French writer of natural history, which the Rev. J. G. Wood does on this side of the Channel. But in this volume it is difficult to ascertain for what M. Figuier is to be held responsible. We are told that "the History of the Ocean is to a large extent, but *not wholly*, compiled" from one of M. Figuier's volumes, but that "the larger portion of the work is a free translation of that author's latest work," and that "other chapters are compiled from various sources; they will not be found in either of M. Figuier's volumes." After these naive admissions, we may well ask what is the book? Truly a very patchwork of compilation, utterly without authority as a work of reference! We must admit that the various compilers who have had a share in the

volume, have frequently avoided misstatements, while they have popularized the history of the inhabitants of the sea from the zoophyte to the vertebrate fish. Yet we meet with random writing and vague exaggeration more frequently than we expect, even in a French compilation. Thus we are told that the little Janthina shells inhabit the deep sea, and often form banks of many leagues in extent! Another marvelous story is that of a cuttlefish 60 feet long, not counting its arms, which are represented as about 40 feet more and weighing 4,000 pounds, which encountered a French corvette. The fish, according to the illustration taken on the spot and given here, should have been more than a match for the ship (Figure 5). The editor, however, suggests (in, we presume, 'compilation' Latin) that this should be taken *cum grano salis*.

In this paragraph the reviewer first rakes the translator over the coals for the confusion over what was Figuier's work and what was not. He then opines that it is a very patchwork of compilation, utterly without authority as a work of reference, and finishes off by pointing out some errors (I smile at the statement, "…vague exaggeration more frequently than we expect, even in a French compilation"). The reviewer goes on to suggest that the only value the book has is as a children's book and even there because of its pictures:

The best portions of the book are those on the Acephalæ and the Echinoderms, which are very fairly illustrated. Some of the plates are spirited, and all of them accurate in this portion of the volume. The latter portion is less complete, the plates rather sensational, and some interesting facts, such as the existence of water-snakes, altogether omitted. Yet the book, with all its faults, and they are many, may be useful in leading children to inquire into the nature of the creatures they find by the sea-shore. It ought to be taken by schoolboys to the sea-side, and its pictures may afford much home amusement besides. These, excepting in the lower forms of life, have scarcely been chosen with judgment. Every common shell of our coasts, even our black garden slug, the common cowrie, and shells seen on every cottage chimney-piece, are figured elaborately, while the world of shells was before the artist from which to choose. We fully appreciate the value and the necessity of popularizing technical knowledge, but we do trust that when M. Figuier's translators produce their next volume of science for the million, in the forthcoming "Insect World," they will give us engravings not more, nor better executed, but better selected.

My reading of Figuier's *Les Poissons, les Reptiles et les Oiseaux* did have some additional value. In his *The Ocean World* Figuier talked about Publius Vedius Pollio (born 1st century BC - died in 15 BC) who was a Roman equestrian of the 1st century BC, and a friend of the Roman emperor Augustus, who appointed him to a position of authority in the province of Asia. In later life he became known for his luxurious tastes and cruelty to his slaves - when they displeased him, he had them fed to moray eels (or lampreys; the exact fish is not certain) that he maintained for that purpose, which was deemed to be an exceedingly cruel act. In a highly rhetorical passage, the Christian writer Tertullian stated that after exe-

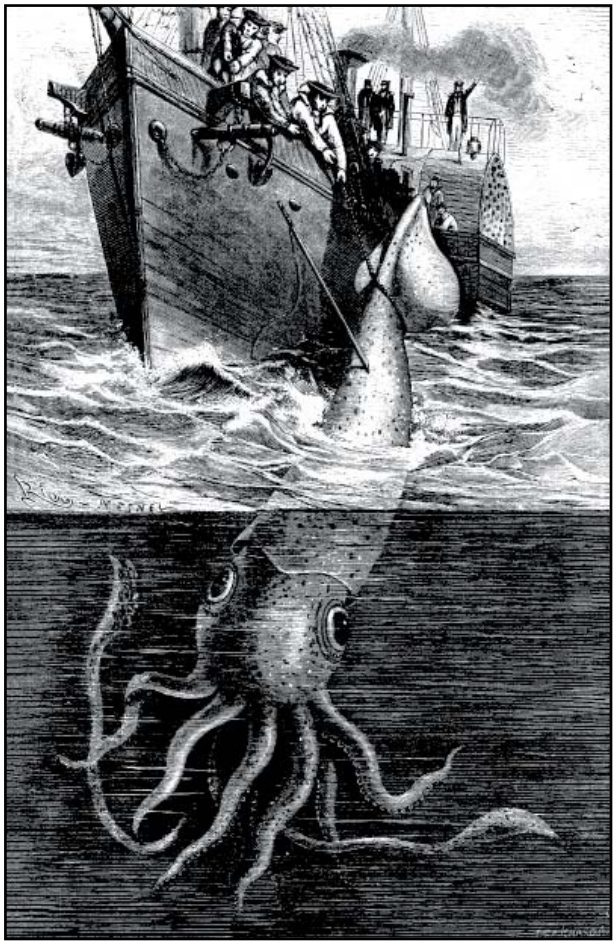

Figure 5:
"Gigantic Cuttle-fish caught by the French Corvette Alecton, near Teneriffe."
From Figuier's "The Ocean World."

cuting slaves, Vedius had his lampreys "cooked straight away, so that in their entrails he himself might have a taste of his slaves' bodies too."

When Vedius tried to apply this method of execution to a slave who broke a crystal cup, Augustus (Vedius's guest at the time) was so appalled that he not only intervened to prevent the execution but had all of Vedius's valuable drinking vessels deliberately broken.

This incident, along with Augustus's demolition of the massive villa he inherited after Vedius's death in 15 BC, were frequently referred to in antiquity in discussions of ethics and of the public role of Augustus. Vedius died in 15 BC and among his many heirs, Augustus received a large part of Vedius's estate, including his villa on the Gulf of Naples, along with instructions to erect a suitable monument on the site. The emperor demolished the house and constructed in its place a colonnade in honor of his wife Livia, which he dedicated in 7 BC. During or shortly after Augustus's reign, Ovid praised his demolition of Vedius's house as a grand statement against immoral luxury made even at the emperor's own cost. Also in the 1st century AD, Vedius's story was used by the philosopher Seneca and by Pliny the Elder. In two ethical treatises, Seneca used Vedius's treatment of the cupbearer and Augustus's response to illustrate the extremes to which anger could lead and the need for clemency. Although Pliny the Elder mentioned Vedius's lampreys in his *Natural History* while treating varieties of fish, Pliny was no admirer of Augustus and noted the man's friendship with Augustus while ignoring the story of the latter's clemency. His handling of the story has been seen as "a gratuitous jibe" at the emperor.

In *The Ocean World*, Figuier did not show an artist's rendition of this practice but in *Les Poissons, les Reptiles et les Oiseaux* he did and I include the illustration here (Figure 6).

THE GARDENER'S AQUARIUM

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, February 22, 2014

In the process of working on my monograph, "Who invented the aquarium?" (Klee, 2012), a good friend of mine asked, "Who was the first aquarist to use the word "aquarium?" After some additional research I determined that it was Robert Warington, writing in the January 1852 issue of *The Garden Companion, and Florists' Guide*.

It should be noted that some erroneous information has appeared on this subject, mainly in dictionary entries and in Wikipedia posts. For example, The Oxford Universal Dictionary (third edition, 1933) states the date of first use as 1854 and a Wikipedia article reads: **Philip Henry Gosse was the first person to actually use the word "aquarium," opting for this term (instead of "aquatic vivarium" or "aqua-vivarium") in 1854 in his book *The Aquarium: An Unveiling of the Wonders of the Deep Sea***. In point of fact, although Philip Gosse undeniably was responsible for the popularization of the term "Aquarium" in the fish hobby sense, he was not the first one to use it. Warington preceded him. Gosse himself did not claim priority in this matter, the following being his clear and elegant explanation of why he used the term:

A neat, easily pronounced and easily remembered, significant, and expressive term is so advantageous, that it is worth taking some trouble to select the best. For the subject of this volume some have chosen the word Vivarium, and I have myself occasionally used it. The only objection to it is that it lacks distinctness of signification. It literally means any enclosure in which living animals are kept; and the ancients used it to signify a park, a rabbit-warren, and a fishpond; indeed, I am not sure whether our word "warren," is not "Vivarium" Saxonised. Thus it is quite as applicable to the whole Zoological Garden as to any particular house, yard, or tank in it. To avoid this indefiniteness, others have used the term Aqua-vivarium. The objection to this is its awkward length and uncouthness, which render it unsuitable for a popular exhibition or domestic amenity. I have adopted the word Aquarium, as being free from the objections which lie against the other two, while it possesses the neatness of the former, and the definiteness of the latter.

He goes on to say (and here lies the subject of this monograph):

The term had already been in use among the botanists, to designate the tanks in which aquatic plants were reared; and the employment of the same term for our tanks is not forbidden by the character of the service to which they are put, since this is not an alteration, but only an extension. The growth of aquatic plants is still a most important and pleasing feature of our pursuit, and the addition of aquatic animals does not at all detract from the appropriateness of the appellation.

In my "Who invented the aquarium?" monograph I discussed what I call "The Gardener's Aquarium," leaning heavily upon John Loudon's An Encyclopædia of Gardening (Loudon, 1824) in which he showed several examples of the more ornate aquaria and suggested that fish might be added to them.

Loudon's 1,311-page Encyclopædia was the finest reference book on the subject at the time and is still highly regarded to this day. He has been described as the "father of the English garden" and without him it is unlikely that we would have the modern garden in its present form, and indeed the passion (or obsession) for gardening both professionally and as a hobby. Loudon's work as a journalist and author led to the "democratization" of gardening. Through his articles and books, the pleasures of gardening, growing plants and garden visiting became available to people at all levels of society, either in their own modest gardens or in public areas such as parks. When Loudon was born in 1783, the Landscape movement was at its height for those who had the land and the wealth to afford it. It is due to Loudon that the gardener took over from the landscape designer in the 20th century.

Although Loudon referred frequently to aquaria and showed numerous examples, he did not supply a precise definition. This was left to his future wife, Jane C. Webb, a most extraordinary woman (Figure 1). In 1827 Webb published – anonymously - a novel titled *The Mummy!* She was a contemporary of Mary Shelly who, nine years earlier, had written *Frankenstein,* also written anonymously since women in those days had difficulties getting published. It drew many favorable reviews, including one in 1828 in *The Gardener's Magazine* on the inventions proposed in it.

The novel starts in the year 2126. There were air mattresses, mirrors that transmitted images over distances, and an apparatus that drew water from a rain cloud. Travel was by balloons, inflated with hydrogen gas and propelled by a mercury-based gas produced from an electrical machine. Smaller versions of the balloons were in the form of aerial horses that dandies could ride. Mail was placed into balls and discharged by steam cannons. Every town had a wire net to catch the balls and there was a special ball that made a distinctive noise as it passed through the air to let the recipients know a letter was forthcoming. There were houses fitted with grooves on the bottom that fit on railroad tracks so they could be moved at their owner's convenience. This was science fiction when Jules Verne wasn't even born yet!

Figure 1:
Left: John Claudius Loudon (1783-1843)
Right: Jane C. Webb Loudon (1807-1858)

How they met is told in Jane Loudon's own words:

About this time Mr. Loudon formed his first acquaintance with me. My father died in 1824; and, finding on the winding up of his affairs that it would be necessary for me to do something for my support, I had written a strange wild novel called *The Mummy,* in which I had laid the scene in the twenty-second century, and attempted to predict the state of improvement to which this country might possibly arrive. Mr. Loudon chanced to see the review of this book in the *Literary Gazette,* and, as among other things I had mentioned a steam-plough, it attracted his attention, and he procured the work from a circulating library. He read it, and was so much pleased with it, that he published, in *The Gardener's Magazine* for 1828, a notice of it under the head of "Hints for Improvements;" and he had from that time a great desire to become acquainted with the author, whom he supposed to be a man. In February, 1830, Mr. Loudon chanced to mention this wish to a lady, a friend of his, who happened to be acquainted with me, and who immediately invited him to a party, where she promised him he should have the wished-for introduction. It may be easily supposed that he was surprised to find the author of the book a woman; but I believe that from that evening he formed an attachment to me, and, in fact, we were married on the 14th of the following September.

Although Loudon was 24 years older than Jane, she cared deeply for him. In her 1840 book, *Instructions in Gardening for Ladies*, she dedicated the book to him thusly: **To J.C. Loudon, Esq., F.L.S, H.S., Z.S., etc., to whom the author of the following pages owes all the knowledge of the subject she possesses, this work is dedicated by his affectionate wife…** In 1843, John Loudon died of lung cancer, leaving her with a 10-year-old daughter, Agnes, who would grow up to author children's books. At the time, they had been married for fourteen years. Jane wrote: **I do not attempt to give any description of the talents or character of my late husband**

as an author; his works are before this world, and by them he will be judged; but I trust I may be excused for adding, that in his private capacity he was equally estimable as a husband and a father, and as a master and a friend.

She quickly became fascinated with her husband's field of horticulture and gardening, and in the meticulous manner her husband needed for his researches, acted as his secretary, copyist, researcher, note taker and even his co-author on some of his books. The Loudons were considered the leading horticulturalists of their day, and their circle of friends included Charles Dickens and William Makepeace Thackeray.

Part of Jane Loudon's understanding about gardening was due to the influence of John Lindley, an important figure in horticulture who lectured regularly at the Royal Horticultural Society and campaigned to get women interested in gardening. She attended his lectures and became one of his ardent followers, becoming one of the foremost popularizers of horticulture for women in the 1800's.

For centuries, the sole purpose of books written for female gardeners had been to show how ladies might supervise the care of flower and herb gardens, not to do any gardening themselves. When it appeared in 1840, Jane Loudon's *Gardening for Ladies* broke new ground by being the first ever practical hands-on guide for green-thumbed gentlewomen. It was an immediate success, selling 1,350 copies on the day of publication and more than 200,000 in total. It was largely through Jane Loudon that gardening became an essential pastime for women and has remained so ever since. That she was also an accomplished illustrator is shown in Figure 2, which shows examples of her artwork from her books.

In 1841 she published *The Ladies Companion to the Flower Garden, being an alphabetical arrangement of all the ornamental plants usually grown in gardens and shrubberies; with full directions for their culture*. In this book she defined the gardener's aquarium as follows:

AQUARIUM - A pond, basin, or cistern of water, for the growth of water plants. In a pond in the open garden, the plants may either be grown in pots, plunged to the depth of one or two feet in the water, or they may be planted in the bottom of the pond. The former is generally the best mode, because the plants are by that means kept distinct, and the stronger cannot overpower the weaker. At the same time very strong ground plants, such as the white and yellow water-lilies, do not flower freely unless in the free soil, or in very large tubs. There are few greenhouse aquatics, but a number of stove plants, which require to be grown in water; such as the Indian Lotus, or *Nelumbium,* etc., and these are necessarily grown in pots of moderate size. The most suitable soil is a rich loam. The papyrus, though properly speaking it is a marsh plant, is generally grown in an aquarium. See MARSH PLANTS.

It is clear from this definition that gardeners considered the aquarium to be any container of

Figure 2:
Examples of Jan Loudon's artwork, taken from her publications.

water - large or small - that contained aquatic plants.

I was interested in how early the term "aquarium" was applied by gardeners to water vessels containing aquatic plants since I was relying largely on Loudon's Encyclopædia. My strategy was to work my way back from its 1824 publication date and the first reference I uncovered was George Tod's *Plans, elevations and sections, of hot-houses, green-houses, and aquarium, conservatories, &c. recently built in different parts of England, for various noblemen and gentlemen*, published in 1812.

Technological improvements in sheet glass production in the eighteenth century made glass architecture more easily possible, and interest in hothouses was strong on both sides of the Atlantic for agricultural, scientific and aesthetic reasons. Greenhouses extended fruit and flower growing seasons and/or allowed cultivation and study of exotic species of non-native plants. "Winter gardens" could also be social spaces for entertaining guests in human-created Edens. In the American colonies, orangeries were built at Mount Clare and Mount Airy in Richmond County, Virginia, as early as the 1760s. George Washington's preliminary plans and construction notes for an orangery at Mount Vernon still exist. Advertisements in early New York City newspapers suggest that greenhouses were also popular there, allowing urban residents the benefits of nature and the countryside.

Tod, a British surveyor and hot-house builder, provided color illustrations and descriptions of 26 "glass houses" in his book, chiefly of his own design. However, one was titled, **"An Aquarium, executed for the Most Noble the Marquis of Blandford at Whiteknights, Berkshire."** The aquarium (Figure 3) was 36 feet in length overall, and the actual tank within was 7 x 16 feet. The depth generally was 18 inches except for two 4-foot long end sections that were 30 inches deep. The greenhouse was heated by a flue at the ground level and the tank itself also was heated by its own flue. As Loudon described it:

A cistern occupies the interior of the house, having a walk round it; it is lined with lead, and filled with a mixture of mud and water, proper for the reception and growth of such plants as require aqueous nourishment. A flue goes round, directly under the bottom of the cistern, for the purpose of keeping the water of a certain temperature. Another flue goes round the house above ground, and terminates in a chimney at the northwest corner. The bottom of the cistern, to receive the lead, is formed with slates, supported by transverse bars of cast-iron; a bottom of wood would have been more convenient for laying the lead upon, but as the flues are so near the bottom of the cistern, danger of fire was apprehended. The cistern is supplied with water by means of a pump placed at a convenient distance for that purpose.

The original specifications were published in 1806 by Josiah Taylor and since this date is close to the turn of the century, it is probable that the word aquarium in the gardener's sense was also used in the 1700's.

In 1745, England enacted a tax on glass that was not repealed until 1845, making greenhouses and aquariums such as this one affordable to only the very rich and the Marquis was no exception. Between 1798 and 1819, Whiteknights was the scene of vast extravagance and wild entertainments, all at the expense of the Marquis (later the 5th Duke of Marlborough). It became the most celebrated estate in the Country, magnificently furnished, displaying many great masters, with a wonderful wine cellar and an unrivalled library. The splendid gardens, beautifully laid out with the rarest of plants, were its greatest attraction however. It was the envy of kings. Unfortunately, the Duke went bankrupt in 1819 and had to retire to Blenheim where he lived the remainder of his life off a small annuity granted to the first Duke by Queen Anne. The Whiteknights Estate was sold off and the house, along with the aquarium, was demolished in 1840 by a mob of the Duke's angry creditors.

The Marquis' aquarium represented the highest end of the spectrum of the gardener's aquarium; a pit containing water was its lowest. An intermediate aquarium was a pond and John Loudon described one in detail (Figure 4):

The shape and size of the aquarium must depend on the extent and style of the flower-garden of which it forms a part. In all cases the bottom, if not naturally

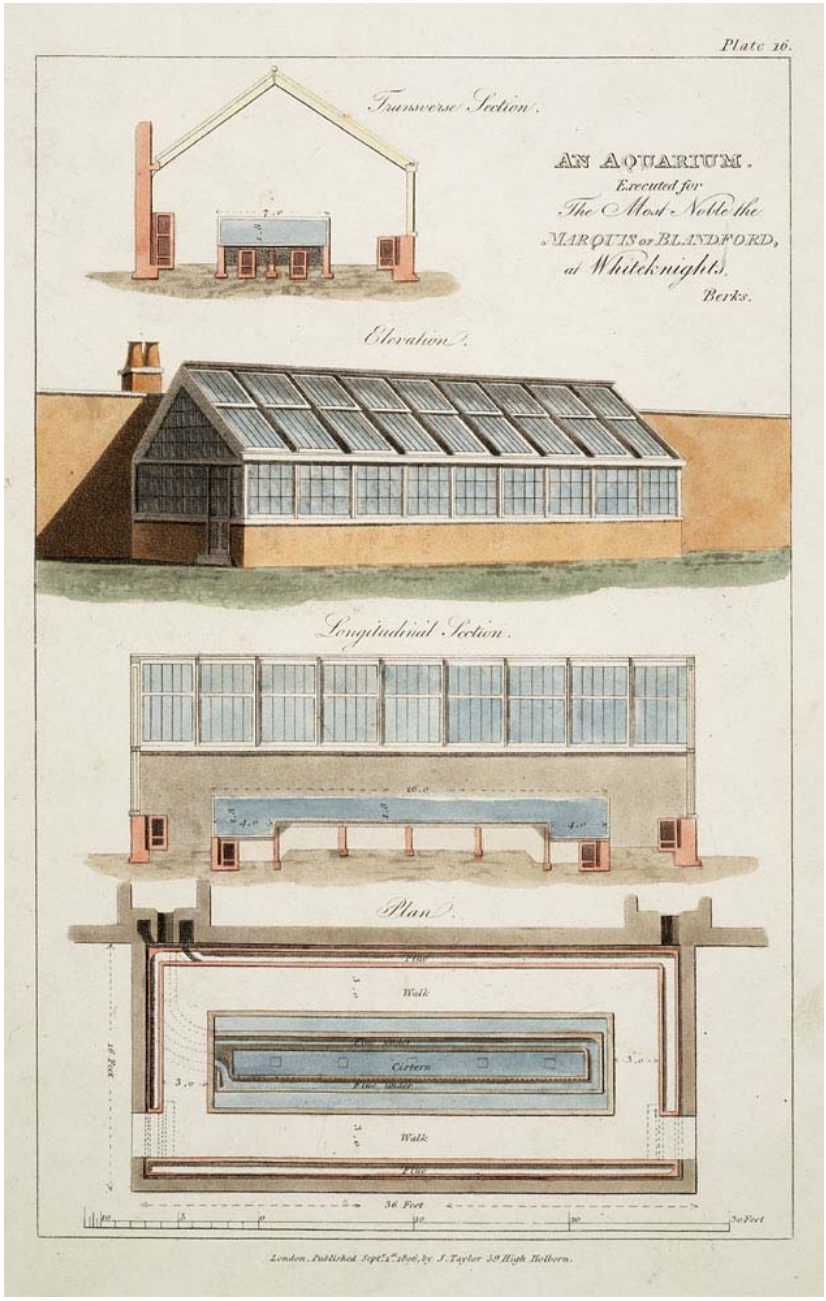

Figure 3: The Aquarium of the Marquis of Blandford,

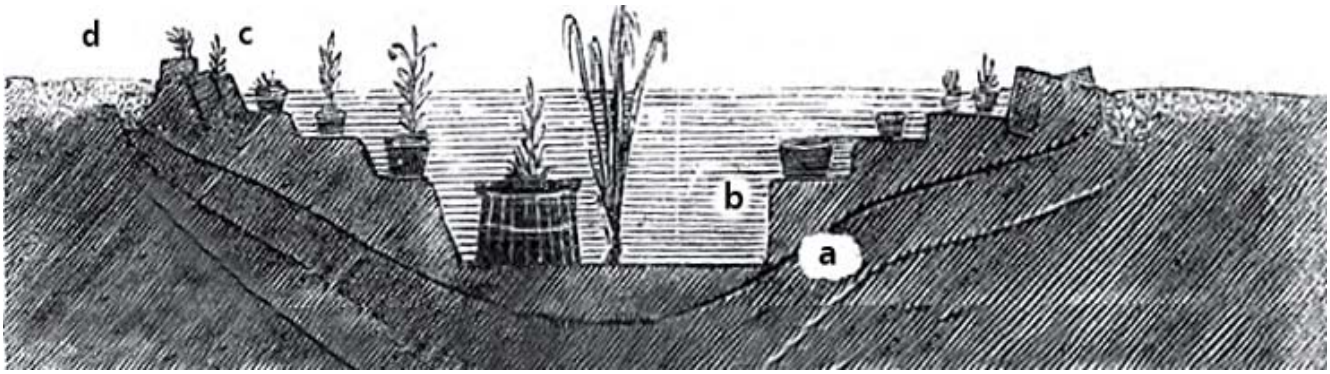

Figure 4: The pond aquarium (from *An Encyclopædia of Gardening* (Loudon, 1824).

retentive, must be rendered so by a stratum of tempered (or puddled) clay (a); the side should be formed in terraces, or steps descending towards the centre (b), to hold pots of plants which grow in shallow water, while those that require deep water, as the bulrush, typha (cattail), etc., may be planted in the ground, or in large tubs placed in deep water. The margin of the aquarium may either be finished with regular masonry or brickwork; or, what, in some situations, has a better effect, with rough stones, conglomerated vitrified bricks, or flints (c), in the Interstices of which marsh plants will thrive exceedingly. The whole may be surrounded by a drain and gravel-walk (d), raised a few inches above the level of the water. Many of the aquatic plants, as Nymphæa, Nuphar, Menyanthes, Villarsia, Butomus, Hottonia, etc., are highly beautiful; and, considering that some exotic species, as Amaryllis, Lobelia, Crinum, etc., will thrive in water in our climate, the aquarium ought not to be wanting in any flower-garden.

I have made here much mention of John and Jane Loudon in examining how gardeners used the word aquarium in the Nineteenth century. That they were remarkable people and that their coming together is a charming and touching story of true love is admittedly beside the point of this monograph.

Along these lines and reminiscent of Jane Austen's "Pride and Prejudice," there was a real Mr. Darcy in the form of the 4th Earl of Harrington at Elvaston Castle in Derbyshire. There is a botanical connection here since in 1830, William Barron was appointed to oversee the Earl of Harrington's gardens where virtually nothing had ever been done to improve or decorate the grounds. Because the Earl wanted to relocate three cedar of Lebanon trees, each 39 feet tall, Barron devised a method for moving really large trees, and was the man responsible for the relocation in 1880 of the great Buckland yew, mentioned in the Domesday Book of 1086 and reputed to be perhaps

Figure 5: Left: Charles Stanhope, 4th Earl of Harrington (1780-1851); Right: Maria Stanhope, Countess of Harrington (1797-1867). The countess was the former actress, Maria Foote.

1500 years old at the time of its moving. The tree, with a massive root ball and an estimated total weight of 56 tons, was moved approximately 203 feet to a new location and replanted where the tree has continued to thrive, a monumental feat of both engineering and surgical botany. It became by far Barron's most famous achievement.

A year after Barron had joined the Earl's service, at the age of fifty the Earl married the beautiful though promiscuous actress, Maria Foote, previously implicated in several salacious and high-profile affairs and 17 years younger than he (Figure 5). The marriage, however, was a success, and for the next twenty years, having forced to retreat from Society, the earl and his actress wife lived at Elvaston in total solitude. The earl's instructions were: "If Queen Victoria comes, show her around, but admit no one else!"

Of course the real reason that the Loudon's figure so much in this monograph is that John Loudon, more than anyone else, wrote in great detail about the gardener's aquarium, and Jane Loudon was the first one to define it. Perhaps this will make up a little for my straying from the real subject!

SO, WHO WAS THE FIRST?

Pinning down "firsts" is a perilous endeavor. One may assert that so-and-so was the first on record for doing something, only to have another researcher later uncover an earlier reference that shows someone else preceded him or her. To avoid embarrassment, I'll use qualifiers to my statements as I now, so to speak, wade in unfamiliar waters.

Since the plans for the aquarium of the Marquis of Whiteknights were published in 1806, it is safe to assume that the word was used in the 1700's and perhaps even earlier. In 1655, Olof Rudbeck (1630-1702), a professor of medicine at Uppsala University in Sweden (he discovered the lymph system) and for several periods its *rector magnificus* (Figure 6), founded a botanical garden, then situated in the center of Uppsala, close to the Fyrisån river). In later years, Carl Linnaeus named an aquatic plant, *Rudbeckia*, after him. The garden was primarily used for teaching botany and pharmacy, and by the end of the century more than 1 800 species were grown there, many of them for the first time in Sweden. The garden was largely destroyed by a fire in 1702 and since the university could not afford to restore it, it was left unattended for a period of 40 years.

Linnaeus (Figure 7) became responsible for the garden in 1741 and had it rearranged according to his own ideas, documented in his *Hortus Upsaliensis* of 1748. Under his supervision, it turned into one of the foremost gardens of its time. Through contacts with fellow scientists all over the world, Linnaeus was able to gather thousands of foreign plants in cultivation. They were grown in parterres either based on

ecology or following the classes of the sexual system.

Although Uppsala University commissioned the famous architect Carl Hårleman to design the garden, Linnaeus was responsible for the planting, including three ponds for plants typical of streams, lakes and marshes. In his 1742 prologue to his *Hortus Upsaliensis*, Linnaeus defined the following terms under the heading of "Aquaria:" (1) Aquarium fluviatile, (2) Aquarium lacustre and (3) Aquarium palustre (Figure 8), denoting respectively a river pond aquarium, lake pond aquarium and marsh pond aquarium. If this is the earliest use of the word "aquarium" by gardeners, it is also the first time the plural of the word was used. If so, then historically the plural of aquarium should be aquaria, not aquariums. Figure 9 shows the garden as it existed in Linnaeus' time and the locations of the three types of aquaria. Figure 10 shows a sketch of the garden made in 1770 before the garden was moved from the Fyrisån river, the location being unsuitable for gardening as the grounds were very swampy.

The boldfaced lines that follow are taken from Linnaeus' *Hortus Upsaliensis* of 1748 (translated):

The Lake Pond, which is star-shaped and an excellent masterpiece of the gardener's, contains only plants with floating leaves, such as Nymphaea lutea and alba, Hydrocharis, etc. The gardener who built the pond was named Dietrich Nietzel and had been recruited by Linnaeus from Holland. In front of the pond, Linnaeus placed a statue of Venus, bought in 1758 from Piperska trädgården in Stockholm. It caused a scandal in Uppsala, as the Medicean Venus was completely naked. Common newts, *Triturus vulgaris*, prosper in the pond's sun-warmed water. Linnaeus thought that they caused much damage in Uppsala's ponds, but that they could be got rid of by pouring salt into the water. Today it is a protected species.

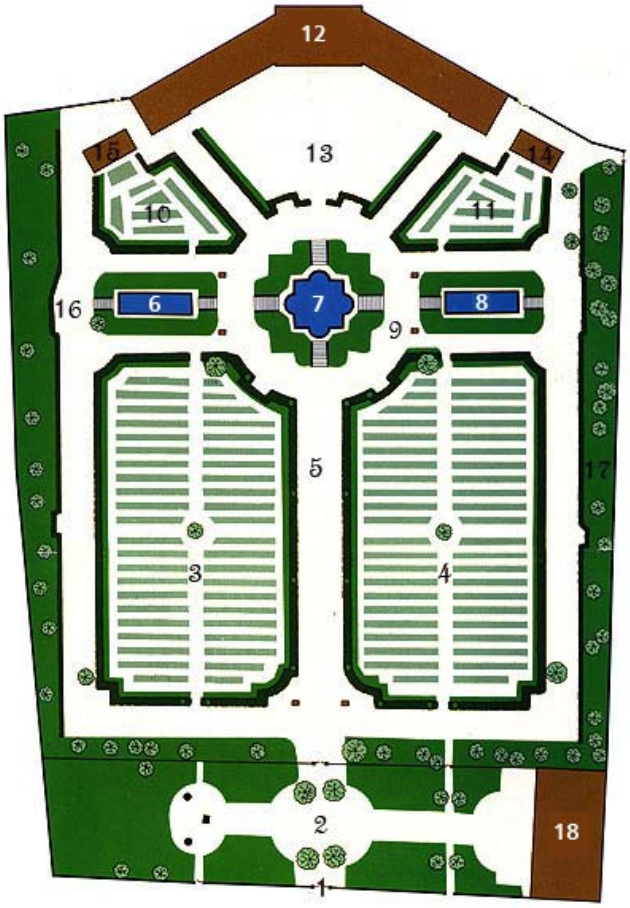

Figure 9: Sketch of the Linnaean Garden.

6 = The River Pond (Aquarium fluviatile)
7 = The Lake Pond (Aquarium lacustre)
8 = The Marsh Pond (Aquarium palustre)

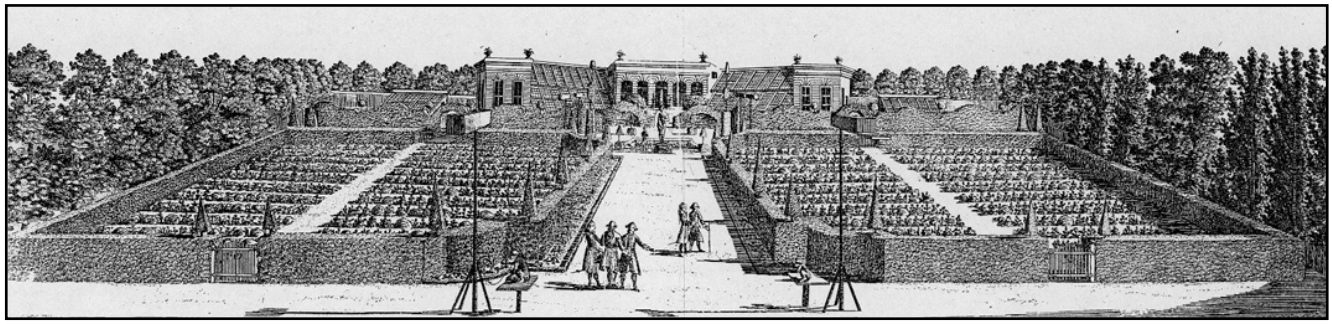

Figure 10: Linnaean Garden, engraving of 1770.

In the River Pond, river and lake plants such as Hottonia, Hippuris, Myriophyllum, Potamogetones, Sagittaria, Utricularia, etc., are grown. The sides of the pond are covered with 20 different species of Carex. The River Pond was deeper than the Marsh Pond but shallower than the Lake Pond. Different species of sedge grew along its sides, such as bladder sedge *Carex vesicaria* and cyperus sedge *C. pseudocyperus*. In the middle of the pond, mare's tail *Hippuris vulgaris*, pondweeds *Potamogeton*-species, and arrowhead *Sagittaria sagittifolia* flourished. Linnaeus argued that all cultivation should be based on knowledge of the plants' natural habitats: climate, soil and humidity. His ponds were the first-ever ecological plantations in a botanical garden.

The Marsh Pond is surrounded by walls or horizontally placed logs, which separate the water from solid ground; in between them is a space full of marsh mud, in which marsh plants have been planted. The Marsh Pond was the shallowest of the three and filled with marsh mud. Linnaeus' three ponds were fed water from a spring flowing through the garden. The water was led from east to west through hollowed-out logs which had been buried in the ground. The Marsh Pond was the shallowest of the three and filled with marsh mud. Nowadays, twinflower *Linnaea borealis* is grown in the Marsh Pond. Linnaeus had great difficulty in getting it to flourish in the garden and succeeded only in growing it in a flower pot.

The question now arises whether Rudbeck had ponds in his garden and therefore might have preceded Linnaeus in the use of the term "Aquarium." In 1675, Rudbeck published a four-volume, 2,500-page tome titled *Atlantica* (*Atland eller Manheim* in Swedish), and included in his book was a sketch of his garden (Figure 12. However, an examination of the sketch shows no ponds whatsoever. Whether Linneaus was

the first gardener to use the term "aquarium" is a matter of supposition. However, considering the influence he had on the botanists of the day, it is not unreasonable to assume that his usage of the word affected them and those who followed.

THE "KILLIFISH" THAT ISN'T A KILLIE

By Albert J. Klee, Ph.D.
(Aquarium Hobby Historical Society, Yahoo Files, April 4, 2014)

By way of background, *Chologaster cornuta*, commonly known as the "Swampfish" and, more rarely, "Ricefish" or "Riceditch Killifish," is a freshwater fish of the family Amblyopsidae. *Chologaster* literally means "mutilated belly," referring to the poorly developed ventral fins. This fish occurs near vegetation and debris in swamps, ponds, ditches, slow-moving streams, pools and backwaters in the Atlantic Coastal Plain drainages, from southeast Virginia to central Georgia. In such habitats, its thigmotaxic tendency (i.e., the movement of an organism either towards or away from the stimulus of physical contact) is shown by the difficulty in seining these individuals from the roots and debris of their preferred habitat along edges of submerged weed banks which border sand-bottomed channels. Their habitats are rich in potential food for the fish, like amphipods, ostracods and copepods. The males are commonly 1.6 inches long, but may be as large as 2.8 inches. The fish are short-lived, i.e., only up to two years.

Now on to some history. In 1853, after his return from a tour through the southern and western states, Louis Agassiz wrote the following letter to James Dwight Dana (Agassiz, 1853):

I would mention foremost a new genus which I shall call *Chologaster*, very similar in general appearance to the blind fish of the Mammoth Cave, though provided with eyes; it has, like *Amblyopsis*, *the anal aperture* far advanced *under the throat*, but is *entirely deprived of ventral fins*; a very strange and unexpected combination of characters. I know but one species, *Chologaster cornutus* Ag. It is a small fish scarcely three inches long, living in the ditches of the rice fields in South Carolina. I derive its specific name from the singular form of the snout, which has two horn-like projections above.

This wasn't much of a description and neither the genus nor the species would be accepted as valid today, but in 1872 Frederic Ward Putnam filled in the details, thereby making both the genus and species acceptable to other ichthyologists (Putnam, 1872). I'll spare the reader the details of the description of the specimens since the following excerpt will be of greater interest to aquarists:

By the kindness of Professor L. Agassiz, who has placed all the specimens of the family contained in the Museum of Comparative Zoology in my hands for study, I am enabled to give a figure and description of this interesting species from the three specimens in the Museum, which were labelled as the originals of *Chologaster cornutus* Ag., from Waccamaw, South Carolina, presented by Mr. P. C. J. Weston, 1853. The largest of these specimens was distended with eggs and I was enabled to compare the ovary with that of *Amblyopsis*. From its being single and the eggs very large, I have no doubt that it is a viviparous fish like the other genera of the family.

With regard to his last statement, Putnam was in error. Although incubation in the buccal cavity has been reported in other members of the Amblyopsidae, such as *Amblyopsidae*, this is probably not the case for the Swampfish, as the volume of the eggs is too large to fit. In the light of the observations on the spawning behavior of pirate perch, which share the character of a jugular placed anus, it seems probable that the Swampfish likewise deposits its eggs inside root masses. Amblyopsid habitat requirements, feeding ecology, growth rates, life histories and breeding behaviors are largely unknown. For this reason, German aquarists have named *Chologaster* the "Trugkärpfling" or "deceptive cavefish."

In 1882, Jordan and Gilbert combined the descriptions of this fish by Agassiz and Putnam in their "Synopsis of the Fishes of North America (Jordan & Gilbert, 882). Up to this point, however, no common name was reported in the literature until 1896 when Jordan and Evermann (Jordan & Evermann, 1896) listed "Fish of the Dismal Swamp" as its common name. This common name, as well as "Swamp Minnow," also appeared in Smith's "Fishes of North Carolina" (Smith, 1907). The following is from Smith's report:

Although long known from Virginia, South Carolina and Georgia, this species has only recently been reported from North Carolina. Mr. Wm. P. Seal has collected the fish in a large cypress pond near Wilmington where it is "about as abundant as non-gregarious species generally are — such as *Umbra* and *Aphredoderus*"; he has also found it in tidal ditches in the same section, in company with *Gambusia* and *Heterandria*, In Lake Ellis, Craven County, the fish is common, according to Mr. C. S. Brimley; and it may be looked for in other parts of North Carolina in suitable situations. The maximum length does not exceed 2.5 inches.

Regarding the common names for *Chologaster cornuta*, viz., "Swampfish," "Ricefish" and "Riceditch Killifish," the American Fisheries Society is the recognized authority on the common names of fishes that are indigenous to North America and their name is "Swampfish" (American Fisheries Society, 2013).

Driver, in his list of names for various freshwater fishes of the United States with special reference to the area east of the Rockies, cites "Rice-ditch Fish" as its common name (Driver, 1942). The name of the dolt who added the term "killifish" is not known; *Chologaster cornuta* is a member of the family Amblyopsidae, not Cyprinodontidae. Like "Rice-ditch Fish," "Ricefish" most likely was used prior to 1942 as well.

"Swampfish," "Ricefish" and "Riceditch Killifish" all appear in current dictionaries, encyclopedias and Wikipedia accounts, the last-named and the *Columbia Encyclopedia* being the ones most usually cited. Such citations, however, do little to shed light on these names or their frequency of usage.

When a Whale was a Fish

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Post 12457, July 12, 2014)

In 1819, the New York state legislature had recently enacted a law dictating that fish oil be inspected for quality and purity prior to its sale in order to allow better grading and to reduce the tendency of oil merchants to disguise one type of fish oil as an-other. Fish oil purveyors had to submit their barrels for inspection and, of course, pay a fee to the inspector for the privilege. James Maurice, the New York City's fish oil inspector, was suing Samuel Judd, a candle maker and seller of whale oil who had failed to submit his product for inspection; Maurice had fined Judd seventy-five dollars for buying three barrels of fish oil that had not been inspected and wanted to recover his fees and the statutory fines. In his defense, Judd argued that whale oil was not fish oil, so no inspection of his goods or payment of inspection fees was required. Both sides were represented by some of New York's most high-profile lawyers, and the public followed the case with the avidity of American Idol fans.

This somewhat trivial dispute might have been banged away by the thud of a less patient judge's gavel, but instead the trial became a media circus, in part because of a colorful array of witnesses that included a whaler by the name of Preserved Fish, but mostly because of the participation of Samuel Mitchill, New York City's most famous scientist.

Samuel Latham Mitchill (1764-1831) was an American physician, naturalist and politician. He was born in Hempstead, New York and graduated in 1786 from the University of Edinburgh Medical School. He taught chemistry, botany and natural history at Columbia College from 1792 until 1801 and was a founding editor of The Medical Repository, the first medical journal in the United States. In addition to his Columbia lectures on botany, zoology and mineralogy, Mitchell collected, identified and classified many plants and animals, particularly aquatic organisms.

He served in the New York State Assembly in 1791 and again in 1798 and was then elected as a Democratic-Republican to the United States House of Representatives, serving from 1801 until his resignation in 1804. In that year he was elected a U.S. Senator from New York and served from 1804 to 1809. He then served again in the House of Representatives from 1810 to 1813.

Mitchill strongly endorsed the building of the Erie Canal, sponsored by his friend and political ally, DeWitt Clinton. Mitchill suggested renam-

Samuel Latham Mitchill (1764-1831)

ing the United States of America, Fredonia, combining the English "freedom" with a Latinate ending. Although the suggestion was not seriously considered, some towns adopted the name, including Fredonia, New York. Some freebooters even established a short-lived republic under that name in Texas in the late 1820s.

Mitchill was a man of irrepressible energies who was not afraid to speak out loud about the loves of plants and animals; indeed, he was not a man afraid to speak out loud on most any topic. In the early nineteenth century he was one of the great polymaths of the early Republic, New York's most publicly universal gentleman, a man known variously as the "living encyclopedia," a "stalking library," and (to his admired friend Thomas Jefferson) as the "Congressional Dictionary." As a personality, he was affable but also egotistical and pedantic.

In any case, Mitchill enjoyed popularizing scientific knowledge and promoting practical applications of scientific inquiry. Among other things, he tried to teach his fellow New Yorkers the still-controversial science of Linnaean taxonomy based on classifying species according to their internal anatomical similarities, which make a whale decidedly not a fish. In contrast, according to the taxonomy codified in Genesis, which divided animals into those that swam in the deep, crept on land and flew in the sky, a whale was obviously a fish.

When the defense called Mitchill, they believed his scientific authority would make short work of the plaintiff s case. Instead, poor Mitchill was literally laughed out of the courtroom and made to look ridiculous in the court of public opinion for years to come.

For two days, Mitchill sparred with William Sampson, a respected and often wily prosecutor, trying to establish the great differences between whales and fish.

William Sampson (1794-1836) was born in Londonderry, Ireland. He attended Trinity College in Dublin and studied law at Lincoln's Inn, London. In 1790 Sampson was called to the bar in England, and then returned to Belfast where he was called to the Irish bar and as was the custom. There he gained experience working with a senior counsel, a barrister named John Philpot Curran. Curran often represented members of the United Irishmen who had been charged by the British government with criminal libel, sedition or treason and Sampson himself wrote several articles and satires for the United Irishmen newspapers, the Northern Star and the Press.

Anticipating an insurrection, the British government preemptively arrested the leaders of the United Irishmen in 1798 and William Sampson was intermittently imprisoned or exiled in Europe for several years before being allowed to emigrate to America. When he arrived in New York City in 1806, he set up a business publishing detailed accounts of court proceedings in cases with popular appeal and also successfully continued his career in the law.

Sampson's most important case in America was in 1813 and is referred to as "The Catholic Question in America." Police investigating the misdemeanor of receiving stolen goods questioned the suspects' priest, the Reverend Mr. Kohlman; he declined to given any information that he had heard in confession. The priest was called to testify at the trial in the Court of General Sessions in the City of New York; he again declined. The issue whether to compel the testimony was fully briefed and carefully argued on both sides, with a detailed examination of the common law; in the end, the confessional privilege was accepted for the first time in a court of the United States.

The plaintiff's lawyers made much of the fact that Mitchill was happy to admit that there was disagreement even among philosophers about the new classification scheme, reminiscent of creationists who use disputes among evolutionary biologists

to suggest that evolutionary theory in general is wrong. They also played on Mitchill's including man among the primates and by extension making whales more like men than fish. But equally damaging was that a whale not being a fish simply defied common sense. And, in a moment that shocked the standing-room-only crowd, Mitchill declared that "a whale is no more a fish than a man."

It's not that most people who knew anything about whales were ignorant of the features that Mitchill cited as evidence that whales were mammals, such as being warm-blooded, breathing air, lacking scales and giving birth to live young that were fed with milk. For instance, the whalers called upon to testify on the question knew that. But, those features were simply not salient to how most people classified animal life. After science was defeated on the stand, the defense took another taxonomic tack on the case that made much more sense to the jury. They argued and called merchants to testify that, regardless of whether whales were fish, whale oil and fish oil were entirely different commercial products, with different uses and sold at different prices. A customer who ordered fish oil would not expect to receive whale oil and vice versa.

In the end, though, the plaintiff won his case by appealing to regional prejudices: Many of the witnesses for the defense were "easterners" from Boston and such parts, and a jury of New York Knickerbockers proved loath to kowtow to such foreign ways of thinking and speaking. A whale, the jury foreman announced to the assembled crowd of journalists, gossip mongers and wharf dwellers, was in fact a fish. The press taunted Mitchill for days afterward. "Pray Sir, how goes it with whale oil now?" wrote New York's Evening Post. "Is it oil of fish, or of flesh, or of red herring?"

Ironically, however, the wording of the statute was changed soon after the trial to exclude whale oil from inspection, not because science finally triumphed, but thanks to the influence of whale oil merchants whose profits suffered from paying the inspection fees.

A Matter of Definitions

By Albert J. Klee, Ph.D.

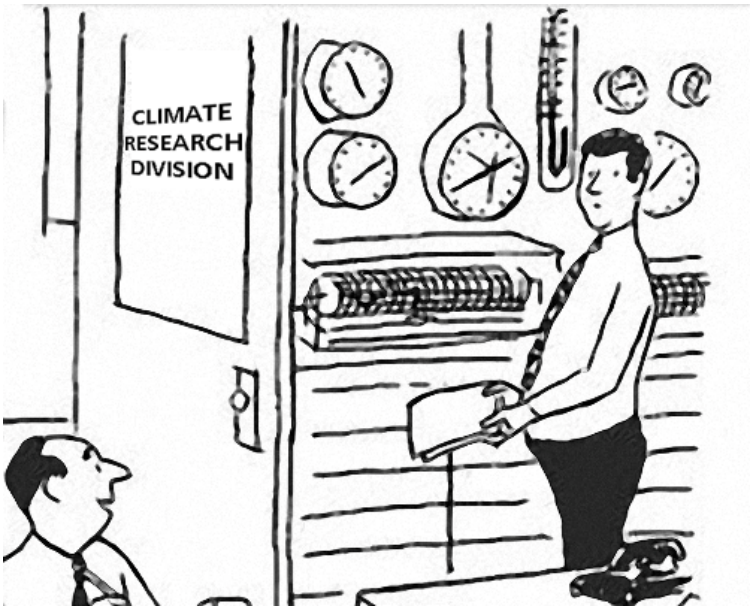
(Aquarium Hobby Historical Society, Yahoo Post 12460, July 15, 2014)

Before I started writing about aquarium history (i.e., "A History of the Aquarium Hobby in America," Aquarium Illustrated, January-February 1964, Vol. 1, No. 1), I wondered at times what was meant by "the aquarium hobby" and what constituted an "aquarist." Pressed for time, I ducked these questions for almost forty years until I started to write "The Toy Fish," published in 2003.

In Chapter 3 I wrote:

"There is also, alas, a problem with precisely what is meant by the word, 'hobby.' Consider the following dictionary definitions: (1) 'A subject or pursuit of absorbing interest, undertaken primarily for pleasure during one's leisure time,' (2) 'An individual pursuit to which a person is unduly devoted,' and (3) 'A favorite occupation or topic, pursued for amusement.' The first two definitions rfequire a stricter criterion, i.e., absorbing interest or undue devotion; the third is much less demanding. None, however, specify the number or kind of tanks a person must maintain before it becomes a hobby, nor is there any standard scale available to us by which we can measure the degree of 'absorbing interest' or 'undue devotion.' Even if such a scale existed, it would be hopeless to attempt to apply it to aquarists who lived a century or two ago. We may ask ourselves whether Anna Thynne was a hobbyist, or A.A. Maconochie, or some unknown American who maintained several jars of native fishes during the Presidency of Andrew Jackson, but the answers are in no way clear.

"It has also been customary to equate the start of the aquarium hobby with the introduction of the so-called principle of the 'balanced aquarium.' As late as 1991, for example, one writer stated: 'Gosse's concept of the balanced aquarium has been crucial in the development of fishkeeping as we presently know it.' However, this principle is neither indispensable nor even of any real importance in keeping aquarium fishes. From ancient times to the present day, thousands upon

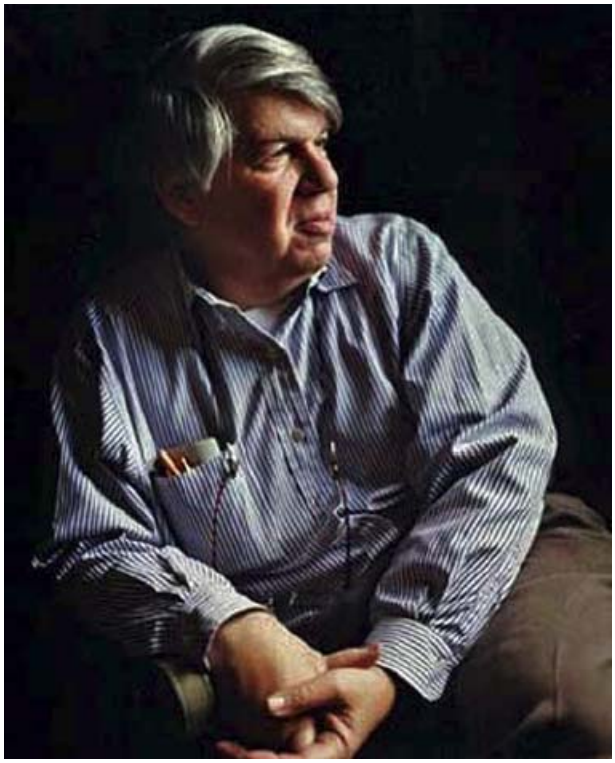


"I figure there's a 40% chance of fog and a 10% chance we know what we are talking about."

thousands of aquarists have kept fish successfully using no plants whatsoever."

At this point I argued (with myself) that since the aquarium hobby was described by my book, it perforce was defined. There the matter sat until 2005 when I re-visited the subject in a monograph I wrote for the AHHS titled "The Four Stages of the Aquarium Hobby." This material was incorporated into the Third Edition of the Toy Fish published in 2009. In Chapter 1 I wrote:

"When did the aquarium hobby start? Who 'invented' the aquarium? What do we mean when we say the 'aquarium hobby' or, for that matter, the 'aquarium'? These questions have presented difficulties for hobby historians precisely because there are no universally agreed-upon definitions. Trying to pin down a concise explanation of the meaning of a word or a term sometimes is - to paraphrase a remark of my grandmother's - akin to attempting to estimate the number of angels that can dance on the head of a pin. Even if we were to agree on these definitions, and bear in mind the line from Lewis Carroll's Through the Looking-Glass and What Alice Found There: 'When I use a word,' Humpty Dumpty said, in rather a scornful tone, 'it means just what I choose it to mean - neither more nor less,' there is no guarantee that this will take us any 'forwarder' on our quest to elucidate the hobby. It also should be recognized that, in defining an object, the definition then limits the object, and this may have unforeseen consequences.



Stephen Jay Gould (1941-2002)

"One way out of this dilemma is to avoid definitions and instead describe the major stages in the development of the aquarium hobby."

Thus, via description rather than definition, I introduced the concept of the Four Stages of the Aquarium Hobby, a construct that has served and still serves its purpose well.

One article I read with great interest while writing the 2003 edition of the Toy Fish was titled "Seeing Eye to Eye, Through a Glass Clearly," which was included in "Leonardo's Mountain of Clams and the Diet of Worms," written by Stephen Jay Gould and published in 1998. Gould (1941- 2002) was an American paleontologist, evolutionary biologist and historian of science. He was also one of the most influential and widely read writers of popular science of his generation.

Here, Gould talks briefly about Roman piscinae:

"I do not, of course, claim that this invention [Gould is talking here about Warington's aquarium] marks the first domestic display of aquatic organisms. The owner of any respectable Roman villa could look down upon the animals in his fishpond. Similarly, the simple bowl had allowed, also since classical times, the contemplation of a fish or two in the more direct, edge-on, eye-to-eye orientation (through glass, or some other transparent medium that did not always come

easily or cheaply before the last few generations)."

Gould, however, dismisses the Roman piscinae as aquariums from the standpoint of lack of stability and an eye-to-eye viewpoint:

"But these precursors are not aquariums in the technical sense, for they lack the defining feature: a stable community of aquatic organisms that can be viewed, not from above through the opacity of flowing waters with surface ripples, but eye-to-eye and from the side through transparent glass and clear water."

Actually, they are aquariums in the technical sense, as I will show later. With regard to stability, Gould contends:

"A fishbowl presents a temporary display, not a stable community. The water quickly goes foul and must be changed frequently (engendering the amusing and frustrating problem, so well-remembered by all childhood goldfish enthusiasts, including yours truly, of netting your quarry for temporary residence in a drinking glass while you change the water in his more capacious bowl - a process that can keep Grumpy the Goldfish going for a while, but surely cannot sustain a complex community of aquatic organisms). The concept of an aquarium, on the other hand, rests upon the principle of sustained balance among chemical and ecological components - with plants supplying oxygen to animals, fish eats the growing plants and snails (or other detritus feeders) scavenging the wastes and gobbling up any algal film that might grow on the glass walls. Western science did not discover the basic chemistry of oxygen, respiration, carbon dioxide and photosynthesis before the late eighteenth century, so the defining concepts scarcely existed in a usable way before then. The aquarium represents but one of many practical results for this great advance in human knowledge."

The problem here is that Gould is describing the situation in England in the 1850's. Since that time, Western science has discovered, invented or adapted aeration, filters, plastic plants, artificial lighting and silicone, to name but a few that influence what we call an aquarium. Gould, therefore, is not defining the aquarium but merely one kind of aquarium.

With regard to the eye-to-eye and from the side through transparent glass and clear water requirement, Gould writes:

"Little examples of big principles strike me as most intriguing of all - for I declare my allegiance with several common mottoes proclaiming that God, the devil, or any matter of great pith and moment, lies in the details. I believe that we can identify one of these admittedly small but 'obviously' permanent and universal modes of seeing as, instead, a direct legacy of the mid-nineteenth-century aquarium craze, and therefore not much more than one hundred years old as a Western way of knowing.

"How shall we draw marine organisms and more-general scenes of underwater communities? The answer to such an inquiry seems so evident that we may wonder why anyone would bother to pose the question at all. We always draw such scenes in their 'natural' orientation today: in the 'eye-to-eye' or edge-on view, where a human observer sees marine life from within - that is, as if he were underwater with the creatures depicted, and therefore watching them at their own level. Isn't this orientation obviously best? After all, we wish to show these creatures as they live, pursuing their ordinary behaviors and interactions. How else could we possibly draw them except from within their own marine environment?

"I can only imagine one reason for a strong convention of such strikingly suboptimal illustration. Artists must then have avoided—or not even been able to conceptualize - the eye-to-eye, within-

their-own-environment viewpoint so ‘naturally’ favored today. Illustrators must have eschewed this edge-on orientation because most people had never seen marine organisms in such a perspective before the invention of the aquarium, and the craze for maintaining such a display as a rustic adornment in the home converted the formerly inconceivable (because unseen) into a commonplace. Water is usually muddy and largely opaque when in motion. No technology of face masks, diving bells, snorkels or oxygen tanks existed - and humans do have to come up for air after very short periods of potential observation. The vast majority of Western people (including most professional sailors) couldn’t swim, and wouldn’t think of immersing themselves voluntarily in marine waters. So where, before the invention of aquariums, would most people ever have seen (or even been inclined to imagine) marine organisms in their own environments? The conventional, if uninformative, view from the shore (and down upon the waters) surely represented the ‘natural’ way of human knowing before aquariums opened a new perspective.”

This paragraph sets the theme for his “Seeing Eye to Eye, Through a Glass Clearly.” Once again, however, Gould is describing the situation in England in the 1850’s where Western science had advanced so that now the contents of an aquarium could be seen edge-on, eye-to-eye. What Gould is overlooking is that the word “aquarium” is a Latin term that simply means any container of water. In our hobby it is implied that it contains aquatic organisms, fish in particular. In fact there is a precedent for using the word aquarium in this way that dates back to 1742 when Linnaeus used it for aquatic plants. Plants were implied when gardeners used the word aquarium, analogous to fish being implied when fish keepers used the word aquarium. As the Romans might have said, “Si fractum non sit, noli id reficere” (If it ain’t broke, don’t fix it”). “Aquarium” was never broken, so there was never any need to waste time re-defining it.

There is one instance in the aquarium hobby, however, when definitions must be present and they also must be precise and that is when the question of priority arises, such as who or what was “first.” I’ll discuss two examples, starting with “Who Invented the Aquarium?” Note however, that pinning down “firsts” is a perilous endeavor. One may assert that so-and-so was the first on record for doing something, only to have another researcher later uncover an earlier reference that shows someone else has precedence.

In my monograph on this subject published here in the Files section in 2012, I pointed out that before one attempts to pin down a “first,” one must devise a set of criteria and I selected three.

The first criterion was that the water in the aquarium was neither aerated artificially nor changed. Implicit was that the basis for the aquarium was the relationship between plants and the animals, i.e., that plants absorbed the carbon dioxide that the aquatic animals generated whilst the animals absorbed the oxygen that the plants generated. Thus, like Gould, I was describing a particular kind of aquarium.

The second criterion was that the claim was published and had priority of publication, and the third was an assessment of its impact on the aquarium hobby in the Nineteenth Century. This last criterion, however, was optional and my findings were summarized both with and without it.

As a matter of simplification and in order to provide multiple credits, I considered four categories for “firsts” in the monograph: the freshwater aquarium sans fishes, the freshwater aquarium with fishes, the marine aquarium without fishes and the marine aquarium with fishes.

These criteria clearly set specific limits to the general question, ‘Who Invented the Aquarium.” However, it is highly likely that they reflected what was really meant by this otherwise meaningless query. No one would seriously consider looking for the answer to this question in the Twentieth Century or later.

My second example addresses the question, ‘Who were the first aquarium hobbyists?” Historically the contenders have included the Sumerians, Assyrians, Greeks, Egyptians, Romans and Chinese. However, even if their fishponds were used for religious, ornamental, agricultural or scientific purposes, this does not mean that these cultures had an aquarium hobby. Before one can attempt to answer this question, therefore, one must define what we mean by that term. After sidestepping this chore for decades, I was finally forced to confront the issue.

My definition is based upon Occam's razor, a principle of parsimony, economy or succinctness used in problem-solving devised by William of Ockham. I used a version here that states that among competing definitions, the one with the fewest elements should be selected. Other, more complicated definitions may ultimately prove better, but - in the absence of any certainty that they are absolutely required - the fewer elements that are included, the better. Thus the definition of the aquarium hobby I used was: “A subject or pursuit involving fishes, undertaken primarily for pleasure during one’s leisure time and to which a person is notably devoted.” Using this definition and based upon the available historical information, my answer to “Who were the first aquarium hobbyists?” was clearly the Romans. "Piscina" was merely one particular kind of aquarium, and this was their name for it.

Ockham chooses a razor

MY AQUARIUM OF BLACK BASS, ETC.

by GEORGE KAMPER

(Aquarium Hobby Historical Society, Yahoo Files, August 1, 2014

The following is an article that appeared in *Nature's Realm*, Vol. II, No. 5, May 1891, written by George Kamper. Kamper was born in Germany in 1854 and immigrated to the United States where he became a citizen in 1877. He settled in Danville, Illinois, his occupation noted in the US 1880 census as a "news dealer." He was, however, an avid angler and constructed an unusual aquarium as an attraction for his store. In addition to providing three fish illustrations, I have modified the legends in Kamper's diagram, making them larger and bolder in order to make his description easier to follow. AJK

Four years ago I built for one of the show windows of my store an aquarium for keeping specimens of the various kinds of fish caught in the waters of our county. It is built to fit the irregular angles of the window, about as follows:

Front sides, **AB** and **BC**, are plate glass; back sides, **CD, DE** and **EA**, and the bottom, are wood, lined with sheet lead. The sides are ten inches high inside and the bottom contains about eleven square feet surface. At **E** the water pipe **M** comes over the top, and under pressure from our city water-works a steady jet of water is thrown through a very small nozzle down into the tank. The water stands twelve inches deep, making a total of about eighty gallons, and overflows at **F**, four inches below the top of the tank, into the back tank, **GHI**. This back tank fills to a seven-inch depth and then the water passes from the overflow, **K**, down through the cellar into the sewer.

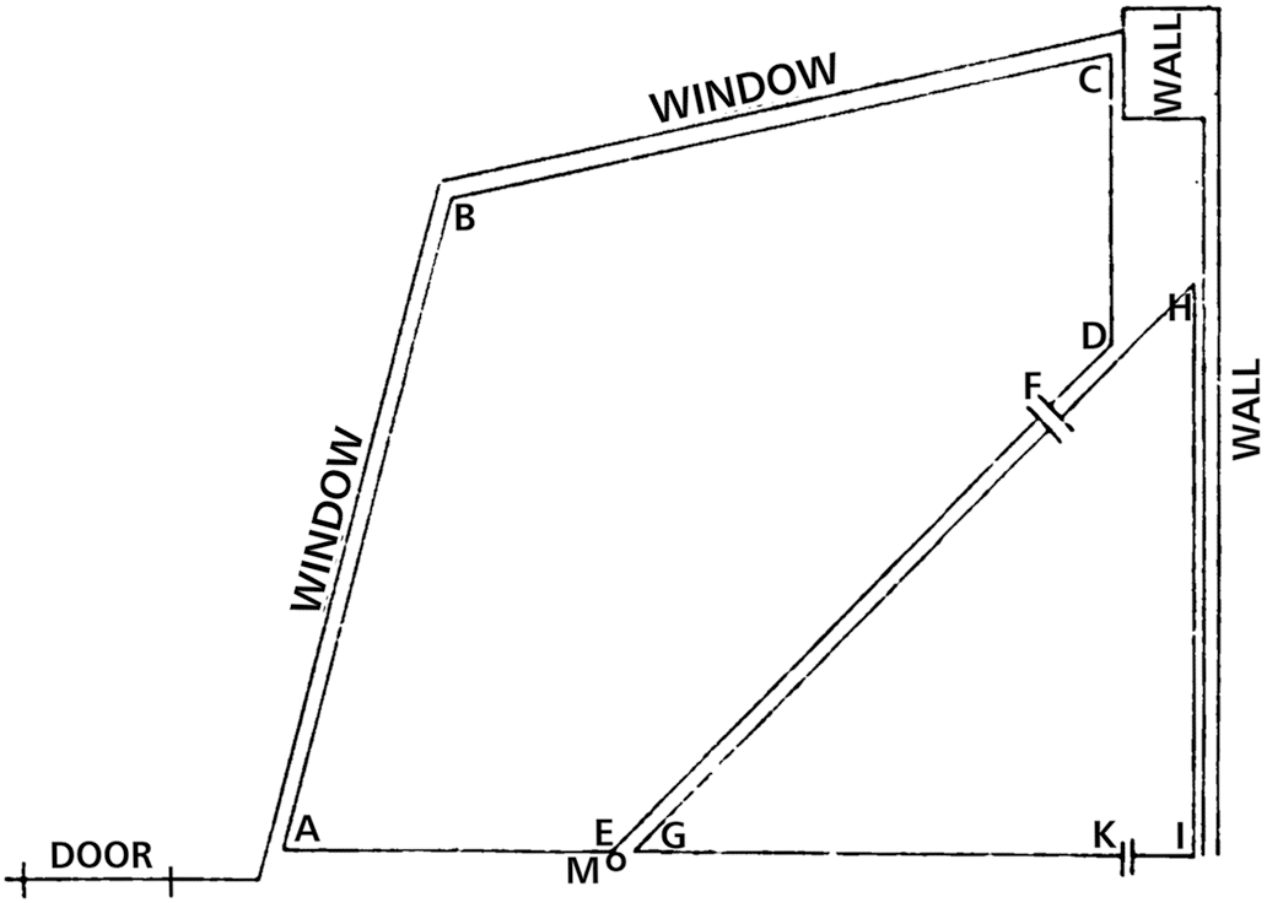
When the fish eat there is necessarily some excrement and undigested particles of food, such as minnow bones, claws of crawfish, etc. This offal tends to befoul the water, and if not removed will produce the so-called "aquarium disease." To avoid this filth disease I have covered the bottom of the tank with small rocks and pebbles, between which the sediment gathers and remains until I clean it out. I clean the tank about once a month during the summer season in the following manner: I turn the water pipe **M** to throw the water into the back tank at **G**; catch the fish with a landing net and put them in there also. Then with twelve feet of one-inch rubber hose I siphon the accumulated filth out of the main tank and wash it clean of green slime, etc. Before putting the fish back I clean them also by holding them under the strong jet of inflowing water, which cuts the slime from their bodies and makes the back tank look like a tub full of soapsuds. This cleaning must be done when the fish have empty stomachs, otherwise it will make them vomit. By these means I have succeeded in avoiding the aquarium disease among my fish, and they are in a healthy condition.

The sketch gives you a fair idea of the size and general arrangement of my aquarium, and I will now tell you something about its inhabitants, and a few incidental observations. I will begin with the statement that, excepting one large carp, which remained only forty-eight hours, no fish have ever been in my aquarium that were not caught legitimately with hook and line in public water adjacent to Danville. The first were put there in March, 1887, and the suckers were put there simply to fill up until the bass began to bite. About April 25 of the same year I had replaced the suckers with twelve small-mouthed black bass, weighing from one to three and a half pounds each ; three rock bass or goggle-eyes, two bullheads, one small channel catfish and one eel. The two largest bass were a female very heavy with eggs, weighing three and a half pounds, and a male fish a trifle longer but more slender, weighing three and a quarter pounds. The female had been caught in the Vermilion River under the Wabash Railroad bridge, and the male in the North Fork, above the dam. Near the middle of May I noticed that on warm days the male fish would take possession of the center of the tank and compel all the other fish, except the large female, to huddle in the corners. The large female

appeared to be at liberty to do as she pleased; the two had evidently decided to mate and nest, and the male seemed to do the fighting for both of them. They were a handsome couple, and naturally I was much interested in the probable outcome of their courtship.

On May 20 I was out of the city, remaining away overnight, and returned the next morning. As I stepped from the train on to the depot platform the first man I met accosted me with. “George, your fish are all dead,” and I heard the same unwelcome news several times before I reached my store, where I found the case as bad as represented. All the bass, the goggle-eyes and the channel catfish, were laid out in a row; every vestige of the color of life had left them; they were pale as ghosts - dead. Standing near them, viewing them with a sad face (he also had learned to love them), and somewhat in fear of my wrath, was my clerk, Willie. To my question, “Willie, how did it happen?” he answered: “Mr. Kamper, I hardly know. When I opened the store this morning the water was only dripping a little and the fish were dead.” Further questioning brought the information that, before closing the store the preceding night, Willie had turned down the strong pressure to enable him to draw a cup of water to drink, and he had forgotten to turn it on again. The absence of pressure had permitted a speck of dirt to lodge in the nozzle, and the flow of water stopped entirely. Soon after daybreak the policeman on this beat noticed my fish showing signs of distress, gasping for breath and rolling and tumbling as if in delirium, and also that the water had stopped. He hunted for me at my rooms and at the hotel, but I was not in the city. When Willie came at 7 o’clock life had left all of the fish except the eel and the two bullheads. These, I was told, kept their mouths near the surface, and they survived.

About the middle of May the bass in our rivers begin to nest, and as for that reason I could not immediately stock my aquarium with bass, I filled it temporari-



ly with channel catfish. The catfish were rather unsatisfactory, on account of their habit of huddling together in the darkest corner during the day, feeding only at night after all the lights were turned out and everything was dark and quiet. When bass fishing again began in August, I soon replaced the catfish with a fresh lot of bass, but none were as interesting as the large pair that was killed in the disaster of May 20.

With the approach of winter I decided that the water would be undesirable in my window during the cold weather, and I also needed the show window for holiday goods, etc., therefore about the middle of November I killed the fish, shut off the water and removed the tank. This ended the first year. In March, 1888, I again put my aquarium in the window, turned on the water and filled up with suckers and bullheads until the bass commenced to bite.

By the latter part of April I again had a lot of bass ranging in weight from one and a half to two and a half pounds each, but although some of these were heavy with eggs, I saw no signs of mating or attempting to nest, and in July the fish dropped their spawn, which went to waste.

I feed my fish principally with minnows, of which I bring two or three bucketful's at a time from the river. At the store I assort them, throwing the largest and choicest into the back tank for future use as bait, and throwing the balance to my fish for feed. After a few months of this practice I noticed that the bass appeared to understand the meaning of the rattling of the minnow buckets, and this set me to experimenting. Though they were at first somewhat timid, the bass soon ceased to fear my hand in the water near them, and before long they boldly took hold of minnows held by me, and forcibly pulled them out of my hand. When they are not hungry, they are of course beyond my control, but if they want something to eat it is different. They will then come to- my hand, permit me to chuck them under the chin, and appear to say by looks almost as eloquent as words, "Give me something to eat," and I seldom let them beg in vain.

Of course I felt proud of them, and became so attached to them that I dreaded the approach of winter, for I did not want to kill them, and could not keep them in my window during the winter months. I had plenty of room in my cellar, but how about the food supply? Could I winter my pets? Still undecided what to do, 1 noticed that as the water became colder the appetite of my fish diminished, and then it dawned on me that they might live through the winter without food.

On the day before Thanksgiving I moved my aquarium into the cellar, changed the water pipe to supply the same kind of a stream down there, and put the fish into winter quarters. On January I, 1889, during a period of mild weather, I induced some boys to go to a sheltered bluff facing south and dig some worms. They brought me a can full of choice earthworms, and I went down with them to inter-view my pets. The fish seemed to be comfortable in the cellar twilight; the slow, regular motions of their fins necessary to maintain their position, and the slight and almost imperceptible movements of their jaws and gill covers in the act of breathing, were the only signs of life about them. I held in front of them some of those long, fat earthworms, curling and twisting, but they would not touch them, though they had the previous summer taken many such out of my hand with evident relish as a change of diet. I even hung a large worm over the snout of one of the fish, but he leisurely shook it off and permitted it to fall to the bottom. Being convinced that the fish would not eat, I ceased to worry about their winter food supply, emptied the worms into the water and left them.

The following March I moved the fish upstairs again, finding them all plump and healthy, and the worms still crawling about in the bottom of the tank. As the water became warmer the fish regained their appetite and began to feed, rather slowly at first, but with increasing vigor as spring ripened into summer. The summer of 1889 was a repetition of the preceding one, in so far that the bass had lost their fear of the hand of man, and remained tame and healthy. During that summer I put in with them for a few weeks a channel catfish weighing five pounds. He was a handsome fish, with a small head, and slender,

graceful body, beautifully marked with black dots on the pale blue skin, and made a grand fight when I captured him, but the brute had no sense whatever. Any motion throwing a shadow over the water frightened him, and I found that in his fright, rushing about with horns sticking out stiff, he had injured some of my bass. 1 was compelled to take him out and kill him.

During the winter of 1889 to 1890, I kept twenty bass in the cellar, putting them down earlier than the preceding fall, and before they had entirely stopped feeding; I put with them a batch of minnows, which they ate in the cellar. When 1 again moved them upstairs in March I found that my tank was very foul, the fish were very slimy, and those that had been horned the preceding summer by the large catfish were very sore in the injured spots. I took the injured ones (four in number) back to the river, where I hope they have found a doctor to heal their wounds. The uninjured ones 1 washed carefully; with the warm weather they regained their full appetite, and the six largest are in my tank to-day. Last fall I waited until the fish had quit feeding before I put them into the cellar again, and did not attempt to winter so many, and the result is that there is not a mar or blemish on one of them. They are upstairs in my window again, and enumerate as follows:

Three rock bass or goggle-eyes, weighing between, four and six ounces each, which I have had about two years. One channel catfish, which I caught in June, 1889, when he weighed one and three-fourths pounds; he now weighs over three pounds, and has lost much of his unreasoning natural fear. Two scale carp, one weighing three-quarters of a pound, which I caught last August, and the other one caught in April, 1889, when it weighed one and a half pounds, but which now weighs three pounds.

CHANNEL CATFISH, *Ictalurus punctatus.*

Last, but not least, ten small-mouthed black bass, six of which are of the lot caught in April, 1888; one has been in my possession since September, 1889, and the other three since October, 1890. The largest one is the two and a half pound fish of the spring of 1888; he has grown very little in length, but considerable in thickness and depth, and now weighs three and a half pounds. The other nine bass weigh from three pounds six ounces down to two and a half pounds, and the aggregate weight of the ten is thirty-one pounds.

You see by above enumeration that I have not confined my attention strictly to bass, and you can readily understand that under the circumstances a thorough “fish crank” can pick up many odd bits of information on the subject of his hobby.

As my back tank is a very convenient place for fresh-caught fish until I am ready to use them, I always endeavor, when fishing, to keep my catch alive. After landing a fish I string him by carefully putting a string through be-tween the gills and the outer gill cover (never between two red gills), and then out at the mouth, drawing it through slowly, so as not to draw blood from the gills. I tie a separate loop for each fish, so they do not strain each other’s gills, and tie them in the water until I am ready to go home. If I am on foot I carry the fish home by the strings, and, if in a conveyance, they are laid down in the bottom of the wagon. When the weather is cool fish may be kept out of water an hour or even longer, and regain their health, but a carry of only fifteen or twenty minutes through a hot summer sun often kills them. Bass are more hardy and able to bear more exposure than the channel catfish. The small wound made by the hook in the hard jaws of a bass scarcely shows the next day, but in the jaws of a channel catfish the hook wound often festers and remains sore for several weeks.

Small-mouthed bass have always been quick to grow accustomed to their changed surroundings; they soon begin to feed, and soon cease to become frightened at unusual motions or shadows, but have always strenuously objected to having a landing net put un-

der them. They permit me, and apparently enjoy to have me rub their backs and sides with a stick, somewhat similar to dogs who like to have their heads scratched.

With large-mouthed bass my experience has been quite different. I have often tried to make one of them a permanent resident in my aquarium, but have not succeeded. They remain wild, refuse to eat, and finally sicken and die.

I made my last attempt with a three-pounder last summer. He had not been injured in the catching, had to bear only ten minutes of carrying on a moderately cool day, and arrived at my aquarium without showing any sign of weakness, swimming off as soon as put in the water. I never saw him feed, and at the end of three months he looked so shrunken and miserable that I took him back to the river in disgust, determined not to try any more experiments with large-mouthed bass. Catfish also have been unsatisfactory tenants in my aquarium. The bullheads and the flat-headed marbled catfish have become diseased after six months or a year, probably because they persisted in lying so close to the filth which gathers between the rocks in the bottom, and they had no mud to crawl through to clean themselves. Probably, also, I did not take as much pains to wash and clean them as I did my other fish.

Channel catfish have shown no tendency to become diseased (they are not mud rooters), but their wild and unreasoning fear, which causes them on the slightest provocation to rush about with stiff horns, added to their strength and agility, makes them rather dangerous for their neighbors. The one now in my tank was wild all of the first year, but he was not large enough to do any damage. Of pike we have only a few small ones in our river, still I have several times put a pike fifteen inches long into my aquarium. Suckers we have plenty, and I have tried them of all sizes, large and small, but the small-mouthed black bass seem to possess an inveterate hatred against pike and suckers. They swallow either if less than seven inches long, and viciously attack the larger ones, biting them till they die.

Rock bass or goggle-eyes, even if only three inches long, are permitted by their lordly and somewhat vicious neighbors to live in peace. They soon become reconciled to their new quarters, soon begin to feed, and thrive about as well as their messmates, the small-mouthed black bass. Carp are also permitted by the other fish to live undisturbed. Sunfish live all right, but unless they are more than three inches in diameter, their career ends inside of the bass. Eels live in peace and health with their neighbors (I have found the tendency to become diseased only in the bullheads and mud catfish), but they have too much curiosity, and are forever climbing out of the aquarium. Many times have I found them on the floor and put them back into the water, but invariably their final end has been to climb out at night and die before I found them the next morning. The last eel I had (thirty inches long and two and a half pounds in weight), was probably cured of his roving propensities by being very near the point of death several times before he was found and restored to the water, for he remained in the tank an entire year without climbing out.

One Sunday evening last August I happened to come to the store, and I found quite a crowd collected in front. One of my old pet bass had jumped out and died, lying between the tank and the window. I could not understand it - the bass ought to have known better. The next morning my eel was on the floor, dead.

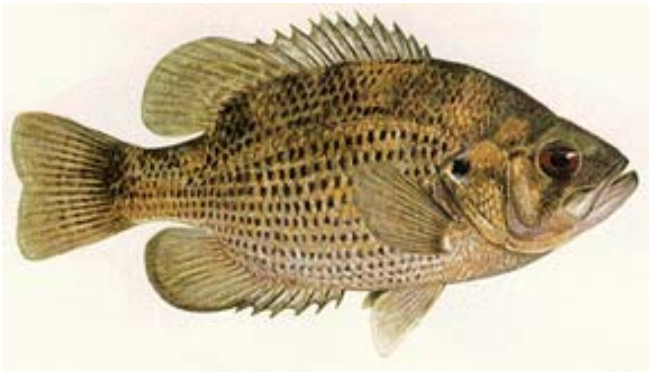
Something was surely wrong, and on investigation I found that a large snapping turtle, which I had temporarily put into the back tank until I was ready to eat him, had managed to climb over into the main tank. How he succeeded I can’t imagine, but I could hardly blame the bass and the eel for wanting to avoid the company of the ugly intruder. You may rest assured that I promptly put the big snapper into an iron cage until I was ready to kill him. This summer I intend to make one more attempt to keep an eel.

Last September the owner of a private pond presented me with a carp weighing seven pounds. I put it into the tank, but the brute was sighing for its native mud and would not be contented. It was too clumsy

to climb out, but managed to throw water ten feet high, and in less than forty-eight hours it had pounded its tail fin into shreds, knocked most of the skin from the top of its head, and had the general appearance of having been run through a threshing machine. It went from the tank into the bake oven.

During these four years of feeding my fish, I have of course paid some attention to their preferences in food, and their manner of taking it.

For bass, minnows are undoubtedly the great staple food, and of these the larger are preferred to the smaller. Whenever I give them a lot of minnows of various sizes, from two to five inches long, they always pick out the largest ones first, and take the smaller ones only after no larger ones are left. Black bass, rock bass and channel catfish will eat crawfish, but they prefer minnows. I have often found my fish eager after minnows when they ignored crawfish. One day last summer, when my fish had been without food for several days, I brought from the river a six-quart minnow bucket filled solid (without water) with crawfish, and another bucket filled with minnows. I set the bucket with the minnows into the back tank, and dumped the crawfish into the main tank. The bass immediately commenced to feed, but after twenty minutes they had quit entirely, and the bottom of the tank was still swarming with crawfish. I then emptied in the bucketful of minnows (more than a hundred shiners, two or three inches long), and the fish immediately commenced to feed again, making the water fairly boil. Five minutes afterward they had taken all of the minnows, and their bellies were a sight; bass, goggle-eyes and channel catfish, all were stuffed till it seemed their skins would burst.



ROCK BASS, *Ambloplites rupestris.*

All of my fish enjoy a few worms occasionally, and during the summer I sometimes catch a lot of grasshoppers, which are always taken quickly by the bass and goggle-eyes.

Last summer some workmen, digging under a coal house in the rear of my store, caught some mice, which I induced them to bring in and throw to my fish. Five of the mice were alive and kicking, and, as soon as they struck the water, each were promptly caught by a bass and swallowed. The sixth mouse had been killed in the catching, but before it had stopped the motion caused from throwing it, a bass had it. The fish held the dead mouse only a second or two, when he spit.it out, and it floated lifeless on the surface; none of the fish would or did eat it. A boy once brought me a live sparrow, full-feathered and nearly full-grown, which I threw into the tank. The bird was struggling in the water, and within five seconds from the time it was thrown in, one of the large bass caught it - and he swallowed it, too. The sparrow was a big mouthful for the bass, but slowly and gradually I saw the tail feathers disappear, and finally I could see a large lump in the body of the fish.

The capacity of the stomach of a fish is wonderful. My oldest bass one day came to my hand seventeen consecutive times, taking and swallowing a three-inch shiner each time, before he was willing to stay back and give the other fish a chance. Sometimes, when their stomachs are filled so they can hold no more, the bass continue to catch minnows, squeeze and kill them, and spit them out. What fisherman of any considerable experience in fishing with bait for small-mouthed black bass, has not been tantalized by having run after run, when the bass simply squeezed and killed his minnows and then dropped them? And when this tiger spirit possesses the fish, what can equal the satisfaction that the fisherman feels when he beats the bass at his own game, and captures him by spinning a dead minnow? Spinning, not with a gang of a thousand hooks, or six hooks, or three hooks, but with a plain, single Sproat hook [i.e., a fishhook having a circular bend, named after W. H. Sproat, a 19th century angler who invented it circa 1865-1870] on a single gut leader. But I am digressing from the subject of “My Aquarium.”

In August, 1889, I was attacked with sickness, and for four weeks I was unable to go after feed for my pets. Some of my friends went several times, but there were ten days when my fish had received nothing to eat, and they were ravenous. They certainly were hungry enough to eat fresh meat if they could be made to eat it at any time, so I tried them, and threw in some pieces of fresh beef. As fast as the pieces of beef struck the water they grabbed for it like a pack of hungry wolves. Every bass in the tank snatched a piece of beef, and every one of them spit it out again. The bass, when hungry, appear to be willing to swallow anything that wriggles, but they certainly refuse to swallow anything that does not show some signs of life.

My carp was neglected during the summer of 1889, and as he had to sustain life as best he could, he has learned to eat minnows. He readily takes small minnows, if killed or crippled so he can catch them. He increased very little in size during 1889, but last summer I fed him bread, and then I noticed a steady growth. The carp is a great forager, always on the move, picking up bits of food, but he does not Stuff himself as full as (he others do. The channel catfish also likes bread, and while feeding the catfish and carp last summer, I found that they can smell the bread. After first noticing this, I experimented a great many times by quietly dropping bread, kneaded into balls to make it sink, into one corner, when both fish were four or five feet away, with heads turned in the opposite direction. After the bread had been on the bottom a few seconds, the catfish and carp would suddenly turn, swim directly to the bread, and begin to feed on it. They could not have seen me drop the bread and must be able to smell it.

While the channel catfish are fond of and are expert in catching live minnows and crawfish, they are almost omnivorous, and will also eat beef, liver, bread, corn, mussels or fresh water clams, worms, and in fact anything that has not become stale and putrid.

According to my experience the bass, channel catfish and carp eat practically nothing when the temperature of the water is near the freezing point; their appetite increases or diminishes as the water becomes warmer or colder, and during the heat of summer they consume enormous quantities of food. A bass fresh from the river in the spring tastes quite different from one equally fresh from the river in the fall, and I have noticed in cleaning fish, that in April, when the scales are scraped from a bass the fish is clean, but in early November, when the water is fully as cold as it was in April, slime continues to ooze out of the fish after the scales are scraped off, and after repeated scrapings this slime still comes. I have often thought that possibly this slime or oil, which permeates the entire body of the bass after the summer period of strong feeding, but is absent after the winter's period of fasting, is the surplus vital power stored up during the feeding time, which sustains the fish during their periods of fasting.

My aquarium has been for myself and friends a source of much interest and pleasure, and if any brother angler wants to try the experiment, I shall be pleased to give him further information about details for building and managing a similar one.

Note: Kemper's report covered a five-year period (1887-1891) and provided a host of information on the maintenance and behavior of a number of species of native fishes that deserves to be recorded for posterity. He also provided information on the materials of construction of his tanks but no details of the frame or what he used to seal the sides and bottom. Unfortunately, *Nature's Realm* ceased publication with this issue so Kemper's offer to provide more detailed information never saw the light of publication.

SMALLMOUTH BASS, *Micropterus_dolomieui.*

MULERTT MISCELLANEA

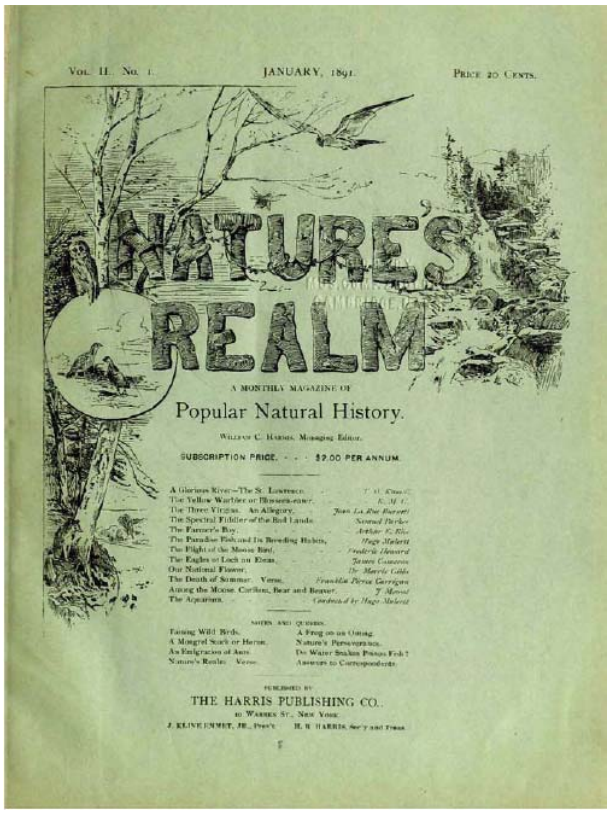
by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Miscellaneous Yahoo Posts, July-August 1, 2014)

In 1890, William Charles Harris (1830-1905) started a magazine called *Nature's Realm*. Harris was a publisher in New York City but was mostly known as a writer on angling, including the books, "The basses, freshwater and marine," "The fishes of North America that are captured on hook and line," "Salmon and Trout" and "The Practical Angler," as well as the magazine, *The American Angler*.

NATURE'S REALM

In volume II, No. 1 of *Nature's Realm*, dated January 1891, Mulertt wrote a feature article titled "The Paradise Fish and its Breeding Habits." In this issue he also started a monthly column that featured an article by him, this one being on goldfish). In subsequent issues Mulertt's article was followed by queries that he answered.



***Nature's Realm*, Volume II, No. 1, January 1891. In this issue Mulertt wrote a feature article on the Paradise Fish and also started a monthly column devoted to aquarium matters.**

Nature's Realm ceased in 1891 after 5 issues and in the following year, Mulertt started re-publishing The Aquarium after a hiatus of 12 or 13 years. It is interesting to speculate whether this would have happened if *Nature's Realm* had not ceased publication.

AN AUTHORITY

It is also interesting to note how highly regarded Mulertt was on fishkeeping in this country. The following is from the *Buffalo Evening News*, Thursday, February 27, 1902:

AN AUTHORITY ON FISH
Editor Evening News:
In "Everybody's Column" on Feb. 22, a correspondent signing 'H. K. D.' asked about trouble with gold fish, which was detailed. The aquarium expert of this country is Hugo Mulertt, 280 Fenimore street, Brooklyn, N. Y. He has published a book on "The Goldfish and its Culture," and issues a publication called "The Aquarium." The U.S. Fish Commission recognizes him as an authority. Undoubtedly he would answer an inquiry, but the possession of his book would enable an amateur aquarium keeper to solve the problem for himself.
STATE FOREST FISH AND GAME COMMISSION, Albany, N.Y., Feb. 14.

FAMILY

In 1870 Mulertt and his wife (Franciska, who also was born in Germany) had a daughter (Anna) in Virginia while he was working at the Bellevue High School. Bellevue High School, a private, classical academy for boys that was primarily attended by the sons of famous men, was established in 1866. Its first session was in 1866 and had seventy boys in attendance. The school drew students from all over the nation, especially the deep south.

It is not known whether Mulertt's wife died or they were divorced but by 1892 he was re-married. In the September-December 1904 issue of the *Oswego Palladium*, it was reported that his wife, Lena,

…has recently written a charming and dainty little book in the German language. It is called 'Der Dackel auf Reisen' ('The Dachshund on his Travels'). Mr. and Mrs. Mulertt made a trip from New York to Wiesbaden, Germany, and took the little dog with them. The dog is supposed to tell in his own words what he saw on his travels. Though we are to considered it to be only dog talk, the story is told in a pure and simple German that is admirable. The little volume is specially adapted to the use of either grown persons or children who are beginning to read German. The proceeds of the sale of 'Der Dackel auf Reisen' go to the maintenance of a home for aged and invalided women teachers.

Hugo Mulertt and his dwarf dachshund.

The full title of this 63-page book was "Der Dackel auf Reisen. Seine Reise-Erlebnisse, von ihm selbst erzählt. Für die Jugend bearbeiten" ("The Dachshund Traveling. His travel experiences as told by himself. Written for young people") and it was published in Wiesbaden by R. Bechtold & Co. in 1904.

Note: Although Dachshund is a well-known German word, in modern German they are more commonly known by the name Dackel or, among hunters, Teckel. There is a discussion of Mulertt's dwarf dachshund – one third the usual size – and a picture of it being held by Mulertt is included here.

WORLD WAR I

In 1912 Hugo Mulertt ended his active participation in the hobby - some forty-three years of service - by retiring to Wiesbaden, Germany. However, World War I began on July 28, 1914. The following is from the Brooklyn Daily Eagle, Sunday, November 15, 1914:

"MADE IN GERMANY" CAUSED WAR, HE SAYS Hugo Mulertt, Former Brooklynite, Declares Jealousy Bred Conflict. "A Fight to the Bitter End." Praises Unanimity of All of Kaiser's Subjects in Striving for Victory over Foes.

George E. Saulnler of 290 Fulton Street has received an interesting letter from Hugo Mulertt, an American citizen and former Brooklynite, who is now living in Wiesbaden, Germany. He gives an interesting picture of war conditions in Germany. The writer says:

"The long-expected has come at last. I have written you a narrative letter of my personal impressions, but none other than mail written in German, and unsealed, were forwarded - Germany swarmed with spies! I could not mail it. I have it still in my possession, and shall forward it to you Hugo Mulertt and his dwarf dachshund. when carriage of mail is safe again. Since yester day we are allowed to mail English letters, but still unsealed.

"You are, no doubt, well supplied with lies and fed on misrepresentations and 'cruelties' concerning the German army, all manufactured by Germany's enemies for a purpose. I imagine that a certain New York paper especially is having 'the feast of its life.'

"But don't be alarmed by these reports. Germany is fighting its battles with a large, thoroughly trained, disciplined and well equipped army and navy, which are directed by able staffs, backed by a filled treasury. Last week the country issued a public loan for 1,500,000,000 marks at 97-1/2 at 6 per cent. Last Saturday at 1 p.m. the subscriptions closed. The result: 4,400,000,000 have been subscribed, and all this by Germany alone. There is not a single man of the enemies on German soil, save as a prisoner. These latter we have by the hundred thousand already and among them the best English battalions, as the Gordon Highlanders, including their famous colonel.

"Yes, the long-expected war is here. However, it was not made in Germany, although 'Made in Germany' made it. Preparations for it began in 1878 when United Germany rose as a new star on the horizon. Jealousy, pure and simple, came to be, The Kaiser tried his best to the last to prevent this war by being prepared to face it. He was courteous and amiable toward all nations, but England, seeing her chances to 'down' Germany vanishing day by day, 'forced the season.' We Americans know England from experience. To me their act seems suicide. As far as I can judge, Germany will come out of this conflict a Greater Germany, and we all shall be obliged to restudy the political geography of the world.

"Business goes on as usual, excepting, of course, the foreign trade, which is entirely at a standstill. (Praises be, I have laid in a goodly supply of teas.) One would not think, by the appearance of the streets, that this country is successfully defending its independence on four different fronts at the same time, not counting in the navy, were it not that the many bandaged soldiers one meets on the promenade and in the parks give proof of the severe fighting that is going on. All engaged in this gigantic struggle, including the enemies, have the conception that it means 'to the finish' this time. The losses are enormous. On about August 10 I was informed by a non-com of the quartermaster's department that they had supplied 9,000,000 men with new boots, two pairs each. This may give you an idea of Germany's forces. To the regular quota there reported 2,500,000 volunteers! We have no more political parties. All are Germans. The Socialists turned out to be just as loyal Germans as any of the rest! At one time we had about 500,000 soldiers, all in new uniforms - gray, similar to those the Johnnies had, the so-called campaign uniform - encamped here. We belong to the radius or rayon of Mayence, a stronghold of the first class.

"Let me know at once when this letter reaches you, that you received it. It goes via Rotterdam; but these boats, although Dutch and neutral, are frequently 'brought up' by English cruisers, are searched and the German mails, including papers, are seized and thrown overboard. The last mail I had from America is dated August 4. I intended to be in Brooklyn in September, but the outbreak of this war changed my programme,"

It should be noted that Mulertt was an American citizen and had fought for the North during the Civil War. (His reference to the gray uniforms "… similar to those the johnnies had…" was to the name given to Confederate soldiers by Northern soldiers during the Civil War.) The "We Americans know England from experience" most certainly referred to the Revolutionary War and the War of 1812.

The following is from the "Annual Report of the Adjutant- General, of the State of New York for the year 1895. Registers of the First Dragoons, Oneida Independent Company Cavalry, First, Second, Third and Fourth Provisional Cavalry, in the War of the Rebellion." Under the heading of First Provisional Cavalry is the following entry:

MULERST (sic), CHARLES H. - Age, 19 years. Enlisted, January at Kingston; mustered in as private, Co. C, Tenth Cavalry, January 10,1865, to serve one year; wounded, April 7,1865, at Farmville, Va.; captured, April 9, 1865, at Appomattox C. H., Va., while in the act of capturing a Confederate battle-flag; released from prison at Lynchburg, Va., date not stated; transferred to Co. C, this regiment, June 24, 1865; mustered out with company, July 19, 1865, at Clouds Mills, Va.; true name Hugo Mulertt.

Although the immediate trigger for the war was the June 28, 1914 assassination of Archduke Franz Ferdinand of Austria, heir to the throne of Austria-Hungary, a resurgence of imperialism was the underlining cause. This New Imperialism (the qualifier "new" is to contrast with the earlier wave of European colonization from the 15th to early 19th centuries) was a period of colonial expansion by the European powers, the United States and Japan during the late 19th and early 20th centuries. The period was distinguished by an unprecedented pursuit of overseas territorial acquisitions.

Re Mulertt's reference to "made in Germany," the German Empire came to rival Britain as Europe's primary industrial nation during the latter half of the 19th century until World War I. Since Germany industrialized later, it was able to model its factories after those of Britain, thus making more efficient use of its capital and avoiding legacy methods in its leap to the envelope of technology. Germany invested more heavily than the British in research, especially in chemistry, motors and electricity.

The United States didn't join the war until 1917. In January 1917, Germany resumed unrestricted submarine warfare, realizing it would mean American entry. In the infamous "Zimmerman Telegram," the German Foreign Minister invited Mexico to join the war as Germany's ally against the United States. In return, the Germans would finance Mexico's war and help it recover the territories of Texas, New Mexico and Arizona. The United Kingdom intercepted the message and presented it to the US embassy in the UK. From there it made its way to President Wilson who released the Zimmerman note to the public, and Mulertt's Pension Record

Died Sept 1. 1927 | Reported OCT 18 1927

Remarks: Alias - Charles H. Mulertt.

Letter to Finch 9/29-27

Mulertt's Pension Record showing Date of Death.

showing Date of Death. Americans saw it as an act or situation provoking or justifying war. After the sinking of seven US merchant ships by submarines and the publication of the Zimmerman telegram, Wilson called for war on Germany, which the US Congress declared on April 6, 1917. Oddly enough, the United States was never formally a member of the Allies but became a self-styled "Associated Power." In any event, Germany had miscalculated, believing it would be many months before American soldiers would arrive and that their arrival could be stopped by U-boats.

It is difficult to imagine Mulertt's feelings when the United States joined the war, three years after this letter was sent, involving the country in which he was born and the country in which he spent most of his life and fought for. One also wonders how Mulertt fared in Germany as an American citizen during these times.

However, Hugo Mulertt started receiving a United States Civil War pension in 1885 and this continued to be paid until his death in Germany in 1927, at which time he was 80 years old. There is no evidence that he returned to the United States for any visits after he retired to Germany in 1912.

A MATTER OF FROGS

In the May 25, 1890 issue of *The Brooklyn Daily Eagle*, an article appeared titled "The Girls Cut Up Frogs." It was a report about the Packer Institute , reputed to have the best equipped and most thorough course in natural history of any academic school in the country. After interviewing Dr. Backus, the principle of the Institute, the reporter interviewed Mulertt, his portion comprising a bit over 70% of the article:

The collection is the work of Hugo Mulertt, a German who is now on his second year of duty at the Institute. Hugo is an enthusiast on these matters. He has been an agent of the United States Fish Commission in the West and came from the employ of Commissioner Baird to the Institute. He is a Fellow of the Imperial Russian Society of Acclimation. Hugo has the unlimited resources of the Fish Commission at his command and has selected through it what he could not obtain himself. He began his exhibition of the collection by leading his visitor up to the windows of a class room where, along the frame, were arranged a row of jars, ten in all. This was his frog factory. Frogs of all sizes and varieties can be had at an instant's notice. The frog is really a wonderful creature. He has ten distinct stages of development from the egg to the finished product. He begins as an exceedingly small wog, becomes a pollywog, acquires legs and loses his tail and finally develops into the real bullfrog of commerce. Each stage of development was shown in Hugo's Jars, so that by simple observation the student could at once comprehend the wonderful process. Many varieties of frog, the cricket frog, a tiny, spunky little thing; the Presberry's tree toad, not much larger; the wood frog, the marsh frog, the green frog and the leopard frog, filled out the jars and boxes on the next window sill. Then there was a skeleton of a frog, neatly mounted, to hand around the class room. When needed, some of these frogs are given over to the physiology class and dissected. Nearby was a big case of cocoons, where the development of the moth was shown from day to day. When the scholars have seen the moths come out of the cocoons Mulertt mounts them and puts them in a frame.

Some near relatives of the frog were discovered sporting in an aquarium on a stairway landing. These were salamanders: first the common spotted newt, erroneously called water lizard in this vicinity; then a Mexican salamander, larva and adult; a water dog or dog headed salamander from Ohio, and the German salamander, a rare specimen from the Hartz Mountains. He is an orange and black little beast, of whom preposterous stories are told of his ability to put out fires. He ate an American worm that Hugo gave him with a relish for alien food that was remarkable. He is quite intelligent and comes around to the side of the jar to watch the scholars at recess. The last of the frog's relatives was found up in the natural history room. He bore the euphonious name of hell bender and he will be sacrificed

under the dissecting knife in a few days by a member of the advanced class of comparative anatomy. It may be stated that the aquariums of the institute contain specimens of all the varieties of fresh water plants from Florida to Maine and California. A marine aquarium in the same room nourishes star fish, sea anemones, of which seventeen have been dissected this term, crabs, corals, sponges and other marine life. A lonesome crayfish or fresh water lobster, occupies a jar all by himself. A dragon fly hatchery stands in the window. The flies hatch under water, come up and dry and spread their wings under a wire netting. Pond waters from Tennessee, Virginia, Florida, Ohio, Pennsylvania and many other States make up a collection for microscope work. There is also a collection of growing plants for the botany class, which were raised from the seed by the young botanists themselves.

Most interesting among the fresh water plants is a fish eating plant, which grasps the little fishes just out of the egg and destroys them. The properties of this plant were discovered five years ago by Hugo and some follow workers. The Fish Commissioner, Eugene Blackford, now denies this attribute of the plant and Hugo has got plants and fish in preparation to demonstrate the truth of his asseveration to the great fisherman. The ascertaining of this fact is of great commercial importance in the propagation of fish. Where this plant is, there is no use of placing fish spawn. The most elaborate single exhibit of Hugo's collection is his salmon hatching trough, where in a great basin of running water the pupils may watch from day to day the origin of salmon. Hugo has this year hatched the ordinary salmon, the landlocked salmon, salmon trout and California salmon.

Besides the living, Hugo has collections of specimens preserved in alcohol, large cases of stuffed birds, beasts and reptiles, and the like. When the teachers desire any particular animal or plant, or part of either, for demonstration in class work they call upon Hugo, who goes forthwith and gets it. He showed two requisitions, as they are called in the class room, for ox eyes, to be used in the study of the eye in the physiology classes of next week. He goes to the butcher's and gets the eyes. In the same manner he has provided rabbits, cats, pigeons, snakes, codfishes and turtles, all of which have been dissected by the students this term. A dozen or more pigeons were thus sacrificed to a better knowledge of anatomy last week. Often a chicken or a partly hatched egg is called for. The Institute has a very complete set of microscopes, both for the use of the biology and botany classes; sets of dissecting tools and section cutters of the latest pattern. Advanced text books are used and the branches of study especially those of biology and comparative anatomy, are carried well along into the work of the best of our colleges.

The last and particular pride of Hugo are his Japanese gold fishes, which have been in the large aquariums in the main hall all Winter, but are now relegated to the fountain basin in the yard. Her he has "comets" and "fantails" imported directly from Japan, the latter being exactly like those pictured on Japanese fans, and "nymphs" of his own raising, but of Japanese extraction, of undoubted parity and aristocratic lineage.

MULERTT VERSUS BLACKFORD

The Eugene Blackford mentioned in this article and also referred to as "the great fisherman" was Eugene G. Blackford (1839-1904), born in Morristown, New Jersey. He was educated in the public schools and when about twenty-five years of age embarked in business as a fish-dealer in Fulton market. Through his efforts the red snapper, whitebait, pompano and other varieties of fish were first introduced into the New York market and, through him, the methods of freezing, shipping and storing fish were improved. His one stand grew to thirteen, elegantly fitted up at a cost of about $22,000, with aquariums built of marble, hard woods and glass, and filled with live fishes. In 1872 Blackford began to give attention to the history and propagation of fishes. He early made the acquaintance of Professor Baird of the Smithsonian Institution, who was then United States

Eugene G. Blackford (1839-1904).

Commissioner of Fish and Fisheries. When the American Fish Culturists' Association was organized he became a prominent member and their treasurer. At their annual dinner in 1876 he procured and prepared for the banquet no less than fifty-eight kinds of fish. He was in charge of the fish exhibit at the Centennial Exhibition in 1876. The year before, he began an annual trout exhibition at his establishment in New York, which attracted admiring crowds from all parts of the country. He collected and shipped 130 tons of exhibits to the International Fishery Exhibition held in Berlin in 1880. In 1878 a species of fish from Florida, which was first described scientifically by Professor Good and Dr. Bears of the Smithsonian Institution, was named *Lutjanus Blackfordii*, in honor of him. Besides being the most extensive fish merchant in New York City at the time and perhaps in the world, he was appointed one of the four commissioners of fish and fisheries of the State of New York in 1879, and was instrumental in establishing a hatching station for sea and fresh-water fish at Cold Spring harbor on the north shore of Long Island. He conducted an investigation into the decrease of oysters in the waters of New York, and published papers in the Reports of American Fish Culturists' Association on whitebait and other fishes, and the question of legislative protection of ocean fisheries. He was most influential in supporting the establishment of the museum of the Brooklyn Institute of Arts and Sciences, and in 1877 he referred to the necessity of an aquarium in New York City and he expressed the hope "… that a public enterprise might be started which would be a free public institution." It is always interesting to note that biographies and obituaries are frequently positively slanted toward their subjects, leaving out material that provides a better understanding of them. With regard to Blackford, I'll discuss four examples.

From The World: New York, Friday, May 24, 1872:

A TURTLE'S TRIALS

Mr. Bergh Prosecutes a Fish Dealer - Cruelty to a Turtle - Interesting Testimony and Fishy Evidence - Why the Fins Should be Tied - The Jury Disagree. In the General Sessions Wednesday one of Mr. Bergh's cases occupied the attention of the court for the greater portion of the day. The charge was one of alleged cruelty to animals, the victim on this occasion being a turtle. The defendants were Eugene O. Blackford, a dealer in fish and turtle, and Lawrence Green, a man employed by him to drive a cart. Assistant District- Attorney Fellows conducted the prosecution and the defendants were represented by John H. Authon and G. W. Blunt. Recorder Hackett presided. The indictment was framed under two or three different sections of the law against cruelly transporting or wickedly and inhumanely torturing any living creatures.

The issue here was tying the turtle's flippers and placing them on their backs during transportation. Bergh testified that the back of the animal in question was broken and very much shattered, that blood was trickling from its belly and from holes in its fins [flippers] that were tied together with cords and therefore arrested both men. Blackford maintained that it was necessary for the good of their health to have this done (and this, in fact, was true). However, he further testified that the turtle was in a sound, Eugene G. Blackford (1839-1904).

healthy condition, with no damage done to its back shell, leaving it up to the jury to decide who was telling the truth.

The jury retired, being unable to agree on a first counting of noses, and after some two hours' absence they returned to court. The foreman said they had not yet agreed, and asked the court for some explanation as to the question of intent. The court said that intent, if any existed, was to be gathered from the evidence. Another brief consultation among the jurors, and still no agreement followed. There being no prospect of their agreeing, as the foreman stated, they were discharged from further consideration of the case. They stood ten for conviction to two for acquittal. Blackford had barely squeaked by.

From: The Yonkers Statesman, Westchester County, December 11, 1885:

OPPOSITION TO EUGENE BLACKFORD
Albany, Dec. 11 – The opposition to the reappointment of Eugene Blackford as Fish Commissioner does not diminish. Charges have been brought against him by the St. Lawrence Anglers' Association, the chief complaint being that Mr. Blackford has looked too much after his own interests.

There had been objections from many to his reappointment and all were dutifully recorded in the newspapers of the day, this one just being a single example. In the following year, the outgoing Governor of New York State did not re-appoint Blackford. Blackford and his supporters argued that his replacement was not legal (a matter of meeting a requirement as to the appointee's official domicile); however, it clearly was in the Governor's powers to not reappoint him.

From: The Press, New York, May 2, 1894:

BLACKFORD SUED FOR LIBEL
Considers the Fisherman's Telegram Defamatory, Senator William H. Reynolds of Brooklyn has instructed his counsel, Mr. Shenstone, to begin a suit for criminal libel against Eugene G. Blackford, formerly State Fish Commissioner. The latter, who is the leader of the movement to secure the abolition of steam railroad traffic on Atlantic Avenue, sent a telegram to the young Senator during the recent session of the Legislature. It had reference to the bill to carry out Mr. Blackford's wishes, and read as follows: "Are you buncoing me on Atlantic Avenue Railroad Bill? There seems to be nothing in the way of passage except want of action on your part. Your district will hold you responsible for its fate. Eugene G. Blackford." Mr. Blackford ignored the Senator's request for a withdrawal of the language used, and the suit will follow. Mr. Reynolds says he fought for the bill against great odds. It is a matter of note that the Long Island Railroad Company, which fought the bill, had an agent in the Senate chamber for two weeks. He went away only when assured that the bill would be strangled.

It is interesting to note that the reporter's last two sentences were a subtle way of suggesting that Reynolds indeed was sabotaging the bill. Blackford's attorney filed a demurrer stating that buncoing was not a defamatory word but it was overruled by a Supreme Court judge who said:

The words used are easily capable of being construed as imputing to the plaintiff as a member of the Legislature that he was not acting in good faith to the defendant and the public, but that he was duping or deceiving them by covertly and actually opposing a bill which had been introduced in the public interest, and which he had promised and was pretending to further. Such conduct on the part of a legislator would be very dishonorable, and, therefore, a writing falsely attributing it to him would be a libel per se. That the defamatory suggestion is conveyed in the form of a question does not save it from being libelous. The question conveys the meaning that the plaintiff was making the defendant and his constituents generally victims of his duplicity, and thus victimizing them, which is a recognized meaning of "to bunco."

However, the fact that Reynolds was a public figure and the libel laws applied differently to him

and the claimed libel was in a private communication - a telegram - the case ultimately was dismissed.

From: *The Rome NY Daily Sentinel* 1885:

FUN IN THE MARKET.

An Eel That Couldn't Be Held Even as Well as an Ordinary Eel "Anyone who lifts that eel out of the tank may have it," said Eugene Blackford yesterday to a crowd of persons who stood in Fulton Market before an open aquarium watching a large eel moving gracefully about in the water. It attracted attention because it was not a common looking eel, such as may be bobbed for any day at low tide in Newtown Creek. A hardy-looking fisherman, who had probably caught many eels in his time, asked Mr. Blackford if he was in earnest, and being assured that the offer was made in good faith he tacked up the sleeves of his pilot - jacket and after briefly explaining to the crowd the precise manner in which an eel should be grasped to prevent it gliding through the fingers he plunged his hands into the water to practically illustrate how the thing was done. He seized the eel very artistically, but, with a sharp explosion of blasphemy, he let it go again before he had brought it to the surface. The eel swam around indifferently. It had evidently grown accustomed to such experience. The fisherman followed it with his eyes. "It stung me bad," was the only explanation he cared to offer to the wondering spectators. Just then a whistling boy came up, and looked at the eel because the others were looking at it.

"I don't see anything uncommon in him," he said, contemptuously. "I've ketched bigger ones than that."

"Say, Bob" said the fisherman, struck with an idea, "pick that eel out of the tank and follow me down to South street with it, and I'll give you a quarter." Without stopping to make any inquiries as to the legitimacy of the offer, the independent lad grasped the eel. He liberated it immediately and uttered a yell that brought in the policeman who twirls his club just outside the fish market to see what the matter was."

Later in the day many persons touched the eel and tested its curious powers. After the contact some shrieked, some laughed and some looked frightened; but none essayed to meddle with it a second time. New comers continued to touch it, until Mr. Blackford, fearful that its vitality might be exhausted, put it into a high closed tank, and pasted this legend upon the glass: "Gymnotus, or Electric eel." The tank contained several "hellbenders," and the eel shocked them very much and caused them to spring around in the liveliest manner. It was given to Fish Commissioner Blackford by Mr. Donald Burns, who received it early yesterday morning from the Amazon River. Captain Bears brought it with him in the steamship Finance. He is rather a handsome creature, and a great point in its favor is that it keeps its mouth always shut, except at meal times, and seems to breathe through two rows of holes on its head and neck. It is about two and one-half feet long, and rather disproportionately thick. It has a heavy fin, like the keel of a boat, running along the belly the entire length of the body. The throat is of orange color, and the head, though short and clumsy, is ornamented with two little flaps that look like ears. It can ad-

An Artists Rendition of "FUN IN THE MARKET."

minister an electric shock as powerful as that of a small battery. A man yesterday touched it with a steel fish-knife and he felt the shock as forcibly as if he had touched it with his bare Hands.

This clearly was outrageous on the part of Blackford, who obviously thought it was a great joke. That he subjected a small boy to the shock of an electric in such a manner would nowadays have placed Blackford beyond bars for a few years and/or a stiff fine.

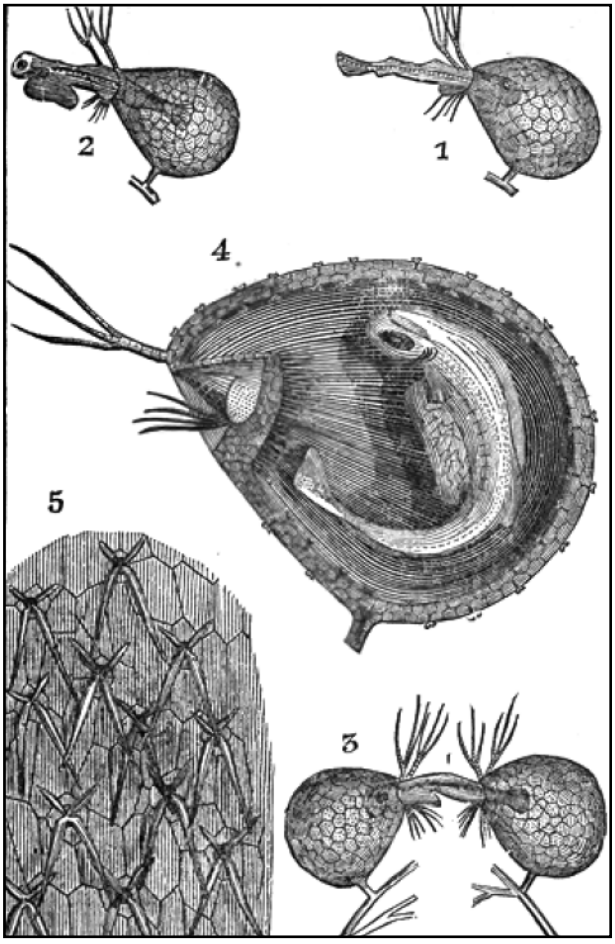
THE ARGUMENT IS WON

Because Blackford was much more known to the public than Mulertt, it might be supposed that the argument was a sort of David and Goliath confrontation and, as results go, so it was.

In "Practical Carp Culture," by L. B. Logan and published in 1888, Logan includes two articles concerning piscivorous plants, the first by E. Halperine that was published in the *Bulletin of the United States Fish Commission*, Vol. V, No. 23, September 15, 1885 and one following by G. E. Simms, Jr. (of Oxford, England), the latter being first published in the *Fishing Gazette* in May 31, 1884 (and also published two months later in the *Bulletin of the United States Fish Commission*, Vol. IV, No. 17, July 30, 1884). On this subject, i.e., the fish-eating habits of the Greater Bladderwort, *Utricularia vulgaris*, Simms has the priority. However, Logan prefaces the Halperine article with the following:

Among the strangest and most interesting enemies of the carp, are a class of carnivorous plants, that until recent years were not known to capture any other animal life than that of Insects and plants captured young fish, was Hugo Mulertt, so often quoted in this work, and it is but justice to call attention to this fact, while we give the description and illustration of another taken from the Bulletin of the United States Fish Commission.

That Mulertt was already recognized as an expert in this area, it also should be noted that in the Eighteenth Report of the Commissioners of Fisheries of the State of New York published in 1890, Bashford Dean says with regard to his information regarding the behavior of the Greater Bladderwort in aquaria, **"I am indebted for much valuable information to the kindness of Mr. Hugo Mulertt."** At the time of the Packer Institute article, Mulertt had known about the Greater Bladderwort for six years, while Blackford apparently was unaware of all the information garnered by Mulertt and others during this time. In scientific circles Blackford is cited as being an "ichthyologist" but he had little impact in this field and I, for one, would not have characterized him as such. He was a fisheries man and, in that field, he did make significant contributions. When came to the aquarium, however, he should have listened to the real expert of the time.



Details of the mode of capture of a fish by *Utricularia vugaris*, from Halperine, Bulletin ofthe United States Fish Commission, Vol. V, No. 23, September 15, 1885.

A Summer Cruise on the Coast of New-England

by Albert J. Klee

(Aquarium Hobby Historical Society, Yahoo Files, September 8, 2014)

PART I: DRAMATIS PERSONAE

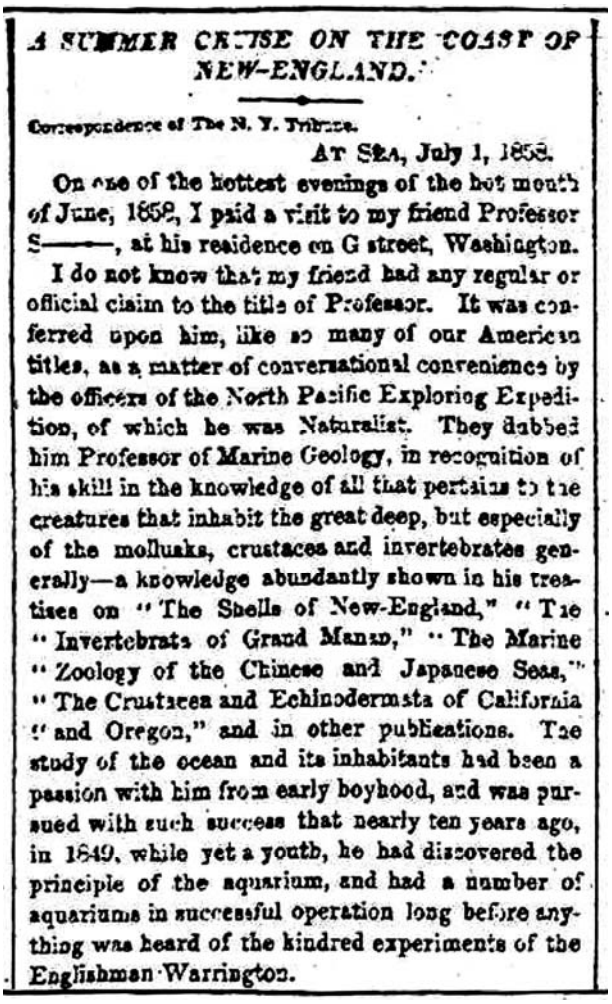
While I was examining past issues of the *New-York Daily Tribune*, I came across a report by one of their correspondents in their July 17, 1858 issue titled "A Summer Cruise on the Coast of New-England." In it the author referred to **"the Professor" who, "...in 1849, while yet a youth, he had discovered the principle of the aquarium, and had a number of aquariums in successful operation long before anything was heard of the kindred experiments of the Englishman Warrington (sic)."** He also wrote, **"I do not know that my friend had any regular or official claim to the title of Professor. It was conferred upon him, like so many of our American titles, as a matter of conversational convenience by the officers of the North Pacific Exploring Expedition, of which he was Naturalist."**

The North Pacific Exploring and Surveying Expedition, also known as the Rodgers-Ringgold Expedition, was a United States scientific and exploring project from 1853 to 1856. It was a naval and commercial survey of those parts of Bering Straits, the North Pacific Ocean and the China Seas frequented by American whaling ships and by trading vessels in their routes between the United States and China. Extensive natural history collections were made on the expedition, mostly by William Stimpson, its Chief Zoologist. Voila! The Professor was uncovered and my interest in this series of reports now knew no bounds.

ROBERT CARTER

The author was Robert Carter (1819-1879). In brief, Carter was a United States editor, historian and author. He was also involved in the formation of the Republican Party and, as I will show later, an avid aquarist.

Carter was born in Albany, New York, and received a common school education and passed one term in the Jesuit college of Chambly, Quebec. At 15, he was appointed at the state library at Albany as assistant to the state librarian, who was also his guardian. In 1841 he went to Boston where he formed a lifelong friendship with James Russell Lowell, and together they began *The Pioneer, a Literary and Critical Magazine*, a monthly magazine which the *Cyclopædia of American Literature* said was "of too fine a cast to be suc-



A SUMMER CRUISE ON THE COAST OF NEW-ENGLAND.

Correspondence of The N. Y. Tribune.

AT SEA, July 1, 1858.

On one of the hottest evenings of the hot month of June, 1858, I paid a visit to my friend Professor S———, at his residence on G street, Washington.

I do not know that my friend had any regular or official claim to the title of Professor. It was conferred upon him, like so many of our American titles, as a matter of conversational convenience by the officers of the North Pacific Exploring Expedition, of which he was Naturalist. They dubbed him Professor of Marine Geology, in recognition of his skill in the knowledge of all that pertains to the creatures that inhabit the great deep, but especially of the molluaks, crustacea and invertebrates generally—a knowledge abundantly shown in his treatises on "The Shells of New-England," "The "Invertebrata of Grand Manan," "The Marine "Zoology of the Chinese and Japanese Seas," "The Crustacea and Echinodermata of California "and Oregon," and in other publications. The study of the ocean and its inhabitants had been a passion with him from early boyhood, and was pursued with such success that nearly ten years ago, in 1849, while yet a youth, he had discovered the principle of the aquarium, and had a number of aquariums in successful operation long before anything was heard of the kindred experiments of the Englishman Warrington.

The first appearance of Robert Carter's "A Summer Cruse on the Coast of New-England, New-York Daily Tribune, July 17, 1858.

cessful." Nevertheless, its want of success was due, not to the editors, but to the publisher who mismanaged it and failed when but three numbers had been issued. Among the contributors were Edgar Allan Poe (Poe's "The Tell-Tale Heart" first appeared here), Nathaniel Hawthorne, John Greenleaf Whittier, John Neal (author and literary critic) and Elizabeth Barrett (later Elizabeth Barrett Browning).

Carter next spent two years in editing statistical and geographical works, and writing for periodicals. His story, "The Great Tower of Tarudant," ran through several numbers of the *Broadway Journal*, then edited by Poe. In 1845 he became a clerk in the post office at Cambridge, and from 1847 to 1848 was private secretary to William H. Prescott, widely recognized by historiographers to have been the first American scientific historian.

Carter joined the Free Soil Party in 1848. The Party was a short-lived entity in the United States, active in the 1848 and 1852 presidential elections, and in some state elections. Founded in Buffalo, New York, it was a third party, single-issue party that largely appealed to and drew its greatest strength from New York State. The party leadership consisted of former anti-slavery members of the Whig and the Democratic Parties. Its main purpose was opposing the expansion of slavery into the western territories, arguing that free men on free soil comprised a morally and economically superior system to slavery. They opposed slavery in the new territories and sometimes worked to remove existing laws that discriminated against freed African Americans in states such as Ohio.

In 1850 Carter wrote a series of articles for the *Boston Atlas* in reply to Francis Bowen's attack on the Hungarian revolutionists. The Hungarian revolution of 1848 started when Hungarian patriots organized mass demonstrations in Pest and Buda (today Budapest) which forced the imperial governor to accept their 12 points of demands. This resulted in von Metternich, the Austrian prince and foreign minister, resigning. In turn, Emperor Ferdinand promised Hungary a constitution, an elected parliament and the end of censorship. The revolution grew into a war for independence from the Austrian Empire and the new government was initially successful against the Habsburg forces but eventually, after one and a half years of fighting, the revolution was crushed when Russian Tsar Nicholas I marched into Hungary with over 300,000 troops. Hungary was thus placed under brutal martial law and the Austrian government restored. Carter's articles were republished in the pamphlet, "The Hungarian Controversy: An Exposure of the Falsifications and perversions of the slanderers of Hungry" (Boston, 1852) and caused the rejection of Bowen's nomination as professor of history at Harvard.

From 1851 to 1852 Carter edited the *Boston Commonwealth*, the chief exponent of the Free Soilers and for two years he was secretary of the state committee of the Free Soil Party. In the summer of 1854, he obtained the consent of the committee to call a convention, which he did without any assistance, sending out thousands of circulars to men whose names were on the committee's books. The convention met in Worcester

Robert Carter (1819-1879)

on July 20 and was so large that no hall could contain it; hence its session was held in the open air. A short platform drawn up by him was adopted, together with the name he proposed - "Republican" -and on his motion a committee of six was appointed to organize the new party, John A. Andrew being made its chairman. (Andrew was an American lawyer and politician in Massachusetts and in 1860 was elected Governor of Massachusetts. He led the state's contributions to the Union cause during the American Civil War and was a guiding force behind the creation of some of the first African-American units in the United States Army, including the famed 54th Massachusetts Infantry.) Thus was born the Republican Party.

In 1855 Carter edited the *Boston Telegraph* and in 1856 he edited the *Atlas*. In 1857 the *Telegraph* and *Atlas* were united with the *Traveller* and after the failure of the *Traveller* he removed to Washington, where he was special correspondent to the *New York Tribune* until 1859.

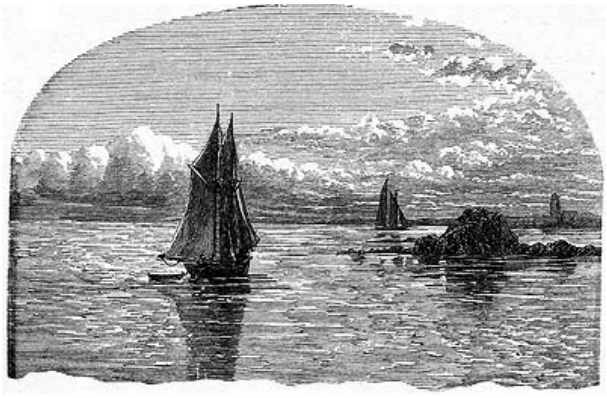
Carter's next activity was with George Ripley and Charles A. Dana on the first edition of the *American Cyclopædia* (1859 to 1863) in which many important articles were from his pen, including "Egypt," "Hindostan," "Mormons," and the history of the United States. In January 1864, he was appointed private secretary of the treasury agent whose headquarters were at Beaufort, South Carolina; and from July of that year until October 1869, he edited the *Rochester, New York, Democrat*, doing such work for it as was seldom done on any but metropolitan journals.

When news came of the assassination of President Lincoln, he wrote, without consulting any book or memoranda, an article giving a brief but circumstantial account with dates of every celebrated case of regicide. He was editor of *Appletons' Journal* from 1870 to 1873, and then became associate editor for the revision of the *American Cyclopædia*, writing articles on "Jefferson Davis" and "The Confederate States of American." In 1874 impaired health compelled him to discontinue his literary work, and in the next three years he made three tours in Europe. His "A Summer Cruise on the Coast of New England" (first published in Boston, 1864) passed through several editions, the last being published in 1888.

WILLIAM STIMPSON

William Stimpson was born in Roxbury, Massachusetts in 1832, the son of Herbert Hathorne Stimpson and Mary Ann Devereau Brewer. The Stimpsons were of the old colonial and Revolutionary stock of Massachusetts, the earliest known member of the family being James Stimpson, who was married in 1661 in Milton. William Stimpson's father was an ingenious inventor and a leading merchant of Boston in the mid decades of the nineteenth century. It was he who invented the "Stimpson range," famous in its day throughout New England. He also made improvements in rifles, devised the first sheet-iron cooking stove and suggested the placing of the flange on the inside of railway car wheels instead of on the outside as had been the custom. His son was to inherit his energy, love of social life, enthusiasm and brilliant wit. Indeed, in so far as we are now able to determine, the qualities which gave character to Stimpson's spirit were all present in his father. Of his mother we know little, for she died at an early age.

In William Stimpson's boyhood his father moved



from Roxbury and built a house in the charming village of Cambridge, and in the green fields and shaded groves of this region young Stimpson was to mature that love of nature which seemed born within him and which throughout life was to dominate his every thought and action. When fourteen years of age he read with delight Edwin Swett's work upon geology, and soon after this a copy of Gould's "Invertebrata of Massachusetts" filled him with an exultant enthusiasm.

In school he was a brilliant pupil. He graduated from the Cambridge High School in 1848, winning the gold medal, the highest prize of the school. In September, 1848, he entered the Cambridge Latin School, and that he did well in his studies we have good evidence in the mastery he displayed in the use of Latin in the description of marine animals in his "Prodromus descriptionis animalium evertebratorum, quae in Expeditione ad Oceanum Pacificum Septentrionalem, a Republica Federata missa, Cadwaladaro Ringgold et Johanne Rodgers Ducibus, observavit et descripsit W. Stimpson" of 1860.

His father looked with disfavor and even with alarm upon the son's tastes for the natural sciences, realizing that there was no "living" to be made through such studies. Thus it was that in 1849 the boy agreed, obedient to the paternal advice, to enter the engineering office of Fletcher and Parker of Boston. Here, though his heart was elsewhere, his head was efficient for he made a true calculation of the cost of constructing the Boston and Lynn Railroad. It is amusing, however, that his estimate was rejected as being too costly, but when the road was completed it was found to be correct. This surely must have pleased his father, who was at the time the President of the Cambridge Horse Railroad, but his opposition to the son's career as a naturalist was only overcome when William Stimpson received the appointment as naturalist of the North Pacific Exploring Expedition in 1852.

In 1848 he had begun the study of shells with William G. Binney, a distinguished malacologist. The year 1849 was memorable, however, for things other than Stimpson's attempt to force himself to become an engineer as he joined the American Association for the Advancement of Science and also became a member of the Boston Society of Natural History, to whose volumes he was soon to contribute many notable papers. In October, 1850, he broke finally away from the distasteful affairs of engineering, and became a student under Louis Agassiz at Cambridge.

In September, 1849, Stimpson had made his first attempt at dredging, and in July, 1851, he visited Eastport (Maine) and Grand Manan (an island in the Bay of Fundy) for this purpose, this being the beginning of that long series of expeditions which were to entitle him to be recognized as the first naturalist systematically to dredge along the

Foreground: Stimpson is seated on the left, across from fellow Megatherium club member Henry Bryant (1820-1867). Standing directly behind Stimpson is Robert Kennicott (1835-1866), his arm about the shoulders of Henry Ulke (1821-1910).

American coast. Those who accompanied him never forgot the enthusiasm, cheerfulness, and brilliant, always kindly, wit of Stimpson, genial lover of mankind and of nature as he was. As we shall see, a reflection of his rare and lovable spirit appears in the "Summer Cruise on the Coast of New England."

No hardship ever deterred Stimpson in this labor of his heart's desire, and in 1849 he enlisted as a member of the crew of a fishing smack in order that he might dredge off the Newfoundland Banks.

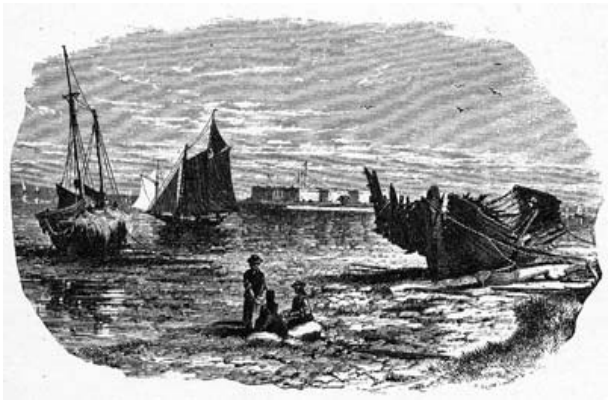
Wherever Stimpson went stories arose respecting his ready recourse, his energy, decision of character, and kindly wit. It is said that when in the Solomon Islands he wandered dangerously far along the shore, savages suddenly attacked him with spears and finally knocked him down. Realizing that they cared more for his tobacco pouch than for his life, he threw it a full twenty feet away, and while his tormentors rushed for the prize he made his quick exit toward the ship.

That Stimpson was also quite a diplomat we have evidence that, although a Northern sympathizer, he courted and became engaged to Miss Annie Gordon, of "Font Hill," near Ilchester, Maryland, daughter of a prominent Secessionist family of that State. Indeed, whenever a Southern victory occurred, Stimpson's prospective father-in-law came himself to announce the fact, while he invariably sent his Negro valet to announce "Yankee" successes. This difference in viewpoint, however, did not prevent the marriage of Stimpson to "Miss Annie" on July 28, 1864.

In 1868, at the early age of 36, he was elected a member of the National Academy of Sciences, having already become a corresponding member of the California Academy of Sciences, the Academy of Natural Sciences of Philadelphia, the New York Lyceum of Natural History and other associations I have already mentioned. In 1860 the Columbian University (now the George Washington University) expressed its appreciation of his services to science by conferring upon him the honorary degree of Doctor of Medicine, this being the only collegiate degree he ever received.

After returning from the North Pacific exploration in 1856, Stimpson studied at the Smithsonian Institution in Washington, devoting his energies to the arranging and description of his collections; he also visited England, where he dredged along the coast. His influence upon the social side of the scientific life of Washington was profound, for he was the founder of two scientific associations. The more social was the Megatherium Club, of which much has been written about the excesses in drink and revelry that attended the informal meetings of the club. The stories are probably all true, including the fact that Joseph Henry, Secretary of the Smithsonian, evicted them from their quarters at the Institution because they were too loud, ran sack races in the great hall on days when inclement weather kept them inside, and serenaded his daughters!

Stimpson also instituted other more or less temporary "organizations," among them the Polymythian Society of Monosyllables, which, despite its humorous name, contributed 9 per cent of the *Proceedings of the Academy of Natural Sciences of Philadelphia* in 1861. A more serious organization was the Potomac-side Naturalist's Club, the first biological society in Washington and the forerunner of the Washington Academy of Sciences.



VIEW FROM SOUTH BOSTON

When fellow club member Robert Kennicott left his post as director of the Academy of Science in Chicago, Stimpson went to that city to take his place. There he gathered one of the most extensive natural history collections in the United States. The academy was destroyed in the Great Chicago Fire of 1871 (later rebuilt), and almost all of Stimpson's works and specimens were lost. He died the following year of tuberculosis while suffering a deep depression.

THE PROFESSOR, THE ASSYRIAN AND THE ARTIST

In his account, Carter supplied sobriquets to his three companions: "the Professor," whom we know was Stimpson, another dubbed "the Assyrian" and the third called "the Artist." The Assyrian, so-called by Carter because of his striking resemblance to the type in face and beard was Francis Henry Underwood (1825-1894), an American editor and writer, and the founder and first associate editor of *The Atlantic* in 1857. Underwood worked in Kentucky from 1845 to 1850, but his hatred of slavery caused him to quit the state and became an ardent supporter of the Free Soil Party. He was later appointed American Consul at Glasgow in Scotland. He and Carter were very close friends.

The identification of the Artist, however, is much more of a mystery. In his memoir of Stimpson, Alfred Goldsborough Mayer, a noted marine zoologist and entomologist who knew him, writes (Mayer, 1918):

A reflection of his rare and lovable spirit appears in the "Summer Cruise on the Coast of New England," by Robert Carter, published in Boston in 1888, wherein "The Professor" is Dr. Stimpson, and the artist is his friend Robert Kennicott.

Kennicott (1835-1866) was an American naturalist and herpetologist, a founder of the Chicago Academy of Sciences and who served the Smithsonian where he was an active field investigator; he died tragically young, only 32 years old, while on an expedition to the Yukon.

However, I was puzzled by this identification. For one thing, references to the Artist on the trip described him making sketches, not fishing. Kennicott's interests would have been similar to that of Stimpson and not in making drawings of the type mentioned by Carter.

For another, Carter arrived in Boston on July 3rd where he met Stimpson and Stimpson's friend, Samuel Tufts, Jr. where they boarded the rented sloop and sailed to Swampscott to make certain necessary arrangements for the trip. From there, Stimpson and Carter sailed to Plymouth and, arriving on July 5th, collected Underwood and the Artist. If Kennicott had been the Artist, it seems more likely that he would have accompanied Stimpson to Boston and met Carter there.

The 1888 edition of The Summer Cruise had an introduction by Robbiter Johnson so I consulted

"The Assyrian, Francis Henry Underwood (1825-1894)

this with a hope that he might have some information about the Artist. This, however, was to no avail since his introduction was about Carter, not his book. The 1888 edition of The Summer Cruise had an introduction by Robbiter Johnson so I consulted this with a hope that he might have some information about the Artist. This, however, was to no avail since his introduction was about Carter, not his book. I next examined the 1977 edition, edited with a foreword by Daniel Ford and here things got interesting. Here is what Ford had to say:

As for his shipmates on that immortal cruise, they have been identified by F.M. O'Brien, antiquarian bookseller of Portland and one of Carter's many admirers. O'Brien happened upon a first edition, in-scribed by "the Professor" in 1865 and naming all who were aboard: The Professor was Dr. William Stimpson, who joined the North Pacific expedition at the age of twenty, and who spent many years thereafter classifying the materials he had gathered at the Smithsonian Institution. The Artist was a certain Henry Carey, who is otherwise unidentified. And the thirsty Assyrian was Francis Henry Underwood. Lawyer, editor, novelist and consular official, he helped establish the *Atlantic Monthly* as the voice of the anti-slavery movement in New England.

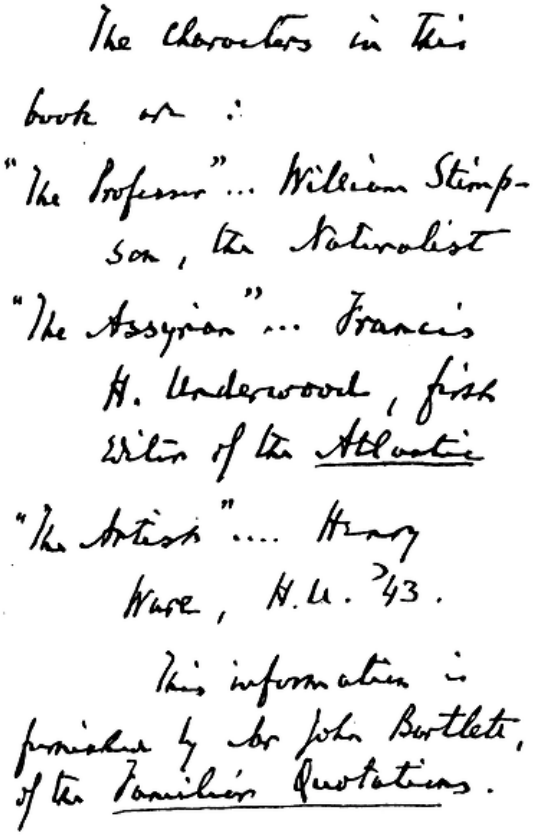
Now either William Stimpson wrote this inscription or he did not. If he did not, then any remarks concerning the Artist in the inscription are worthless since we do not know if the author is authoritative.

If Stimpson did write this inscription, then either his identification of the Artist as "Henry Carey" was correct or incorrect. As I will shortly show, his identification was incorrect. Clearly he did not remember the Artist well – save for his first name, which he had to have used frequently on the trip – since he provides no information about him, something he did do with Carter and Underwood. It is my contention that Stimpson did write the inscription but remembered so little about the Artist that he stated his last name incorrectly, as no one with the name "Henry Carey" has ever been shown to be associated with Carter or Underwood. This, then, was another dead end. I then proceeded to examine other editions to see if anyone else had tried to identify the Artist and Voila! I found my missing Artist.

The book in question was an 1864 edition (the first edition) in the Harvard University library, given to it by an unknown donor. Written on a flyleaf was the following (see the accompanying figure):

The characters in this book are: "The Professor… William Stimpson, the Naturalist; "The Assyrian"… Francis H. Underwood, fish Editor of the Atlantic; "The Artist"… Henry Ware, H.U. '43. This information is furnished by Mr. John Bartlett, of The Familiar Quotations."

John Bartlett (1820 - 1905) was an American writer and publisher whose best known work, "Bartlett's Familiar Quotations," has been continually revised and reissued for a century after his death. He compiled a massive concordance of



The characters in this book are:
"The Professor"... William Stimpson, the Naturalist
"The Assyrian"... Francis H. Underwood, fish Editor of the Atlantic
"The Artist".... Henry Ware, H.U. '43.
This information is furnished by Mr John Bartlett, of the Familiar Quotations.

Written by an unknown donor on a flyleaf of the Harvard University's copy of "A Summer Cruise on the Coast of New England."

Shakespeare, published in 1894, that is still the standard work of its kind. Bartlett was born in Plymouth, Massachusetts. His father was a descendant of Mayflower Pilgrims, Love Brewster, a founder of the town of Bridgewater, Massachusetts; Elder William Brewster, the Pilgrim colonist leader and spiritual elder of the Plymouth Colony; and John Alden, who was hired as a cooper in Southampton, England, just before the voyage to America and who along with the Brewsters were signers of the Mayflower Compact.

A very bright boy, he was reading at age three and had read the entire Bible by nine. He finished school at age sixteen and went to Cambridge, Massachusetts, where he worked for the University Bookstore that served Harvard. He rose to be the firm's senior partner in 1878 and retired from the firm in 1889. In addition to work on quotations (he oversaw nine editions of his book), he wrote on fishing and chess. In 1892 he donated his collection of books on angling, fishes and fish culture (some 1014 books and 269 pamphlets!) to the Library of Harvard College. Known for his memory for quotations and trivia, “Ask John Bartlett” became a byword in the community when someone was stumped.

As it turns out, however, the unknown donor got the wrong end of the stick in identifying Henry Ware. The donor’s reference to “Henry Ware, H.U. ’43” was to Henry Ware, Jr. (1794 - 1843), an influential Unitarian theologian and early member of the faculty of Harvard Divinity School. This, however, was the wrong Ware since he had died 16 years before the cruise.

One of Henry Ware Jr.’s brothers was William Ware, (1797-1852), an American romance who achieved literary recognition chiefly from his authorship of two historical romances, “Zenobia, or the Fall of Palmyra” and “The Triumph of Aurelian.” One of his sons was Henry Ware (1825 - 1885), named after his grandfather, the most famous of the Wares and influential in the formation of Unitarianism and the American Unitarian Association in the United States. This is the Ware that Bartlett had in mind in his reply to the donor.

The following is from Underwood’s memoir on the poet, James Russell Lowell (Underwood, 1893):

For some years between 1853 and 1859, Lowell received a few of his Cambridge friends on Sunday afternoons in his study, a front room in the third story. On Friday evenings there was another gathering, ostensibly for whist, at the house of each of the party in turn. Of those who were members of the whist-club, Dr. Estes Howe, Robert Carter, Henry Ware and Lowell are dead; the survivors are John Holmes, John Bartlett, and the present writer. In social meetings Lowell was naturally the leading spirit, and the one whose talk no one was willing to miss; yet he was never the imperious Johnson of the club; everyone had his chance. The conversation took a wide range over literature and art, as well as the field of politics, on which lines of battle were forming, then little suspected. In the tranquil, peace-loving North “coming events” did not “cast their shadows before.”

All these men had much in common - an appreci-

John Bartlett (1820-1905)

ation of humor, a love of books and mellowness, and individual hobbies which made them interesting to themselves and to their fellows. Henry Ware's hobby was music and sketching. From John Holmes's letters about the club (Holmes was the younger brother of Oliver Wendell Holmes, Sr.) it might inferred that they were epicures, but their epicurism was innocent, and their relish for a dish or for a bottle of "the rosy" seems to have been an echo of the talk of bygone clubmen in books. The importance of their little circle lay in the fact that it afforded the best conditions for strengthening friendship.

The cruise must have been a lively topic of conversation in the Whist Club both before and for many months afterwards. Bartlett, of course, was a member of the club and had a keen memory for details. It explains why Underwood and Ware joined the cruise in Plymouth, which as the crow flies is only 33 miles away from Boston where these two good friends lived.

Ware graduated from Harvard in 1847 with a degree in law. In 1855 he took a position as Legislative Clerk in the Massachusetts State House and from 1862 to 1865 was the Military Secretary, with the rank of Major, for the Governor of Massachusetts. From 1867 to 1869 he was Assistant Adjutant-General in the Massachusetts Militia, with the rank of Lieutenant-Colonel. Afterwards he was secretary to the United States Senate at Washington, D.C. After retiring from his law practice in Cambridge in 1875, he became the Keeper of the Bates Hall Department in the Boston Public Library. In 1877, effective in May of the following year, he was removed from that position.

Following Justin Winsor's resignation as Librarian in May of 1877, Dr. Samuel Abbott Green, one of the Trustees of the Boston Public Library from 1868 to 1878 and the high-handed and extremely cantankerous Librarian of the Massachusetts Historical Society from 1868 until his death in 1918, was placed in a temporary position as "Trustee in charge" that continued for more than a year.

One can gather enough about the formidable Dr. Green from scholars who met him at their peril in later years at the Massachusetts Historical Socie-

From left to right: John Homes, Dr. Estes Howe, Robert Carter and James Russell Lowell.

ty, he was hardly the ideal successor. Obviously the library ran along, for it was not only well organized, but Winsor had persuaded his valued assistants to restrain their natural inclinations to resign also. Even the newspapers were worried about "fresh progress to be set on foot" and the *Sunday Herald* of December 1877 made some sharp observations concerning the Trustees' experiments "in the direction of incommoding its patrons, di-minishing the circulation, and impairing the usefulness and acceptability of the library" that had involved the removal of Henry Ware, Keeper of Bates Hall, and Arthur A. Brooks, Assistant Keeper of the Lower Hall, both of whom victims of Greene's policies. The *Sunday Herald* suggested to the Trustees "that they let well enough alone until they are in position to offer the vacant superintendency to a man qualified to carry on the institution, and leave the change and new experiments to him." The advice was not promptly heeded, for no appointment was made until the fall of 1878 and by this time a great deal of damage had been done to the library, including Ware's dismissal.

Note: Additional support for the confirmation of Ware as "the Artist" appeared in George Street's history of Mount Desert (Street, 1905).

SAMUEL TUFTS, JR.

Samuel Tufts, Jr. (1817-1902) was born in 1817 in Wilmington, Massachusetts, an inland town about 16 miles northwest of Boston. When a young man, he was apprenticed to a shoemaker in nearby Woburn. Tufts left that town when shoemaking by hand was replaced by machine work. He moved to Swampscott and later to Lynn, Massachusetts, a coastal shoe-making city, about 9 miles north of Boston. Although shoemaking by machines also took over in Lynn, the larger industry there may have offered more opportunities. In 1847 he married Miranda Chubb, who died the following year, but within a month he married Elizabeth Ann Marshall.

Tufts spent most of his life as a shoemaker and proprietor of express and furniture moving businesses. During the 1850s, when he lived in Swampscott and Lynn, Massachusetts, adjacent seacoast communities, he collected shells and conducted an aquarium stocking business.

As I have also previously mentioned, in October 1850 Stimpson became a student under Louis Agassiz at Cambridge. Joseph Bassett Holder (1824–1888), a native of Lynn and who had practiced medicine there was a friend and colleague of Agassiz and helped Stimpson in dredging around Nahant. Holder was also a founder of the Lynn Natural History Society in 1842 and so is likely to have known Tufts. Through Holder, it is possible that Tufts became acquainted with Stimpson but like the question of how Carter first met Stimpson, this is not known with certainty.

Although Tufts' observations sometimes were published locally, they were conveyed to the wider natural history community through the publications of more prominent naturalists including William Greene Binney, whom I have mentioned previously, Augustus Addison Gould, a conchologist and malacologist of high reputation, and William Stimpson.

In Stimpson's "Synopsis of the Marine Invertebrata of Grand Manan" in the *Smithsonian Contributions to Knowledge* dated 1853, Stimpson

PLYMOUTH

wrote in his description of his new species, *Idotaea tuftsii* (now *Chiridotea tuftsii*) the following:

I have dedicated this species to Mr. Samuel Tufts, of Lynn, Mass., one of our most active marine zoologists, to whom I have been often indebted for new and curious forms of deep sea animals from Massachusetts Bay.

However, as our interest in Tufts is in his aquarium stocking business and not his shell collecting, the following is from the *Proceedings of the Essex Institute*, February 25, 1858:

The remainder of the evening's session was occupied with a pleasant conversational discus-sion about marine and fresh water aquaria, suggested by a Circular of Samuel Tufts Jr., of Lynn, and read to the meet-ing by H. Wheatland. The uses, to which, such apparatus could be applied in studying the habits of aquatic animals, insects and plants, and the best modes of constructing them and how to stock them so as to secure health and active life, came under consideration.

A small aquarium, made with a glass-dish employed by George D. Phippen, afforded him much recreation and in-struction. He alluded to his pleasure in visiting the seashore in quest of specimens and his success in keeping them alive.

Tufts also donated "Living actinia and other marine animals for aquarium" to the Smithsonian Institution in 1857 and "Living marine animals from Massachusetts, for the aquarium" in 1858. The aquarium in question was described in *Scientific American* in 1857 and most likely Stimpson was the one responsible for its placement and upkeep in the Smithsonian:

The Smithsonian Aquarium at Washington.

A fine marine aquavivarium, or aquarium, has been prepared at the Smithsonian Institu-tion, where the public can now inspect its curious contents. It is said that an eminent French zoologist, in order to prosecute his studies on marine animals of the Mediterra-nean, provided himself with a water dress, glass helmet and breathing tubes, that he might walk about under water, and mark the habits of the various creatures pursuing their avocations. Anyone who will visit the Smith-sonian aquarium may enjoy the same opportu-nities, and become acquainted with the strange animals and plants of the sea without diving to gaze on them.

The aquarium is simply a glass tank, erected on a table, and filled with sea-water, in which flourish marine plants and animals without any aid, or even changing the water.

The bottom of the Smithsonian aquarium is an imitation of the bottom of the sea, com-posed of silver sand, coarse sand and pebbles. In the center is a mass of rock, giving shelter and concealment to such animals as like con-cealment, while jotted about arc growing specimens of fuci [a type of brown algae] **and algae. In this miniature ocean cave are about three hundred specimens of animal vitality, belonging to some thirty-eight species of fishes, molluscae, crustacae and polypes. Some of these burrow in the sand, or modestly hide among the pebbles; others, like the hermit crabs, having taken possession of vacant suits of submarine armor, flourish about belligerently, ready for a fight. Some are perfectly transparent, like animated particles of jelly; others arc enshrined in their shells. The curious "horse-fish" paddles about with his filmy dorsal fin; and a lethar-gic clam protrudes its siphons, enveloped in a shaggy fringe; a solitary flounder was evi-dently annoyed when rooted out, and imme-diately burrowed himself again in the sand; while two pugnacious crabs fought gallantly over an *amphitrite auricoma*, which had been obligingly sacrificed that we might see its golden combs.**

Finally, the following are Carter's comments in Chapter III upon viewing Tufts' store on July 4th (Carter ends the chapter heading with "A Scientific Shoemaker"):

Mr. Tufts had come on board while we were at breakfast, and wishing to see his aquariums I went ashore with him in his dory. We landed on a beach in front of his shop, which is almost at the water's edge, and I spent half an hour very agree-ably in examining his tanks, of which he had several in fine condition. Mr. Tufts is a shoe-maker,

MARBLEHEAD

with no more education from schools than every boy in Massachusetts receives. He has educated himself by books and observation in natural history, till he has become in his specialty — marine zoology — a very intelligent naturalist. For a year or two past he had devoted himself to collecting and selling materials for stocking aquariums, the demand for which two or three years ago was considerable in our principal cities. The Smithsonian Institution and the Boston Society of Natural History employed him in this capacity. To those who ordered from him the materials for stocking an aquarium, he sent a keg or barrel of sea-water, and a box of two compartments, — one containing the sea-weeds and some of the animals, the other containing the more delicate animals in a bottle or jar. While aquariums were in fashion he had full occupation in this pursuit, but I learn that recently he has relinquished it.

Tuft's natural history activities finally ended when he relocated to Cambridge, Massachusetts around 1860.

PART II: THE SUMMER CRUISE

THE IDEA FOR THE SUMMER CRUISE IS BORN

On one of the hottest evenings of the hot month of June, 1858, I paid a visit to my friend Professor S—, at his residence on G. Street, Washington.

I do not know that my friend had any regular or official claim to the title of Professor. It was conferred upon him, like so many of our American titles, as a matter of conversational convenience by the officers of the North Pacific Exploring Expedition, of which he was Naturalist. They dubbed him Professor of Marine Zoology, in recognition of his skill in the knowledge of all that pertains to the creatures that inhabit the great deep, but especially of the mollusks, crustacea, and invertebrates generally,— a knowledge abundantly shown in his various treatises on the marine zoology, not only of New England, but of the Chinese and Japanese seas. The study of the ocean and its inhabitants had been a passion with him from early boyhood, and was pursued with such success, that, in 1849, while yet a youth, he had discovered the principle of the aquarium, and had a number of aquariums in successful operation long before anything was heard of the kindred experiments of the Englishman Warrington.

It was a fearfully hot night; one of a long succession of hot nights and days through which I had patiently sweltered and sweated, in the vain expectation that time and endurance would gradually accustom me to being broiled and parboiled, as they are said to render eels tolerant of, if not acquiescent in, the process of being skinned alive. But a frame acclimated to the moderate heats and invariably cool nights of the sea-coast of Massachusetts, could not readily become insensible to the influence of an atmosphere which at midnight, as well as at noonday, maintained a heat greater than the average heat of the torrid zone. I sought refuge at the Professor's, because his house, though not materially cooler than the rest of the city, was intellectually and imaginatively cooler. It abounded in objects suggestive of refreshing ideas. There were crabs and shells that had been dragged from the sunless depths of the Arctic Ocean; fishing-lines and dredges that had explored the cool abysses of Kamtchatkan and Siberian seas; drawings of icebergs and glaciers; and, what particularly was wont to give an agreeable chill to my fancy, a picture of the prodigious snowy cone of the great Japanese volcano, Fusi-Yama, made by a native artist at Simoda, where the Professor himself purchased it.

The Professor, with nothing on but a shirt and the thinnest of pantaloons, was stretched on a sofa, with a cigar in his mouth, languidly smoking, and contemplating through his gold spectacles the ungainly proportions of a monstrous dor-bug he had just captured. Our conversation opened, of course, on the weather.

"I cannot stand it any longer," he said; I shall start on a cruise on the coast of Maine next week, and you had better come along, if you do not want to die of a fever. You look horribly bilious already, and a few days more of this heat will use you up entirely. Let us go and cool off at Grand Manan. I spent two months there some summers ago, fishing and dredging, and can assure you that it is the finest place on our whole coast."

WHITE HEAD, NEAR PORTLAND

"For crabs, I suppose, Professor. All places are classified by you for good or bad with relation to their production or non-production of crabs."

"For crabs, yes, - but not alone for crabs. The scenery is superb - grander than anything you will see this side of the Saguenay. Huge, rocky cliffs, a thousand feet high, rise right out of deep water, and are broken into the wildest and most romantic caves and inlets. They are the haunt of nearly all kinds of sea-birds, from the herring-gull down to Mother Carey's chickens. We shall catch there and on our way down the coast every species of fish that swims in our seas."

"Including the whale?"

"The whale is not a fish," responded the Professor, gravely, overlooking the levity of my interruption in his scientific sense of its zoological inaccuracy, "but I promise you we shall see whales in abundance. We shall also catch sharks, and kill seals and porpoises. But, in short, if you will come along, we will run into every harbor from Provincetown to Eastport, and fish and dredge till you have seen at least one specimen of every creature that swims the sea or dwells on the bottom. Then, if you will, you can write a book about the aquarium which shall be a little more reliable than that trumpery thing of Edwards's which you sent me yesterday."

"What is the matter with that?" I asked. "It seemed to me a clever and entertaining book."

The Professor launched into an elaborate and energetic criticism, the details of which I cannot now recall, and to which I must confess I paid little attention, for the amount of it seemed to be that Mr. Edwards had transferred a few species of mollusks from the English seas to ours, and was not very careful in the spelling of his scientific names.

I intimated that the orthography of these uncouth appellations was of little consequence. The Professor shook his head. The young men and maidens who were going with such enthusiasm into the formation of aquariums would be led into a shocking confusion of names and species. Besides, some of the plates were wrong. "On plate No. 5, for example, a species of *Lymnea* is figured as *Physa heterostropha*, and on — "

"That will do. I give up Edwards, on condition that you do not utter another of those jawbreakers during the entire evening. But how shall we go to the Grand Manan? "

The Professor's hint about my bilious appearance had privately decided me to take an abrupt leave of the national capital. I already felt a fever in my veins.

"I have written to my friend Tufts, the aquarium maker and stocker at Swampscott - you have heard me speak of him? To engage me a good, clean, stout fishing-smack of from ten to twenty tons, and also two experienced boatmen, one of them, if possible, old Captain Widger, who went with me on my cruise last year. I shall hear from Tufts in a day or two, and you had better get ready at once, for I shall be off like a flash the moment I can get away."

In reply to my inquiries into the nature and extent of the requisite preparations for a cruise of a month's duration, the Professor said:

"Put two pairs of pantaloons, two thick coats, and a vest or two, the oldest and worst you have, into a bag - a gunny-bag or a potato-sack will do. Put in, also, a couple of flannel shirts and drawers, and a half a dozen or a dozen of thick woolen socks, and an old felt hat. Buy a couple of the thickest red-flannel shirts you can find, a pair of thick-soled cowhide boots, a tight-fitting cloth cap, a cheap straw hat, and a pair of oilskin or India-rubber pantaloons - oilskin is best, for it doesn't smell so abominably as India-rubber. Put these, with two or three pairs of old slippers, in the bag, and tie it up tight. Put a couple of linen shirts, more or less, as you please, and a decent suit of light summer clothes, in a valise, so that you can go ashore at Salem, Portland, Eastport, and other civilized places, and see your friends if you have any. That is all the outfit you will need. I will look out for supplying the vessel with provisions and table-ware. I will also provide pens, ink, paper, pencils, and envelopes. If you want to take notes, put in your valise two or three

PORTLAND

blank-books - loose sheets of paper are always getting lost."

"And the damage?"

The Professor has an abhorrence of slang phrases, except those which he uses himself.

"I suppose you mean the expense," he replied. 1 cannot exactly tell till I hear from Tufts what sort of craft he has engaged, and on what terms; but if we get one or two others to go and share expenses, the 'damage,' as you call it, will be from $50 to $100 apiece."

This was satisfactory, and I made my preparations accordingly. I put nothing in the bag beyond what the Professor indicated, except a pair of India-rubber overshoes, which I subsequently found of essential service when the deck was too wet for slippers, as was frequently the case.

Two or three days later the Professor came to see me in high glee, intense delight gleaming through the perspiration that rolled down his face from the heat of a walk in the sunshine. He flourished an open letter in his hand.
"Tufts writes that he has engaged the sloop Helen and her owner, Captain Gurney, and that Captain Widger will go if we want him. The sloop was built for a yacht, is stout and tight and roomy, with four berths. She measures seventeen tons, and draws five and a half feet of water; has not been much used for fishing, and is consequently clean and in good condition."

"The price?" I suggested.

"Seven dollars and a half a day, including the two men. I shall write to have her brought to Boston on Friday next, and we will start the next day."

The book that Carter had given to Stimpson was Arthur Mead Edwards' "Life Beneath the Waters, or the Aquarium in America" that had just been published earlier in the year. That Carter was an aquarist not only is evidenced by this and by Stimpson's comment that after the cruise Carter could write a book **"...about the aquarium which shall be a little more reliable than that trumpery thing of Edwards's..."** but by Carter's desire to stop off and see Tuft's aquariums and his shop in Swampscott. It is interesting that Stimpson thought little of Edward's book. He was not alone in this as it had received unfavorable reviews from many critics.

THE TRIP

It might seem odd that Stimpson and three people of such divergent backgrounds as his got along with no problems whatsoever. However, the trip was undertaken partly for fun and partly for scientific research in marine zoology so there was something of interest for all. More important is the fact that Carter, through his interest in aquariums, knew Stimson well, both of them residing in Washington D.C. at the time. In short, as Carter was an aquarist and Stimpson was the first American aquarist of record, they had a mutual interest. It is not known how or where Carter and Simpson first met, but they were in Cambridge from 1849 to 1851 and in Washington from 1857 to 1859.

The cost of the trip was shared among the four participants. The plan was for Stimpson and Carter to travel to Boston where they would be met by Stimpson's friend, Samuel Tufts, Jr. and board the rented sloop, Helen (32 feet and 7 inches long with a beam of 12 feet, 5 inches). From there they would sail to Plymouth and collect Ware and Underwood. From there they would continue on to Marblehead, Gloucester, Rockport, Portsmouth, Portland, Mount Desert and Bar Harbor. At the time, Stimpson was 26 years old, Carter was 40, Underwood was 34 and Ware was 34. In his preface Carter describes the trip:

"The fishing voyage of which this book is a record was made in 1858, during my summer vacation from the

WHALE'S BACK LIGHTHOUSE

arduous duties of a Washington Correspondent of the *New York Tribune*, and the narrative originally appeared in the form of letters to that journal. In that shape it met with considerable favor, especially from sportsmen and naturalists; and its publication in a permanent form, at this late day, is due, in part, to the assurances I have received from high scientific authority that its sketches of the fishes of our Northern seas, of their habits and resorts, and of the methods of taking them, are not without value as contributions to Natural History. I can only say upon this point, that I have spared no pains to make my statements accurate, not only by careful personal observations, but by freely consulting and using the writings of our best American ichthyologists."

SAILING ON A SMALL BOAT

In 1984, my wife and I, along with an entomologist friend and his wife, a guide and a captain, sailed throughout the Galapagos in the 34-foot sloop, the Nixe, the smallest charter in the islands at the time. Since sloop Stimpson and his companions used was even smaller – 32 feet, 7 inches, I can well appreciate the problems in living in such close quarters. Carter's observations on this subject follow:

The sloop's cabin, which was low, but suf-ficiently broad, contained four berths, two on each side. The Professor and myself took one side, the two seamen turned in on the other, while Mr. Tufts kept watch on deck, as there was some reason to apprehend that the sloop might drift, the only anchor we had ready for use being a small one.

Late in the evening, the dory returned from Plymouth, bringing off the Artist, who, much to our surprise and pleasure, was accompanied by the Assyrian, as his friends are wont to call him, from his striking resemblance, in face and beard, to the Ninevite sculptures dug up by Layard and Botta. Their arrival completed the number we had fixed upon as desirable for the cruise, four being in fact as many as the sloop could possibly accommodate. The seamen, indeed, for the rest of the voyage slept on the cabin floor, having relinquished their berths to the new-comers.

I did not dress, for on board the Helen, during this cruise, we have undressed only when we bathed or went ashore, in which latter case, to prevent misconception, I will state that after undressing we dressed ourselves again in shore clothes; the main constituents of shore clothes being coats and white shirts. White shirts and coats we put on, however, only when visiting some considerable place, like Gloucester, Ports-mouth, or Portland. At other places we gener-ally went ashore in our sea rig, consisting of panta-loons well smeared with the slime of fish, and bleached with constant drippings and splashings of sea water, and thick red-flannel shirts, one or more shirts being worn at a time, according to the weather or the fancy of the wearer. The Pro-fessor, whose ardor in pursuit of science exposed him most to the wet, generally arrayed himself in three shirts at once; the oldest in service being worn uppermost and outermost.

Getting up, as I said, soon after daylight, and giving myself a shake by way of making my toi-lette, I could scarcely keep from laughing as I looked around the little cabin. The Professor, whose berth was on the same side with my own, was sleeping almost in a sitting posture, his back propped up by a pillow, a great coat, and a huge volume of the United States Coast Survey Re-port. He had fallen asleep while reading, for his unextinguished lamp yet burned dimly beside him, and his spectacles were still on his nose. His blanket was lying folded beneath him, and he had passed the night close to the open cabin-door, with no other protection from the cool air than his three shirts. They, however, seemed to be sufficient, for he was sleeping soundly and comfortably.

The Assyrian's berth was opposite to the Pro-fessor's. An extra mattress, which the two sea-men spread for themselves on the floor when they were on board, had been thrust on the top of his mattress during the day. He had neglected to remove it on turning in, and the space that was left between it and the ceiling was barely suffi-cient for his somewhat ample proportions. He had no pillow, and with his head thrown back and his mouth resolutely shut, he was sounding a blast with such sonorous and sustained vigor that I could almost imagine he had served as a trum-peter through all the seventeen campaigns of his famous ancestor, the mighty Temenbar, who, if he writ his annals right on the sculptured walls of his palace, was the most successful and sangui-nary of the long line of Ninevite kings and con-querors. In the

THE HARBOR FROM DORCHESTER$ HEIGHTS

struggles and contortions induced by his inconvenient posture, the Assyrian had twisted his blanket around him in such fashion, that, while a triple fold enveloped his body, his nether continuations were exposed at full length, protected only by his coarse blue pantaloons.

The Artist, on the contrary, was lying, like gray-haired Saturn, "quiet as a stone," snugly wrapped in his blanket, which swathed him as closely as a mummy is swathed by its bandages. He had converted his portmanteau into a pillow, and was taking his sleep with a resolute expres-sion of countenance, which said plainly that he was very comfortable, and did not mean to be disturbed.

I pinched the Assyrian's nose till he opened his mouth, which I have always found an effectual mode of checking a snorer, and went on deck to see the sun rise.

A LEARNING EXPERIENCE

Carter certainly received quite an education from Stimpson on the trip:

The Professor grasped with avidity the roots of the weed. After looking at it attentively a few minutes, he pointed out to me about a dozen snake-armed starfish *(Ophiopholis scolopendrica*), wound around the tendrils of the roots.

"This species," he said," is found only in deep water, and can only be got by dredging. It con-sists, you will observe, of a small central disk of about the size of a ten-cent piece, and five long, slender, spiny arms, which twine like serpents among the roots of the sea-weed. They are often very brilliant, and beautifully variegated in color. Most commonly the disk is red, with a pentagonal white spot in the middle, while the arms are ringed with red and brown."

The Professor next pointed out upon the drip-ping mass something that looked like a large drop of blood. This, he said, was an ascidian, the *Cynthia gutta.* It was a small, flat, leathery disk of a red color, of little thickness, but still sufficient to hold a variety of organs, gills, liver, stomach, intestines, etc., which may be seen upon upturning the envelope of the sac. On the upper surface there are two apertures, one for the admission, the other for the expulsion of the water which passes over the gills.

At one point, Stimpson handed him something and asked:

"What do you think that is?" said the Pro-fessor, handing me a pebble which he detached from the roots of the sea-weed. I looked at it carefully, and replied, "A pebble curiously coated with lime." "What you take for lime is a vegetable, the millipore, much of whose fabric, however, is really composed of carbonate of lime."

The Professor then took the dory and rowed away from the sloop about one eighth of a mile, where he fished for half an hour, apparently with-out much success. On coming alongside he held up to our inspection a beautiful rose-colored fish about eight inches in length.

"What do you call that?" he inquired of the Pilot.

"1 call that a humdruggan."

"A hemdurgan?" said the Professor, repeating the word as Dr. Storer spells it.

"No, a humdruggan," persisted the old fisher-man; "that's what I have always heard it called, — a hum-drug -gan."

It was a Norway haddock. The fishermen call it "rose-fish," "red sea-perch," and "snapper." It is a rare fish on our coast, and seldom eaten when taken; though on the coast of Norway, where it is caught plentifully, it is a favorite arti-cle of food, being considered a great delicacy, and eaten either cooked or dried. It is common in the seas around Newfoundland, and in the deep bays on the southern coast of Greenland it is caught in great numbers, in the way that the Professor caught it, — on baited hooks attached to long lines. It has spines on the head, which the Greenlanders formerly used for needles. The greatest length of the Norway haddock is two feet. It is caught, though rarely, I believe, as far south as New York.

The "humdruggan" or "Norwegian haddock. The Pilot and the Skipper mistakenly considered the spines of this fish to be poisonous.

The Pilot and the Skipper both expressed a good deal of dread of this handsome and apparently harmless fish. They considered the spine poison-ous, and the Skipper related several instances in which he had known persons to be dangerously wounded by handling it. The Professor pooh-poohed at these stories, though it was possible, he said, that a wound made by the spines of the fish might become badly inflamed, as was often the case with wounds made by the claws of a cat or the teeth of a rat.

Carter also learned a lot from those he encountered along the way:

"Our Pilot, as we called him, from his minute knowledge of the coast, generally officiated as steersman, and always as cook. He was sixty- eight years of age, of which fifty-five years had been spent on the sea. He was still as hale, hearty, and active as most men of fifty years. His life had not been without adventure and strange vicissitudes. In 1812, when Congress declared war against England, he was on a voyage to St. Petersburg. On the return from that port his vessel was captured by an English cruiser, and he was sent a prisoner of war to Chatham, where he remained upward of a year, and was exchanged and released just before the transfer of the American captives to the fatal prison of Dartmoor. During the rest of the war he sailed from his native Marblehead in a privateer, which made a good many captures, and had three or four engagements with armed merchantmen. He continued to make long voyages for some years after peace was restored, but finally settled down into the steady pursuit of the fisheries, in the course of which he had become familiarly acquainted with almost every bay, harbor, island, headland, reef, shoal, and rock, from Cape Cod to Labrador."

A MARINE MUNCHAUSEN

In the evening we received visits from several Swampscott skippers, whose vessels, like our own, were windbound in the port. One of these men sat with us till midnight, spinning the most mon-strous and incredible yarns, which he narrated with a serene gravity that would almost have per-suaded the hearer to believe any lie. He was a marine Munchausen of the first water, and his adventures were nearly as wonderful as those of the renowned Baron himself.

We spoke of snakes. On this topic he spread himself amazingly. He had often seen the sea-serpent, and once when cruising for swordfish off Nantucket, had harpooned the monster from the deck of his vessel, and had been towed out to sea a hundred miles in thirty minutes, when the line broke and the creature got away.

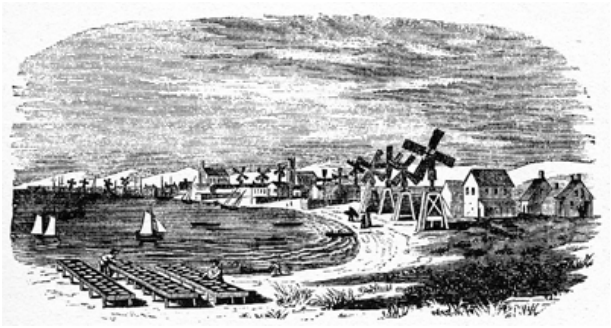
"Rattlesnakes? Yes, sir; I *have* seen rattle-snakes. Some years ago, I grew tired of the sea, and took a farm in Illinois. I had a meadow on the prairie of three hundred acres, and when it came haying-time rattlesnakes were so thick there, that of seven Irishmen I sent to mow it one morning, five were bitten so that they died instantly, and the other two were only saved by keeping them constantly drunk with whiskey for more than a month. That job cost me a barrel of good Bourbon, beside the funeral expenses of the dead men."

"And you lost your hay?" said the Professor.

"Not at all. I had seen too much of snakes to be bluffed off in that way. I had a pair of boots which had been given to me at Buenos Ayres by General Rosas, of the kind worn by the Guachos on the Pampas when they go out to hunt the jaguar. They are made of the toughest bull's hide, doubled, and I was confident that if they could resist the jaguar's claws they could the fangs of the rattlesnake. They came up to my hips, and I put them on one fine morning, and taking a scythe, went into the meadow and began to mow. The snakes came at me, a dozen at a time, and whenever they struck their fangs into the tough leather it held them fast. I took no notice of them, but kept on mowing till they hung in such numbers about my legs that the weight became troublesome, and then I stopped mowing and cut them off with the scythe. I had to do this about once in half an hour, and when I went home to dinner there were so many heads hanging to the boots that you could scarcely see the leather. The boys picked off enough to fill a peck measure heaping full, and when I came home to supper they got off as many more. I kept this up for a fortnight, and by that time, I can tell you, snakes were getting rather scarce in that particu-lar meadow."

"What became of them boots?" inquired our Pilot, who had listened to this narrative with much apparent interest.

"Them boots," said the visitor, lighting one of the Captain-General's Havanas with much deliber-ation, and rolling the weed slowly between his lips, evidently to gain time for invention, "them boots saved my life not long afterwards. You see, I soon got tired of farming and went to sea again. I bought a brig in New York and started on a trad-



PROVINCETOWN

ing expedition to the west coast of Africa. Off the Cape de Verdes we had about the worst storm I ever saw in my life, and were driven ashore in the night a little south of Cape Blanco, where the Great Desert comes down to the sea. The brig struck a reef running out under water a considerable distance. The next day a whole tribe of Arabs appeared on the beach mak-ing signals to us. I went ashore to see what they wanted, and as I did not like to expose the boat's crew to harm, before going I put on them iden-tical boots, which I had always kept with care, in order that I might wade from the boat to the beach. As the water was shallow, the boat could keep a good way out beyond the reach of the javelins and spears of the Arabs, who did not seem to have any fire-arms. As soon as I landed I was seized and hurried off over some sand-hills to their camp. Knowing enough of their language to understand most of what they said, I soon found that they meant to entice my crew on shore, make slaves of them, and plunder the ship.

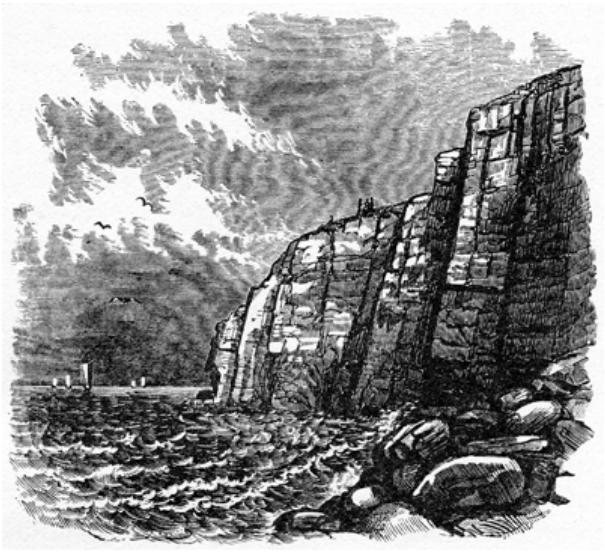
As a part of this plan, they treated me civilly for a time, only taking off my boots, which seemed to strike their fancy in a way that I could not at first comprehend. But I soon found that they were almost wholly out of provision, though they had plenty of water, and that they meant to make soup of the boots. They accordingly put them into a big iron pot, over a fire, and in about an hour invited me to partake of the broth. I de-clined, and they ate it themselves. In half an hour afterwards every mother's son and daughter of them was as dead as Julius Caesar. There was rattlesnake poison enough in them boots, sir, to destroy all the Arabs of Arabia. The next day we got the brig off without material damage, and we found gold-dust enough in the camp of the Arabs to make every one of the crew a rich man. That was on the whole the most successful voyage I ever made.

"But speaking of snakes, if you want to see snakes you must go to the East Indies. I was once lying at anchor in a little port on the coast of Sumatra, waiting for a cargo of pepper. The weather was intensely hot, and we left all the hatches open at night. I got up early one morn-ing and found the gunwales of the ship nearly down to the water's edge. Supposing that we had somehow sprung a leak and were sinking, I roused up the men and sent a couple of them down the main hatchway to see what the matter was. They did not come back, and after waiting a few min-utes I sent the mate, who looked in cautiously with a lantern, and reported that there was a serpent in the hold, and that he had probably swallowed both the seamen, as the feet of one of them were sticking out of his mouth. From the depth to which his weight had sunk the ship he was evidently a big one. Prompt measures were necessary. I di-rected the men to rig a tackle and fall, on the main yard, and let down a stout rope with a running noose right over the hatchway. I then mustered all our fire-arms and gave the snake a volley to rouse him. He soon reared his head out of the hold, I dropped the noose over it, the men ran him up, while the mate and I with axes chopped him in two. He was so long, sir, that it took the whole forenoon to haul him out by sections, cut him up, and throw the pieces overboard."

THE ASSYRIAN - A MAN WHO LIKED HIS TIPPLE

By way of introduction, in 1851 Maine was the first state to pass a prohibition law in the United States. The law prohibited the sale of all alcoholic beverages except for "medicinal, mechanical or manufacturing purposes." The Massachusetts legislature passed a "Maine Law" in 1852 but it was struck down a year later by that state's Supreme Court. Two years later, in 1855, the legislature passed a revised prohibitory liquor law to avoid the constitutional flaws of the first law. In this account, the Assyrian (Underwood), found himself in Provincetown, Massachusetts where the law was obeyed, at least on the surface; "medicinal" alcohol, however, was widely available at pharmacies and the Assyrian was not to be deterred from his usual libation.

We found the descendant of Ninus and Semiramis in an unsatisfied state of mind. As we rowed off, he gave us his opinion of Provincetown. The place, he said, was dry and dreary to the last degree, with a very repulsive-looking set of inhabit-ants. After walking about for some



CASTLE HEAD, MOUNT DESERT

time, he ven-tured to inquire of one of the natives for a tavern. The man directed him to an edifice which bore upon its front, in large letters, the words "Union House." He entered, and was accosted by a dentist, the sole occupant, who offered to pull his teeth on moderate terms. On learning, however, what his visitor wanted, the dentist directed him to a neighboring apothecary as the only man in town who kept for sale anything to drink. The Assyrian, in his usual confident way, demanded a cocktail. The apothecary looked at him for some moments with the air of a person who is too much astonished to speak, and then replied, with grave deliberation, "1 do not know what you mean by a cocktail."

The Assyrian, in his turn, stared with astonish-ment. Here was a depth of ignorance hardly credible. At length he intimated that he wanted something to drink. He was offered soda-water, qualified, at his choice, with lemon, strawberry, pineapple, sarsaparilla. He shook his head. Was there nothing else? "Nothing."

A bright idea flashed on the Assyrian. He de-scribed to the apothecary the method of concoct-ing a cocktail. The apothecary listened like one to whom a new science is unfolded. Gradually light dawned upon his mind. He produced, from some dusty shelf, an almost forgotten solitary bot-tle of sherry bitters. The Assyrian seized it with alacrity. In the absence of anything better, cocktails could be made with sherry bitters. The other requisite materials were on board the sloop.

Supper was ready when we got on board. We found the flounder savory, the lobster was boiled enough, and before turning in at nine o'clock we drank with the Assyrian a cocktail of his com-pounding to the speedy enlightenment of Prov-incetown in the knowledge of national beverages.

A TRIP NOT DEVOID OF THRILLS

Soon after passing Dread Ledge, the scene of numerous shipwrecks, the Professor, who was basking in the sunshine on the taffrail of the sloop, watching the medusae floating by, was suddenly startled by the apparition of a large shark within a foot or two of his elbow. The creature was probably attracted by the sight of the Professor's red shirt, for, before starting this morning, we had discarded our shore clothes, and reduced our integuments to panta-loons and red-flannel shirts. The shark remained alongside but for a minute or two, after which he was not seen again.

Just at midnight we were all roused from sleep by a great crash in the cabin. Tumbling out of my berth in a hurry, I found the little sloop tossing and pitching furiously. The table, which ex-tended the whole length of the cabin, and which we had left, on turning in, covered with books, cups, lamps, and miscellaneous articles, had got unfastened, and at length upset by the rolling of the vessel. The Skipper and the Pilot were al-ready on deck, where, by the uproar, it was evident that something was going wrong. Fol-lowing them I learned that the tide was setting strongly up, while a northwest wind was blowing strongly down the bay. The conflict of these two forces produced a rough sea, under the effect *of* which our craft was dragging her anchor and drift mg toward a not very distant reef. The sky was overclouded, and the darkness was relieved only by the intermittent flashes of the revolving-light. The seamen were at work forward trying to pre-vent the vessel from drifting, in which they at length succeeded, though only partially; for the Pilot muttered as he went below, that if the wind did not freshen, he guessed she'd not drift much before daylight.

The temperature lowered very rapidly. There was a gust of rain, and then suddenly we were engulfed in a dense fog, which, however, did not rise high above the surface of the water; for I was struck by the strange appearance in the air of the topmasts of the surrounding vessels, while their hulls were entirely hidden. Gradually the fog turned into rain, and by nightfall the weather was so cold that we were fain to go to bed at dark to keep ourselves warm. The wind was north- east, and blowing pretty hard, and I noticed, be-fore turning in, that the Skipper and the Pilot were busy rigging a large anchor, which we had on deck, but which we had not yet had occasion to use. They predicted that the wind would increase in the night, and, as it was blowing di-rectly into the harbor, we should be likely to need an addition-

PIGEON COVE

al anchor. The old Pilot said that he remembered a north-east storm, many years ago, in which every vessel in the harbor was driven ashore.

The prediction of the seamen was verified. About midnight we were roused by an outcry on deck, and, turning out, found that the wind was blowing almost a gale, and that the sloop, in spite of her additional anchor, was drifting under the impulse of wind and waves directly upon the great black rock which rose from the water a hundred yards southwest of us. She drifted slowly, and we watched her progress with some anxiety. Fortunately, when we were about fifty yards from the frowning rock, our anchors caught in the moorings of another vessel and arrested our dan-gerous progress.

THE PRACTICAL JOKERS

As the Skipper said that this was a good place for fish, we got out our lines while the Pilot was getting dinner. Before we had caught anything the meal was ready, and we went below, leaving our lines in the water, in hopes of finding that some fish had been foolish enough to hook himself during our absence.

It so happened that I was first on deck after dinner. I tried the lines, but found nothing caught. The Assyrian's line was over the stern, and, as the tide was running very fast, he had let it out to its whole length of several hundred feet. I hauled it in to see that it was still baited, and as no one had yet followed me out of the cabin, I was enticed by the opportunity to play the Assyrian a trick. A huge stone jug weighing many pounds, and capable of holding several gallons, stood near me on the deck empty. It was our principal water-jug, and the Skipper had placed it there to have it handy, intending to take it ashore and fill it after he had cleared away the dinner-things. The temptation was irresistible. I quickly tied the end of my friend's line to the handle of the jug, and lowered it overboard. The strong tide swept it far along until it had gurgled full of water, when of course it sank plumb. I returned to my own line, and presently caught a large cod, the sound of whose flapping on deck brought out my comrades with the exception of the Skipper, who remained to put the cabin to rights a little.

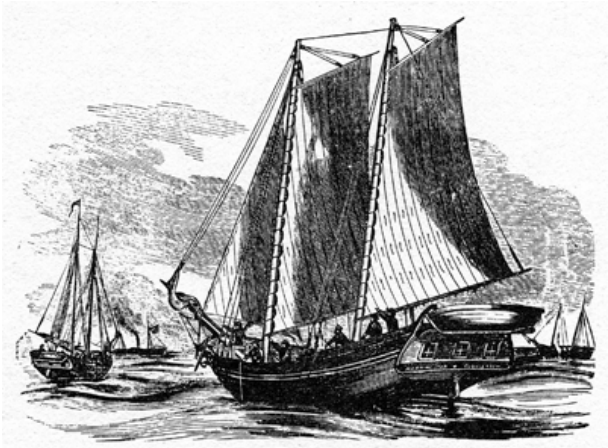
The Assyrian, cigar in mouth, sat down on the taffrail, and gently fingered his line with the air of a man who has had a satisfactory dinner, and does not yet care to exert himself to catch fish for supper. Presently, however, he had a bite, and began languidly to pull up his line. The unusual weight soon made itself felt. The Assyrian grew suddenly excited. He said nothing about halibut, for previous disappointments had made him reticent of expression on that point, but halibut was evidently in his mind, by the gingerly way in which he handled his line, holding it in readiness to yield judiciously in case the monster should suddenly put forth his strength. We gathered round to witness the struggle. The gentleman from Nineveh tugged and tugged, growing gradually more and more astonished at the weight of his capture, and the passive nature of his resistance, for the halibut, as the fishermen often told us, never yields without a desperate and powerful contest. At length his prize reached the surface. Without remark the Assyrian quietly lifted it on board, amid roars of laughter, and as he passed into the cabin to relight his cigar, good-humoredly nodded to me, saying,—

"I'll pay you for that, my boy, before you are much older." He kept his word.

By and by the Skipper put the jug into the boat, and the Assyrian and I went ashore with him to a fisherman's cottage, the only house in sight…

The men of the fisherman's family were away, but there were several women at the house, who received us kindly, and gave us milk and berries. The Assyrian speedily made himself at home with the ladies,—and when I proposed to go to the beach, about two hundred yards from the house, to take an ocean bath, he refused to accompany me, but offered to wait where he was till I came back. The Skipper had gone to his sloop with his jug of water, to invite the Artist and Professor on shore to partake also of milk and berries. So I went alone to the sea, and strolled along the beach till I came to a convenient pile of rocks, out of sight of the house, and took off my clothes, and went in.

The water was awfully cold, though the air was warm,—and being unable to swim, and so not daring to plunge boldly, I endured fearful torture in the heroic efforts to get a thorough bath. A few rods farther along from where I went in, there was a large rock almost covered by the water, to which I determined to go, calculating that by the time I could reach it, and return, I should



COD-FISHING SCHOONERS

have had as much sea-bathing as it was desirable, or, for me, possible to endure.

I reached it easily enough, and after clinging to it for a moment thoroughly chilled, turned to go to the shore.

Conceive my consternation at beholding, as I looked around, a woman approaching along the beach from the direction of the house. A tall, elderly female, wearing a veil, and carrying a parasol. Evidently she was bent on a sea-side stroll. She must have seen me if she had looked in my direction, for the distance that separated us was inconsiderable. But she walked with her eyes cast down, either wrapt in thought, or searching for shells and pebbles, I could not determine which. Nor did it much matter. I was nearly dead with cold, but of course could not quit the shelter of the water while the lady was in sight. If she only kept onward, however slowly, I thought I could hold out, for, thank heaven!, there was a rocky point at no great distance which would conceal her, or rather me, from view as soon as she should pass it. So I crouched behind the rock to which I was clinging, shuddering with anguish as the chill waves rolled in succession over me.

The lady was provokingly slow. She lingered, she stopped, she stooped to examine every shell and every pebble. I grew almost frantic with suffering, and was twenty times on the point of crying out, and warning her off. Still, I trusted she would pass without seeing me, and thought I could endure a little longer.

At length she reached the rocks, among which I had deposited my clothes. She did not notice the garments apparently, but, after pausing for a minute, coolly sat down, and, to my horror and despair, pulled a book from under her shawl, and began to read.

I could stand it no longer. All the tales I had ever heard of persons who had died from staying too long in the water rushed upon my memory. I felt convinced that I was not only blue around the mouth, but blue all over. It seemed as if I had been in the water at least two hours. I should certainly die. But death itself was preferable to this infernal cold, which caused my very bones to ache. Positively I could stand it no longer.

I began by coughing, gently at first, afterward more vigorously. It did no good. She was absorbed in her book, some foolish novel, doubtless,—confound the author! I hemmed, hawed, hooted.

I splashed the water. All to no effect. A horrible thought flashed across me: perhaps she was deaf,—as deaf as Dame Eleanor Spearing. I tried to get a stone from the bottom to throw at her, or rather near her, in hopes of attracting her attention, but found I could not reach bottom without putting my head under water. It suddenly occurred to me that the tide was rising, and that my post would no longer be tenable even if I could stand the cold. That settled the question.

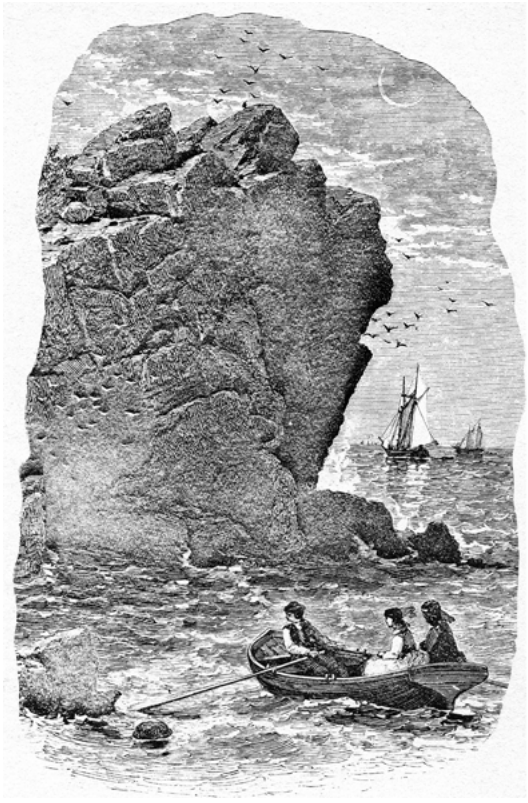
"Hallo! hallo there!" I shouted, with all the force of my lungs.

"Hallo, yourself! What are you making such a row for? Aren't you ashamed to yell at a lady in that way?"

I recognized the voice at the first word, and was beside the speaker before the sentence was finished. Throwing up the veil, which had concealed his features, the Assyrian burst into a laugh, in which, though at first I thought of stoning him, I finally joined. He had persuaded the women at the cottage to lend him his disguise, in order to repay me, as he had promised, for the affair of the jug. I forgave him for the sake of the provocation, though he had put me to direful torture,—but we entered then and there into a compact to desist from such pranks for the future.

CONCLUSION

"A Summer Cruise on the Coast of New-England" is a fascinating read and I recommend it highly. (It can be downloaded free from the Internet.) From it I learned more about William Stimp-



son, the man. I was introduced to Samuel Tufts, Jr., an important historical figure in the aquarium hobby. And finally, I learned that one of the founders (and by many considered to be the most significant) was an aquarist. What a wealth of treasure from a single book! One last excerpt from the very end of Carter's book:

The next day I embarked on the steamer for Rockland and Boston, while the Artist and the Assyrian left the island by way of a bridge, which; at its northern end, connects Mount Desert with the mainland. The Professor and the seamen, after we bade them farewell, hoisted sail with a fair wind for Edgemoggin Reach, and thence back to Portland and Swampscott, where they arrived in due time.

It is related of the Caliph Abdalrahman, the mightiest and most magnificent of the Moorish monarchs of Spain, that he wrote toward the close of his life the following declaration:
"I have now reigned above fifty years in victory or peace; beloved by my subjects, dreaded by my enemies, and respected by my allies. Riches and honors, power and pleasure, have waited on my call, nor does any earthly blessing appear to have been wanting to my felicity. In this situation, I have diligently numbered the days of pure and genuine happiness which have fallen to my lot; they amount to *fourteen. O man I place not thy confidence in this present world!"*

The Caliph Abdalrahman must have been hard to please. For my part, I can confidently say that during our cruise I enjoyed at least twice as many happy days as fell to the lot of his Majesty during his whole reign; and such, I am sure, would be the avowal, on their part, of my friends the Professor, the Artist, and the Assyrian.

PART III: THE ISSUES

CHARLES E. HAMMETT, JR.

In 2007, the husband/wife team of Fred and Juditha Burchsted wrote an article about Samuel Tufts, Jr. titled "Samuel Tufts, Jr. (1817–1902), a Massachusetts shell collector and aquarium stocker" (Burchsted, 2007). The following is their introductory paragraph:

The lives of minor naturalists are poorly documented, yet much of the development of local natural history depended on such individuals. For each prominent naturalist, author or explorer, there were many minor workers who dredged in the town harbor or collected butterflies in local woodlots. A full picture of the history of natural history requires the excavation of the lives of this significant component of the natural history community. These more local naturalists sometimes published their results, but more frequently sent specimens or information to more major figures, often professionals with limited time for fieldwork (Keeney, 1992; Welch, 1998). While a vast literature documents the lives of prominent naturalists, working-class naturalists who collected, published local lists, and explored the natural history of their own localities, are little known.

Barring one exception I agree wholeheartedly; the sentiment should be circulated more widely and more often.

The Burchsted's examination of Tuft's life with regard to his shell collecting activities is par excellence and I recommend it to all interested in the history of marine invertebrates. However, with regard to his aquarium stocker activities they make several serious errors, including the assertions that:

1. Tufts is the only known American aquarium stocker of the 1850s;

Charles E. Hammett, Jr. (1822-1902).

2. Tufts is the only American aquarium stocker of this era whose methods have been recorded;
3. Carter's description of Tufts provides the only known example of the activities of an American aquarium stocker of the 1850s craze.

None of these assertions are true and so we come now to Charles E. Hammett, Jr. (1822-1902), born in Newport, Rhode Island in 1822. A notable resident of the city, in 1844 he started in business as a grocer and two years later he sold out and opened a bookstore. Hammett, besides looking after his book and stationery business, at different times engaged in various other branches such as tuning pianos and sewing machines. For many years he conducted a bookbindery, which gained a reputation for solid and artistic work. At another time he was extensively engaged in the manufacture of envelopes and paper boxes; then in the mounting and framing of pictures; in inventing games and manufacturing them for the trade; in making maps; and in the publishing of books and pamphlets, the translation of some of which from the French and German was done under his direction. Hammett amassed one of the largest libraries in Newport; the published bibliographies of which are owned now by the Newport Historical Society's library collection.

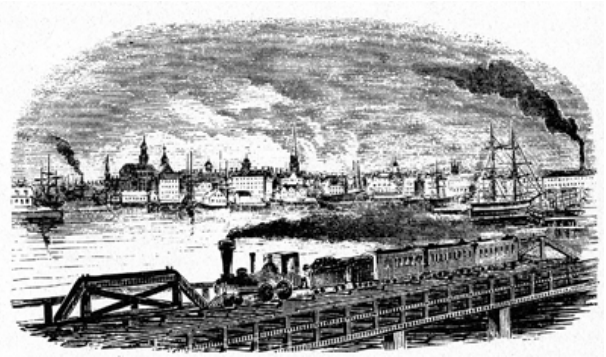
Somewhat of a Renaissance man, to all of these interests Mr. Hammett gave the closest personal attention, and frequently he took a hand in the manual work itself. Mr. Hammett was also identified with the public life of Newport. He was for years a member and chairman of the school committee, he was one of the original members of the park commission, a trustee of the Savings Bank of Newport, a director of the Redwood Library, a trustee of the Newport Hospital and one of the original incorporators of the Newport Historical Society in 1854. Mr. Hammett was the first bookseller in Rhode Island, if not in New England, to employ women as assistants. Added to all this, at one time he was an aquarium stocker.

The following is part of an article that appeared in *Scientific American* in 1857. It was written by Hammett and titled, "The Aquarium or Aqua Vivarium":

My first attempt was with gold fish (*Cyprinus*); but not being able to obtain the proper plants, I stocked a confectioner's glass jar with a few other plants from the sea, and there soon appeared a large number of small animals, which, viewed by lamplight, were very interesting. I have found that very deep and narrow tanks, of various shapes, have not succeeded so well as those having a much greater breadth than depth. The tank which I successfully stocked was of an octagonal form, of thirty inches in diameter and about eight in depth. Excepting the great difficulty of rendering it tight, this tank has succeeded admirably. After being in use for a long time, the rockwork is still covered with vegetation, and crabs, minnows, eels and mollusca still sport and wrangle in the home which they have so long occupied.

The study (for study it is) of Aquaria is yet in its infancy in this country; and we may reasonably hope that when those who are close observers of Nature become interested in this matter, we shall learn much more of the "private life" of the inhabitants of the ocean than we have ever hitherto known. Probably no such facilities for the study of natural history have ever been offered as are now presented by the Aquarium. We have in our rooms, where we may examine it at our leisure, a sort of section of the ocean, whose inhabitants may be examined in their natural abode, and under most favorable circumstances. With such facilities it will be easy to learn more in a few months' observation than we have heretofore been able to learn by years of examination of dead or dying specimens.

Tanks may be made of various forms. The simplest are made of confectioners' jars or any open-mouthed glass vessels. These will answer very well for small specimens; but the best kind, most proper for the fish, and well suited for observation, are those made in a rectangular form, with four glass sides. It has been found very diffi-



PORTSMOUTH

cult to make these permanently tight, and at the same time free from the taint of cement. This has, however, been remedied, I believe, by some of the dealers in tanks, so that they may now be purchased so constructed as to be put into use without fear of leakage.

In a fresh water tank we have no anemones nor hermit crabs; but we have newts, the stickleback which builds its nest beneath the waters, the water beetles, the tadpoles, and numberless others, which fully compensate for the absence of those that are found only in seawater.

The speedy popularity of this piscatorial and botanical "institution" - the Aquarium - is undoubted. All that is needed is to exercise patient perseverance, regular attention, and, above all, perfect cleanliness. No decayed matter, animal or vegetable, must be permitted in the tank. A strict care to not overstock or crowd the animals and a determination to overcome obstacles will insure success; and the Aquarium will become - what it has already become to thousands in Europe - a "new pleasure."

Appended to the article was the following editorial comment:

Mr. Hammett's modesty forbids his intimidating in the above article that he is prepared to furnish Aquaria tanks of superior construction (an improvement of his own) to such persons as may desire to try their skill in raising the pisces, molluscs, and articulates of the mighty ocean, and to derive instruction from serving the life and habits of those curious creatures.

In July 1858, Annie Rebecca Coggeshall – the first female American aquarist of record – wrote her second article on the aquarium (Coggeshall, 1858a). The following is an excerpt:

We trust that many of our readers, stimulated by the account of an Aquarium which was given in our number for February, are proposing to set one up for themselves. The best tanks, so far as we know, that are made in this country, are those of Mr. C.E. Hammett, of Newport, Rhode Island. But the tank is of little importance, if one cannot get the water, the seaweed, and the stock; and therefore Mr. Hammett undertakes to supply these also. He will send, not the water itself, but the salts obtained by evaporation from the quantity of water necessary for each aquarium. These are to be dissolved in clear spring-water, (previously boiled, to insure its containing no injurious living matter,) and then the aquarium, having first had a bed of cleanly-washed sand put upon its bottom for about an inch or an inch and a half in depth, and this in turn covered with a thin layer of small pebbles - though these last are not essential - is to be filled with it. Then the seaweed, which is sent so packed as to preserve

Hammett's book store, circa 1898.
Hammett is standing outside in the photograph.

its freshness, is to be put in. It will be attached to small bits of rock, and these should be supported by or laid upon other pieces of stone, so raised as to secure a free passage for the water about them, and so afford places of retreat for the animals. The stock will be sent, if it is to go to any distance, in jars, and anemones, crabs, shell-fish of various kinds, and many other creatures, will be found among it.

The *Bulletin of the Newport Historical Society* provides us with a more intimate view of Hammett's aquarium activities (Powel, 1915):

True, we were finally only wedged and taken to see Mrs. Berry's pretty little aquarium after our woes were ended, and the descent from Avernus was not so bad, while the tall, black haired, rather sad gentleman dismissed us from the top of the stairs.

That little aquarium of Mrs. Berry's came from the maker or inventor of improved aquariums in the United States, a member of this Society who long outlived its foundation, and who contributed to local literature one of the most practical, wise compilations ever made in the City of Newport—Mr. Charles E. Hammett and his "Bibliography" [the reference here is to Hammett's "A Contribution to the Bibliography and Literature of Newport, R.I., 1887]. My first remembrance of Mr. Hammett—owing to the greater attractions of the sealing-wax, wafers, pens and pencils, and ruled paper, including also unattractive school books of Mr. Barber, the bookseller—was not in the Main Street, but energetically finishing, with his own bands, the interior of a gigantic sea-water aquarium that he had been requested to provide and construct for the Academy of Natural Sciences in Philadelphia, a great honor indeed.

Well, the iron-framed aquarium was being set up in state, in a large library room near a window, a dusty one too, on the rear lower floor, a curtain or blind was going up, (and the sea-water was coming in casks from Cape May) and Mr. Hammett was daubing putty or something here, there and everywhere within the glass box. A lot of my father's scientific friends passed in and out, quite curious. Sometimes Mr. Hammett, on his knees, peered over the top—the tank was about six or seven feet long and half as high—and asked for something, and every one scurried to help.

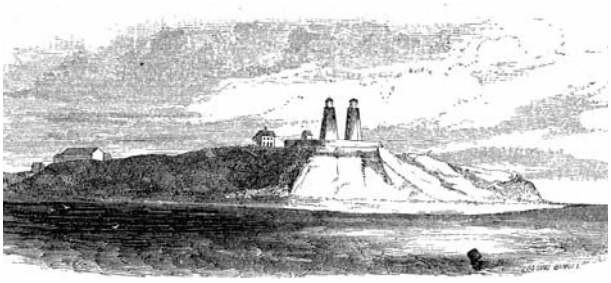
Now my father so often said that Mr. Charles Hammett had one of the most classic cameo-like heads that he had ever seen, that fox years after, when I saw Mr. Hammett moving to and fro, within the oval counter formerly in his book store, I privately considered him "Neptune, the God of the Sea." Did any one ask Mr. Hammett about any book that he did not know of or any topic for which he could not advise a good one?

The aquarium Hammett was building for the Philadelphia Academy of Natural Sciences was commissioned in March 2, 1858 and this is probably the year Powel is writing about. If Powel's reminiscences are accurate, the tank must have been somewhere in the area of 100 gallons, assuming the width was half the height. It is interesting to note that Arthur Mead Edwards - the author of the first aquarium book published in the United States – also commented on Hammett's tanks (Mead, 1867): **By far the best aquaria I ever saw were made by the well-known publisher, C.E. Hammett, of Newport, R.I.**

Lastly, here are some details - with an amusing commentary - of Hammett's aquarium business (Smith, 1859):

Aquaria.—Mr. Charles E. Hammet [sic] makes and furnishes Aquaria at Newport, R. I. His agent in Philadelphia is J. W. Queen, 924 Chestnut Street. It is rather amusing to read his list of prices of the living contents: Green weeds are 10 to 12 cents each; Sea Anemones, (Actinia) 12 to 75 cents; Star Fish 12; Serpula 12; Crustacea 12 to 37; Molluscs 12 cents to $4.50 per doz.; Fish 6 to 50 cents each: all "according to kinds and quality." All appliances are to be had: as, net on copper wire with handle, 25 cents; copper hook on handle for arranging objects, 12 cents; spoon on handle for removing objects, 20 cents; real sea water, per gallon, 10 cents, and so forth. Soldier Crabs, King Crabs, Flat Fish and Sticklebacks, with "small Sheep's Head," and "small Lobsters," at "reasonable prices." It must be a novel feeling to those long neglected marine wonders to find themselves in "a lady's parlor," and the pets of a fire-side. At best it is only a little to be preferred, some experiences prove, to being boiled at once, for want of proper care.

Hammett was in an ideal location for providing both marine and freshwater animals and plants. S. Jacob, who had an aquarium stocking business in Newport a quarter century after Hammett got out of the business, wrote (Jacob, 1886): **Say about what**



you want and I will guarantee you satisfaction, having the Atlantic Ocean at my front door-step and the Narragansett River at my back door.

Annie Coggeshall knew Hammett well. She was born in 1819 in Newport and lived in that city when Hammett also lived there. Her father was David M. Coggeshall (1772-1847), a banker who was a trustee of the Long Wharf Public School and a benefactor of the Redwood Library, both of Newport. After her father died she moved into a house owned by her cousin, Mary A. Coggeshall. Annie (named after her mother) was a school teacher while Mary managed the home; they remained together, unmarried, for many years until Mary died in 1894. Annie died just three years later, in 1897. In addition to the previous article cited, Hammett was also mentioned in an article she wrote about Aquidneck Island: (Coggeshall, 1858b):

By following the advice of some experienced person, you may avoid all those failures which are apt to attend the experiments of a tyro. I will direct you to our pioneer in aquarian science, Mr. Charles E. Hammett. He can furnish you with all you want, give you most efficient aid, and add thereto a great amount of practical information.

Hammett undoubtedly provided Coggeshall with a great deal of information on the maintenance of fish and other animals in the aquarium and most likely introduced her to the hobby.

With regard to Samuel Tufts, Jr., Carter remarked that **"For a year or two past [Tufts] had devoted himself to collecting and selling materials for stocking aquariums."** This means that Tufts was definitely in the business in 1857 but not for certain in 1856. However, clearly the same can be said for Hammett. The Burchsteds (Burchsted & Burchsted, 2007) mistakenly claim that **"...Tufts is the only American aquarium stocker of the 1850s,"** overlooking the fact that Charles E. Hammett was in the business at the same time as Tufts.

When one is deciding who was first for something, that something ought to be clearly defined, in this case what is meant by "aquarium stocker." My definition is: "One who supplies aquariums, aquarium equipment and live animals, including fish, to the public." Using this definition, Hammett is definitely the first aquarium stocker; all we know about Tufts is that he supplied "sea-water… sea-weeds and "animals."

Finally, it should be noted that pinning down "firsts" is a perilous endeavor. One may assert that so-and-so was the first on record for doing something, only to have another researcher later uncover an earlier reference that shows someone else preceded him or her. Caveat, lector!

ISABELLA JAMES

Isabella Batchelder was born in 1819 in New Ipswich, New Hampshire, four months after Queen Victoria's birth. James died a few months after the Queen, and thus lived through the whole Victorian era. Her grandfather, Samuel Batchelder, was a Minute-man and rode with his father, Jonathan Batchelder, from their home at Riall Side, Beverly to Lexington on the Alarm, April 18, 1775. Her father was a wealthy industrialist, known as the "Nestor of cotton manufacturing," Isabella was a member of the upper middle class and was tutored

Isabella Batchelder James (1819-1901)

privately. Consequently, she knew almost everyone of importance in the literary and artistic fields of the time. As Isabella recalls,

In 1824 I went to Concord, New Hampshire, to the house of my Aunt West, as my mother was to have her portrait painted by Morse, afterwards the inventor of the electric telegraph. He was then thought to be an excellent portrait painter, his execution was very fine, and delicate, and is now considered too much so for effective work in oils. I was allowed to run about the room at my pleasure and Morse would let me watch his work, which seemed to be wonderful as I saw the face growing upon the canvas. The likeness was good, excepting the mouth, and Morse promised to improve that at some future day as he did not consider the picture finished. He was called away to paint, for New York City, I think, a portrait of Lafayette, who had just arrived in this country on his last visit to the scene of his early labours.

In 1851 she was married to Thomas Potts James, a botanist of some standing. In her writings, therefore, she afterwards signed them "Isabella James." James died in 1901 at the age of 82.

In their bibliography, the Burchsteds list Isabella James' article in the *North American Review* of July 1858 as "Anonymous." This is unfortunate as Isabella James was the first authoritative writer of record on aquarium matters, besting David Cheever by three years.

The information that William Stimpson kept aquaria as early as 1849 appeared almost simultaneously in July of 1858 in the writings of James and Carter. Although Carter's account was somewhat briefer, his description was similar to that of James, even down to the misspelling of Warington's name as "Warrington." It is clear that Carter's information came directly from Stimpson; where then did James obtain hers?

It is unlikely that James obtained it from Stimpson for three reasons:

1. They never were in proximity at the same time;
2. They circulated in entirely different social circles;
3. They had no interests in common.

Regarding the last, James' interests were primarily in botany and early American history; Stimpson's was primarily in marine invertebrates. How then did she come to write her article on the aquarium? Was it because she knew Robert Carter?

As it turns out, James and Carter were in proximity at the same time, they circulated in the same social circles and they held interests in common.

Isabella James first met James Russell Lowell in 1841, just after he had graduated from Harvard Law School. Over the years they became close acquaintances, to the point where she called him "Jim." The following are excerpts from her reminiscences of Lowell (James, 1937):

I have been reading the biographical sketches of Russell Lowell, as he is now called, but who was when I was so well acquainted with him, familiarly known as Jim Lowell. So many errors have crept into the press that I am tempted to set some of them right. He was a few months my senior and we both belonged to the same "set" in the university town of Cambridge, Massachusetts, to which I went as a young lady.

The circle in which he moved was what Cabot Lodge has styled "respectable Boston." Nathan Hale, Senior, at whose house I so often met him, was the editor of the "respectable Daily" otherwise the *Boston Advertiser*.

Many a pleasant evening can I recall when Lowell and W. W. Story, now the celebrated sculptor, displayed their histrionic talent in the then fashionable game of "Charades" in which they both excelled, while "Questions and Answers" brought out to perfection Lowell's powers of brilliant repartee.

After Isabella James was married, she and her husband moved to Brattle St., Cambridge where they lived with her father, Samuel Batchelder, who was well-known to the members of Lowell's whist club (Holmes, 1917) James also knew John Holmes quite well. In the 1870s, she was the chairman of the Organization of the Ladies' Centennial Committee of Cambridge, Massachusetts, a group that oversaw the publication of an account of Cambridge as it was in 1776 (Gilman, 1876). Not only was James one of the contributors, Holmes was also.

Like Carter, Isabella James was an abolitionist. She worked during the American Civil War for the United States Sanitary Commission, a private relief agency created by federal legislation in 1861 to support sick and wounded soldiers of the U.S. Army. During the war she visited military hospitals and afterwards served as president of the Pennsylvania branch of the Freedman Commission of the Protestant Episcopal Church, which sent teachers to the South to open schools for former slaves.

As I mentioned at the beginning of this monograph, in 1841 Robert Carter went to Boston where he formed a lifelong friendship with James Russell Lowell, and together they began *The Pioneer, a Literary and Critical Magazine*. Indeed, Lowell called him "his true friend and brother" (Hale, 1899) and was affectionately dubbed by him in the Whist Club as "the Don" (Underwood, 1893). There is no doubt that through Lowell, James and Carter were known to each other as more than just passing acquaintances. They all shared similar views and met frequently, and held this close association over the course of many years.

Because of his interest in the aquarium, it is understandable that Carter was the one who persuaded James to write a paper about it, passing on to her all of his information he had about William Stimpson.

THE NORTH AMERICAN REVIEW

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Message 12530, September 14, 2014)

One of the magazines that gave me much trouble when researching aquarium hobby history was the *North American Review* (NAR). The publication was founded in Boston in 1815 by its first editor, William Tudor (1779-1830) and other members of the Anthology Club (or Anthology Society). The club was organized in 1804 in Boston, Massachusetts by the Rev. William Emerson, father of Ralph Waldo Emerson. It was their intention to rival the leading British magazines and until the *Atlantic Monthly* was founded in 1857, the NAR was perhaps the foremost magazine in the US.

The collection of issues can be searched via key words and when I entered "aquarium" I was led to the following article that began:

ART. VI.— 1. The Aquarium, an Unveiling of the Wonders of the Deep Sea. By Philip Henry Gosse, A. L. S., etc. London: John Van Voorst. 1855.

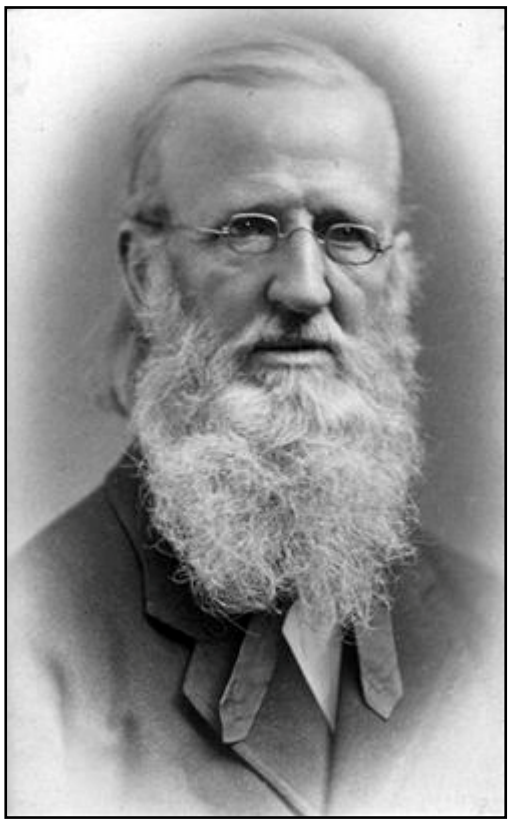
2. The Book of the Aquarium and Water Cabinet. By Shirley Hibberd. London: Groombridge and Sons. 1856.

There was, however, no author. As it turned out, the first seventy-seven volumes were published anonymously, and this included both authors and editors. The editors were selected by a committee of advisers and by design remained anonymous while acting as editor. All reviewers also remained anonymous. However, the names and affiliations of the authors of submitted manuscripts were known to the editor, but were not known by the external reviewers during the review process. By this policy the NAR hoped to avoid selection bias in the submission process, to limit any actual and or perceived bias in the review process, and to test the premise that quality submissions can be drawn to the NAR journals without relying on the identity and affiliation of the journal's editor and or reviewers.

In short, the NAR was sadly in need of a thorough index. Fortunately, such an index was prepared by William Cushing. He was born in Massachusetts in 1811, graduated from Harvard in 1832 and entered the divinity school there in 1839. He preached until 1857 when he removed to a farm in Clinton, Massachusetts. He went back to Cambridge in 1868 and became an assistant librarian at the Harvard library. He left in 1878 and thereafter engaged in literary pursuits. His published works include "Index to the North American Review" (1878), "Index to the Christian Examiner" (1879), "Initials and Pseudonyms" (1885-1888), and "Anonyms, a Dictionary of Revealed Authorship (1889)." Cushing's scholarship was not only invaluable, it was nothing short of amazing. Cushing died in 1895.

In the introduction to his Index, Cushing writes:

The fullest sources of information, in regard to the past and present writers, have been opened to me by the past



William Cushing (1811-1895)

and present editors, by the late and present publishers. I am able to furnish the names of the writers of nearly all the principal articles; and of nearly all the critical notices, except during the editorship of Dr. Palfrey, who is too infirm to give me any information. Note: John Gorham Palfrey was editor from July 1836 to January 1843.

Thus, using Cushing's Index I was able to identify Isabella James as the author of the article in question.

However, as readers of the *North American Review* know, the books placed at the head of an article serve often, like the preacher's text, merely to suggest the subject of the article. In this case it appeared that the article was simply a review of books by Gosse and Hibbert. The article actually contains little mention of these two books save for a quotation or two. The article is actually a tour de force on the principles of and the practical aspects of establishing and maintaining an aquarium. For example, at one point James observes:

There is one important fact which all aquarians must learn sooner or later, though they may not at first know the scientific reason for it, and will perhaps refer their success to mere chance. The pleasant writer of My Aquarium, in the Atlantic Monthly, does not appear to know why her third attempt succeeded after two failures, although the fact of the presence of the Infusoria is distinctly stated. If we will only learn of nature, each stagnant pool in our country-walks may teach us that these lower forms of life are the scavengers of the water.

The reference here is to Annie Rebecca Coggeshall's article in the February 1958 issue of *The Atlantic Monthly*; James had explained the problem in a previous paragraph:

Sea-water contains the spores of plants, and the germs of many forms of animal life, which may have development in the tank; and when these births occur, it is a special gratification to the possessor. But such germs may also decay and cause putrescence; and if a tank is neglected, the water is liable to get cloudy, the stones black, the sides of the vessel semi-opaque, and the animals diseased.

James, who had a serious interest in botany, also took issue with Gosse:

We cannot agree with Mr. Gosse in his opinion, that the vegetable kingdom is an appendage to the aquarium which must be tolerated on account of its use. To the eye of most persons, the soft green of the Ulva, and the delicate crimson tracery of the Dasya and Delesseria, are quite as beautiful as the fishes and mollusks which sport under their branches. A taste for gathering and arranging these lovely forms of nature has been prevalent of late years, and no one can deny that, when the delicate fronds of the sea-weeds are expanded and fastened upon paper, they form a more exquisite picture than any which the hand of man can make. Why, then, should we not admire them even more, spread out in their native element, where the grouping of graceful forms is more striking than that of the terrestrial flora?

Cushing's Index is in two parts: (1) Given the reference, the author is listed and (2) Given the author, his or her articles are listed. Using the latter I found that James had written five articles for the NAR (listed here in bibliographic citation form):

James, Isabella, "Darlington's Memorials of Bartram," *North American Review*, Volume 70, Issue 146, January 1850.
James, Isabella, "Michaux's North American Sylva," *North American Review*, Volume 86, Issue 179, April 1858.
James, Isabella, "The Aquarium," *North American Review*, Volume 87, Issue 180, July 1858.
James, Isabella, "Gray's Botanical Text-Books," *North American Review*, Volume 87, Issue 181, October 1858.
James, Isabella, "Prince Gallitzin," *North American Review*, Volume 88, Issue 183, April 1859.

As I have mentioned, Isabella James was not only deeply interested in botany, she helped Darlington with his illustrations when he was writing his book on John Bartram. Furthermore, at the time she was writing these articles she was corresponding with or married to Thomas Potts James, a botanist noted as the "Father of North American Bryology." The following is from "A Biographical Sketch of Thomas Potts James," by J. T. Rothroch, read before the American Philosophical Society on May 19, 1882:

"In December 1851, he married Isabella Batchelder. This most fortunate union was the result of an acquaintance which began but fifteen months before, and which grew out of a correspondence between Dr. Darlington, Miss Batchelder, Mr. James, and Dr. Gray, relative to the publication of the letters of John Bartram. For more than thirty years Mr. James found in his wife a sympathy in all his work, and a cultured mind capable of appreciating and aiding in his own literary labor."

In Meehan's Monthly of October 1901, her obituary includes the following:

Mrs. James was also a botanist of rare accomplishments. In knowledge of mosses, she ranked among the leading American authorities; and, though of an unpretentious, modest disposition, had an extensive correspondence with those who were desirous of learning all about these beautiful plants.

In the Library of the Gray Herbarium there is a polished manuscript by Isabella James containing biographical descriptions of botanists, generally 1 to 3 pages on large sheets. It was intended to be accompanied by portraits, autographs and flowers, but only a few pressed plants bearing the names of botanists are with the present manuscript. James' biographies were intended to be a "Flora's Valhalla." For each botanist there was to be a biographical sketch, a portrait or view of birthplace or residence, a figure of a plant dedicated to the botanist and a facsimile of an autograph letter. She started this collection in 1850 and worked on it for some years. According to a preface written by her in 1860, she "had to do a lot of research to assemble the biographies."

Since three of the five articles are about botany, this is further evidence that Cushing's information can be relied upon. In the criticism of Gosse's comments on plants, the author of the aquarium article demonstrated a knowledge of marine botany that was absent in the popular magazines of the time. Isabella James, however, did have that knowledge.

James wrote for a number of different magazines and I cite the following:

James, Isabella, "Trees and Pleasure Grounds in Pennsylvania, *The Horticulturist*, vol. 5, no. 6 pp. 251-255, December 1850.

James, Isabella, "Our American Silva," *The American Exchange and Review*, in 12 parts from Vol. VI, No. 6, p. 376, February 1865 to Vol. VIII, No. 6, p. 405, February 1866.

James, Isabella, "American Forests," *Lippincott's Magazine,* Vol. 1, pp. 596-602, June 1868.

It is interesting to note that both *The Horticulturist* and *The American Exchange and Review* followed the policy of not identifying their authors (*The Horticulturist* attributed her article to "A Massachusetts Subscriber," although the editor did give part of the game away by his comment, "We thank our fair correspondent for making so fine a specimen of ornamental planting known to us." However, by the time wrote her article for *Lippincott's Magazine* in 1868, the practice was falling into disfavor and she was acknowledged as its author. Her series of 12 articles in *The American Exchange and Review* was a tour de force in that she practically wrote over half of the magazine published from February 1865 through February 1866.

I have read all of the 19 articles I have cited in this monograph and have come to recognize her writing style down to its nuances and do not hesitate in claiming that she, indeed, was the author of "The Aquarium" article.

Lastly, it is interesting to note that in Cameron's book on Thoreau's readings (Cameron, Kenneth Walter, "Henry Thoreau's Reading, A Supplement with Areas for Fresh Explorations," Transcendental Books, Hartford, CT, 1991), his entry for the aquarium article in the year 1858 does not list the author as "Anonymous" but as "Isabella James." In my view, therefore, "James should be credited with authorship of the aquarium article directly, not buried in a footnote.[1]

[1]Cushing consulted Francis Bowen to determine that Isabella James was the author of the 1850 article, and Andrew Peabody for the other four articles. The editors of the NAR most assuredly knew who their authors were.

FRANCIS BOWEN (1811-1890)
NINTH EDITOR OF THE REVIEW

The successor of John Gorham Palfrey to the editorship of the *North American Review* was Francis Bowen, who became the ninth editor, and also the proprietor in January, 1843. The outstanding feature of his successful connection with this publication was the fact that during the ten years of his editorship he contributed more than a fourth of the articles in the periodical. He was born at Charlestown, Massachusetts, September 8, 1811, and was educated at Phillips Exeter Academy and at Harvard College, where he graduated in 1833. Two years later he was invited by the University to become instructor in intellectual philosophy, a position he held until 1839, when he resigned in order to have leisure for travel and study in Europe. He lived some time in Paris, where he met the distinguished scholars of the day.

ANDREW PRESTON PEABODY (1811 - 1893)
TENTH EDITOR OF THE REVIEW

Andrew Preston Peabody was an American clergyman and author. Born in Beverly, Massachusetts, Peabody was descended from Lieut. Francis Peabody of St. Albans, who immigrated to Massachusetts in 1635. He learned to read before he was three years old, entered Harvard College at the age of twelve, and graduated in 1826, the youngest graduate of Harvard with the single exception of Paul Dudley (class of 1690). In 1833 Peabody became assistant pastor of the South Parish (Unitarian) of Portsmouth, New Hampshire; the senior pastor died before Peabody had been preaching a month, and he succeeded to the charge of the church, which he held until 1860. In 1853 to 1863 he was proprietor and editor of the *North American Review*. Peabody was preacher to Harvard University and the Plummer professor of Christian morals from 1860 to 1881, and was professor emeritus from 1881 until his death in Boston, Massachusetts, shortly before his 82nd birthday.

POSTSCRIPT

The last publisher of *North American Review* during its initial run was Joseph Hilton Smyth, who purchased the publication in September 1938. Within a couple of years Smyth also purchased *Living Age, Current History* and *The Saturday Review of Literature*.

From the September 14, 1942 issue of *Time Magazine*:

One of the mysteries of contemporary publishing has been a cadaverous onetime pulp writer named Joseph Hilton Smyth...Last week the FBI solved the mystery. Publisher Smyth, arrested with two cronies, pleaded guilty to charges that he got $125,000 from the Japs in four years, paid by Manhattan's Japanese Vice Consul Shintaro Fukushima. The down payment on June 21, 1938, was $15,000.

It turns out that between the initial 1938 payment and December 1941 the Japanese government had paid out over $125,000 to Smyth and associates to establish or buy publications for the purpose of spreading Japanese propaganda. Again, from the same issue of *Time*:

Thereupon Living Age promptly denounced the Open Door as a perfidious British invention, sugared Jap aggression, pooh-poohed the U.S. stakes in the Far East." The article closes "If convicted the three face ten years in jail, a $10,000 fine, or both.

In its October 1942 issue, *Current History* maintained that Smyth during the months that he held an ownership interest in the publication did not control editorial policies. He pleaded guilty and in November of 1942 was sentenced to seven years in

Joseph Hilton Smyth (1901-1972)

Federal prison, the judge commenting that if the crime had been committed after the outbreak of war he would have imposed the maximum sentence of ten years in jail and a fine of $10,000. After his release Smyth returned to writing spy novels and other pulp fiction under the shortened name of Joseph Hilton.

In 1943, Alan Hynd wrote "Betrayal From the East: The Inside Story of Japanese Spies in America" (Robert M. McBride and Co., New York, 287 pages, 1943). The following is from a review of the book that appeared in *The Pittsburg Courier*, Saturday January 8, 1944:

A noteworthy tribute is paid to Negro Americans in an account of the activities of Joseph Hilton Smyth, Irvine Harvey Williams and Walker Grey Matheson and the Tokyo -financed propagandist publication, The Living Age.

Writes Mr. Hynd: "In the meantime Smyth had also organized a Negro news syndicate to service Negro papers throughout the country. This came to light when the FBI received complaints from Negro newspaper editors that Smyth's service contained Japanese propaganda. When the FBI looked into some of the columns that had been emanating from Smyth's service they saw something far more dangerous than had yet appeared in the columns of The Living Age. The material that Smyth was writing would have, had the astute editors not seen through it and refused to publish it, sown the seeds of discord among Negro readers and probably produced race riots like those in June 1943. Smyth's columns openly praised Japan and stated that the Negros were getting a raw deal from the United States. It was further indicated, if one read when Japan would rule the world."

In 1945 the book was made into a movie starring Lee Tracy and Nancy Kelly.

THE EARLY HISTORY OF THE MANATEES OF THE NEW YORK AQUARIUM:

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, January 10, 2015)

When zoos receive animals like penguins, sea lions, seals, manatees and even crocodilians, they generally stay with the zoo but in the case of the Bronx Zoo in the early 1900's most of them were housed in the New York Aquarium, on the theory, I suppose, that if it lives in water it belongs in an aquarium. Such was the case with New York Aquarium. However, except for the odd crocodilian or two, the Aquarium had a difficult job keeping these animals alive during this period.

The first penguin the Aquarium exhibited, for example, didn't last very long. It was a Humboldt penguin and was not used to the summer heat of the city. As an emergency measure it was transported every evening to the roof of the Aquarium to escape the heat that had built up in the Aquarium during the day. Sea lions and seals also need cold air but it was not practicable to bring these animals up to the roof and even if it were the heat during the summer and the polluted air of the city would not have made any difference. In short, at the time the Aquarium was not equipped to display these animals and they had short life spans there.

The story was much the same with the manatees, although their early account is complicated by - of all things - bullet wounds. The following appeared in the NEW YORK SUN of September 6, 1903, announcing the arrival of the first manatee to appear at the Aquarium:

THE AQUARIUM'S SEA COW.

An Eight-Footer Captured In the Sebastian River in Florida.

The great attraction at the Aquarium now is the manatee or sea cow, that was received from Florida on Thursday, and which is now installed in the pool so long occupied by that great fun maker, the West Indian seal. The seal was a big fellow, but this manatee is a bigger creature still, being eight feet in length and weighing about 800 pounds.

This manatee was taken in the Sebastian River, a branch of the Indian, on the east coast of Florida, on Aug. 25, by C. W. Schoonmaker and Capt. John Lynn, of Cocoa, Fla., acting for Mrs. C. F. Latham of Grant, Florida, with whom the New York Zoological Society, under whose management the Aquarium now is, had made a contract for the supply of a manatee. Mrs. Latham had previously supplied to the society other specimens of the animal life of the region.

When taken alive the manatee is captured with a net having a 14-inch mesh.

The manatee hunters spent eight days on the river before they captured this one. There were other manatees about, and one other at least approached the net in the course of that time, but not until the eighth day did they get one where they could secure it.

Thus taken, the manatee was placed in a stout cypress box and taken to Jacksonville, whence it was shipped to this port in the steamer Apache.

On its arrival at the Aquarium the great box was lifted bodily over the side of the pool In which the animal was to be put, the manatee swimming out of its own accord.
As matters go now this is a big one; manatees have been taken that were thirteen feet in length. In the National Museum at Washington there may be seen the skeleton of one that long, but Florida manatees in recent years have not commonly been so big as formerly, and, indeed, at one time, hunted for sport, they came to be in danger of extinction.

Then the Florida Legislature made laws for their protection, and now the manatee is again numerous in the Florida waters, which it inhabits. Special permission was obtained from the Florida authorities for the capture of this example for the Aquarium.

The manatee, or sea cow, is an aquatic mammal, found in salt and in fresh water, but making its home generally in brackish waters and in the lower waters of rivers; it is strictly herbivorous, subsisting on the vegetation found in the water it inhabits.

In its general appearance the manatee much resembles a great seal; it has, however, no hind flippers, but only two forward flippers, and it has a broad, flattened tall. The manatee's tail at once suggests that of the beaver.

As I have mentioned, the life of a manatee at the New York Aquarium was short, and just five months later, the following appeared in the NEW YORK SUN on February 13, 1904:

FLORIDA IS DEAD
Not the State, but its Namesake, the Sea Cow, at the Aquarium.

Florida, the manatee, or sea cow, named for the genial State from which she was brought four months ago, has fallen a victim to the rigorous New York weather. With all its heat the air of the Aquarium was not salubrious enough for her and she caught pneumonia last week.

She was a rare specimen, weighing 750 pounds. Very few of her species have lived as long as she in captivity in the North. Manatees are rare, but the Aquarium managers hope to get another this summer. Florida will be stuffed and mounted in the Museum of Natural History.

A little more information (somewhat belated, however) appeared in the NEW YORK EVENING POST on April 30, 1904:

During the last five months the collector was kept extremely busy as a purveyor to the sea cow or manatee, which required a diet of salt-water eelgrass and pond weed. It chewed up exactly 90 bushel baskets of eelgrass and 20 of pond weed during the five months that it lived in the Aquarium.

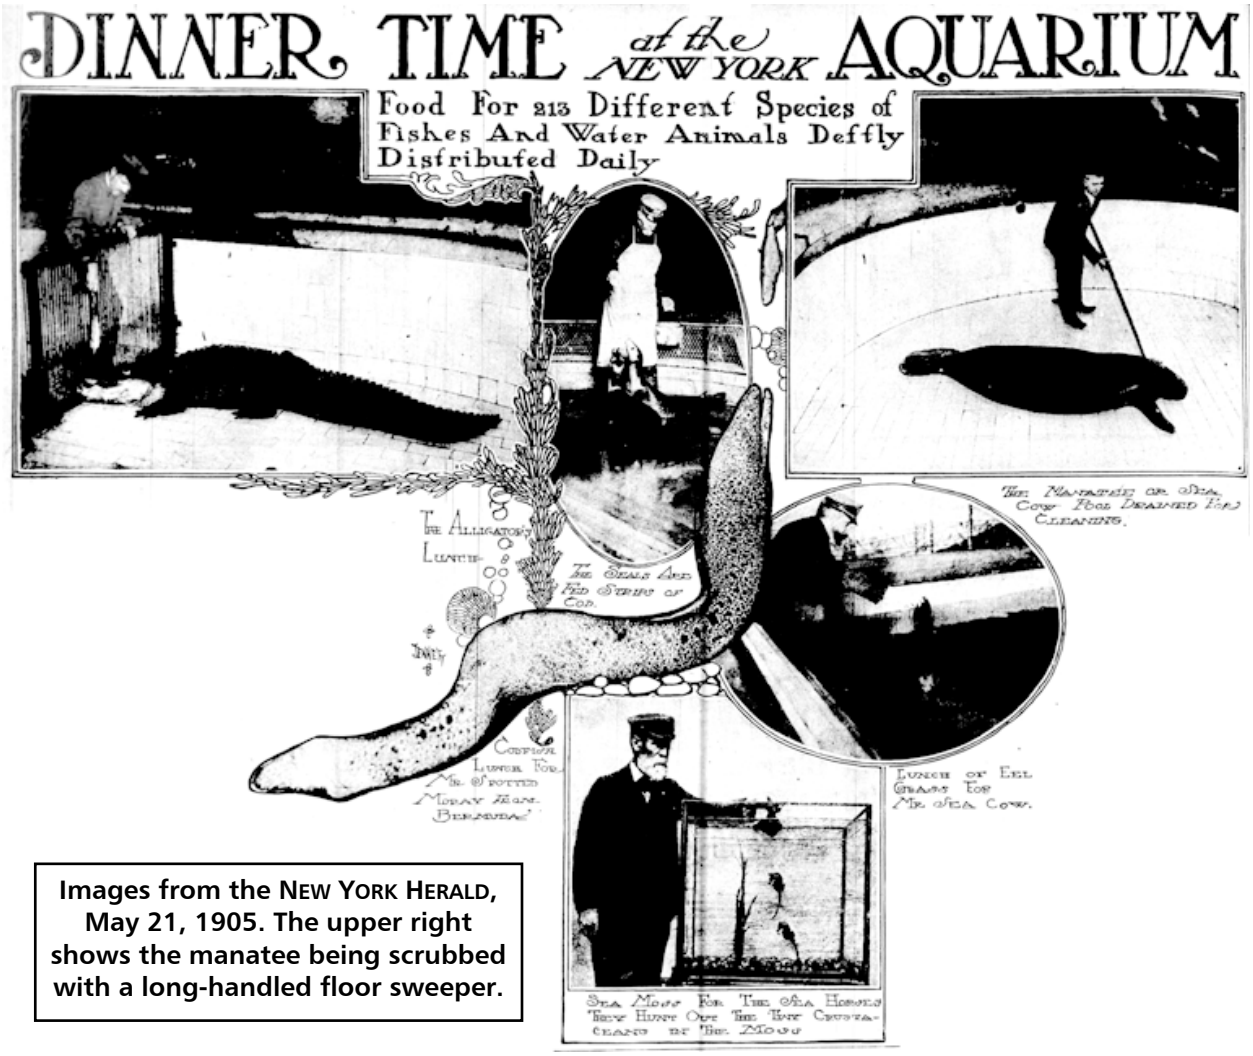
Undaunted, the Aquarium tried again during the summer of 1904 with much greater success. The following is from the NEW YORK HERALD, May 21, 1905:

SOME NEW ARRIVALS.

Among the chief specimens of the Aquarium at present, from its size as well as from the fact that it is almost new to the general eye, is the curious sea cow or manatee from Fort Worth, Florida, probably the only one in captivity. The first successful picture ever obtained at close range, showing the peculiar head and nostrils of one of these creatures raised out of the water, is herewith reproduced. The animals in their wild habitat are very shy and cautious, disappearing immediately upon approach. Owing to their| peculiar tropical habits, they are given special treatment and care, such as a suitable warm temperature, between 70 and 72 degrees, for the water of their pool and a sufficient quantity of nourishing food. Eel grass and lettuce leaves strongly tempt their appetite. The former, however, is used in more abundance when obtainable; a bucketful is usually given for a meal.

The manatee is a female, eight and one-half feet long, weighing six hundred pounds, and was captured by "Alligator Joe" at Palm Beach in a large drag seine of extra strong manila hemp, made for the purpose. Numerous attempts were made at different times for a month, and seven manatees escaped and broke through the net before one was finally obtained. The female was placed about June of the last year in a tile lined pool, twenty feet long by thirteen feet wide, with a depth of four feet of water. The latter is renewed nightly.

The feeding of the animal is watched with unusual interest by the visitors. Mr. W. De Nyse with a suspended handful of eel grass can coax the manatee to raise her head and neck completely out of the water. Sea cows have a peculiar structure, having no front teeth, hind limbs or hip bones, but a huge beaver-like tail. Their bones are said to be the heaviest known among mammals. The best view of the creature is obtained when the water is drained from the pool for tank cleaning, when the whole form is strikingly outlined against the white tiling. The home of the sea cow in the United States is limited to the Indian River lagoons of the east coast of Florida. Other species are found in various tropical regions. In captivity they live seldom longer than five or six months, but the present specimen has survived nine months.



Images from the NEW YORK HERALD, May 21, 1905. The upper right shows the manatee being scrubbed with a long-handled floor sweeper.

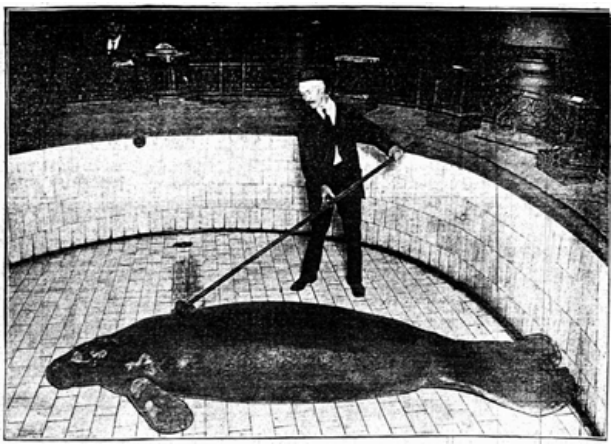
The care and express transportation on such a large individual is considerable, and almost equals its sale value. A huge tank was constructed and filled with just enough water to float the massive body. The price asked by the local fishermen for such a scarce and valuable show mammal ranges from $100 to $200. An attempt will be made this spring by the same hunter to capture a male mate. It is said the female hold their young while being nursed in almost human like fashion, keeping the baby sea cow gently and firmly pressed to their sides by means of the fore flipper. Hence they have been thought to be the last of the far fabled mermaids.

This manatee died in the early summer of 1906 but the following article appeared in the August 12, 1906 issue of the NEW YORK TIMES just after its death, either it was overlooked by the editors or it was just too late to cancel its publication:

AQUARIUM ATTRACTION.
The Manatee; or Sea Cow, Seen by Many Visitors

At the New York Aquarium the star attraction which is just now putting all of the other aquatic boarders in the background, is the newly arrived manatee, or sea cow. Unusual interest attaches to this strange and grotesque monster of the Florida waters, from the fact that it is the largest specimen of its kind in captivity in the world at present. The creature is 10 feet 6 inches long and weighs 1,000 pounds.

Owing to a restriction placed by the State of Florida on the catching and exporting of these fast disappearing animals, they are difficult to obtain. The record-breaking specimen is the gift of A. W. Dimock. It was caught near the head of Broad River, on the west coast. To float the big creature comfortably during the long voyage to New York



SCRUBBING THE MANATEE. From the August 12, 1906 issue of the NEW YORK TIMES.

a narrow wooden box over twelve feet long and filled with water was employed. On reaching the pier in this city the box with its weighty occupant was hurried to the Aquarium, and the monster was delicately emptied out of its cramped berth into the more roomy quarters of the pool.

Though considerably bruised from close confinement during the trip, a flood of fresh warm water soon revived the exhausted creature, and the ponderous body slowly moved about.

Sea cows have a peculiar structure. They have no teeth, hind limbs, or hips, but a huge, beaver-like tall. It is said the females hold their young while being nursed in almost human fashion, keeping the baby sea calf gently and firmly pressed to their side by means of the fore flipper, like veritable mermaids. The best view of the curious animal is obtained when the water is drained from the pool for tank cleaning. This is not seen by the visitors, who get only a shadowy outline of the manatee through the water, or when he rises to breathe at intervals varying from five to eight minutes.

The Tribune man, through the courtesy of Director Townsend and W. De Nyse, in charge of the marine collection, had an opportunity to obtain a striking photograph of the manatee stretched out on the floor of the pool and showing an attendant with a long brush giving it the first shampoo, The water in the pool is kept at 72 degrees. Nightly the water is drained off, the animal brushed and fresh water let in. When stranded on the tile floor of the pool the animal is helpless and seldom moves. In about ten minutes the water flows in and reaches to a depth of four feet. This affords a comfortable swimming space, the pool being 20 by 13 feet.

The diet for this bulky and important boarder is mainly eel grass, supplemented by lettuce leaves and celery tops. An Aquarium food collector spends much of his time around Graves-end Bay and the nearby inlets searching for eel grass. The feeding of the sea cow is watched with unusual interest by visitors. Mr. De Nyse with a suspended handful of eel grass has coaxed the animal to raise head and neck nearly a foot out of the water. In captivity the manatee seldom lives longer than six months.

The following death notice of the manatee actually appeared in the August 10, 1906 issue of the NEW YORK TIMES:

AQUARIUM'S SEA COW DEAD,
Blood Poisoning the Result of the Valuable Amphibian's Bullet Wound.

The Aquarium's $3,000 sea cow died yesterday of blood poisoning, due to the rifle bullet that some hard-hearted Floridian fired into her back some time before the agent of the New York Aquarium purchased her at Miami, Fla., a little less than two weeks ago.

Why the purchasing agent did not discover the hole In the manatee's back is not known, for one of the very first things that the experts attached to the Aquarium found out about the now famous sea cow was that there was a big hole in her back, which their practiced eyes knew did not bode well for the future health of the ungainly amphibian, to get which the city had gone to such expense.

When the sea cow arrived at New York a week

FEEDING THE MANATEE. From the August 12, 1906 issue of the NEW YORK TIMES.

THE EARLY HISTORY OF THE MANATEES OF THE NEW YORK AQUARIUM:

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, January 10, 2015)

When zoos receive animals like penguins, sea lions, seals, manatees and even crocodilians, they generally stay with the zoo but in the case of the Bronx Zoo in the early 1900's most of them were housed in the New York Aquarium, on the theory, I suppose, that if it lives in water it belongs in an aquarium. Such was the case with New York Aquarium. However, except for the odd crocodilian or two, the Aquarium had a difficult job keeping these animals alive during this period.

The first penguin the Aquarium exhibited, for example, didn't last very long. It was a Humboldt penguin and was not used to the summer heat of the city. As an emergency measure it was transported every evening to the roof of the Aquarium to escape the heat that had built up in the Aquarium during the day. Sea lions and seals also need cold air but it was not practicable to bring these animals up to the roof and even if it were the heat during the summer and the polluted air of the city would not have made any difference. In short, at the time the Aquarium was not equipped to display these animals and they had short life spans there.

The story was much the same with the manatees, although their early account is complicated by - of all things - bullet wounds. The following appeared in the NEW YORK SUN of September 6, 1903, announcing the arrival of the first manatee to appear at the Aquarium:

THE AQUARIUM'S SEA COW.

An Eight-Footer Captured In the Sebastian River in Florida.

The great attraction at the Aquarium now is the manatee or sea cow, that was received from Florida on Thursday, and which is now installed in the pool so long occupied by that great fun maker, the West Indian seal. The seal was a big fellow, but this manatee is a bigger creature still, being eight feet in length and weighing about 800 pounds.

This manatee was taken in the Sebastian River, a branch of the Indian, on the east coast of Florida, on Aug. 25, by C. W. Schoonmaker and Capt. John Lynn, of Cocoa, Fla., acting for Mrs. C. F. Latham of Grant, Florida, with whom the New York Zoological Society, under whose management the Aquarium now is, had made a contract for the supply of a manatee. Mrs. Latham had previously supplied to the society other specimens of the animal life of the region.

When taken alive the manatee is captured with a net having a 14-inch mesh.

The manatee hunters spent eight days on the river before they captured this one. There were other manatees about, and one other at least approached the net in the course of that time, but not until the eighth day did they get one where they could secure it.

Thus taken, the manatee was placed in a stout cypress box and taken to Jacksonville, whence it was shipped to this port in the steamer Apache.

On its arrival at the Aquarium the great box was lifted bodily over the side of the pool In which the animal was to be put, the manatee swimming out of its own accord.
As matters go now this is a big one; manatees have been taken that were thirteen feet in length. In the National Museum at Washington there may be seen the skeleton of one that long, but Florida manatees in recent years have not commonly been so big as formerly, and, indeed, at one time, hunted for sport, they came to be in danger of extinction.

Then the Florida Legislature made laws for their protection, and now the manatee is again numerous in the Florida waters, which it inhabits. Special permission was obtained from the Florida authorities for the capture of this example for the Aquarium.

The manatee, or sea cow, is an aquatic mammal, found in salt and in fresh water, but making its home generally in brackish waters and in the lower waters of rivers; it is strictly herbivorous, subsisting on the vegetation found in the water it inhabits.

In its general appearance the manatee much resembles a great seal; it has, however, no hind flippers, but only two forward flippers, and it has a broad, flattened tall. The manatee's tail at once suggests that of the beaver.

As I have mentioned, the life of a manatee at the New York Aquarium was short, and just five months later, the following appeared in the NEW YORK SUN on February 13, 1904:

FLORIDA IS DEAD
Not the State, but its Namesake, the Sea Cow, at the Aquarium.

Florida, the manatee, or sea cow, named for the genial State from which she was brought four months ago, has fallen a victim to the rigorous New York weather. With all its heat the air of the Aquarium was not salubrious enough for her and she caught pneumonia last week.

She was a rare specimen, weighing 750 pounds. Very few of her species have lived as long as she in captivity in the North. Manatees are rare, but the Aquarium managers hope to get another this summer. Florida will be stuffed and mounted in the Museum of Natural History.

A little more information (somewhat belated, however) appeared in the NEW YORK EVENING POST on April 30, 1904:

During the last five months the collector was kept extremely busy as a purveyor to the sea cow or manatee, which required a diet of salt-water eelgrass and pond weed. It chewed up exactly 90 bushel baskets of eelgrass and 20 of pond weed during the five months that it lived in the Aquarium.

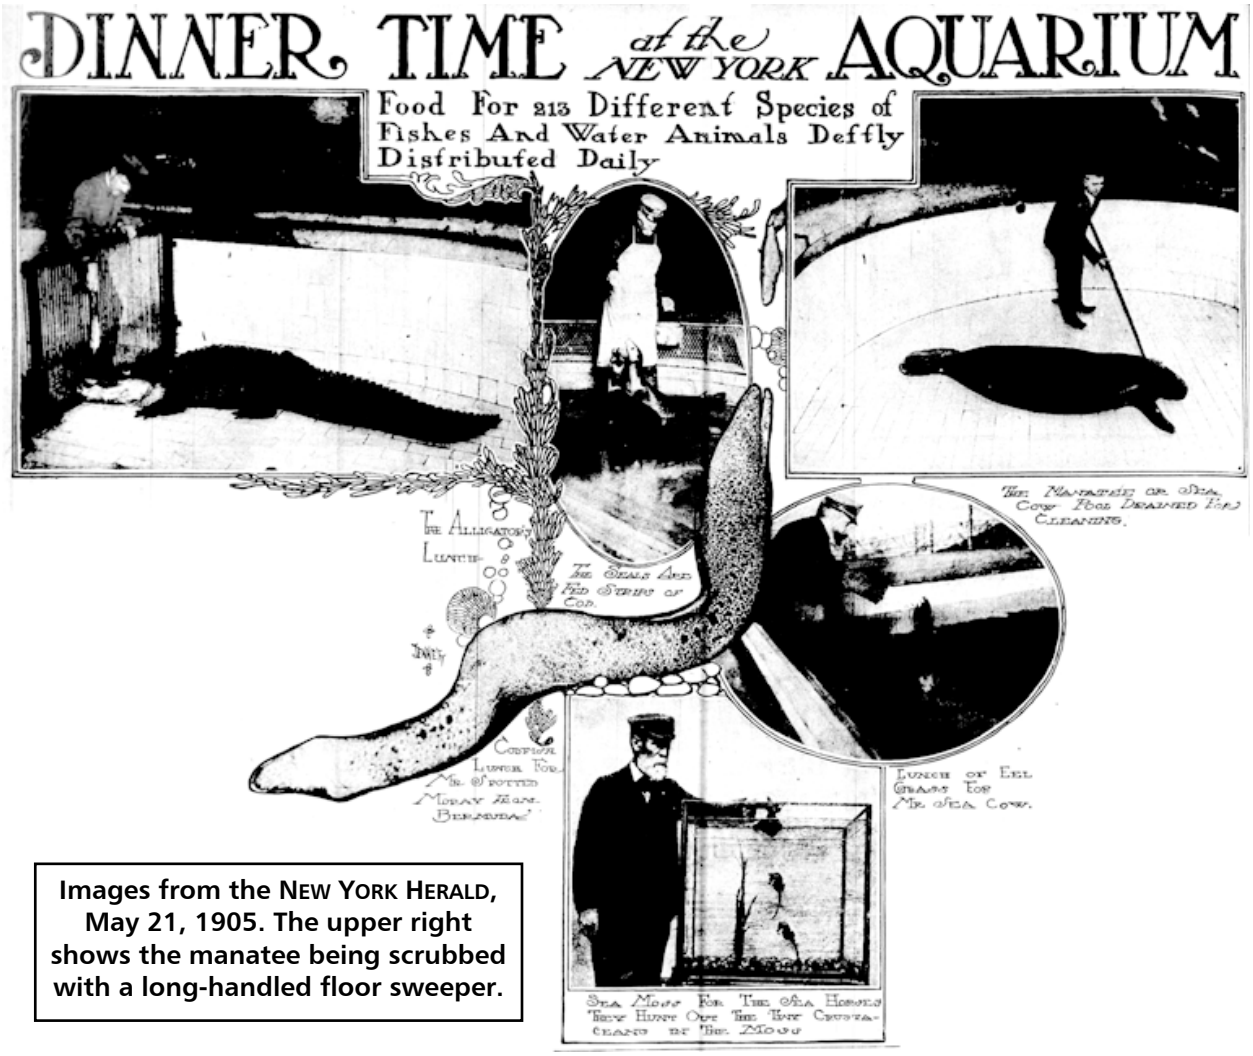
Undaunted, the Aquarium tried again during the summer of 1904 with much greater success. The following is from the NEW YORK HERALD, May 21, 1905:

SOME NEW ARRIVALS.

Among the chief specimens of the Aquarium at present, from its size as well as from the fact that it is almost new to the general eye, is the curious sea cow or manatee from Fort Worth, Florida, probably the only one in captivity. The first successful picture ever obtained at close range, showing the peculiar head and nostrils of one of these creatures raised out of the water, is herewith reproduced. The animals in their wild habitat are very shy and cautious, disappearing immediately upon approach. Owing to their| peculiar tropical habits, they are given special treatment and care, such as a suitable warm temperature, between 70 and 72 degrees, for the water of their pool and a sufficient quantity of nourishing food. Eel grass and lettuce leaves strongly tempt their appetite. The former, however, is used in more abundance when obtainable; a bucketful is usually given for a meal.

The manatee is a female, eight and one-half feet long, weighing six hundred pounds, and was captured by "Alligator Joe" at Palm Beach in a large drag seine of extra strong manila hemp, made for the purpose. Numerous attempts were made at different times for a month, and seven manatees escaped and broke through the net before one was finally obtained. The female was placed about June of the last year in a tile lined pool, twenty feet long by thirteen feet wide, with a depth of four feet of water. The latter is renewed nightly.

The feeding of the animal is watched with unusual interest by the visitors. Mr. W. De Nyse with a suspended handful of eel grass can coax the manatee to raise her head and neck completely out of the water. Sea cows have a peculiar structure, having no front teeth, hind limbs or hip bones, but a huge beaver-like tail. Their bones are said to be the heaviest known among mammals. The best view of the creature is obtained when the water is drained from the pool for tank cleaning, when the whole form is strikingly outlined against the white tiling. The home of the sea cow in the United States is limited to the Indian River lagoons of the east coast of Florida. Other species are found in various tropical regions. In captivity they live seldom longer than five or six months, but the present specimen has survived nine months.



Images from the NEW YORK HERALD, May 21, 1905. The upper right shows the manatee being scrubbed with a long-handled floor sweeper.

The care and express transportation on such a large individual is considerable, and almost equals its sale value. A huge tank was constructed and filled with just enough water to float the massive body. The price asked by the local fishermen for such a scarce and valuable show mammal ranges from $100 to $200. An attempt will be made this spring by the same hunter to capture a male mate. It is said the female hold their young while being nursed in almost human like fashion, keeping the baby sea cow gently and firmly pressed to their sides by means of the fore flipper. Hence they have been thought to be the last of the far fabled mermaids.

This manatee died in the early summer of 1906 but the following article appeared in the August 12, 1906 issue of the NEW YORK TIMES just after its death, either it was overlooked by the editors or it was just too late to cancel its publication:

AQUARIUM ATTRACTION.

a narrow wooden box over twelve feet long and filled with water was employed. On reaching the pier in this city the box with its weighty occupant was hurried to the Aquarium, and the monster was delicately emptied out of its cramped berth into the more roomy quarters of the pool.

Though considerably bruised from close confinement during the trip, a flood of fresh warm water soon revived the exhausted creature, and the ponderous body slowly moved about.

Sea cows have a peculiar structure. They have no teeth, hind limbs, or hips, but a huge, beaver-like tall. It is said the females hold their young while being nursed in almost human fashion, keeping the baby sea calf gently and firmly pressed to their side by means of the fore flipper, like veritable mermaids. The best view of the curious animal is obtained when the water is drained from the pool for tank cleaning. This is not seen by the visitors, who get only a shadowy outline of the manatee through the water, or when he rises to breathe at intervals varying from five to eight minutes.

The Tribune man, through the courtesy of Director Townsend and W. De Nyse, in charge of the marine collection, had an opportunity to obtain a striking photograph of the manatee stretched out on the floor of the pool and showing an attendant with a long brush giving it the first shampoo, The water in the pool is kept at 72 degrees. Nightly the water is drained off, the animal brushed and fresh water let in. When stranded on the tile floor of the pool the animal is helpless and seldom moves. In about ten minutes the water flows in and reaches to a depth of four feet. This affords a comfortable swimming space, the pool being 20 by 13 feet.

The diet for this bulky and important boarder is mainly eel grass, supplemented by lettuce leaves and celery tops. An Aquarium food collector spends much of his time around Graves-end Bay and the nearby inlets searching for eel grass. The feeding of the sea cow is watched with unusual interest by visitors. Mr. De Nyse with a suspended handful of eel grass has coaxed the animal to raise head and neck nearly a foot out of the water. In captivity the manatee seldom lives longer than six months.

The following death notice of the manatee actually appeared in the August 10, 1906 issue of the NEW YORK TIMES:

AQUARIUM'S SEA COW DEAD,
Blood Poisoning the Result of the Valuable Amphibian's Bullet Wound.

The Aquarium's $3,000 sea cow died yesterday of blood poisoning, due to the rifle bullet that some hard-hearted Floridian fired into her back some time before the agent of the New York Aquarium purchased her at Miami, Fla., a little less than two weeks ago.

Why the purchasing agent did not discover the hole In the manatee's back is not known, for one of the very first things that the experts attached to the Aquarium found out about the now famous sea cow was that there was a big hole in her back, which their practiced eyes knew did not bode well for the future health of the ungainly amphibian, to get which the city had gone to such expense.

When the sea cow arrived at New York a week

FEEDING THE MANATEE. From the August 12, 1906 issue of the NEW YORK TIMES.

ago last Monday she was taken at once to the Aquarium and put in one of the biggest of the marble-lined pools in the building. It was while feeding her that an employee noticed the hole in her back. The officials of the New York Zoological Society were promptly notified, and three doctors hurried down from the Bronx to perform an operation. The manatee was manacled, and nearly a foot underneath the outer hide the doctors found a .38-calibre rifle bullet. The wound was cleaned and everybody thought that the worst was over,

Wednesday morning, however, when the man who had the job of feeding the sea cow went to her pool he noticed that she was ill. The doctors were summoned and the illness was diagnosed as blood poisoning. Everything that could be thought of to relieve the manatee was done, but it was of no use, and the sea cow grew rapidly worse. At 1 o'clock yesterday morning she sank into a coma, from which it was impossible to rouse her. Three hours later she died.

Although the exact price paid for the manatee has never been made public, no one connected with the Aquarium has ever denied that the report that it was in excess of $3,000 was wrong. As she was on exhibition not quite eight days, the sea cow, therefore, cost the City of New York about $375 a day. The hide of the sea cow will be mounted and presented to the Museum of Natural History. Whether the Aquarium will buy another is not known, but if one is procured it is certain that it will not have a bullet hole in its back if the Aquarium can help it.

The article was quite critical of the Aquarium, raising the issues of why the purchasing agent did not discover the hole in the manatee's back and especially that of the high price paid for the animal, which was quite a lot for 1906, i.e., the equivalent of about $65,000 today.

As it turned out, the $3,000 amount mentioned in the article was not true and the Director of the Aquarium, Charles H. Townsend replied in the August 11, 1906 edition of the NEW YORK TIMES:

THE AQUARIUM'S SEA COW.

It Was Presented to the City by Mr. Dimock, Who Didn't Pay Any $3,000.

To the Editor of the New York Times:
Will you have the kindness to correct an error which has been making the rounds of the newspapers to the effect that the large sea cow which has just died at the Aquarium cost $3,000. As a matter of fact, the animal cost the city nothing. It was presented by Mr. A. Dimock of Marco, Fla., and was transported to New York by the Florida East Coast Railway Company and the Clyde Steamship Company absolutely free of charge.

I think you will agree with me that it is not quite fair to Mr. Dimock and the officers of the transportation companies who have been so generous to allow the report to become current that it was purchased.

As the usual price of a Florida sea cow (or manatee) is $100, the statement that this specimen cost the city $3,000 is somewhat of a reflection on the judgment of those who purchase for the Aquarium.

The animal was very large and. heavy, and died from injuries probably received during capture. It was 10 feet 4 inches long and weighed 910 pounds. The specimen has been turned over to the American Museum of Natural History in Mr. Dimock's name.
C. H. TOWNSEND.
Director of the Aquarium.
New York, Aug., 10, 1006.

This brings us now to Mr. Dimock. A.W. (Anthony Weston) Dimock was born on August 27, 1842 in Yarmouth, Nova Scotia, Canada. Dimock was a Wall Street speculator in the 1870s-80s and at age 23 had dominated the gold market. He was also a steamship line owner, sportsman and early promoter of Florida game fishing. After an astonishing career on Wall Street, Dimock retired and became an author, writing adventure books for boys (Dick among the lumber-jacks, 1910, Dick among the miners, 1913) and magazine articles about outdoor life and nature subjects (Book of the tarpon, 1911, Florida enchantments, 1926). His autobiography, "Wall Street & the Wilds" (1915) is a fascinating read and is available on the Internet as a free download. Dimock died on September 13, 1918.

In 1887 Dimock began photographing wild life in earnest when in the winter and spring he exposed several hundred 5x8 dry plates in the Florida wilds and on the west coast where he had close

encounters with bears and other animals. With regard to Florida, Dimock wrote:

> **I pictured birds of many kinds, on their nests and in flocks, soaring in the air like osprey and man-o'-war hawks, diving for their prey like pelicans or stalking it in the shallows like the great white heron. The roll of the porpoise, or dolphin, and the head of loggerhead and green turtle as they came to the surface to breathe were caught by the camera. The cottonmouth coiled among the mangroves as well as the slow-growing oysters on their branches became food for the camera. The leap of the tarpon, the struggles of the stricken sawfish, and the wing tips of the sportive devil fish as they played above the surface were reproduced on the sensitive plate.**

On September 12th, 1893, Dimock entered the Hunter's Cabin of the Chicago Exposition, where a hunter was exhibiting photographs of wild animals. He was addressing a group of visitors and as Dimock approached him the speaker said:

> **I was the first to take photographs of wild animals in their native surroundings," then pausing a moment and extending his hand toward me he continued, "excepting that man whom I met years ago in the Rockies and again in Florida engaged in the same work.**

Dimock also wrote about the manatees he caught for the Aquarium:

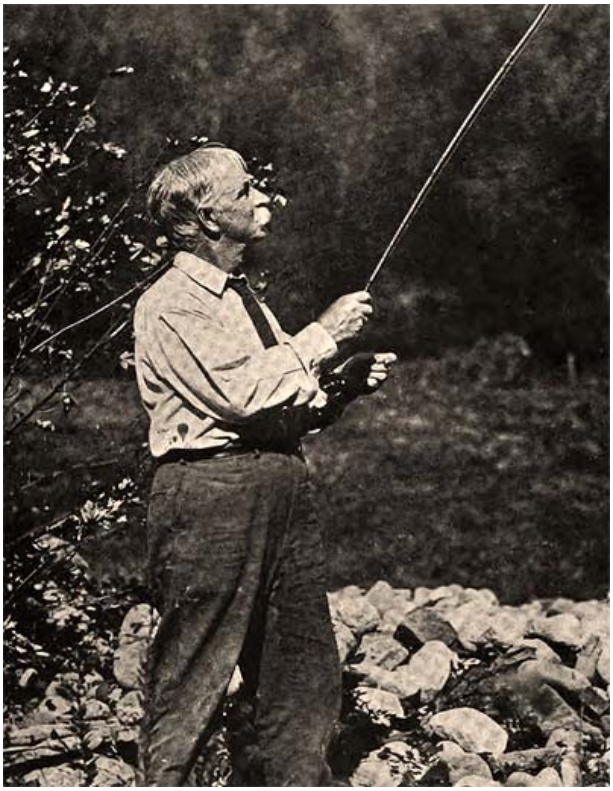
> **We captured manatees for the New York Aquarium and caught crocodiles and pelicans for the Zoo. It was chance that brought the shipment of the manatees, or sea cows. I had looked for them during twenty years without finding one. Then it chanced that I struck a strange creature with my light harpoon, just off of Madeira Hammock. It proved to be my long-sought manatee, eleven feet long and of massive proportions. We were swamped four times while working him into shallow water, where we went overboard with him and handled him until he was unafraid. We made a harness of rope and leaving him fastened to an anchor by a two hundred foot line, in a pasture of manatee grass, sailed for Miami and a telegraph office. I gave the manatee to my friends of the Zoo and of the Aquarium by wire and with great difficulty secured official permission to ship the creature. But when I returned to where I had left my prize I found that he had broken his bonds and shipped himself to parts unknown. Returning to Miami I wired my apologies and the promise to find another manatee if it took me a year, which it did.**

Dimock kept his promise to send another manatee. The following is from the September 8, 1906 issue of the NEW YORK HERALD:

> ***NEW SEA COW IS COMING.***
> ***Florida Man Donates Another Manatee to Replace One Which Died at Battery Park Recently.***
>
> **For a new manatee, or sea cow, which is expected to arrive at the Aquarium any day, a special tank was filled yesterday. A few weeks ago a female manatee, which had become quite an attraction at the "fish theatre," had the bad taste to die.**
>
> **The news of the cow's death reached Florida and A. W. Dimock, of Jacksonville, was so moved that he donated and shipped the manatee, which is en route to this port and destined to become a Battery attraction.**

On October 9, 1906 the new manatee had arrived and the NEW YORK EVENING POST described how Director Charles H. Townsend described the new procedures intended to keep it alive, since it was the fourth manatee received by the Aquarium since 1903:

> **HOPE FOR MANATEE IV.**
> **Aquarium's Latest Specimen is Young and May Avoid its Predecessors' Fate.**
>
> **Director Townsend and his assistants at the Aquarium are lying awake nights devising precautions the new manatee, recently arrived from Florida, alive during the winter months. This is the fourth sea-cow the Aquarium has had, and none of its predecessors has lived more than a few months. They were all full grown, however, and had been injured in capture. The present specimen is young and lusty. A week after its taking, one of the attendants discovered a hole in its side. A veterinary diagnosed the hurt as a gunshot would. He probed, found a bullet imbedded in the cow's blubber and extracted it. Since then manatee is being carefully watched and attended, its wound is healing slowly.**
>
> **"I hope to make a recorded with this manatee by pulling it through the winter and if I succeed in that, there is every reason to hope we can keep it**



Anthony Weston Dimock (1842-1918)

alive and well for two or three years," said Director Townsend to-day. "The great danger is from pneumonia. The manatee comes to the surface every eight or ten minutes to breathe, and the minute it gets a sniff of frost-laden air, over it goes with pneumonia and there's one chance in a million of saving it. It is easy enough to keep the water at the proper temperature, but we are likely to have winter storms that render it difficult to maintain the atmosphere in the building at the proper height. Then, too, there is danger of the night attendants becoming negligent and permitting the temperature to get too low. To guard against this, I intend to cover the manatee's big pool with glass to exclude all drafts, and I shall take other precautions which ought to insure its living."

"It will be a pity if we lose this sea-cow, for we don't know when we could procure another. When we secured its predecessor, the statement was published that it had cost the Aquarium several thousand dollars, and now all the fishermen on the Florida coast are demanding fabulous sums for capturing the animals. As a matter of fact, that and the one now at the Aquarium were presented to us by A.W. Dimock of the Florida East Coast Line, both the railroads and the steamship company furnishing free transportation from Florida to New York."

The reason that the bullet hole wasn't discovered right away was that it was embedded in the manatee's blubber and was causing it no discomfort. In any case, the surgery was successful and two years later, things were looking good for the new manatee. The following is from the February 2, 1908 issue of the NEW YORK SUN, and although it only pertains in part to the manatee, I reproduce it here in its entirety:

SEA DWELLERS AT DINNER. FEEDING THE CAPTIVE FISHES AT THE AQUARIUM.
The Crocodile the Most Indifferent of the Sea Boarders - Fishes That Insist on Certain Delicacies - The Manatee's Shampoo—Spice or Variety In the Menu.

One of the most picturesque sights at the Aquarium in Battery Park is the serving out of the daily rations to the 2,000 captive sea dwellers, little and big. The 100 wall tanks and spacious floor pools are said to shelter the largest colony of fishes - 213 different kinds - ever gathered under one roof in the world. The fact that 2,131,333 persons passed through its doors during the last year, an average of over 5,.000 dally, stamps it as one of the most popular show places in the world.

Getting up the daily menu for the fishes requires more labor and expense than one might suppose. One attendant devotes about half of each day to the preparation of the food, and several others

Dimock captioned this image "There isn't any real danger in clinging to the flipper of a thousand-pound manatee while he slings you around in the water, but it makes a picture quite irresistible to the magazineman."

are kept busy the remainder of the afternoon in feeding the fishes. The food is varied to suit the fishes, and includes beef - sliced, chopped or minced - liver and fish, cod and herring mostly. Minnows, when procurable in abundance, are provided at the rate of ten or twelve quarts daily, and are simply thrown alive into the tanks, where the larger fishes soon dispose of them. Shrimps to the extent of about fifteen or twenty quarts a week, four or five bushels of mussels a year, small crabs, such as fiddler crabs, stone crabs and young blue crabs, by the thousand, marine worms at the rate of 500 or 600 a month, small soft clams in quantities of from 10,000 to 12,000 during the summer season, are also on the menu. The average board bill for the Aquarium's guests for a month is $100.

Among the chief attractions of the Aquarium at present, from the fact that it is comparatively new and rare here, is the curious tea cow, or manatee, from Florida, the only one in captivity in this country. It was presented to the Aquarium by A. W. Dimock and has survived eighteen months, which is the record time for a manatee to live in confinement.

The sea cows in their wild habitat are especially shy and cautious of man, diving and disappearing immediately on his approach. Being of tropical origin, the manatee requires special treatment and care. The water in the pool is kept at a suitably warm temperature, between 70 and 72 degrees. Eel grass and lettuce leaves are its chief fare. The former is used chiefly when obtainable.

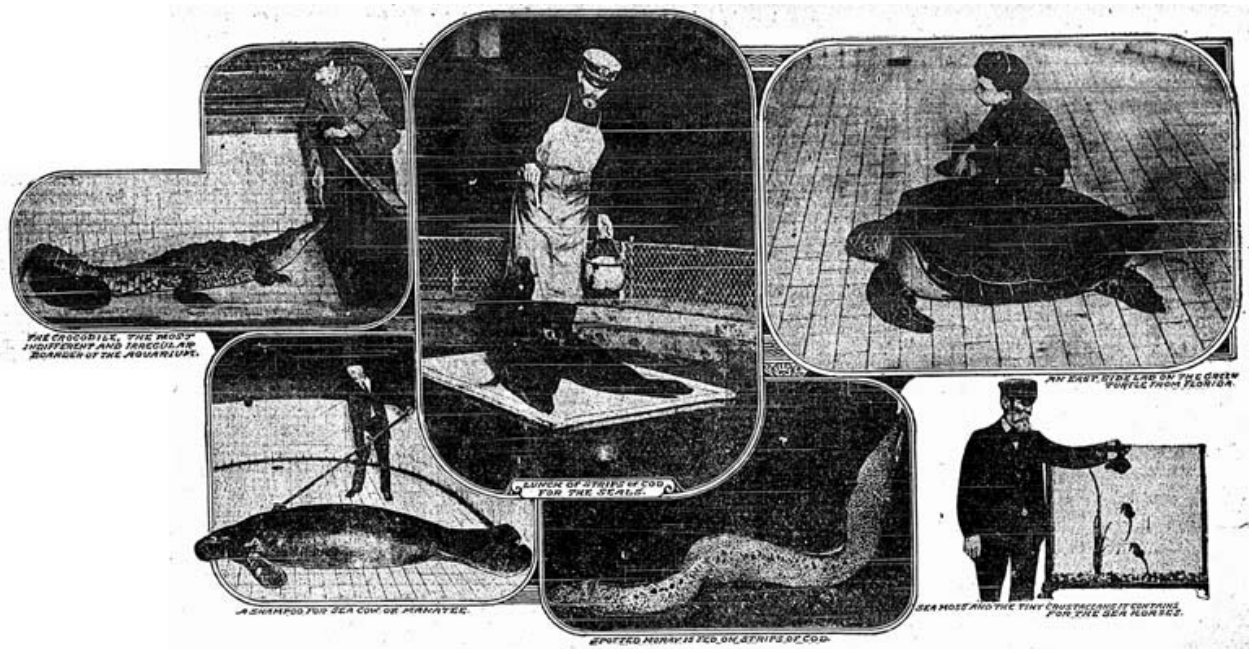
The sea cow was captured in a large drag seine. Numerous attempts to take one had been made at different times for a month, and many broke through the net and escaped before one was finally obtained.

The manatee has considerable swimming space in its tile lined pool, which is twenty feet long by thirteen wide, with a depth of four feet of water. The water is renewed dally.

The feeding of the sea cow is watched with interest by the visitors. The best view of the animal is obtained when the water is run off in order that the pool may be cleaned, thus leaving the whole form or the manatee strikingly outlined. A very clear view of this strange creature is shown in the photograph here reproduced, which was taken after 5 P. M., when all visitors were out.

The picture shows the manner of giving this animal a shampoo. In this process *a* long handled brush is used to brush off the day's accumulation of various substances. The manatee seems to enjoy its daily rubdown and the inflow of fresh water, after which it will settle down in one corner of the pool for slumber.

Another star attraction of the Aquarium is the silver bedecked spotted moray. This extraordinary eel inhabits the caverns, grottoes and coral reefs



"SEA DWELLERS AT DINNER." From the February 2, 1908 issue of NEW YORK SUN.

of Bermuda, and is one of the most interesting of the many strange sea marvels from this tropical isle, which is celebrated for its gorgeous colored fishes.

A whole tank is given up to the display of this brilliant coated moray. The picture here reproduced shows the long serpentine creature in a characteristic attitude as it is about to receive a strip of cod for luncheon. This, the favorite food of the moray, is passed to and fro close to its open mouth, till the animal suddenly gulps the tempting morsel.

In the ocean depths the morays are voracious, even cannibalistic in their habits, and are the terror of the other fishes. With their long bodies partly concealed by being wound around some ledge or crevice they lie in ambush, their jaws with lance-like teeth open half a foot or more, in readiness to dart at and swallow the first unsuspecting victim that swims by.

They are caught in traps and also on hooks. The native Negro fishermen lose no time in cutting off the head of one as soon as it is landed in the boat. If a big specimen happens to get loose a panic is likely to start among the crew and they will jump overboard on the instant.

Of all the Aquarium's boarders the little sea horses, six inches long, are the most fantastic in appearance. They are so named from the close resemblance of their head to that of a horse.

The food necessary to whet their appetite is somewhat odd and hard to obtain. It has been found that they can be kept in good condition only when they are well supplied with grammarus, a very minute crustacean procured by gathering bunches of fine sea moss, which it inhabits
In feeding the sea horse's mouth is placed near the prey, for which it constantly searches, and is suddenly opened. The cheeks being inflated at the same time, the food is captured with the inrush of water. When bunches of sea moss are dropped into the tanks the fish immediately scamper to the bottom and pick out the minute life from the weeds.

The sea horse is probably the only fish having a prehensile tail, which it uses in a monkey-like fashion, constantly anchoring itself to weeds, stones and slicks. The position of the body is usually vertical, especially in swimming.

These little creatures are found all along the American coast from Cape Cod to South Carolina. There is one remarkable feature about them not known generally, Contrary to the rule with the rest of the animal World, the eggs while hatching are carried by the male in a pouch, and the young are asked to return to this for shelter. Hundreds, probably thousands, of baby individuals are thus carried around by the incubating paternal member of the family in his incubating pocket while Mrs. Sea Horse, released of care, roams fancy free.

The clever maneuvers of the little harbor seals from the Maine coast share the popular interest with the sea cows. They are hearty eaters and have stripes of cod and herring for their luncheon. These are usually thrown into the pool, but oftentimes when the seals come up on the platform the food is suspended over their heads for a moment and then snapped at.

These creatures are rapidly disappearing from the Atlantic coast. Owing to their ravages upon the fish, some of the New England States now offer a bounty of from $1 to $3 a head for the destruction of these animals in order to protect the fishing industry.

L. B. Spencer has in the laboratory and in the balanced aquariums many minute fresh water and salt water forms of life which are daintily fed on bits of beef. His collection is especially rich in examples of living coral and fine sea anemones.

This nature study department, supplemented by Mr. Spencer's short lectures and object lesson talks, furnishes a popular educational attraction which is well attended by teachers and school children.

The Florida crocodile is about the most indifferent and irregular of the Aquarium's boarders, as days and even weeks will pass without its taking any food. When rations are to be served the animal is roused from stupor by being punched. Its anger is shown by growling, accompanied by opening its ponderous jaws, in which the attendant swiftly lodges a big fish.

In the floor pool containing the nine large sea turtles of four different kinds the star is a giant green turtle from Florida weighing 313 pounds. His shell is as big as a small dining table. The size may be judged from the East Side boy seated on his back.

This turtle and his mates are fed on a choice menu or clams, eel grass, lettuce and whelks.

POST SCRIPT

After having doubled its weight, the manatee ultimately died of an intestinal disorder. In 1916, the

Aquarium received an entirely different kind of manatee, one from the Amazon. These early attempts at maintaining Amazonian manatees in captivity led to the discovery of the temperature range that these manatees preferred - 78 degrees. By 1939, the Aquarium had little difficulty in keeping any kind of manatee alive for extended periods of time, and with the development of new and better technologies and quarters, the problems in keeping penguins, sea lions, seals and manatees have finally been resolved for all public aquariums.

THERE IS NO SUCH THING AS A FISH!

by Albert J. Klee, Ph.D

(Aquarium Hobby Historical Society, Yahoo Files, February 28, 2015)

Though this be madness, yet there is method in't.
--W. Shakespeare

It is certainly not the least charm of a theory that it is refutable.
--F. Nietzsche

False facts are highly injurious to the progress of science, for they often endure long; but false views, if supported by some evidence, do little harm, for every one takes a salutary pleasure in proving their falseness.
--C. Darwin

An enthusiast sways humanity by...dinning it into our ears that this or that question has only one possible solution; but when once he is gone, an army of quiet and influential people set to work to remind us of the other side and demolish the generous imposture.
--R. L. Stevenson

This essay seeks to analyze cladistics with regard to its assumptions, strengths and weaknesses, and to compare it with its competition.

EVOLUTIONARY SYSTEMATICS

Evolutionary systematics arose as a result of the influence of the theory of evolution on Linnaean taxonomy. The idea of translating Linnaean taxonomy into a sort of dendrogram of the Animal and Plant Kingdoms was formulated toward the end of the 18th century, well before Charles Darwin's book *On the Origin of Species* was published. The first to suggest that organisms had common descent was Pierre-Louis Moreau de Maupertuis in his 1751 *Essai de Cosmologie*, Transmutation of species entered wider scientific circles with Erasmus Darwin's 1796 Zoönomia and Jean-Baptiste Lamarck's 1809 *Philosophie Zoologique*. The idea was popularized in the English-speaking world by the speculative but widely read *Vestiges of the Natural History of Creation*, published anonymously by Robert Chambers in 1844.

Following the appearance of *On the Origin of Species*, Tree of Life representations became popular in scientific works. In *On the Origin of Species*, the ancestor remained largely a hypothetical species; Darwin was primarily occupied with showing the principle, carefully refraining from speculating on

relationships between living or fossil organisms and using theoretical examples only. In contrast, Chambers had proposed specific hypotheses, the evolution of placental mammals from marsupials, for example. Following Darwin's publication, Thomas Henry Huxley used the fossils of *Archaeopteryx* and *Hesperornis* to argue that the birds are descendants of the dinosaurs. Thus, a group of extant animals could be tied to a fossil group. The resulting description, that of dinosaurs "giving rise to" or being "the ancestors of" birds, exhibits the essential hallmark of evolutionary taxonomic thinking.

PHENETICS

A French botanist, Michel Adanson (1727-1806), worked in Africa and used 65 different characters to classify plant families. It formed the philosophical (if not actual) basis for the phenetic or numerical taxonomic (the names are often used interchangeably) methods that followed. In the 1950s, Peter H. A. Sneath of England was working on bacterial classfication systems using computers. Sneath and Robert R. Sokal (Austrian-American biostatistician and entomologist) teamed up in 1963 to produce *Principles of Numerical Taxonomy*. Later, Sneath and Sokal (1973) wrote *Numerical Taxonomy: The Principles and Practice of Numerical Classification*. This became a standard work and started a bandwagon rush by taxonomists to employ these methods in classification. In practice, measurements were made of a large number of characters of a taxon, e.g., at least 60 per plant and often 100 or more. No special importance was attributed to any one of the characters. After the measurements were complete on hundreds of individuals, the data were analyzed statistically with computer programs and cluster analysis or other methods to show purported natural groupings of plants with overall similarities. Systematists' interpretations were thought to be minimized in this fashion.

CLADISTICS

Cladistics (from klados = "branch") is an approach to biological classification in which organisms are grouped together based on whether or not they have one or more shared unique characteristics that come from the group's last common ancestor and are not present in more distant ancestors. Therefore, members of the same group are thought to share a common history and are considered to be more closely related. Cladistics was first proposed by Willi Hennig in 1950 as an alternative to then current systematic methods. It wasn't until 1966, when Hennig's original work was revised and translated into English, that cladistics began to have a substantial impact on English-speaking evolutionists.

Hennig argued that methods current in his day had two fundamental flaws: they were hopelessly subjective, and they failed to properly identify evolutionary relationships. Traditional evolutionary systematics was generally driven by the intuition of the individual biologist, which of course creates problems when disagreements arise because there are no evidential reasons to choose between the two. Phenetics sought to get around this by subjecting characters of organisms to pairwise comparisons, and thus evaluating the overall similarity between taxa (a taxon, plural = taxa - a back-formation from taxonomy - is a group of one or more populations of an organism or organisms seen by taxonomists to form a unit; common taxa among fishes are species and genera). However, such a method would seem ill-equipped to deal with taxa that have similar forms, but are clearly not closely related, e.g. sharks, ichthyosaurs and dolphins. Character weighting then became inherent in the analysis, and it thus became as subjective as traditional Darwinian taxonomy.

The basic idea behind cladistics is that members of a group share a common evolutionary history, and are closely related, more so to members of the same group than to other organisms. These groups are recognized by sharing unique features which were not present in distant ancestors. These shared derived characteristics are called **synapomorphies** (from syn meaning 'together' + apo meaning 'separate' + morph meaning 'form').

Note that it is not enough for organisms to share characteristics; in fact two organisms may share a great many characteristics and not be considered members of the same group. For example, consider a jellyfish, starfish and a human; which two are most closely related? The jellyfish and starfish live in the water, have radial symmetry and are invertebrates, so you might suppose that they belong together in a group. This would not reflect evolutionary relationships, however, since the starfish and human are actually more closely related. It is not just the presence of shared characteristics which is important, but the presence of shared ***derived*** characteristics. In the example above, all three characteristics are believed to have been present in the common ancestor of all animals, i.e., primitive, and so are trivial for determining relationships, since all three organisms in question belong to the group "animals." While humans are different from the other two organisms, they differ only in characteristics that arose newly in an ancestor which is not shared with the other two. Choosing the right characters, therefore, is one of the most important steps in a cladistic analysis.

JARGON YOUR MEMORY

Jargon is the technical terminology or characteristic idiom of a special activity or group. It is commonplace for each science to create their own jargon, and taxonomists are no exception. The philosopher, Étienne Bonnot de Condillac, observed in 1782 that "every science requires a special language because

Proponents of Cladistics. From left to Right: Willi Hennig (1913-1976), Joel J. Cracraft and Gareth Nelson.

every science has its own ideas." Within each field, terms have one or more specific meanings that are not necessarily the same as those in common use and, in many cases, this causes a barrier to communication with those not familiar with the language of the science. Two examples we have just seen are taxa and synapomorphy, and we are about to add another two.

The terms "primitive" and "derived" are often avoided by cladists since those terms have been much abused in the past. Thus the convention is to call the "original" state of the characteristic "**plesiomorphic**" (from plesio meaning 'near' or 'close to' + morph meaning 'form') and the "changed" state "**apomorphic**" (from apo meaning 'separate'). Figure 1 shows examples of apomorphy, plesiomorphy and synapomorphy. Note that in the apomorphy the trait is shared but it is not derived

FIGURE I

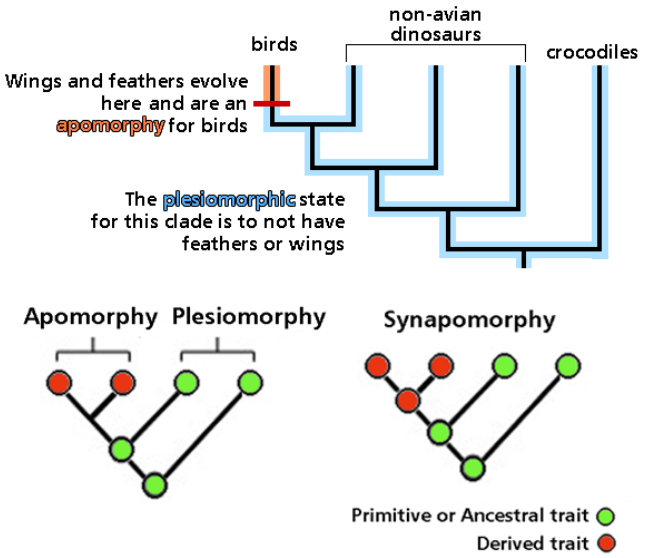

TABLE I

	EVOLUTIONARY SYSTEMATICS	NUMERICAL TAXONOMY	CLADISTICS
Principal proponent(s)	Mayr, Simpson, and Ashlock	Sneath and Sokal	Hennig, Wiley, Cracraft, Eldredge, Nelson, Platnick, Schuh
Operational basis of relationship; what determines relatedness?	All shared characters	All shared characters	Synapomorphies
Weighting of items above; how are the characters evaluated one to another?	unequal, some weighted to be more important than others; derived usually weighted more than primitive	equal or unequal	equal or unequal, depending upon the type of data.
Is it numerical? Can the operational principles be formulated in terms of mathematical algorithms?	No*	Yes	Yes
Is the degree of difference between taxa used to determine relatedness (and resultant taxonomy)?	Yes	Yes	No*
Does its taxonomic applications reflect phylogeny?	Not necessarily*	Not necessarily*	Yes
Underlying principles	Overall similarity, degree of difference, and sister-group relationships must be used to infer relationship and generate classification.	Overall similarity infers relationship; characters evolve at equal rates.	Shared-derived characters infer sister group relationships; classifications should exactly reflect sister group relationships.

*A perceived "weakness" of the approach.

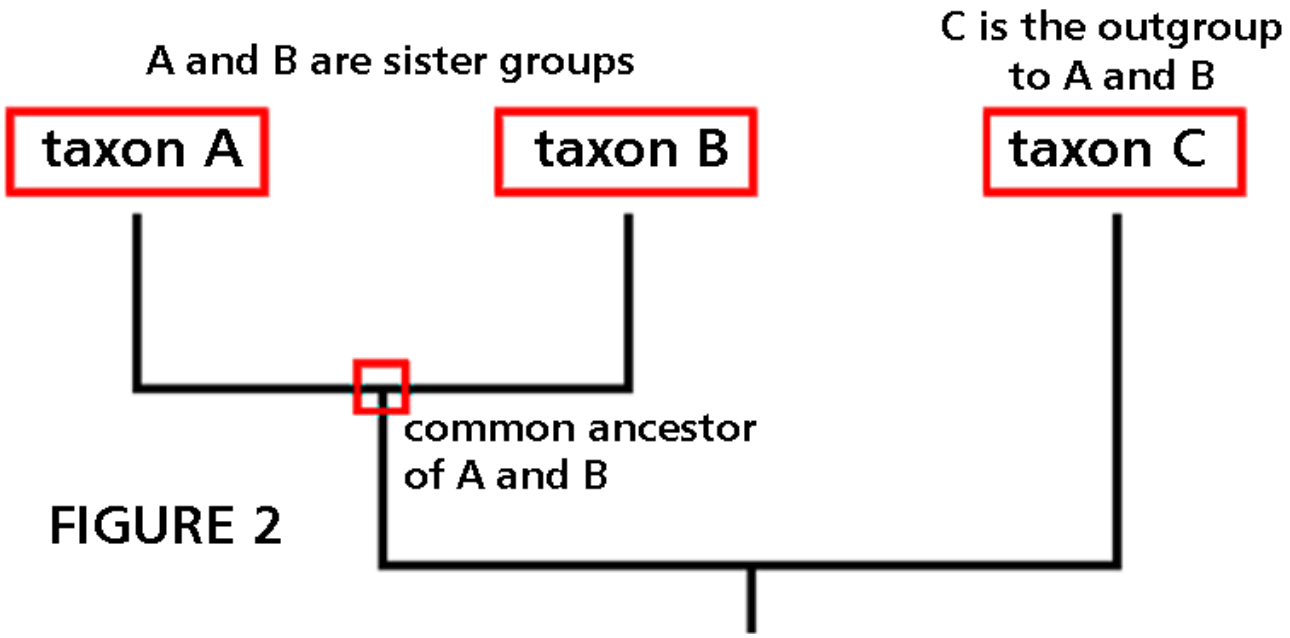

FIGURE 2

from a common ancestor. In the synapomorphy it is.

The three schools are compared in Table I and measure up, roughly, in the following way:
(1) Phenetics is practical (at least in principle) but not objective.
(2) Cladistics is objective and natural but (often) not practical.
(3) Evolutionary classification is a somewhat muddled combination, traditionally useful but not rigorous by any strict criterion.

CHARACTERISTICS OF PHILOGENETIC TREES

A phylogeny, or evolutionary tree, represents the evolutionary relationships among taxa. The tips of the tree represent groups of descendent taxa (often species) and the nodes on the tree represent the common ancestors of those descendants. Two descendants that split from the same node are called sister groups. In the tree shown in Figure 2, species A & B are sister groups — they are each other's closest relatives. Adjacent taxa are called "sister groups" or

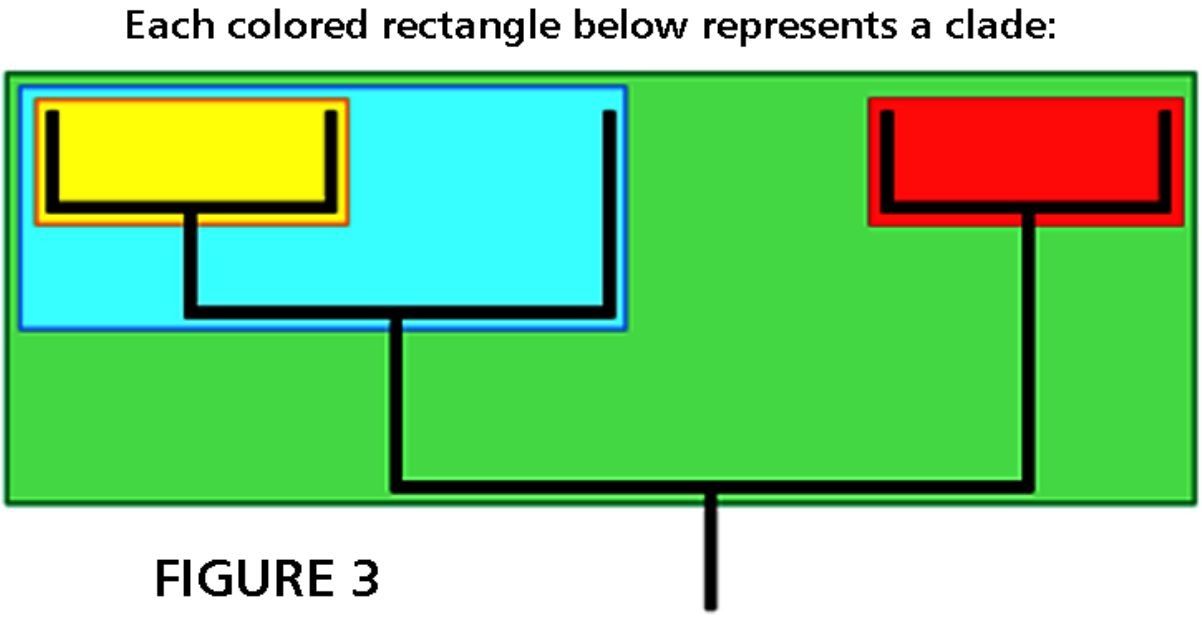

FIGURE 3

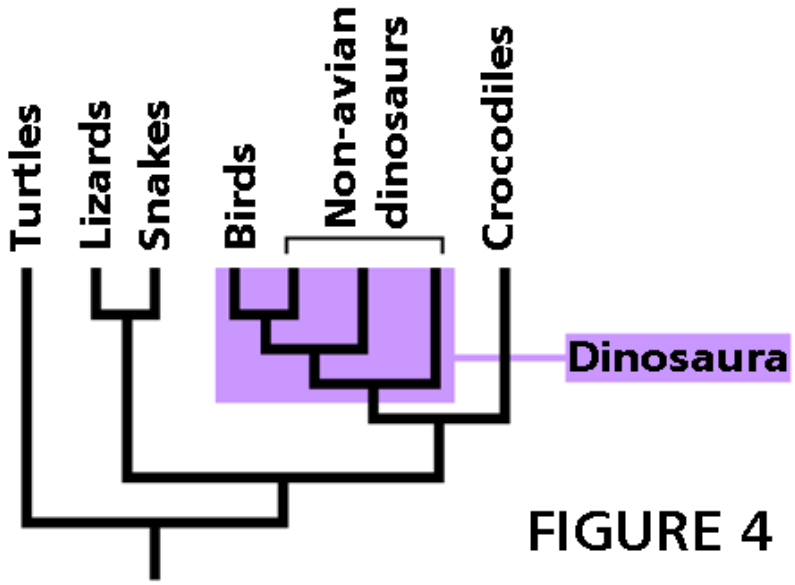

FIGURE 4

"clades." They are usually presumed to be descendants of a common ancestor. My brother and I form a sister group (pardon the confusion of gender) because he is my only sib and neither of my parents had any other children.

Many phylogenies also include an outgroup — a taxon outside the group of interest. All the members of the group of interest are more closely related to each other than they are to the outgroup. Hence, the outgroup stems from the base of the tree. An outgroup can give you a sense of where on the bigger tree of life the main group of organisms falls. It is also useful when constructing evolutionary trees.

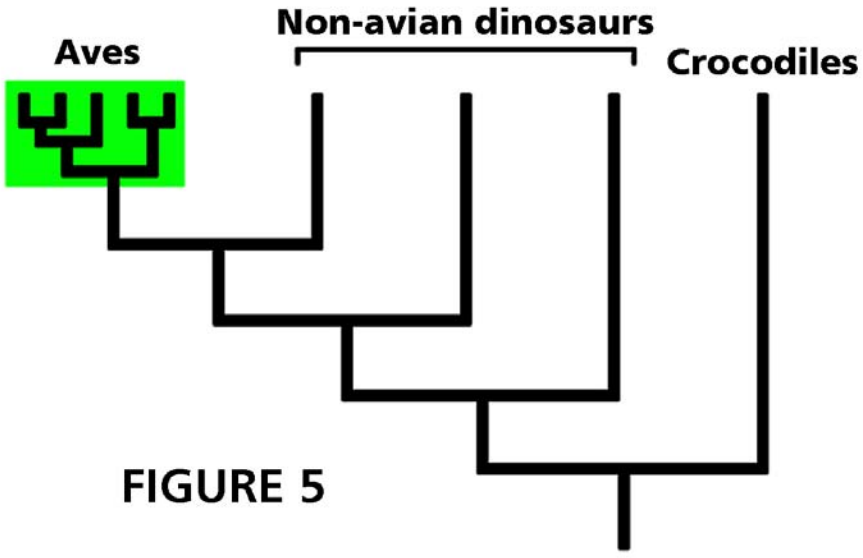

FIGURE 5

Evolutionary trees depict clades. A clade is a group of organisms that includes an ancestor and all descendants of that ancestor. You can think of a clade as a branch on the tree of life. Some examples of clades are shown on the tree in Figure 3 where each colored rectangular represents a clade.

LINNAEAN VERSUS PHYLOGENTIC CLASSIFICATION

In contrast to the traditional Linnaean system of classification, phylogenetic classification names only clades. For example, a strictly Linnaean system of classification might place the birds and the non-Avian dinosaurs into two separate groups. However, the phylogeny of these organisms reveals that the bird lineage actually branches off of the dinosaur lineage, and so, in phylogenetic classification, the birds should be considered a part of the group Dinosauria (Figure 4).

Phylogenetic classification has two main advantages over the Linnaean system. First, phylogenetic classification tells you something important about the organism, i.e., its evolutionary history. Second, phylogenetic classification does not attempt to rank organisms. Linnaean classification ranks groups of organisms artificially into kingdoms, phyla, orders, etc. This can be misleading as it seems to suggest that different groupings with the same rank are equivalent. For example, the cats (Felidae) and the orchids (Orchidaceae) are both family level groups in Linnaean classification. However, the two groups are not comparable:

(1) One has a longer history than the other. The first representatives of the cat family Felidae probably lived about 30 million years ago, while the first orchids may have lived more than 100 million years ago.

(2) They have different levels of diversity. There are about 35 cat species and 20,000 orchid species.

(3) They have different degrees of biological differentiation. Many orchids belonging to different genera are able to hybridize. But the same is not true of cats — house cats (belonging to the genus *Felis*) and lions (belonging to the genus *Panthera*) cannot form hybrids.

WHAT'S IN A NAME?

Biologists deal with phylogenetic classification by de-emphasizing ranks and by reassigning names so that they are only applied to clades. This means that one's use of biological names doesn't have to change very much. In many cases the Linnaean names are perfectly good in the phylogenetic system. For example, Aves, which is the class of birds in the Linnaean system, is also used as a phylogenetic name since birds form a clade (Figure 5). Most of the specific names that one is accustomed to using (e.g., *Homo sapiens* and *Drosophila melanogaster*) have not changed at all with the rise of phylogenetic classification. However, there are some names from Linnaean classification that do not work in a phylogenetic classification. For example, as we shall see, the fishes do not form a clade and thus cannot be a named group in the phylogenetic system.

TYPES OF PHILOGENIC TREES

Just as a genealogist might construct a family tree to illustrate ancestors and descendants within a human family, systematic biologists (taxonomists) construct phylogenetic trees to depict relationships among groups of living organisms. There are several ways to create such trees. The method chosen often depends on the distinctiveness of each taxon, the type and quality of categorical data available, and the scientist's overall philosophy toward classification.

(1) Evolutionary Systematics is a synthesis of phenetics and cladistic principles and so there is no single underlying method of analysis. In the "old days" (before the twentieth century), classification was largely carried out by "gentlemen" scientists who based their identifications of organisms upon a few "important" characteristics and a "gut feeling" developed during many years experience. Proponents of evolutionary systematics today attempt to produce a phylogenetic tree (dendrogram) that faithfully reproduces a taxon's lineage: each junction point represents a common ancestry and the length of each branch reflects the amount (or duration) of evolutionary divergence from the presumed ancestor. Even under the best of circumstances, developing such a dendrogram requires a great deal of speculation because the data is often fragmentary (or entirely absent).

(2) Phenetics is advanced by some systematic biologists who argue that it is pointless to create an evolutionary tree because there is no way to prove whether it is right or wrong. Instead, they advocate the phenetic approach to classification, i.e., grouping organisms entirely on the basis of physical similarities. In a phenogram, each branch point represents a step of increasing similarity - taxa which share the most characters (both primitive and advanced) perch next to one another in the family tree even though they do not necessarily share a common ancestor.

(3) Cladistics, strives to reflect evolutionary lineage without "creating" hypothetical ancestors. This is accomplished by first using an "outgroup" to determine which characteristics are primitive" (ancestral) and which are "advanced" (derived). This outgroup is considered to be distantly related to the taxa whose phylogeny we want to know and let it be our standard. We assume that the character states that it shows are ancestral, and score the other taxa (the ingroup) by comparison with it. A cladogram is constructed by grouping taxa that share the greatest number of derived characters.

CLADISTICS VERSUS PHENETICS

We can illustrate the distinction between cladistic and phenetic analyses by imagining the evolution of metal fasteners that include the rivet, the nail, the screw and the bolt (Figure 6). Since the rivet has the simplest structure we will presume it to be the common ancestor of all fasteners. Among the other fasteners, there are at least seven derived character states (physical characteristics not found in rivets: 1.) notched heads, 2.) rounded heads, 3.) hex

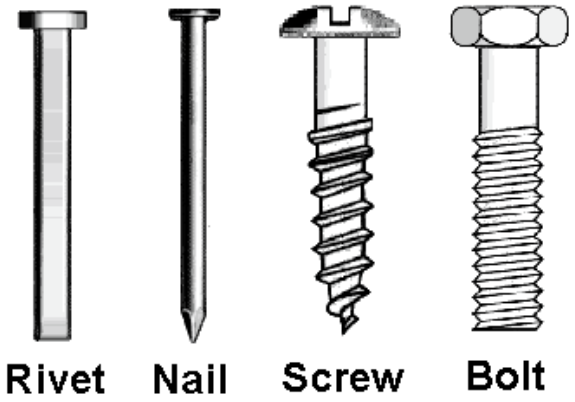

FIGURE 6

heads, 4.) threaded shafts, 5.) tapered shafts, 6.) pointed tips, and 7.) thick diameter.

The character states of all four fasteners are compared in Table II where the symbol "0" represents the pleisiomorphic (primitive or "rivet-like") state and "1" represents the apomorphic (derived or evolved) state.

If the phenetic approach is used to classify these fasteners, they are compared with one another by counting the total number of shared character states (both primitive and derived). If the cladistic approach is used, the comparison is based only upon the number of derived character states shared (see Table III).

Finally, a phenogram or cladogram is constructed by placing "closely related" species next to one another within the family tree. As this "fastener example" in Figure 7 illustrates, phenetic and cladistic analyses do not always give similar results.

Regardless of how they are constructed, phylogenetic trees are usually governed by the Rule of Parsimony, a "simplest is best" precept which dictates that a family tree should contain no more than the minimum number of branch points necessary to accommodate all of the observed character states. Such a constraint is consistent with scientific method, but it may not necessarily reflect the true path of evolutionary change. We shall examine the objections to parsimony later.

TABLE II

Character	Rivet	Nail	Screw	Bolt
Head notch	0	0	1	0
Rounded head	0	0	1	0
Hex head	0	0	0	1
Threaded shaft	0	0	1	1
Tapered shaft	0	0	1	0
Pointed tip	0	1	1	0
Thick diameter	0	0	1	1

THE ASSUMPTIONS OF CLADISTICS

There are three basic assumptions:

(1) Any group of organisms is related by descent from a common ancestor.

(2) At each node (divergence of a population), there are two branching lines of descendants.

(3) Change in characteristics occurs in lineages over time.

The first assumption is a general assumption made for all evolutionary biology. It essentially means that life arose on earth only once, and therefore all organisms are related in some way or other. Because of this, we can take any collection of organisms and

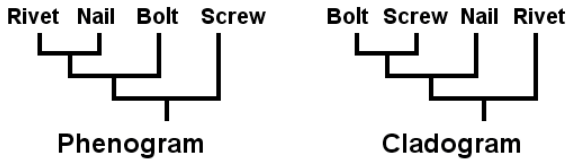

FIGURE 7

determine a meaningful pattern of relationships, provided we have the right kind of information. Again, the assumption states that all the diversity of life on earth has been produced through the reproduction of existing organisms.

The second assumption is perhaps the most controversial; that is, that new kinds of organisms may arise when existing species or populations divide into exactly two groups. There are many biologists who hold that multiple new lineages can arise from a single originating population at the same time, or near enough in time to be indistinguishable from such an event. While this model could conceivably occur, it is not currently known how often this has actually happened. The other objection raised against this assumption is the possibility of interbreeding between distinct groups. This, however, is a general problem of reconstructing evolutionary history, and although it cannot currently be handled well by cladistic methods, no other system has yet been devised which accounts for it.

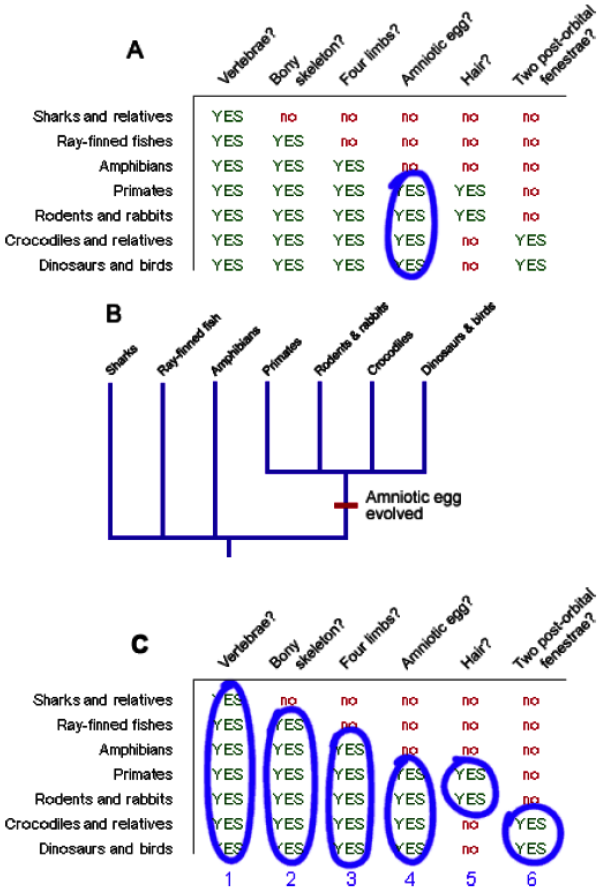
The final assumption, that the characteristics of organisms change over time, is the most important assumption in cladistics. It is only when characteristics change that we are able to recognize different lineages or groups.

CONSTRUCTING TREES 101

A cladistic analysis typically requires the following steps. Though they may seem simple, each step actually requires a great deal of background knowledge and work.

1. Choose the taxa. Let's decide to study the major clades of the vertebrates shown in the leftmost column of the Table shown in Figure 8A. We have selected seven (Note that, for simplicity, many vertebrate lineages are excluded from this example).
2. Determine the characters. After studying the vertebrates, one needs to select a set of traits that seem to be homologies, and build the data table to record your observations. Homologies (homology is from the Greek meaning to agree) are characters that are similar because they were inherited from a common ancestor. Analogies, i.e., characters that evolved through convergent evolution in two separate lineages (like the dorsal fins of sharks and dolphins), are not useful for reconstructing phylogenies. We have selected traits in this example (Note that many relevant vertebrate characters are excluded from this example for the sake of simplicity).
3. Determine the polarity of characters, i.e., figure out the order of evolution for each character. From studying fossils and outgroups closely related to the vertebrate clade, we have hypothesized that the ancestor of vertebrates had none of these features. (Note: This step is not absolutely necessary in some computer algorithms.)
4. Group taxa by synapomorphies Since we have a good idea of what the ancestral characters are (see above), this is not so hard. We might start out by examining the egg character. We focus in on the group of lineages that share the synapomorphic form of this character, i.e., an amniotic egg (A, in Figure 8), and hypothesize that they form a clade (B). We go

FIGURE 8



through the whole table like this, grouping clades (C, in Figure 8) according to synapomorphies.

5. Work out conflicts that arise by some clearly stated method, usually parsimony (minimizing the number of conflicts; see the parsimony section). There are no conflicts here. Every group is a subset of another group.

6. Build the tree following these rules:

(a) All taxa go on the endpoints of the cladogram, never at nodes.

(b) All cladogram nodes must have a list of synapomorphies which are common to all taxa above the node (unless the character is later modified).

(c) All synapomorphies appear on the cladogram only once unless the character state was derived separately by evolutionary parallelism.

Based on the groupings above, the tree shown in Figure 9 is produced.

Note: Parallelism and convergence are not always clearly distinguishable. Features that become more rather than less similar through independent evolution are said to be convergent. Convergence is often associated with similarity of function, as in the evolution of wings in birds, bats and flies. The shark (a fish) and the dolphin (a mammal) are much alike in external morphology; their similarities are due to convergence, since they have evolved independently as adaptations to aquatic life.

Parallel evolution on the other hand implies that two or more lineages have changed in similar ways, so that the evolved descendants are as similar to each other as their ancestors were. For example, the cichlids in Lake Malawi and in Lake Tanganyika all originated from similar ancestral populations. What's more, the cichlids in each of the three lakes have evolved to fill nearly the exact same niches. In Figure 10, the fish on the left come from Lake Tanganyika and the ones on the right are from Lake Malawi. The correspondence in ecology and morphology between the fish of these lakes is a clear example of parallel evolution.

FIGURE 9

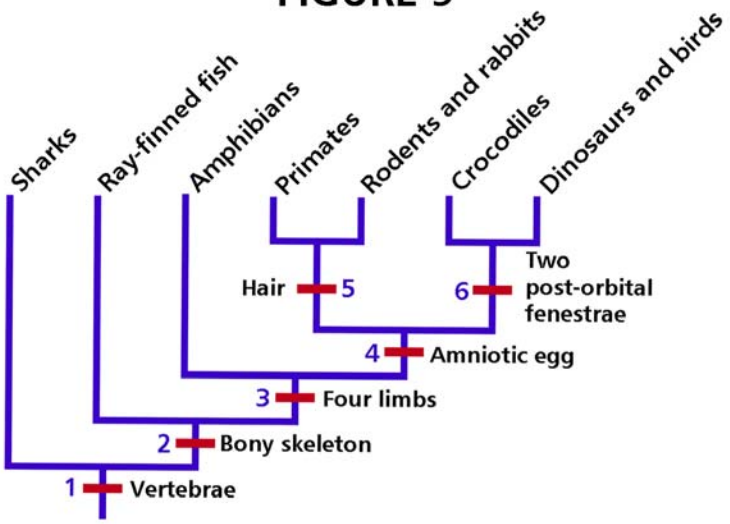


FIGURE 10

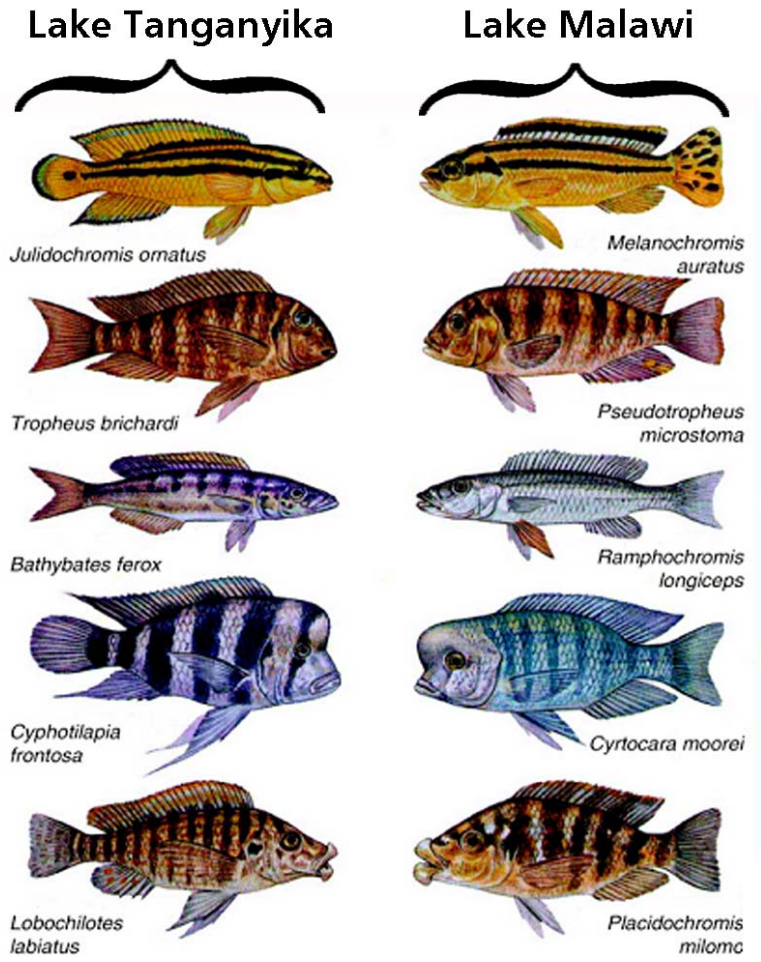
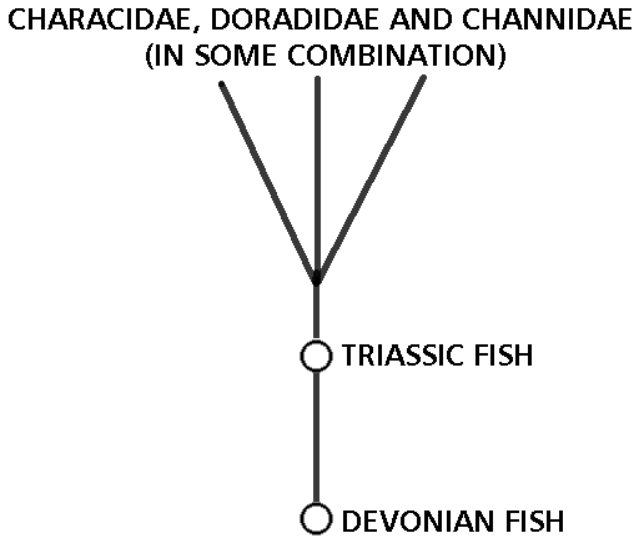


PROBLEMS WITH CLADISTICS

Like any computerized method, cladistics suffers from the problem that the quality of the output it produces is entirely dependent on the quality of the input it is given - or, to put it another way, "garbage in, garbage out." There are several choices that the worker must make before the computer, in all its objectivity, can be put to work, and some further issues may also cast doubt over the results of a cladistic analysis.

For example, poorly chosen characters can yield incorrect results. To take an extreme example, if we applied the cladistic method to three taxa - lions, tigers and convict cichlids - using only the single character "has stripes," we would obviously get the nonsensical result that tigers and convict cichlids are more closely related to one another than either is to lions.

Another way in which a worker's preconceived ideas can affect the result of a cladistic analysis is in the assumptions about the primitive states of the characters. Since we can't know what taxon is actually the most recent common ancestor of those being analyzed, we use a well-understood outgroup as a proxy for that ancestor - that is, a taxon outside of, but as close as possible to, the clade containing the taxa to be analyzed. For example, if we think that the phylogeny looks like this:



Then we might perform the analysis on the assumption that A, B and C's common ancestor had the same character states as the Triassic fish; or, if we decided that its remains are too fragmentary to be used in this way, we might use the less closely related but better represented Devonian fish. In practice, several different outgroups are typically analyzed to help determine the most likely ancestral state of characters. Therefore, the choice of taxa to use as outgroups is clearly a subjective one since it is chosen on the basis of how the phylogeny is likely to look.

The problem, therefore, lies in determining just what is or is not a shared derived character. We have some rough guidelines, and some seat-of-the-pants feelings, but no unerring formulas. If derived characters are sufficiently "complex," for example, we begin to feel confident that they could not have evolved independently in separate lineages and that their mutual presence therefore indicates common descent. Unfortunately, most derived characters are more ambiguous. They tend to be either easy to construct or else so advantageous that several lineages might evolve them independently by natural selection.

In August of 1961 I became interested in the use of electrophoresis techniques in the identification of fishes (this came about as a result of an article which appeared in *Science* magazine **(** Lillevik, H.A. and C. L. Schloemer, "Species differentiation in fish by electrophoretic analyses of skeletal muscle protein**,"** *Science*, Vol. 134, August 16, 1961). Electrophoresis is the movement of charged molecules under the influence of an electric field. Since many biological molecules carry a charge, they can be separated by this technique. Electrophoresis can separate fragments of DNA that were cut with restriction enzymes, creating a visual map of fragment size that is easy to interpret. One of the advantages of electrophoresis is that scientists can separate several samples side by side so they can compare them. The comparison of separated DNA molecules is the basic method behind the DNA fingerprints that forensic scientists use to compare samples from crime scenes with those of suspects. In my case, the method was used to determine the relationship between closely-related *Aphyosemion* species, and was the first ever published on this subject in the aquarium hobby.

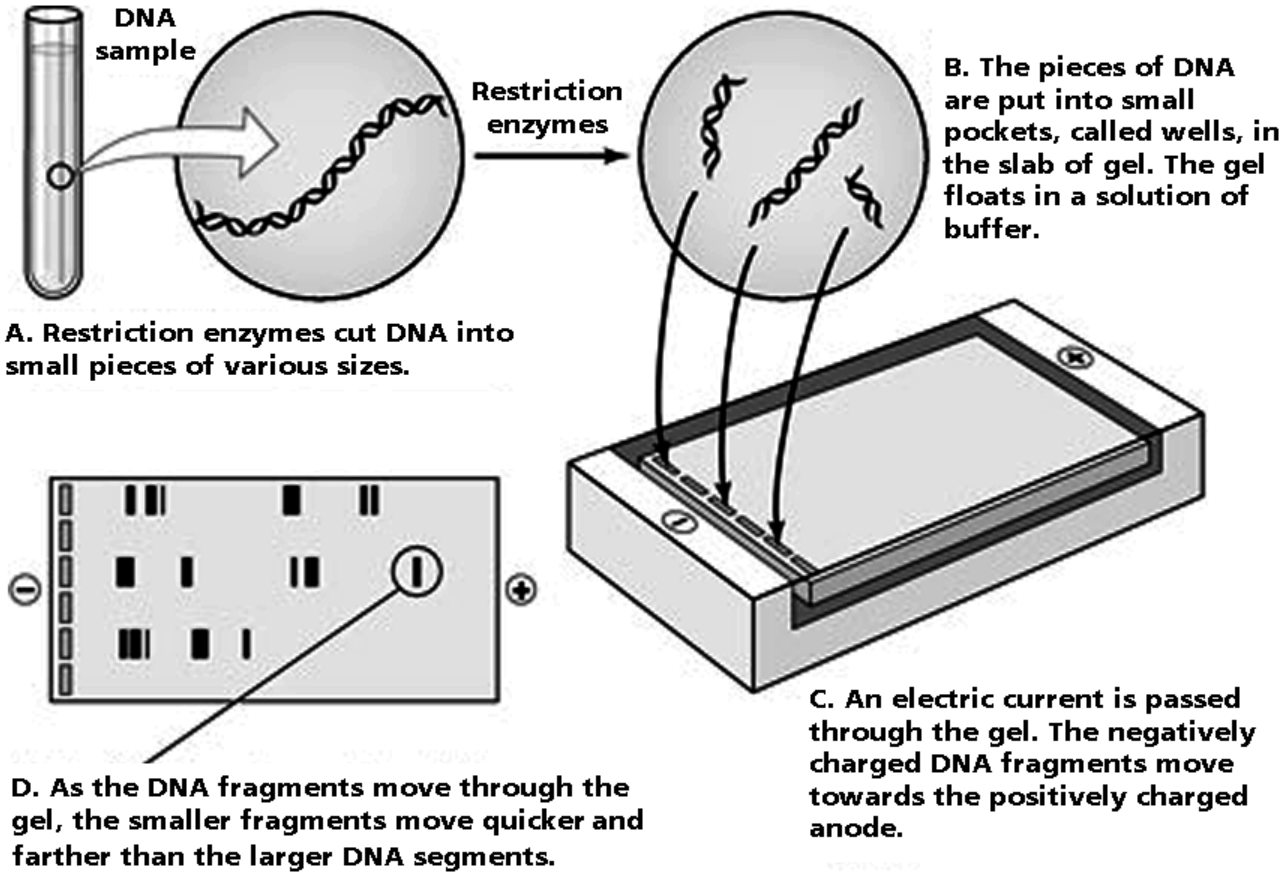
The basic idea is shown in Figure 11. Note that in this diagram, moistened paper can also be used in place of a gel. A DNA sample (part of the ground-up and filtered portion of the fish specimen in this case) is cut into small pieces of various sizes by a restriction enzyme. These pieces are put into small pockets in the slab of gel. An electric current is passed through the gel and the DNA fragments move towards the anode. As they move through the gel, the smaller fragments move quicker and farther than the larger DNA segments. These bands are then brought out strikingly when stained with a dye specific only to protein. Such bands from groups of muscle proteins may "fingerprint" the species in question.

At the time electrophoresis was expensive but, through the courtesy of some good friends and an authority at the Carnegie Institution, I was able to study various forms of *Aphyosemion cognatum* and *A. christyi* (Klee, Albert J., "The Christyi-Cognatum Problem revisited," AKA Killie Notes, Vol. II, No. 1, pp. 8-12 1963). In 1965 I repeated these experiments (Klee, Albert J., "The Bivittatum Group – Part II," Aquarium Journal, March, 1965) with males and females of *Aphyosemion australe*, *Aphyosemion multicolor*, various *Aphyosemion bivittatum* strains and an outgroup, *Aplocheilus lineatus* (Note: These names were the ones used in the hobby when the articles were written; for example, *Aphyosemion multicolor* is now *A. bitaeniatum*).

Figure 12 shows the electrophoretic traces obtained in the last paper; both protein and esterase stains were used, but the figure only shows the esterase stain results. Some of the observations were as follows:

1. *Aplocheilus lineatus* differs markedly from the others (as was expected) in both stains.
2. *A. multicolor* is very nicely separated from *A. bivit-*

FIGURE 11



tatum in aromatic esterase stain. They are also separable in protein stain but to a less dramatic extent.
3. *A. australe* is distinguished easily from *bivittatum* and *multicolor* in both stains, via distance from one band to the next, band intensities and number of bands.

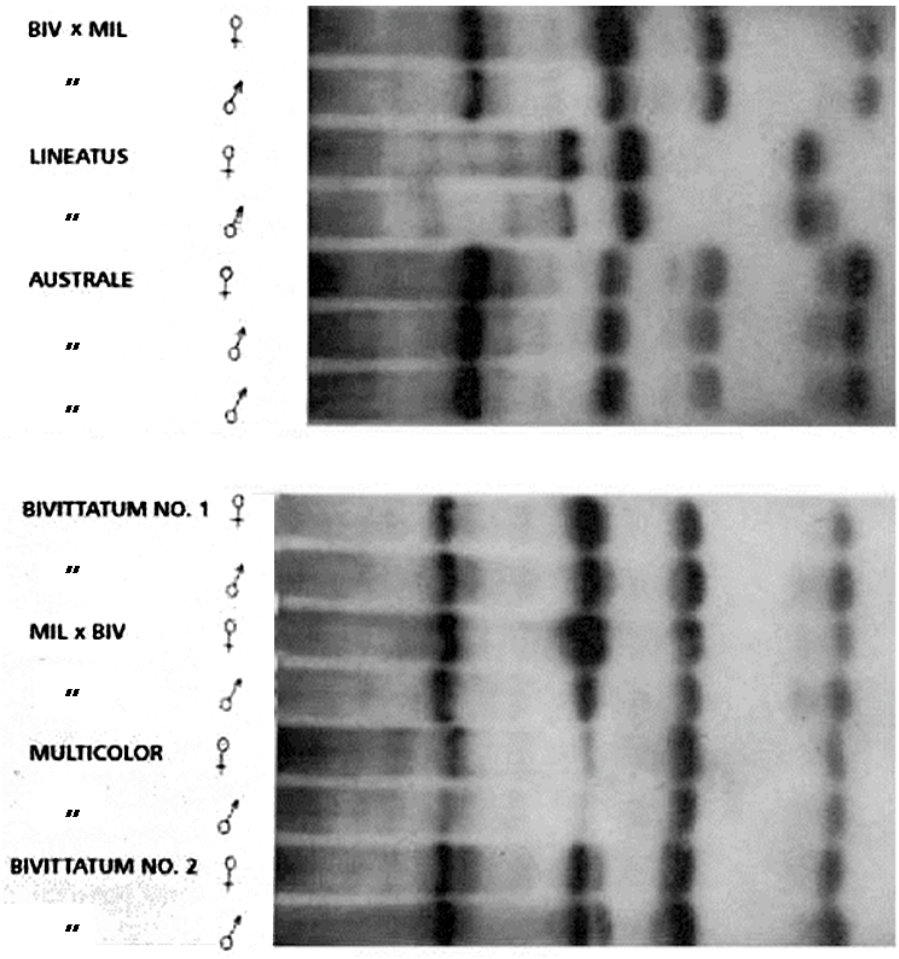
One would hypothesize, therefore, that electrophoretic traces - which are complex - are shared primitive characters in Aphyosemion since the more complex characters that a group shares, the more likely that the group is genealogical – unless there is good reason to regard the characters as primitive, which I did not in this case.

PARSIMONY PROBLEMS AND OTHER METHODS

Consider the problem of inferring how cichlids, killifish and mice are related to each other. Two hypotheses that might be considered are depicted in Figure 13 where f signifies fins and –f signifies no fins. The (CK)M hypothesis says that cichlids and killifish have a common ancestor that is not an ancestor of mice; the C(KM) hypothesis says that it is killifish and mice are more closely related to each other than either is to cichlids. Now consider an observation: cichlids and killifish have fins, while mice do not. Which phylogenetic hypothesis is better supported by this observation?

If finlessness is the ancestral condition, then the (CK)M hypothesis has one character change - no fins to fins - represented by the slash on the cichlid/killifish branch. On the other hands the C(KM) hypothesis has two character changes - no fins to fins on the cichlid branch and no fins to fins on the killifish branch - represented by the two slashes shown. Thus the C(KM) hypothesis is more parsimonious. (Notice that the parsimoniousness of a hypothesis is assessed not by seeing how many changes it says actually occurred, but by seeing what the minimum number of changes is that the hypothesis requires. (CK)M is more parsimonious because it entails a lower minimum.)

FIGURE 12



In choosing the most likely candidate tree, cladistics programs frequently rely on the principle of parsimony, but nature is not always parsimonious since lineages of animals have a way of evolving a feature, then removing it, and then re-evolving it again (this is called a "reversal"). For example, sufficiently basic ancestors of birds were flightless, and birds evolved the feature of flight; but flightless birds such as ostriches and penguins have lost that feature. An analysis using the character "can fly" would be fooled into misreading this as evidence

that penguins are more closely related to the ancestors of birds than to contemporary birds.

Parsimony may be a standard approach but it is not the only basis used in computer programs to determine the cladogram. The methods for calculating phylogenetic trees fall into two general categories:

(1) Distance-matrix methods (also known as clustering or algorithmic methods; much faster than the discrete data methods). Includes UPGMA, Least Squares, Minimum Evolution and Neighbour-Joining methods. **These are phenetic methods**.

(2) Discrete data methods (also known as tree searching methods; more information rich-than distance-matrix methods). Includes Parsimony, Maximum likelihood and Bayesian methods. **These are cladistic methods**.

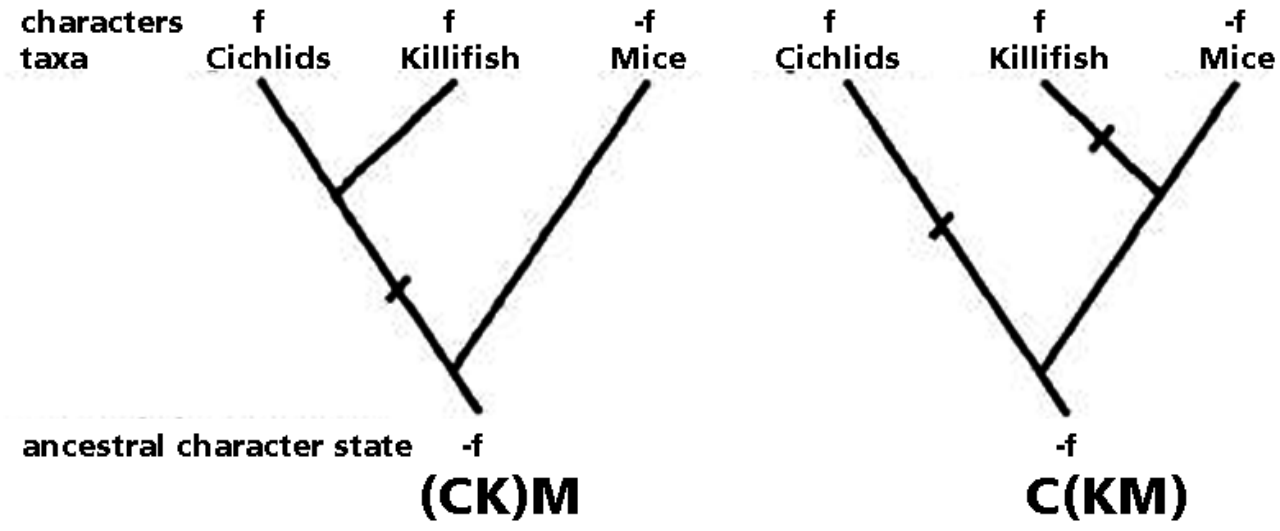
With regard to these three discrete data methods, I have presented an example of parsimony here and one of maximum likelihood in my essay**, "**How Cladists Work" (Aquarium Hobby Historical Society, Files, October 21, 2007). Bayesian inference is similar to maximum likelihood except that it includes prior information regarding relationships into the process of phylogeny estimation.

Quite a few years ago when I was working for the United States Health Service in Cincinnati, Ohio, I was asked by the City Manager of Covington, Kentucky (located right across the Ohio River) if I could solve a problem involving the assignment of crews to their solid waste collection vehicles. At the time, Covington was using a 5-man crew system that required that each crewman get along with the other four, but there was too much strife within the crews and they just didn't get along. As a result, collection efficiency suffered.

About this time I had read Sneath and Sokal's books on mathematical taxonomy and thought I might try one of the clustering algorithms they described. The basic principle behind cluster analysis is fairly simple; it finds groups of objects such that the objects in a group are sim**il**ar to one another and different from the objects in other groups (Figure 14). Since Sneath and Sokal's objects were fish species, I saw no reason why mine couldn't be *Homo sapiens*.

After doing a little research in the social psychology literature, I put together a survey form that essentially asked questions about likes and dislikes and asked the City Manager to have the survey filled out by each of his men. I then took the results and entered into a cluster analysis computer program that enabled me to specify the size of the groups to be identified, which was five in this case. The City Manager used these crew assignments generated by the com-

FIGURE 13



puter and Voila! He had very few problems with internal discord afterwards. Sneath and Sokal were vindicated!

Using different algorithms on a single data set can sometimes yield different "best" cladograms, because each algorithm may have a unique definition of what is "best." Algorithms that perform optimization tasks (such as building cladograms) can be sensitive to the order in which the input data (the list of species and their characteristics) is presented. Inputting the data in various orders can cause the same algorithm to produce different "best" cladograms.

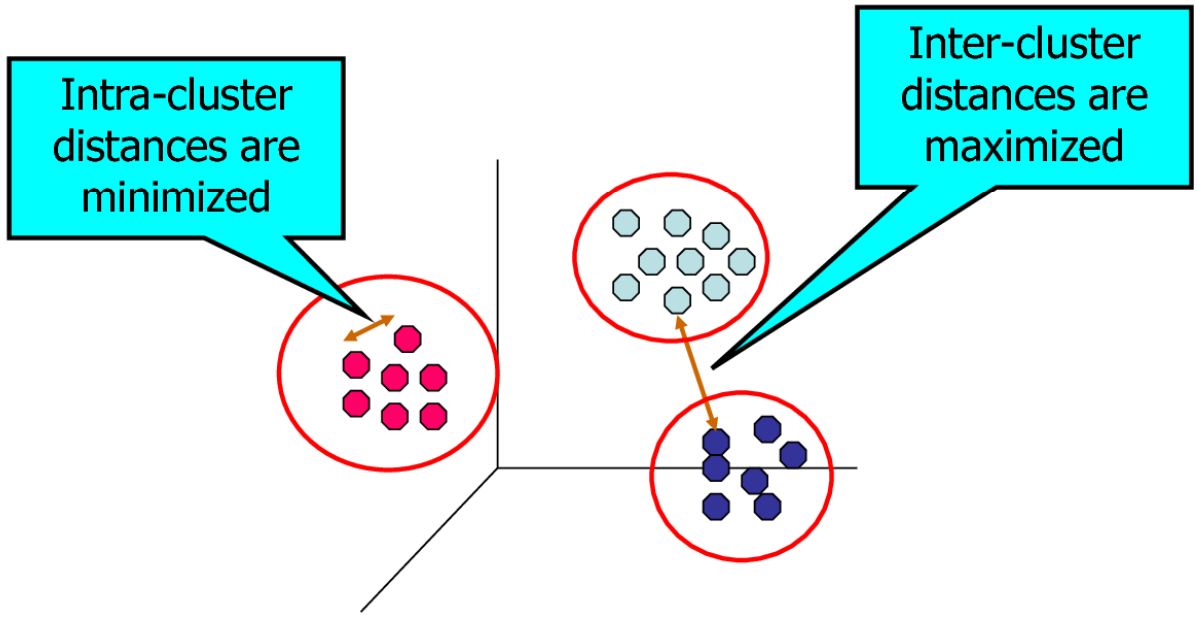
THERE IS NO SUCH THING AS A FISH

With apologies to the members of the Aquarium Hobby Historical Society, I regret to report that there is no such thing as a fish. Most people are confident that they have a pretty good idea of what a fish is. But recognizing fishiness is not as simple or as straight-forward as many might suppose. This is because many fishes lack what are usually thought of as "fishy" characteristics. Characteristics like fins, scales, cold-bloodedness, water-breathing, and even eyes are not shared by all fishes. Some eels lack fins. Lampreys and some freshwater catfishes are completely scaleless, while paddlefishes, some sticklebacks and sculpins are nearly so. Tunas and some sharks are functionally warm-blooded. Mudskippers actually drown if held underwater. Hagfishes and blind cave fish lack eyes. In general, however, most fishes have fins and scales, are cold-blooded, breathe water via gills and have eyes, but it is surprisingly difficult to list characteristics common to all forms.

All known fishes are multicellular organisms that do not manufacture their own food. Therefore they - along with ourselves and many other creatures - are members of the kingdom Animalia. All fishes have a notochord (stiff cartilaginous rod extending along the back), a tubular nerve chord just above it, gill pouches in the throat region, segmental muscle blocks, and a tail posterior to the anus or cloaca. As such, they - along with less familiar creatures such as tunicates, acorn worms and lancelets - are card-carrying members of the phylum Chordata. All fishes have a backbone divided into segmental vertebrae (even those that lack bones), and are therefore members of the

FIGURE 14

Cluster analysis is finding groups of objects such that the objects in a group will be similiar (or related) to one another and different from (or unrelated to) the objects in other groups.



sub-phylum Vertebrata. Vertebrates include many of the most familiar animals: amphibians, reptiles, birds and mammals (including dogs, cats, horses, elephants, whales, apes, and us). Such non-fishy vertebrates are termed “tetrapods” - which means “four-footed,” in reference to the fact that all have two sets of paired limbs.

Living fishes are currently divided into a number of different classes, the two most importamnt being Sarcopterygii (lobe-finned fishes) and Actinopterygii (ray-finned fishes.) Figure 15 shows how these classes of living fishes are believed to be interrelated. Most familiar bony fishes - including sturgeons, gars, eels, herrings, carps, catfishes, salmons, mullets, perches, pipefishes, scorpionfishes, butterflyfishes, gobies, tunas, billfishes, flatfishes, pufferfishes, and many, many others - are placed in the class Actinopterygii. However, it is the class Sarcopterygii to which I would like to draw your attention.

The Sarcopterygii includes “primitive” fishes such as the lungfishes (represented in each of the southern continents by a separate family) and the coelacanth (Latimeria chalumnae), a long-lost survivor from the Age of Dinosaurs living in deep waters off southeastern Africa and Indonesia. They are most notably characterized by having jaws with fixed teeth, a bony skeleton, a skull with sutures, a type of scale known as “cosmoid,” and heavy, lobe-like paired fins (pectoral and pelvic) supported by stout bones. For this reason, they are informally known as the lobe-finned fishes. As their name suggests, lungfishes actually have primitive lungs and breathe not water, but air.

Consider that the tetrapods, too, have jaws with fixed teeth, a bony skeleton, a skull with sutures, and heavy, paired appendages. As we have seen, scales are not at all a defining character of fishiness, nor is breathing by way of gills. Therefore, based on many structural and physiological synapomorphies, the tetrapods not only share a common ancestor with the lobe-finned fishes, but are derived from them (Figure 16). The tetrapods are now generally believed to represent a subclass within the Sarcopterygii. And therein lies a major reason for the difficulties in defining fishes as a group. In a cladistic analysis the lungfish must form a sister group with the sparrow or elephant, leaving the trout in its stream. Fish - as the term is usually applied - is not a monophyletic taxon since if we are to include the common ancestor of the fish-like vertebrates and all of its descendants, then we must include the tetrapods. Thus, frogs, snakes, ducks, kangaroos, elephants, rats, bats, whales, and other mammals, are all sarcopterygian “fishes.” To put this another, more cogent way: cladistically speaking, we are fish.

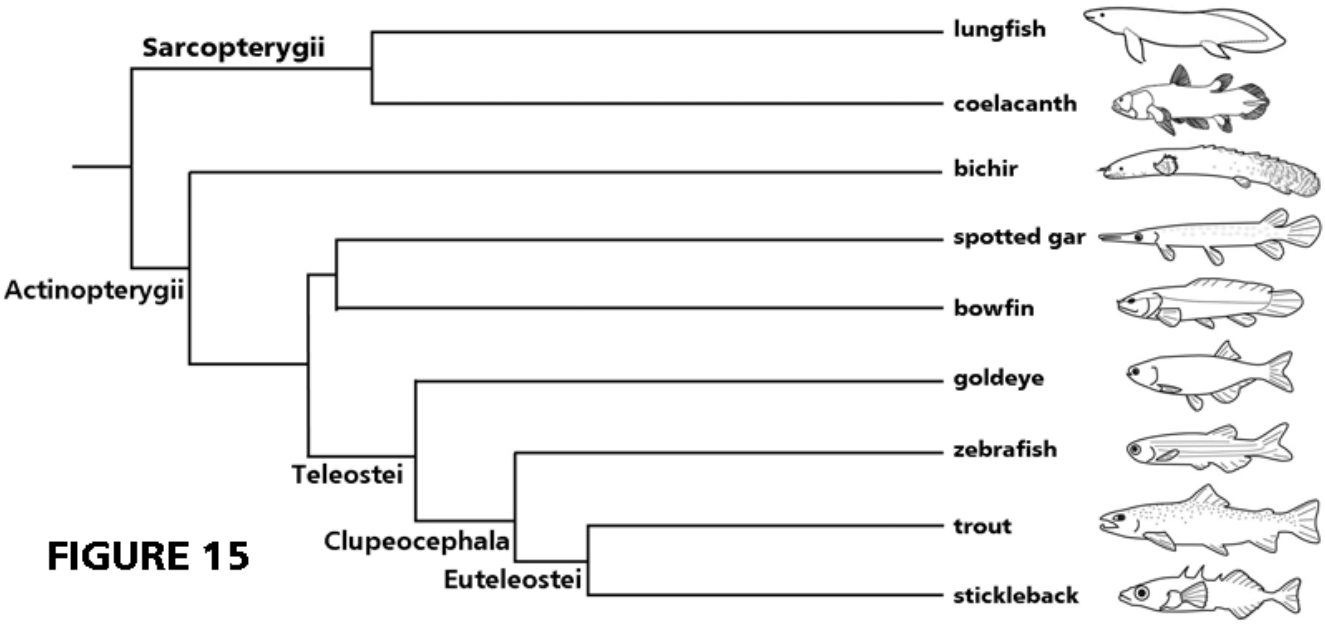


FIGURE 15

No debate in evolutionary biology has been more intense during the past decade than the challenge raised by cladistics against traditional schemes of classification. The cladogram of trout, lungfish and elephant is undoubtedly true as an expression of branching order in time, but must classifications be based only on cladistic information? A coelacanth looks like a fish, tastes like a fish, acts like a fish, and therefore - in some legitimate sense beyond hidebound tradition—*is* a fish.

The problem arises from the two rather different conceptions of "similarity" between organisms. On one hand, cladistics works with branching order alone, rigorously excluding any other notion of similarity. On the other, phenetics focuses on overall similarity alone and tries to escape the charge of subjectivity by insisting that phenetic classifications be based upon large suites of characters, all expressed numerically and processed by computer.

Unfortunately, as we have seen from the nail example, these two types of information - branching order and overall similarity -do not always yield congruent results. Thus the cladist rejects overall similarity as a snare and delusion and works with branching order alone. The pheneticist attempts to work with overall similarity alone and tries to measure it in the vain pursuit of objectivity. The traditional systematist tries to balance both kinds of information but often falls into hopeless confusion because they really do conflict. Coelacanths are like mammals by branching order and like trout by biological role. Thus, cladists

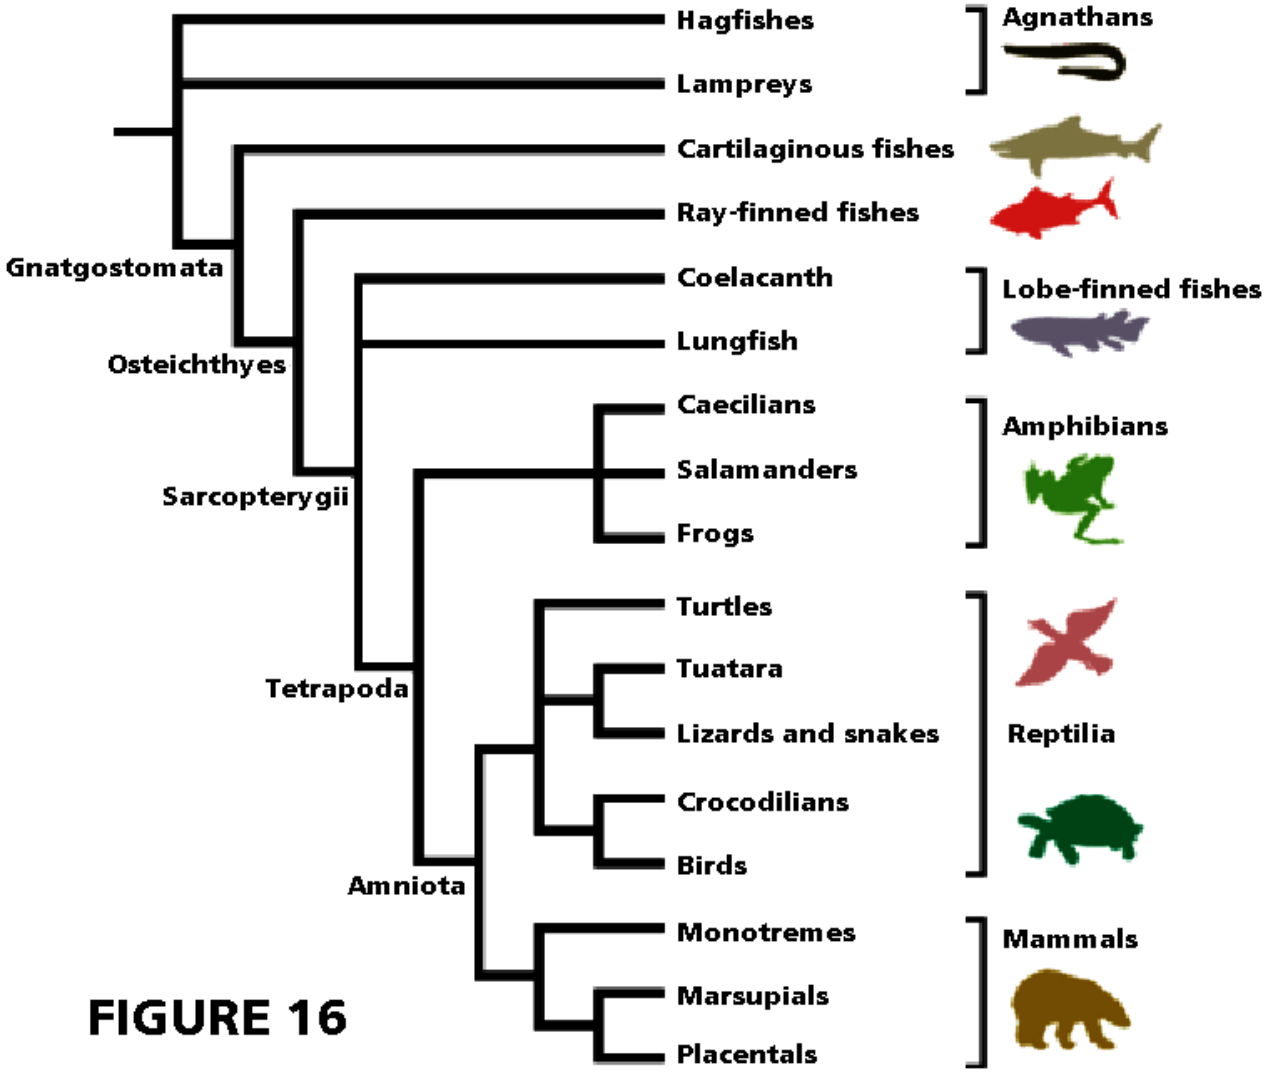

FIGURE 16

buy potential objectivity at the price of ignoring biologically important information. And traditionalists curry confusion and subjectivity by trying to balance two legitimate, but often disparate, sources of information. To quote Stephen Jay Gould from his essay on zebras,*

The world is much more interesting than ideal. Phenetic similarity often correlates very poorly with recency of common ancestry. Our ideal world requires a constancy of evolutionary rate in all lineages. But rates are enormously variable. Some lineages change not at all for tens of millions of years; others undergo marked alterations in a mere thousand. When the forebears of terrestrial vertebrates first split off from a common ancestry with coelacanths, they were still unambiguously fish in appearance. But they have evolved, along numerous lines during some 250 million years, into frogs, dinosaurs, flamingos and rhinoceroses. Coelacanths, on the other hand, are still coelacanths. By branching order, the modem coelacanth may be closer to a rhino than a tuna. But while rhinos, on a rapidly evolving line, are now markedly different from that distant common ancestor, coelacanths still look and act like fish - and we might as well say so. Cladists will put them with rhinos, pheneticists with tunas; traditionalists will hone their rhetoric to defend a necessarily subjective decision.

Nature has imposed this conflict upon science by decreeing, through the workings of evolution, such unequal rates of change among lineages and such a poor correlation between phenetic similarity and recency of common ancestry. I do not believe that nature frustrates us by design, but I rejoice in her intransigence nonetheless.

A HISTORY OF AQUARIUM KILLIFISHES

by Albert J. Klee

(AKA killie notes, Volume 2, Number 3, Summer Issue, 1963)

Data concerning the chronological acquisition of killifishes in this country is almost nonexistent unless we take as our starting point, the post World War II years. Much the same can be said for all other countries with the single exception of Germany. The reasons for this situation in our own country are not hard to find. Prior to World War II there existed but a single American work that merited the appellation, "reference book", i.e., Innes' "Exotic Aquarium Fishes". All others, regardless of isolated merits here and there, were either introductory booklets or rambling discussions of popular topics in the aquarium hobby. Dr. Innes' book has been called, and not without some justification, the fish "bible" for American aquarists. In compiling his catalog of fishes he chose not to imitate the current styles or formats, but rather to devise a new approach, one which still basically has never been improved upon (however, it has been widely copied). Unfortunately, the one weakness of this book was that it failed to include historical information about the fishes it described.

At the same time the first edition appeared, the aquarium hobby in the United States was still in its infancy and few references were available containing such historical data. The situation in Germany was quite different, however. Not only were there numerous books published about aquarium fishes, but the German hobby boasted a number of active periodicals as well. In line with the well- known Teutonic proclivity towards documentation, every new import was duly and quickly written up and reported in print. Thus, the task of the German author was made immeasurably easier. Even to this day, our books fail to list historical information. One must fall back on magazine articles, most of which are deficient in this matter also.

The aquarium hobby was introduced to America mainly via German hobbyists, many of whom migrated to this country. As Germans received new fishes, it wasn't too long before they were sent to friends and hobbyists in America. Thus it would not be far afield for us to discuss the pre World War II chronology of killifish importations into Germany, the data for which is fairly reliable. Such a list is shown in Table I, the nomenclature having been brought up to date. From this listing, a number of things are made clear. Aquarists frequently wonder why our handbooks include species that few, if any, hobbyists have ever seen. Partly this is a matter of copying, one book listing fishes from a previous one. Then too, there is always pressure to be "complete". For example, the first killifish listed in Table I is Valencia hispanica (see figure 1). It is, at 1881, our earliest recorded aquarium killifish. Although it was again imported into Germany during the early 1900's, it has not appeared on the aquarium scene since. However, if one were to avoid all information about this fish, then it would be just our luck to see it re-imported in the near future! In addition, aquarists become interested in fishes only when they know something about them and if information is made available about rare fishes, hobbyists may militate for our importers to obtain them.

Some aquarists may be surprised to learn how "old" in the aquarium sense, some of our killies really are. As a partial listing of "firsts" in the importation of important killifish genera, Table II has been prepared.

Of course, the fishes listed in these tables were not necessarily known by these names at the time. In the early days of our hobby, "*Fundulus*" and "*Haplocheilus*" were common terms. Among those fishes included in the former (besides the fishes we today know under that name) were: *Cubanichthys, Valencia, Nothobranchius, Profundulus* and *Aphyosemion* (especially members of the subgenus *Fundulopanchax*). Among those fishes included in the latter were: *Aplocheilus, Epiplatys, Pachypanchax, Aphyosemion* (especially members of the subgenus *Aphyosemion*), and *Micropanchax*. Forgotten names such as "*Adinops," "Lebias*" and "*Panchax*" were prevalent in those early days. Anyone doing research nowadays using old texts is haunted by these ghosts!

TABLE I: CHRONOLOGY OF KILLIFISH IMPORTATIONS INTO GERMANY PRIOR TO WORLD WAR II

Before 1900
1881 Valencia hispanica
1890 Fundulus majalis
1895 Oryzias latipes
1899 Aplocheilus panchax

1900 to 1909
1903 Rivulus santensis
1904 Pachypanchax playfairii
Aphanius dispar
Fundulus chrysotus
Fundulus notti
Micropanchax schoelleri
1905 Rivulus urophthalmus
Fundulus catenatus
Fundulus diaphanus
Aphyosemion arnoldi
Cyprinodon variegatus
Epiplatys sexfasciatus
Aphyosemion coeruleum
1906 Fundulus heteroclitus
Rivulus ocellatus
Aplocheilichthys spilauchen
Rachovia brevis
Cynolebias bellottii
1907 Aphyosemion gulare
Fundulus grandis
1908 Aphyosemion loennbergii
Aphyosemion liberiensis
Aphyosemion gardneri
Aphyosemion calliurum
Aphyosemion bivittatum
Epiplatys chaperi
Epiplatys longiventralis
Cynolebias nigripinnis
1909 Rivulus isthmensis
Aplocheilus lineatus
Aphyosemion sjoestedti
Rivulus tenuis

1910 to 1919
1910 Fundulus cingulatus
Epiplatys grahami
Rivulus strigatus
Aphanius sophiae
Micropanchax macurus
Cynolebias wolterstorffi
Oryzias javanicus
Oryzias melastigma
Epiplatys senegalensis
1911 Fundulus notatus
Aphanius iberus
Epiplatys fasciolatus
Epiplatys macrostigma
Aphyosemion bitaeniatum
1912 Cynolebias melanotaenia
Oryzias celebensis
Cynolebias elongatus
1913 Aphyosemion australe
Aphyosemion cameronense
Aphanius fasciatus
Nothobranchius guentheri
1914 Jordanella floridae

1920 to 1929
1921 Cynolebias adloffi
1923 Rivulus dorni
1924 Rivulus xanthonotus
Leptolucania ommata
1925 Nothobranchius rachovii
1926 Micropanchax macrophthalmus
1927 Rivulus hartii
Aphyosemion vexillifer
1928 Epiplatys ornatus
Lucania goodei
Aphyosemion multicolor
Aphyosemion oeseri
1929 Aphyosemion splendopleuris
Micropanphax flavipinnis
Rivulus cylindraceus

1930 to 1939
1930 Pterolebias longipinnis
Aphyosemion fallax
Aphyosemion meinkeni
1931 Fundulus sciadicus
Aphyosemion filamentosum*
1932 Profundulus punctatus
Cubanichthys cubensis
Aplocheilus dayi
Aphyosemion rubrostictum
1933 Cynolebias schreitmuelleri
1935 Epiplatys dorsalis
Aphyosemion calabaricum
1936 Aphyosemion roloffi
Nothobranchius orthonotus
1937 Micropanchax katangae
Epiplatys nigromarginatus
1938 Rivulus roloffi
Kosswigichthys asquamatus

*There is evidence to suggest that this fish was imported prior to 1923.

Data for Table I was taken mainly from the following texts:

Anon, "Katalog der Vereinigten Zierfischzuechterein," 1922/1923.
Arnold, J. P., "Alphabetisches Verzeichnis der bisher eingefuehrten fremdlaendischen Suesswasserfische." 1949.
Holly, M; Meinken, H; and Rachow, A., "Die Aquarien- fische in Wort und Bild", 1932 to 1963.

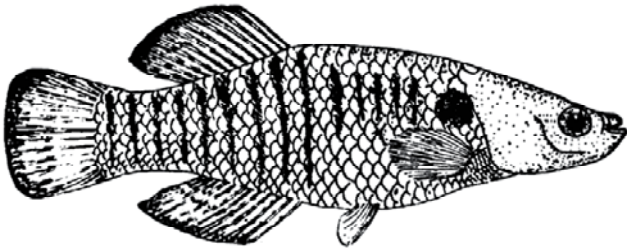
The following is the source of the figure to the right shown below:

Brylińska Maria (Editor), "Ryby słodkowodne Polski" ["Freshwater Fishes of Poland"], Polish Scientific Publishers PWN, Warszawa, Poland, 2000.

TABLE II: DATES OF INITIAL IMPORTATIONS OF IMPORTANT KILLIFISH GENERA INTO GERMANY

1890	**First Fundulus (F. majalis)**
1895	**First Oryzias (O. latipes)**
1899	**First Aplocheilus (A. panchax)**
1903	**First Rivulus (R. santensis)**
1904	**First Micropanchax (M. schoelleri)**
1904	**First Pachypanchax (P. playfairii)**
1905	**First Aphyosemion (A. coeruleum)**
1905	**First Epiplatys (E. sexfasciatus)**
1906	**First Aplocheilichthys (A. spilauchen)**
1906	**First Cynolebias (C. bellottii)**
1913	**First Nothobranchius (N. guentheri)**
1930	**First Peterolebias (P. longipinnis)**

***Valencia hispanica*, the first aquarium killifish.**
The image on the left was the one shown in the original article. However, the shape of the head was Drawn incorrectly. The image on the right shows the shape more accurately.



ENDLER'S GUPPY AND THE DESKTOP COMPUTER

by Albert J. Klee, Ph.D
(Aquarium Hobby Historical Society, Files, March 21, 2015)

Although I have written a good deal about introductory cladistics (all of which can be found in my "Essays on Aquarium Hobby History") Schories et al. 2009 paper in which they stated that "*P. wingei* is now unequivocally defined by the molecular phylogeny as a valid species" contained some techniques in their "Material and Methods" section that I have not heretofore described. To quote from their paper, "Heuristic and branch-and-bound tree searches were performed using both parsimony and distance (minimum evolution). Neighbor-joining (NJ) trees were also constructed. Robustness of the trees was tested by bootstrap analyses using 20000 replicas." In this essay I will endeavor to explain these terms and talk a bit about computation.

NEIGHBOR-JOINING METHODS

Firstly, phylogenetic trees can be drawn with or without a root (see Figure 1). For rooted trees, the root is the common ancestor. For each taxon (usually species or genus in our case), there is a unique path that leads from the root to that taxon, the direction of each path corresponding to evolutionary time. An unrooted tree specifies the relationships among taxa but does not define the evolutionary path. An unrooted tree can be rooted, but for any given unrooted tree there are many possible rooted trees that can be derived. Rooting a tree usually requires identification and use of an outgroup, i.e., a taxon that is more distantly related than the taxa contained within the tree. I mention this because when discussing computer calculations, unrooted trees are simpler to deal with and more often than not, phylogenetic software frequently uses them as a matter of course.

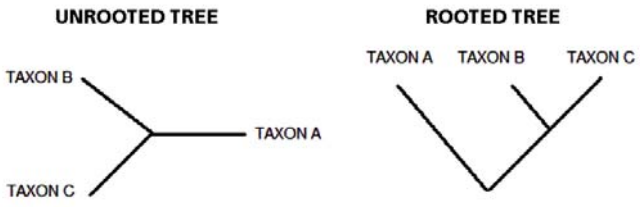


FIGURE 1: ROOTED VERSUS UNROOTED TREES

The Schories paper states: "The molecular data were analyzed with maximum likelihood, parsimony and neighbor-joining methods which yielded almost identical phylogenetic results. The topology of the resulting trees was always the same."

As I have written previously, there are basically two methodologies by which phylogenies can be reconstructed: phenetic and cladistic. Trees made by cladistic methods are referred to as cladograms; phenetic trees are phenograms. However, in colloquial usage, phenogram is barely heard and cladogram has come to dominate, even when phenetic methods are used for tree construction. This annoys cladists no end since the characters entered into the basic data matrix for a calculation are assumed to be synapomorphies, i.e., shared derived characteristics and thus their resulting tree has evolutionary implications. To pheneticists, any characteristic is fair game and thus their tree has similarity implications.

While you might have heard that phenetics is a naughty word, phenetic methods are still widely in use in classification and in molecular systematics. To aquarists, classification is of far more importance than evolution since aquarists usually only want a name for what is being offered as a species or genus and nothing more.

Phenetics has major problems for phylogenetic reconstruction, mostly stemming from differing algorithms, their assumptions and their calculation. That said, there are some undeniable advantages to phenetics, which is why it is still around. It allows us to combine morphological and molecular matrices together, and it is also less skill-intensive – anyone can measure the width of an ant head, but not many can recognize the derived trait that that separates the Formicinae, which is what one would need when working cladistically. Phenetics is thus arguably easier for field guides and identification keys, items of far more importance to aquarists than is evolutionary theory.

Cladistic analyses most often use parsimony as their criterion for determining their tree, whereas phenetic analyses typically use distance-based criteria. What is meant by "distance-based" is that in phenetics, the number of DIFFERENCES between data sets is quantified. To do this, a mathematical formula is used to describe the degree of similarity or distance between each pairwise comparison of taxa. One simple formula is the Simple Matching Coefficient (S) and is defined as follows:

S = [total number of character matches between two taxa] x 100/ total number of characters.

For example, consider the following character matrix where 1 indicates that the character is present and 0 indicates that it is not:

TAXON	DATA									
A	0	1	1	0	0	0	1	1	1	0
B	0	0	0	1	1	1	0	1	1	1
C	0	0	1	0	0	1	0	0	0	1
D	1	1	0	0	0	1	1	1	1	0

Using the above formula, the following distance matrix is constructed:

	A	B	C	D
A	-	0.3	0.4	0.6
B		-	0.5	0.4
C			-	0.3
D				-

After a distance matrix is computed, it is then run through an algorithm, i.e., a procedure or formula for solving a problem. These algorithms fall into two categories: those based on clusters and those based on optimality.

The cluster-based methods are the simplest and since the Schories paper used a cluster-based method, this is what I will describe. What they do is initially combine everything into pairs based on their similarities, forming the tips of the tree. The similarity matrices for the pairings are recalculated, and another round of grouping takes place, forming deeper nodes in the tree. Eventually, when everything is combined into one group, one obtains the final tree.

One of the most often encountered algorithms for doing this is the neighbor-joining method (NJ). NJ is the most popular to use for "quick-and-dirty" analyses – the results are usually astoundingly accurate and the computation is quick. It is commonly used for trees based on DNA or protein sequence data and, as mentioned, the algorithm requires knowledge of the distance between each pair of taxa in the tree.

In Figure 2 we start with a star tree of seven taxa (A). A distance matrix is used to choose a pair of closest nodes for joining, in this case f and g. These are joined to a newly created node, u, as shown in (B). The part of the tree shown as solid lines is now fixed and will not be changed in subsequent joining steps. This process is then repeated, using just the distances between the nodes a, b, c, d, e and u. In this case u and e are joined to the newly created v, as shown in (C). Two more iterations lead first to (D), and then to (E), at which point the algorithm is done, as the tree (unrooted in the example) is fully resolved.

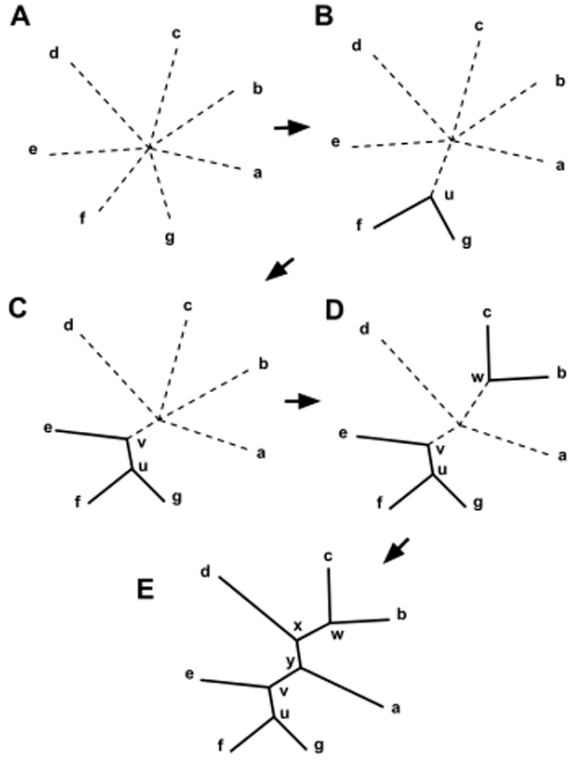

FIGURE 2: NEIGHBOR-JOINING

EXACT METHODS

The Schories paper stated that "Heuristic and branch-and-bound tree searches were performed …" Computerized searches to find cladograms can be divided into two groups: exact methods and heuristic methods. The exact method is shown in Figure 3 using five taxa, A, B, C, D and E. First, three taxa are chosen and connected to form the only possible unrooted resolved cladogram for these taxa (Figure 3, top cladogram). A fourth taxon is then selected (which taxon is chosen is immaterial) and joined to each of the three branches of cladogram 1, yielding three possible networks for four taxa (Figure 3, second row) Note that at this point taxon A has been chosen as the root and all cladograms are rooted. (The majority of the computer algorithms used to estimate most parsimonious cladograms actually generate unrooted networks.) A fifth taxon is then selected and added to each of the five branches of the three cladograms, giving 15 cladograms (Figure 3, rows 3-5) and all taxa have been added. The lengths (i.e., the number of steps or changes in character traits) of all these cladograms are calculated and the shortest, i.e., the one with the smallest number of character changes is the optimal, i.e., most parsimo-nious.

Number of taxa	Number of rooted trees	Number of unrooted trees
1	1	-
2	1	1
3	3	1
4	15	3
5	105	15
20	8,200,794,532,673,891,559,375	221,643,095,476,699,771,875

FIGURE 4: NUMBER OF TREES VERSUS NUMBER OF TAXA

The problem with exact methods is that as the number of taxa considered increases, the number of trees increases much more rapidly, especially with rooted trees (see Figure 4). The taxa in the Schories paper consisted of various specimens taken from different localities of four species of *Poecilia*, plus *Micropoecilia picta* as an outgroup, resulting in a total of 37 taxa. Just for 20 taxa, the number of possibilities that must be evaluated is huge.

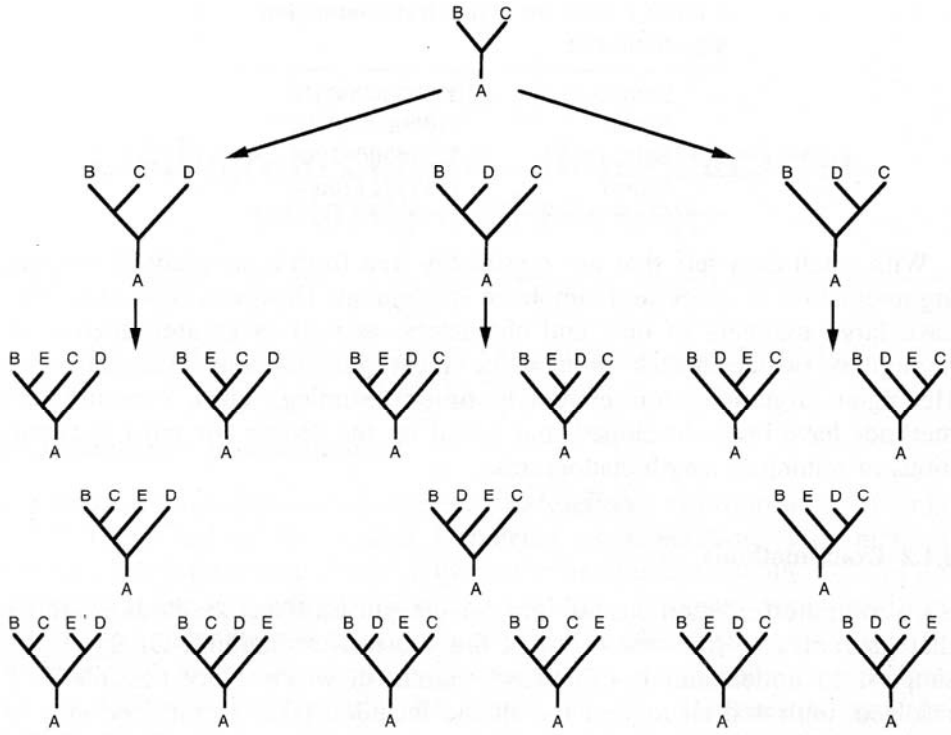

FIGURE 3: EXACT (EXHAUSTIVE) SEARCH

Branch-and-Bound (Figure 5) is an exact technique that does not require every possibility to be examined individually. In this method a cladogram is constructed for all the taxa using one of the heuristic techniques that we will discuss later. The length of this cladogram is stored in the computer memory and called the "upper bound" (100 steps where step = one character change). The Branch-and-Bound method then proceeds as in the exact search routine. As each of the paths is followed, the lengths of the partial cladograms (those in which

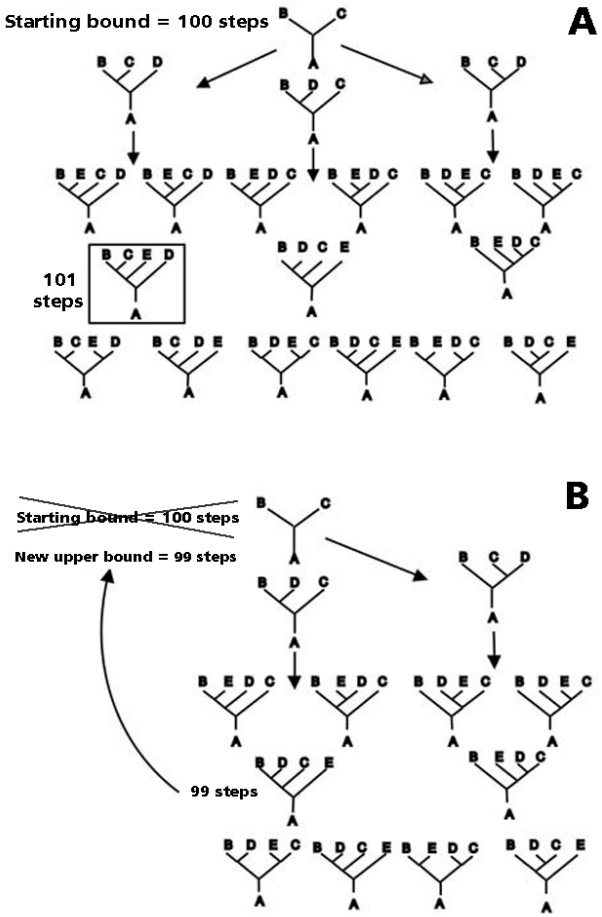

FIGURE 5: BRANCH-AND-BOUND

not all taxa have been yet added) is calculated. As soon as the length of a cladogram in any path is longer than the upper bound, that entire path is abandoned because the addition of more taxa can only increase the length of the cladogram further. If one of the paths is completed and a shorter cladogram is found, this then becomes the new upper bound.

In Figure 5 we started the analysis by assuming that the starting bound was 100 steps. In row 4, however, the cladogram has 101 steps so the whole portion of that part of the tree in part A is discarded (part B of the figure). Note that one of the cladigrams has only 99 steps. This now becomes the new upper bound and the process continues. By this method the number of cladograms that have to be evaluated is drastically reduced. Even so, Branch-and-Bound usually begins to stress most computers at about 15 to 20 taxa.

HEURISTIC METHODS

For larger data sets, approximate or heuristic methods that generally use "hill climbing" techniques must be used. These approaches are essentially trial-and-error and do not guarantee to find all - or even any – of the minimum length cladograms. Thus, certainty of finding the optimal results is sacrificed in favor of reducing computational time.

The heuristic method example here starts with the same first three taxa (Figure 6a). It then adds the fourth taxon, calculates the lengths, and discards all but the shortest (Figure 6b). This means that even if the addition of the next taxon to one of the cladograms now discarded should turn out to yield trees shorter than those retained it will not be considered again; it has already been discarded because of the inferiority of its antecedent cladograms. If there is a tie in the lengths of the cladogram one will arbitrarily be discarded (Figure 6c). It is possible, therefore, that by discarding paths of cladogram building so early we are forced onto a path that may lead to a less than optimal cladogram length.

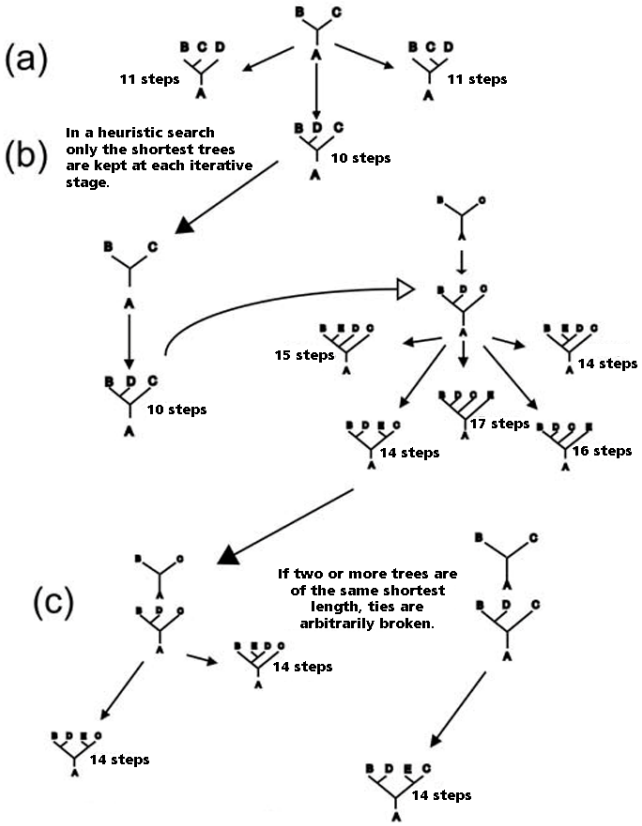

FIGURE 6: HEURISTIC SEARCH

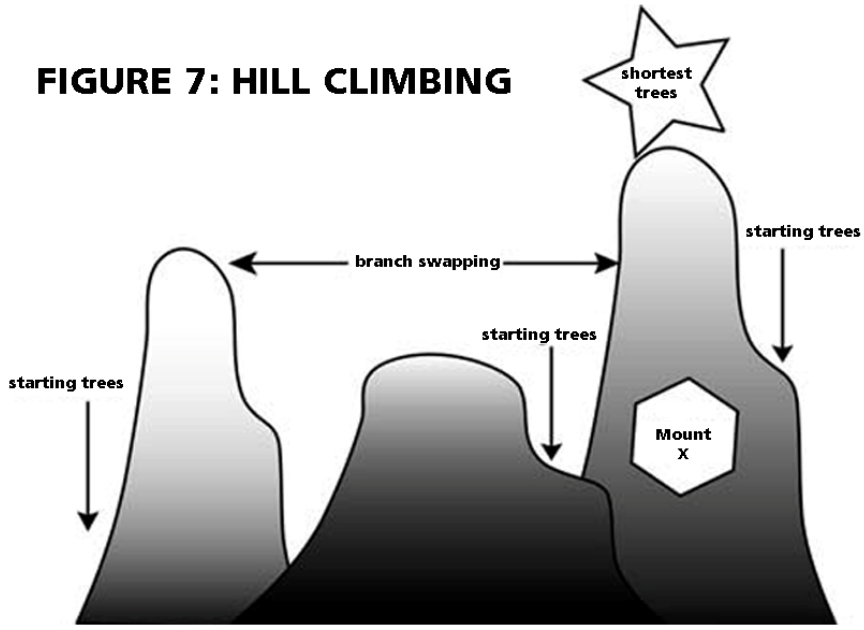

FIGURE 7: HILL CLIMBING

This can be illustrated by using the analogy of a hill climber wishing to reach the highest peak using the shortest route which, in our case, is the shortest cladogram. Figure 7 is meant to illustrate the problem. Each of the mountains represents a path of cladogram construction. If we happened to start on any mountain but Mount X we would never reach the optimal solution and, having started to climb a particular mountain (i.e., started a path of tree building), we cannot go back. We could (1) choose to start somewhere else (on another hill); in other words we could change the order in which we add the taxa; or (2) having started to climb and if we were wearing a rocket backpack, we could jump horizontally from one hill to another in the hope of landing on a more promising hill. Both tactics are invoked in heuristic algorithms.

The order in which taxa are to be added to the heuristic search is called "stepwise addition" and is an attempt to start on different mountains. Figure 8A shows how a single search can maroon the hill climber on a local minimum. In Figure 8B, multiple searches on different starting points increases the likelihood of finding the global maximum.

Another approach, the equivalent of jumping from one mountain to another, performs a series of predefined rearrangements of the cladogram in the hope that a shorter cladogram will be found. This rearrangement, commonly referred to as "branch-swapping," is very hit-and-miss but if a shorter cladogram does exist and sufficient rearrangements are performed, then one of these rearrangements is likely to find it. By using a combination of stepwise addition and branch swapping the heuristic algorithm more than likely will find the shortest tree(s).

In stepwise addition we start with three taxa and then add taxa one at a time at each of the branches of the tree from the previous step. The best tree is retained according to the parsimony (shortest path) criterion. There a number of ways the addition can be carried out and two are shown in Figure 9. In the ASIS sequence we start with taxa A, B and C then add D, E and F at the fourth, fifth and sixth steps. In the Random sequence we start with taxa A, B and C then

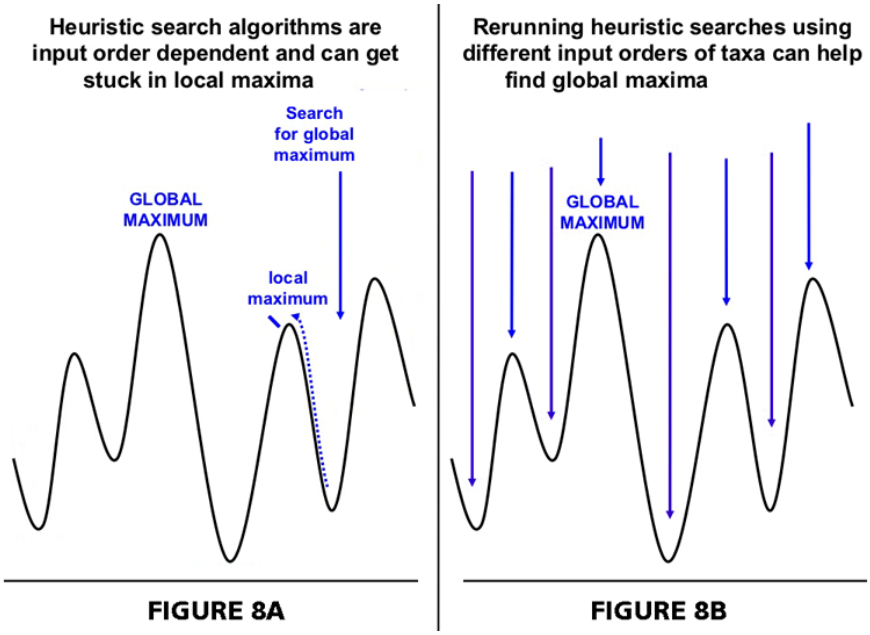

FIGURE 8A **FIGURE 8B**

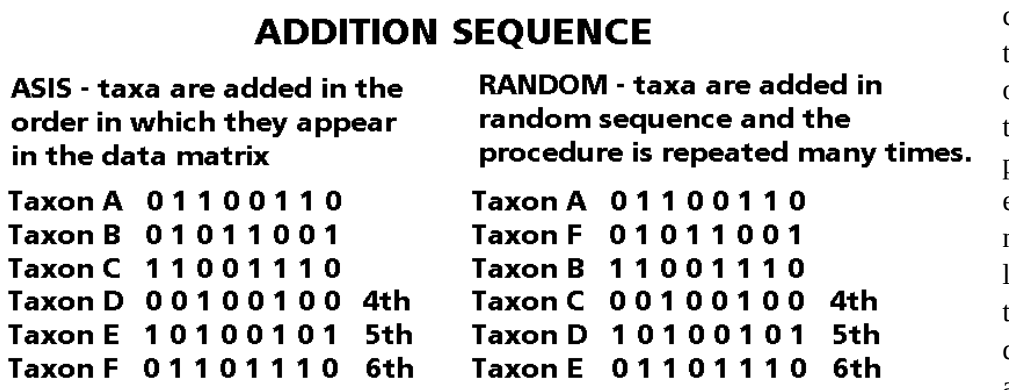

FIGURE 9: STEPWISE ADDITION

add C, D and E (these were selected randomly) at the fourth, fifth and sixth steps. The random addition sequence is most often used. It is also useful in that it can provide a number of different starting points and thereby improve the chances that at least one will lead to the global, rather than a local, optimum.

Branch-swapping algorithms are implemented by all cladistic computer packages. The simplest rearrangement is nearest-neighbor interchange, sometimes referred to as local branch-swapping. For any internal branch, there are just two such nearest-neighbor interchange rearrangements. In Figure 10, the chosen branch (indicated by the short arrow) has a pair of nearest-neighbor groups at either end, A + B, C and D, E + F. One of these from the left end (C) is interchanged with each of those on the right end (D or E + F) in turn to give two new topologies. The procedure is then repeated for all possible internal branches and the lengths of the resulting topologies calculated to determine whether they are shorter.

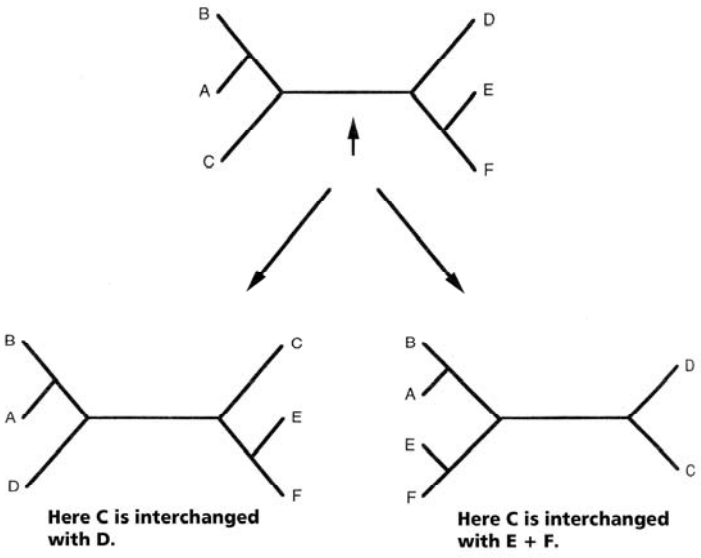

FIGURE 10: BRANCH SWAPPING

Note that the Branch and Bound technique discussed in the exact methods section uses any one of these heuristically-derived minimum lengths as a starting point.

CONSENSUS TREES

Often a tree building routine will report more than one parsimonious tree. In other words, the data used is compatible with more than one cladogram or tree. In such circumstances there are two things that one can do. We can choose one of the trees as the one we favor (the criteria by which we do this are varied and usually based on biological or geological arguments) or we can establish the common elements between the trees, i.e., the lowest common denominator. For the second route, consensus trees are constructed. There are several kinds of consensus trees but I will discuss only two here: Strict and Majority Rule.

Let us assume that as a result of an analysis we ended up with three equally parsimonious cladograms shown in the top row in Figure 11. These are called the starting or fundamental trees because they are the three alternatives derived from the analysis of the data. The simplest way to combine the elements of all three cladograms into one is to show only those components that appear in all three cladograms. By scanning across the three trees we see that relationships differ between A, B and C, and again between D, E and F. However, the two groups, ABC and DEF, are the same in all trees. Therefore if we combine this infor-

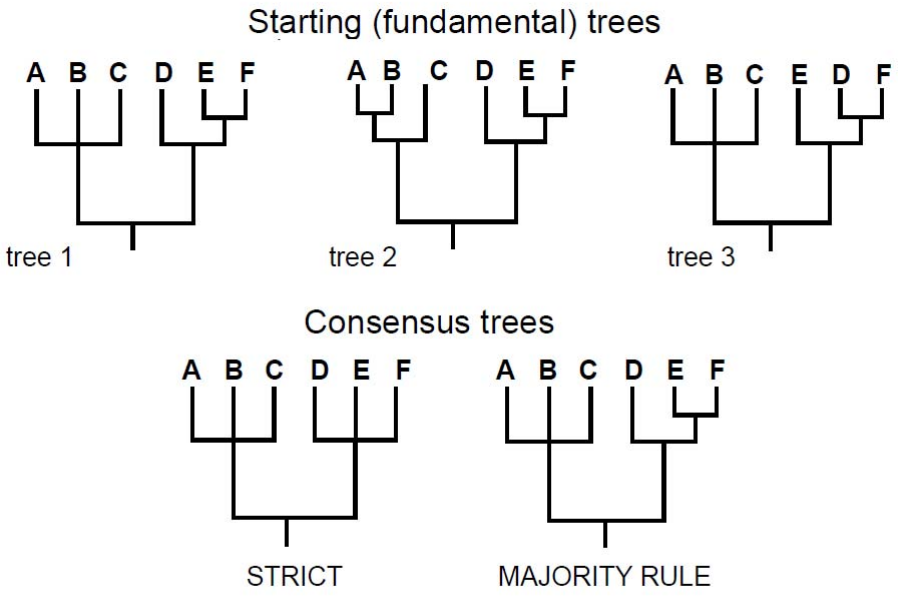

FIGURE 11: CONSENSUS TREE CONSTRUCTION

mation we end up with the tree to the left in the second row. This is known as the Strict Consensus method. Many purists believe that this is the only consensus method that should be considered, all others being tainted by concessions that cannot be justified. Other practitioners think otherwise.

The Majority Rule simply takes those solutions within the starting trees that are found in the majority of the trees. Thus the grouping (A,B,C) is found in two out of three trees and the grouping (D (E,F)) is also found in two out of three.

BOOTSTRAPPING

With the increasing emphasis by systematic biologists on tree construction, questions arose as to how confident one should be in a given phylogenetic tree and how support for phylogenetic trees should be measured. The bootstrap was introduced in 1979 by statisticians to obtain estimates of error in non-standard situations by resampling the data set many times to provide a distribution against which hypotheses could be tested. Very soon after the introduction of the bootstrap, it was applied to questions in phylogeny reconstruction and formally proposed as a method for obtaining confidence limits on cladograms.

Bootstrapping reanalyzes the data of the original character-taxon matrix by selecting (resampling) CHARACTERS at random. In this way any given character can be selected more than once. The start of the method is shown in Figure 12 and, for a change, I will use molecular data - nucleotide characters - rather than morphological data in this example: G is guanine, A is adenine, T is thymine and C is cytosine. The original data set of 4 taxa (A–D) each with 10 nucleotide characters is resampled across characters (with replacement) to produce bootstrap pseudoreplicates. Each pseudoreplicate contains each of the 4 original taxa, but

Original Data Set

Taxa	Characters
	1 2 3 4 5 6 7 8 9 10
A	C G A A C C A C T T
B	C G A A C C G G T T
C	G G T A C C G G A T
D	G C T A G C G C A T

Bootstrap Data Sets

Bootstrap Pseudoreplicate 1:

Taxa	Characters
	8 10 7 4 1 10 2 8 5 3
A	C T A A C T G C C A
B	G T G A C T G G C A
C	G T G A G T G G C T
D	C T G A G T C C G T

Bootstrap Pseudoreplicate 2:

Taxa	Characters
	1 8 10 4 2 9 2 8 5 6
A	C C T A G T G C C C
B	C G T A G T G G C C
C	G G T A G A G G C C
D	G C T A C A C C G C

Bootstrap Pseudoreplicate 3:

Taxa	Characters
	3 2 5 7 1 6 9 4 4 10
A	A G C A C C T A A T
B	A G C G C C T A A T
C	T G C G G C A A A T
D	T C G G G C A A A T

Bootstrap Pseudoreplicate 4:

Taxa	Characters
	7 8 5 8 9 6 4 10 1 5
A	A C C C T C A T C C
B	G G C G T C A T C C
C	G C G A C C A T G C
D	G C G C A C A T G C

FIGURE 12: BOOTSTRAPPING DATA GENERATION

some original characters for those taxa are represented more than once and some not at all.

Each bootstrap data set is analyzed and the cladograms resulting from parsimony analysis of each bootstrap data set are shown in Figure 13. The seven trees from all four of these pseudoreplicate data sets are then summarized in a consensus tree, typically a 50% majority rule consensus tree that shows all clades recovered in more than 50% of all trees (four out of the seven or 57% had the CD clade and four out of the seven or 57% had the BCD clade.

There is, however, a serious and fundamental problem with the bootstrap. This is the requirement that the characters in the original data matrix should represent a random sample of all possible characters. However, in systematic studies, characters are not randomly sampled from independent, identically distributed populations. Rather, they are carefully selected and filtered with the aim of best resolving the relationships of the taxa under study. However, most systematists view bootstrap values as relative assessments of clade support rather than strict statistical values. In this sense, consensus has been reached among practitioners, if not among statisticians and theoreticians. Despite concerns, controversy and confusion over interpretation of bootstrap values, bootstrap analyses have played a prominent role in many phylogenetic studies and likely will remain a key method for assessing nodal support in phylogenetic trees. Given that most systematists are most interested in identifying well-supported groups, the ease of bootstrap analysis using readily-available computer packages ensures that the bootstrap will continue to be widely used in systematic circles for the foreseeable future.

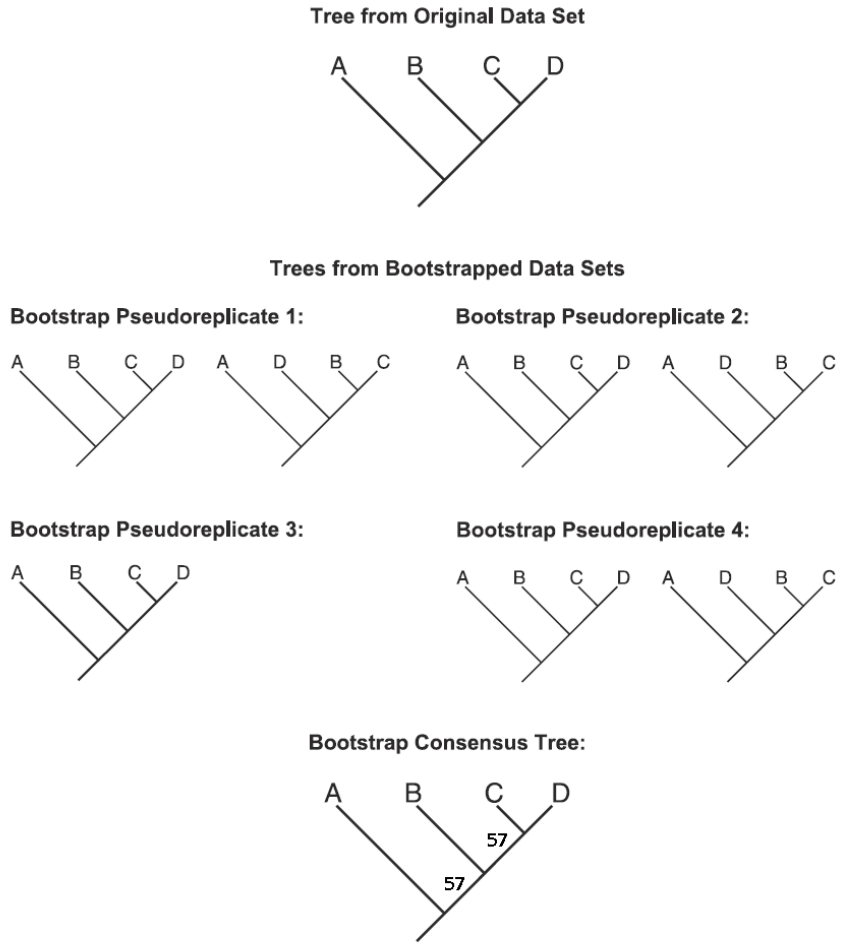

FIGURE 13:
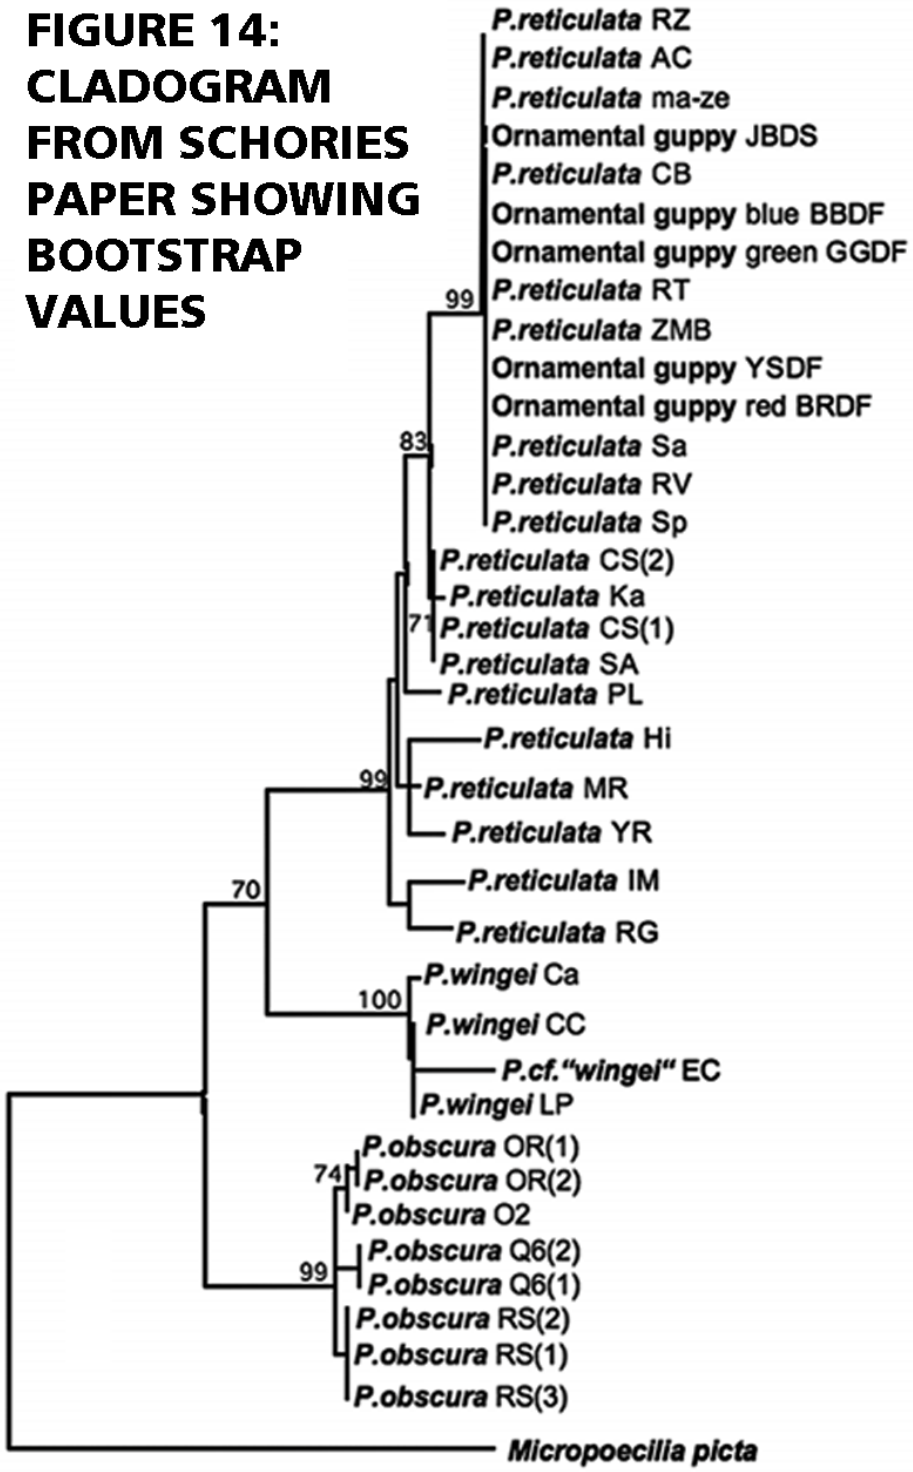
CONSTRUCTION OF BOOTSTRAP CONSENSUS TREE

Cladograms (and phylogenetic trees in general) are typically presented with bootstrap values associated with the nodes. Figure 14 shows a cladogram from the Schories paper showing the relationships among various specimens taken from different localities of four species of *Poecilia*, plus *Micropoecilia picta* as an outgroup, based upon strict consensus of the most parsimonious trees. The bootstrap values for 20000 replicates are shown. Note that some nodes receive bootstrap values of 100%, indicating strong support for these nodes, whereas other nodes receive weaker support.

COMPUTER PROGRAMS

There are many phylogenetic software programs to choose from but my own preferences are PAUP and PHYLIP. PAUP (Phylogenetic Analysis Using Parsimony), written by David L. Swofford of the School of Computational Science and Information Technology, Florida State University,

FIGURE 14: CLADOGRAM FROM SCHORIES PAPER SHOWING BOOTSTRAP VALUES



Tallahassee, Florida, as the name implies originally, only implemented parsimony, but from version 4.0 (when the program became known as PAUP*) it also supports distance matrix, invariants, and maximum likelihood methods and many indices and statistical tests. PHYLIP (PHYLogeny Inference Package), written by Joseph Felsenstein, Professor in the Department of Genome Sciences and the Department of Biology at the University of Washington, Seattle, supports parsimony, distance matrix, and likelihood methods, including bootstrapping and consensus trees. Data types that can be handled include molecular sequences, gene frequencies, restriction sites and fragments, distance matrices, and discrete characters. Both run on Windows and Mac OS X; PHYLIP is free (I have the Windows version on my computer) and the Windows version of PAUP costs $85 (I have used the Windows version on my university's computer). The program used in the Schories paper was MEGA 3.1 and, like PHYLIP, it also is free.

Using phylogenetic software is not for the faint of heart since one has to know the relevant biology and also be comfortable with computers, the latter especially with the free programs since most run from the command line and do not have a mouse interface with the computer.

Two of the PAUP menus are shown in Figure 15 (the PAUP interface is much easier to use than the PHYLIP interface). A glance at the Analysis menu shows that all of the computations I have discussed in this essay are implemented here (the first two menus have to do with data input and intermediate output). The Trees menu is concerned with output and I have shown an example produced by an exhaustive search in Figure 16

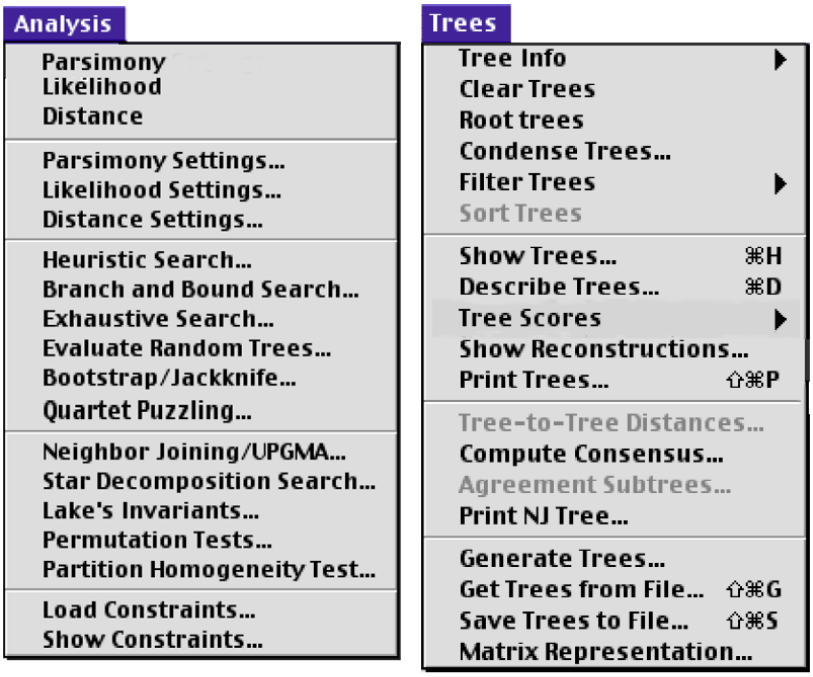


FIGURE 15: PAUP MENUS

where the tree is presented in the form of a distribution. The top of the diagram indicates that four most parsimonious trees were found, one that was just one step longer and seven that were two steps longer. The program can then be used, after selecting any or all of these cladograms, to produce a consensus tree.

Schories, S., M.K. Meyer and M. Schartl, "Description of *Poecilia* (Acanthophacelus) *obscura* n. sp., (Teleostei: Poeciliidae), a new guppy species from eastern Trinidad, with remarks on *P. wingei* and the status of the (Endler's guppy)," *Zootaxa* 2266, pp. 35-50, 2009.

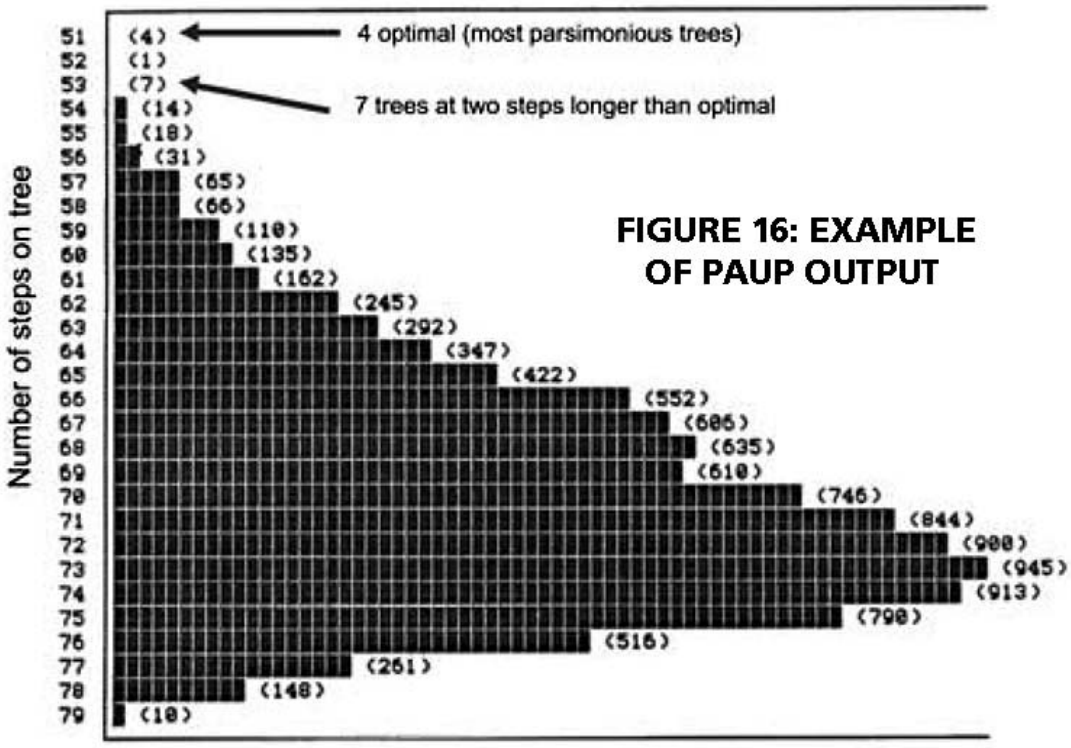

FIGURE 16: EXAMPLE OF PAUP OUTPUT

BAYESIAN INFERENCE IN PHYLOGENY

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, April 11, 2015)

There is no doubt that phylogeny reconstruction has had a major effect on systematic ichthyology, resulting in many name changes of aquarium fishes. There is also no doubt that fish systematics is currently in a period of reevaluation as to the methodology employed to estimate phylogeny. This is not to say that issues such as the use of morphological data versus molecular data or whether or not to combine data for phylogenetic analyses have not been debated in the past. Clearly, these and many other issues have received a considerable amount of debate in the phylogenetic literature. Possibly one of the most rigorously debated topics is the choice of an optimality criterion. In general, there are three basic methods that have been used to estimate phylogeny, including distance, maximum parsimony (MP), and maximum likelihood (ML). The relative merits and shortcomings of these methods have been debated for a number of years.

Numerous comparative studies employing both known phylogenies and simulated data have been very useful in determining under what set of conditions each of the methods "out performs" the others. For example, it is now generally accepted that when rates of change along branches vary greatly, employing a parsimony optimality criterion may be misleading due to "long branch attraction" (LBR). LBA is a phenomenon in phylogenetic analyses (most commonly those employing maximum parsimony) when rapidly evolving lineages are inferred to be closely related, regardless of their true evolutionary relationships.

The problem arises when the DNA of two or more lineages evolves rapidly. There are only four possible nucleotides (the DNA used by living organisms is synthesized using only four DNA bases: cytosine, guanine, adenine and thymine, C, G, A and T, respectively) and when DNA substitution rates are high (a substitution is a mutation that exchanges one base for another such as switching an A to a G), the probability that two lineages will independently evolve the same nucleotide at the same site increases. When this happens, parsimony erroneously interprets this similarity as a synapomorphy (a shared derived character trait).

A simulated example of the LBA is shown in Figure 1. The real tree shows the relationships of five taxa with two taxa (2 and 3) having long evolutionary branches. The tree derived from using the parsimony criterion results in artificially grouping 2 and 3 together because of LBA.

As in Maximum Parsimony (MP), Maximum Likelihood (ML) evaluates alternative trees. However it considers the probability of each tree explaining the given data based on a model of evolution. In this case, the tree with the highest probability of explaining the data is chosen over the other ones. In other words, it compares how different

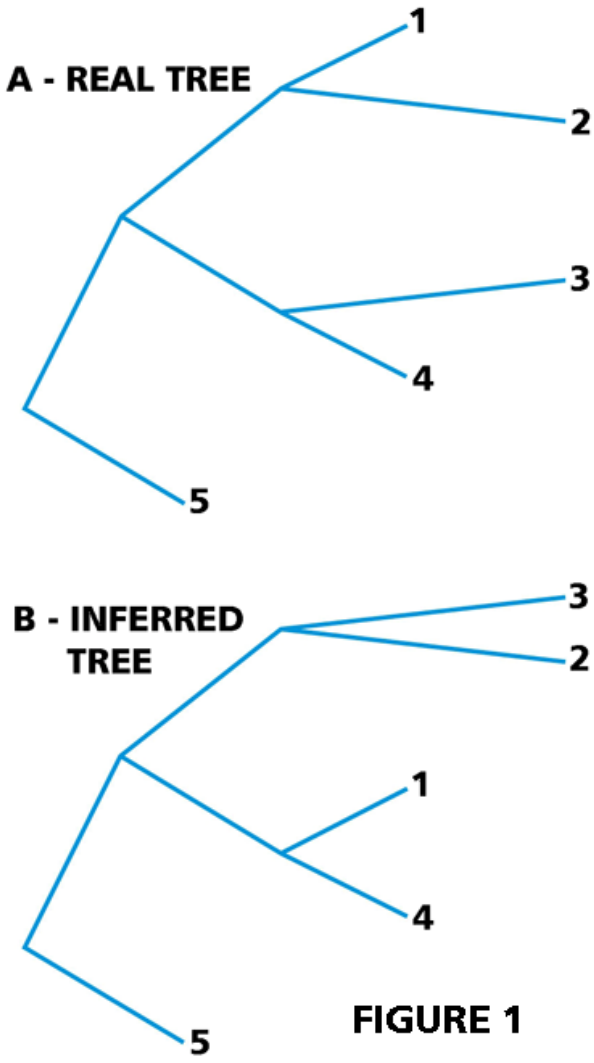

FIGURE 1

trees predict the observed data. The introduction of a model of evolution in ML analyses presents an advantage over MP as the probability of nucleotide substitutions and rates of these substitutions are taken into account, explaining the phylogenetic relationships of taxa in a more realistic way. An important consideration of this method is the branch length, which parsimony ignores, where changes are more likely to happen in long branches than in short ones. This approach eliminates the LBA problem and explains the greater consistency of ML over MP. Although considered by many the best approach to infer phylogenies from a theoretical point of view, ML is computationally intense and it is almost impossible to explore all trees as there are just too many.

Recently, another round of comparative studies has begun to address a new approach for phylogeny reconstruction - Bayesian analysis. Bayesian statistics dates back to the 18th century and is named after the Rev. Thomas Bayes (1701–1761), who first showed how to use new evidence to update beliefs. Its utility for reconstructing phylogeny was suggested initially in 1968 but it is only recently that these methods have become more widely known and relevant computer programs have become available. Like ML, Bayesian inference also incorporates a model of evolution, the main advantages over both MP and ML being that is computationally more efficient than traditional methods, it quantifies and addresses the source of uncertainty and is able to incorporate complex models of evolution.

MONTE CARLO METHODS

Monte Carlo methods are computational algorithms (simply sets of instructions) which randomly sample from some process under study. They are a way of estimating something which is too difficult or time consuming to find mathematically. You could, for example, determine the probably of obtaining 3 heads and 7 tails on a flip of a biased coin that comes up heads 65% of the time mathematically, but hand-held computations would keep you at it for quite a while. On the other hand, you could program a computer to randomly sample from a binomial distribution (the relevant distribution for this example) 50,000 times and to record the number of times 3 heads and 7 tails came. Divide this 50,000 and you have your answer within a few seconds.

MARKOV CHAINS

A simple description of Markov chain is a frog jumping on a set of lily pads. The frog jumps from a lily pad to a lily pad and where it lands depends only on where it was at the time when it jumped and not on where it was in the past. In other words, a Markov Chain is a random process that has the property that the future depends only on the current state of the process and not the past i.e. it is memoryless.

A SIMPLE EXAMPLE OF A MARKOV CHAIN

Suppose that the weather on any given day can be classified into two states only: sunny and rainy. Based on past experience, we know the following:

P(Next day is sunny | Given today is rainy) = 0.50
Since the next day's weather is either sunny or rainy it follows that:
P(Next day is Rainy | Given today is rainy) = 0.50

Similarly, let:
P(Next day is rainy | Given today is sunny) = 0.10

Therefore, it follows that:
P(Next day is sunny | Given today is sunny) = 0.90

The above four numbers can be compactly represented by what is known as a “transition matrix” which represents the probabilities of the weather moving from one state to another.

transition matrix

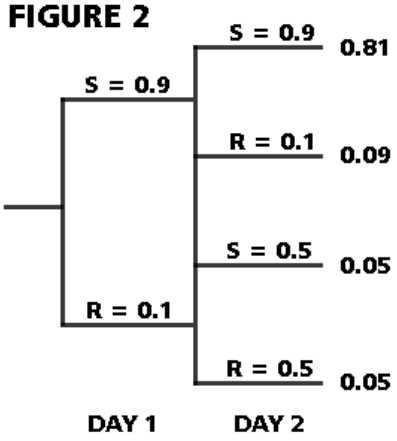
State	Sunny	Rain
Sunny	0.900 000	0.100 000
Rain	0.500 000	0.500 000

Let’s examine the following two questions and answers:

Q1: If the weather is sunny today then what is the weather likely to be tomorrow?
A1: Since, we do not know what is going to happen for sure, the best we can say is that there is a 90% chance that it is likely to be sunny and 10% that it will be rainy.

Q2: What about two days from today?
A2: This might be easier to visualize as we go along by using the tree shown in Figure 2.

FIGURE 2



The next day prediction is as before, 90% sunny, 10% rainy. Two days from now it can also be sunny. The chances of this happening are: 0.9*0.9.

However, on the first day it can be rainy and second day it can be sunny. The chances of this happening are: 0.1 * 0.5. Therefore, the probability that the weather will be sunny in two days is

P(Sunny two days from now) = 0.9*0.9 + 0.1*0.5 = 0.81 + 0.05 = 0.86.
Similarly, the probability that it will be rainy is
P(Rainy two days from now) = 0.9* 0.1 + 0.1 * 0.5 = 0.09 + 0.05 = 0.14

Table I shows that if you keep forecasting weather like this you will notice that eventually the 20th day and after forecast settles down to the following "equilibrium" probabilities," 0.883 and 0.167.

The numbers form what is known as a "probability distribution vector," in this case the equilibrium probability vector. In other words, your forecast for the nth day and the n+1th day remain the same. In addition, Table I shows that the equilibrium probabilities do not depend on the weather today. You would have gotten the same forecast for the weather if you had started off by assuming that the weather today was rainy.

BAYES THEOREM

We are all familiar with the use of classical statistics to examine a current set of data to test specific hypotheses; Bayesian statistics differs in that in addition to the current data, prior knowledge is included in the testing of the hypothesis.

Let A_1, $A2$, ... , A_n be a set of mutually exclusive events that together form the sample space S. Let B be any event from the same sample space, such that P(B) > 0. Then, by Bayes Theorem,

$P(A_k|B) = P(A_k \text{ and } B)/[P(A_1 \text{ and } B) + P(A_2 \text{ and } B) + \ldots + P(A_n \text{ and } B)]$

Note: Invoking the fact that $P(A_k \text{ and } B) = P(A_k)P(B|A_k)$, Baye's theorem can also be expressed as

$P(A_k|B) = P(A_k)\, P(B|A_k)/[P(A_1)\, P(B|A_1) + P(A_2)\, P(B|A_2) + \ldots + P(A_n)\, P(B|A_n)]$ or

$P(A_k|B) = P(A_k)\, P(B|A_k)/[\sum P(A_j)\, P(B|A_j)]$
where the sum ($\sum$) goes from j = 1 to n.

As an example, Marie is getting married tomorrow, at an outdoor ceremony in the desert. In recent years, it has rained only 5 days each year. Unfortunately, the weatherman has predicted rain for tomorrow.

TABLE I

probability distribution vectors

Start = Sunny			Start = Rain		
Day	Prob Vector		Day	Prob Vector	
0	1	0	0	0	1
1	0.900 000	0.100 000	1	0.500 000	0.500 000
2	0.860 000	0.140 000	2	0.700 000	0.300 000
3	0.844 000	0.156 000	3	0.780 000	0.220 000
4	0.837 600	0.162 400	4	0.812 000	0.188 000
5	0.835 040	0.164 960	5	0.824 800	0.175 200
6	0.834 016	0.165 984	6	0.829 920	0.170 080
7	0.833 606	0.166 393	7	0.831 968	0.168 032
8	0.833 442	0.166 557	8	0.832 787	0.167 212
9	0.833 377	0.166 622	9	0.833 114	0.166 885
10	0.833 350	0.166 649	10	0.833 245	0.166 754
11	0.833 340	0.166 659	11	0.833 298	0.166 701
12	0.833 336	0.166 663	12	0.833 319	0.166 680
13	0.833 334	0.166 665	13	0.833 327	0.166 672
14	0.833 333	0.166 666	14	0.833 331	0.166 668
15	0.833 333	0.166 666	15	0.833 332	0.166 667
16	0.833 333	0.166 666	16	0.833 332	0.166 667
17	0.833 333	0.166 666	17	0.833 333	0.166 666
18	0.833 333	0.166 666	18	0.833 333	0.166 666
19	0.833 333	0.166 666	19	0.833 333	0.166 666
20	0.833 333	0.166 666	20	0.833 333	0.166 666

When it actually rains, the weatherman correctly forecasts rain 90% of the time. When it doesn't rain, he incorrectly forecasts rain 10% of the time. What is the probability that it will rain on the day of Marie's wedding?

Solution: The sample space is defined by two mutually-exclusive events: it rains or it does not rain. Additionally, a third event occurs when the weatherman predicts rain. Notation for these events appears below.

Event A_1. It rains on Marie's wedding.
Event A_2. It does not rain on Marie's wedding.
Event B. The weatherman predicts rain.

In terms of probabilities, we know the following:

$P(A_1) = 5/365 = 0.014$ [It rains 5 days out of the year.]
$P(A_2) = 360/365 = 0.986$ [It does not rain 360 days out of the year.]
$P(B|A_1) = 0.9$ [When it rains, the weatherman predicts rain 90% of the time.]
$P(B|A_2) = 0.1$ [When it does not rain, the weatherman predicts rain 10% of the time.]

We want to know $P(A_1|B)$, the probability it will rain on the day of Marie's wedding, given a forecast for rain by the weatherman. The answer can be determined from Bayes' theorem, as shown below.
$P(A_1|B) = P(A_1)\, P(B|A_1) / \sum [\, P(A_i) + P(A_2)\, P(B|A_2)]$
Where the sum ($\sum$) in this case goes from 1 to 2.

Thus,

$P(A_1|B) = (0.014)(0.9) / [(0.014)(0.9) + (0.986)(0.1)] = 0.111$

Note the somewhat unintuitive result. Even when the weatherman predicts rain, it rains only about 11% of the time. Despite the weatherman's gloomy prediction, there is a good chance that Marie will not get rained on at her wedding.

SUBSTITUTION MODELS

The Bayesian approach combines the prior probability of a tree with the likelihood of the data observed to produce a posterior probability distribution on trees. The tree with the highest posterior probability is chosen to best represent a phylogeny. Although Bayesian inference is similar to maximum likelihood (ML) in that it employs a likelihood function and an explicitly stated model of nucleotide substitution, the difference is in the use of a prior probability (see Figure 3). The likelihood is the vehicle that carries the phylogenetic information contained in the data in both maximum likelihood and Bayesian estimation, and the same models of DNA, amino acid, or morphological evolution can be used in both methods.

In biology, a substitution model describes the process from which a sequence of characters changes into another set of traits. In phylogenetics, sequences are often obtained by firstly obtaining a nucleotide

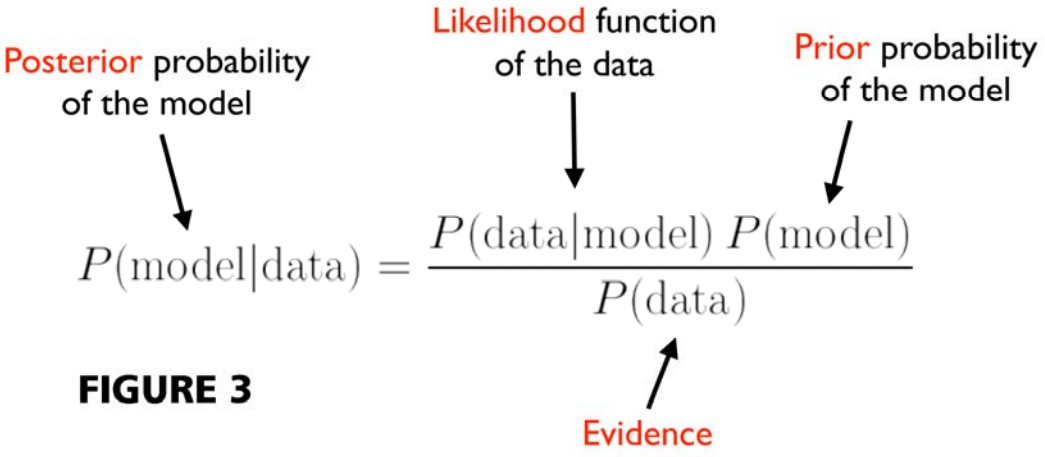


FIGURE 3

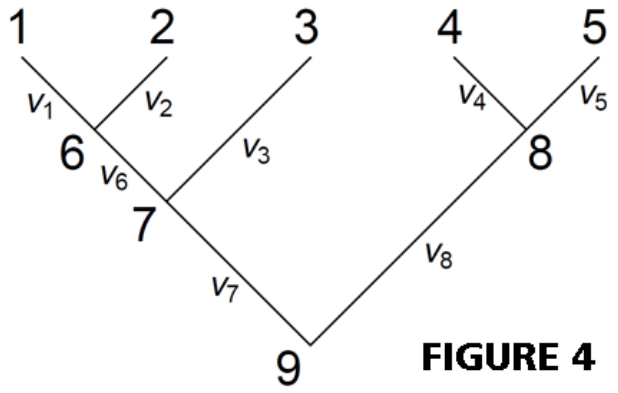

FIGURE 4

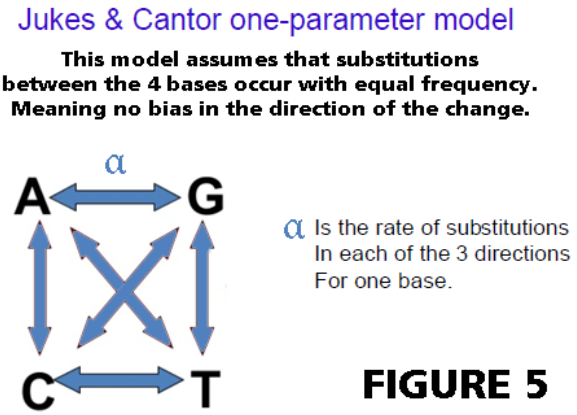

FIGURE 5

and then taking the bases or amino acids at corresponding positions in the alignment as the characters. Sequences achieved by this might look like AGCGGAGCTTA and GCCGTAGACGC.

A Bayesian model consists of a tree (τ_i) with branch lengths specified on the tree (v_i) and a stochastic model of DNA substitution. Figure 4 shows an example of a phylogenetic tree of five species. The tips of the tree are labeled 1, 2, 3, 4 and 5 for the species, and the internal nodes are labeled 6, 7, 8 and 9. The nodes are where the substitution model comes into play. They describe how characters evolve on the tree, and information on the value of the parameters in the model and on the lengths of the branches on the tree.

The parameters of the substitution model vary with the details of the analysis but typically include variables related to the frequency of the character states, biases in rates of change among character states, and rate variation across sites. The simplest model of this type is the one-parameter model of Jukes and Cantor (Figure 5).

The following table shows DNA data for four species.

Species 1	A	A	G	C	**C**	**C**	C	A
Species 2	A	T	A	A	**C**	**C**	G	C
Species 3	C	A	A	T	**A**	**G**	T	C
Species 4	G	G	T	T	**T**	**T**	C	T

Suppose we wished to calculate the probability of going from the character CCAT to character CCGT shown in boldface. Substitution models produce transition matrices like the following one for a CCAT sequence.

	A	C	G	T
A	0.976	0.010	0.007	0.007
C	0.002	0.983	0.005	0.010
G	0.003	0.010	0.979	0.007
T	0.002	0.013	0.005	0.979

The matrix satisfies all the requirements for it to be a Markov chain and after many changes the equilibrium distribution, which is the expected CCAT frequency, is [0.1, 0.4, 0.2, 0.3]. Since

the probability of going from C to C is 0.983,
the probability of going from A to G is 0.007,
the probability of going from T to T is 0.979,

the probability of going from CCAT to CCGT, therefore, is 0.1 * 0.983 * 0.4*0.983 * 0.2*0.007 * 0.3 * 0.979 = 0.0000454.

DETERMINING THE PROBABIILITY DISTRIBUTION OF TREES

Let's say we want to find the posterior probability of the ith tree. We need, however, to know the set of

branch lengths (v_i) and substitution parameters - we'll assume two here (α and θ) – to compute the likelihood. Bayesian inference of phylogeny is based upon the posterior probability of a phylogenetic tree, τ. The posterior probability of the ith phylogenetic tree, τ_i, based on the observed data matrix of DNA sequences (X) is obtained using Bayes formula:

$$P(\tau_i|X) = P(X|\tau_i)P(\tau_i) / [\sum P(X|\tau_j P(\tau_j)]$$

where the summation ($\sum$) goes from j = 1 to s, the number of species. Here, $P(\tau_i|X)$ is the posterior probability of the ith phylogeny and can be interpreted as the probability that τ_i is the correct tree given the DNA sequence data. The likelihood of the ith tree is $P(X|\tau_i)$ and the prior probability of the ith tree is $P(\tau_i)$. The summation in the denominator is over all trees that are possible for *s* species. Typically, an uninformative prior is used for trees, such a uniform distribution, $P(\tau_i) = 1/s$.

The likelihood function, $P(X|\tau_i)$, is integrated over all possible values for the branch length and substitution parameters:

$$P(X|\tau_i) = \int\int\int P(X|\tau_i, v_i, \alpha, \theta)P(v_i)(P(\alpha)P(\theta)dv_i d\alpha d$$

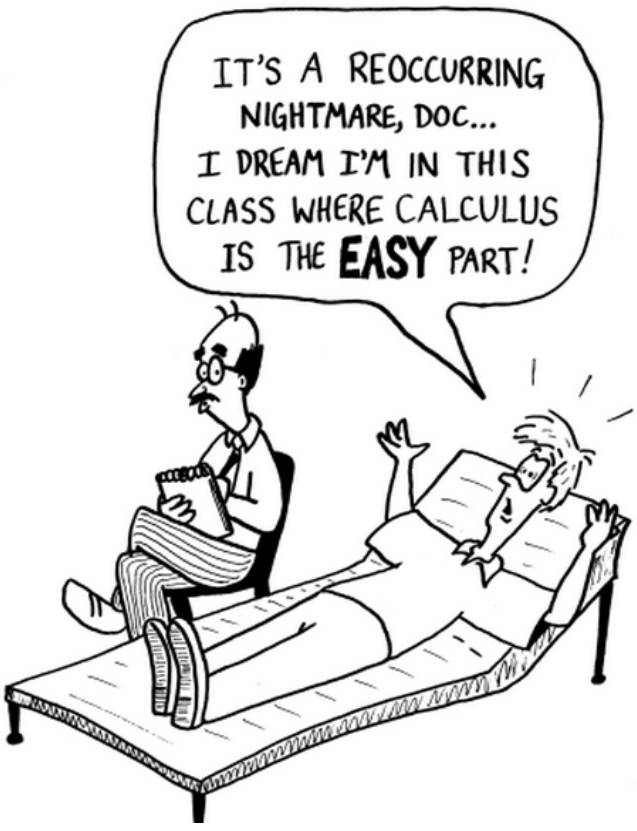
where the integrals sum over all values of the parameters, v_i, α and θ. (For those who are not familiar with calculus, just ignore the dv_i, $d\alpha$ and $d\theta$ terms.)

However, the denominator $\sum P(X|\tau_j P(\tau_j)$ and the integral in the numerator are generally not computable, except perhaps in a few of the very simplest cases. By necessity, then, the posterior probabilities of trees, branch lengths and substitution parameters must be approximated.

There are a number of methods available for approximating such sums, some of which involve sampling procedures. Ideally, one would like to approximate the posterior probability distribution of trees by randomly drawing from the posterior probability distribution of trees. The fraction of the time any tree was drawn would be a valid approximation of its posterior probability. This method is called Monte Carlo integration. Unfortunately, this ideal cannot yet be realized since the method requires that the samples must be independent. However, one can obtain information equivalent to that from independent samples by instead taking much larger dependent samples using the Markov Chain – Monte Carlo (MCMC) method to be described later.

EVOLUTION IS MARKOVIAN

In any phylogenetic tree, the predicted pattern of organisms at any given point in time can be described as "groups within groups," otherwise known as a nested hierarchy. The only known processes that specifically generate unique, nested, hierarchical patterns are branching evolutionary processes. Common descent is a genetic process in which the state of the present generation/individual is dependent only upon genetic changes that have occurred since the most recent ancestral population/ individual. Therefore, gradual evolution from common ancestors must conform to the mathematics



of Markov processes and Markov chains. Using Markovian mathematics, it can be rigorously proven that branching Markovian replicating systems produces nested hierarchies. For these reasons, biologists routinely use branching Markov chains to effectively model evolutionary processes, including complex genetic processes.

Let's examine a genetic example. The simplest type of inheritance of traits in animals occurs when a trait is governed by a pair of genes, each of which may be of two types, say G and g. An individual may have a GG combination or Gg (which is genetically the same as gG) or gg. Very often the GG and Gg types are indistinguishable in appearance, and then we say that the G gene dominates the g gene. An individual is called *dominant* if it has GG genes, *recessive* if it has gg genes and *hybrid* if it has a Gg (or gG) genes. In the mating of two animals, the offspring inherits one gene of the pair from each parent, and the basic assumption of genetics is that these genes are selected at random, independently of each other. This assumption determines the probability of occurrence of each type of offspring. The offspring of two purely dominant parents must be dominant, of two recessive parents must be recessive, and of one dominant and one recessive parent must be hybrid.

In the mating of a dominant and a hybrid animal, each offspring must get a G gene from the former and has an equal chance of getting G or g from the latter. Hence there is an equal probability for getting a dominant or a hybrid offspring (and 0 for a recessive). Again, in the mating of a recessive and a hybrid, there is an even chance for getting either a recessive or a hybrid (and 0 for a dominant). In the mating of two hybrids, the offspring has an equal chance of getting G or g from each parent. Hence the probabilities are 1/4 for GG, 1/2 for Gg, and 1/4 for gg.

Consider a process of continued matings. We start with an individual of known genetic character and mate it with a hybrid. We assume that there is at least one offspring. An offspring is chosen at random and is mated with a hybrid and this process repeated through a number of generations. The genetic type of the chosen offspring in successive generations can be represented by a Markov chain. The states are dominant, hybrid and recessive, indicated by GG, Gg, and gg respectively. The transition probabilities are as follows:

State	GG	Gg	gg
GG	0.500 000	0.500 000	0
Gg	0.250 000	0.500 000	0.250 000
gg	0	0.500 000	0.500 000

Table II shows that at 20 matings they are 0.250, 0.500 and 0.250, after which they remain at these probabilities to within three decimal points. Table II also shows that it makes no difference in which state we started.

HOW MCMC WORKS

Markov Chain Monte Carlo (MCMC) is not the most intuitive concept in statistics. That an iterative algorithm can asymptotically generate dependent samples from a certain target distribution (and what exactly this gobbledygook means) takes a bit of getting used to. One analogy I've found very helpful is to think of MCMC as shuffling a deck of cards.

Suppose we have a deck of n cards. Because we don't want to bother with suits and colors, we'll label the cards 1,2,..,n. For the cards to be shuffled it means that there is no way to tell in which order they will come; every arrangement of the deck is equally likely.

We start out from a sorted deck, i.e. the cards are ordered 1,2,...,n. The goal will be to randomly rearrange the cards such that no order is more likely than any other. One way to proceed is to take out the first card and insert it at a random position in the deck. If we do this many times with the first card this should be sufficient to produce the desired effect; the deck might be in just about any order with equal probability.

The first thing to note is that this shuffling technique can be described as a Markov process. The state space is the space of all arrangements of 1,2,...,n. (If we had just three cards, for example, the state space would include all arrangements of three cards such as (1,2,3), (3,2,1), (2,3,1), etc. The "move" (using MCMC jargon) consists in taking out the first card and reinserting it at random. Since the move depends

only on the current state, we can compute the probability distribution over the next state given only the current state; this makes it a Markov chain.

This description makes several key MCMC concepts a bit more intuitively evident:

(1) *Convergence of the probability distribution*: If we start from a fully sorted set and you ask me to guess what the first card is, I will know it's a 1. If you apply the shuffling move once and ask me to guess again, there will be some uncertainty; it's likely to be a 2, but it could also be a 1 in case you reinserted 1 in the first slot. At the third step there is again a little bit more randomness and I won't be able to guess as precisely. If you shuffle enough times I really won't have a clue; the first card might be any of 1,2,…,n cards with about equal probability. In MCMC parlance, the probability distribution of the Markov process after a large number of moves is, for all intents, the uniform distribution over the state space. Each successive move takes us closer to our target distribution. In other words, it converges.

(2) *Invariant distribution*. MCMC moves leave the target distribution invariant. That's the case here. If you have a deck of cards in your hands and I don't know what order the cards are in, it doesn't matter if you shuffle the cards once more; I still won't know any better. The uniform distribution over all the possible orderings is invariant to a shuffling move.

(3) *Dependent samples*. In MCMC the state of the chain is measured at successive iterations. Each measured state is called a "sample" but it is clear from the example that the samples are not independent since it is relatively easy to guess what the state is at time t+1 if one knows what the state at time t is. Suppose again that we start from an ordered set, which will have the card with value i in spot i. It is quite likely that making one "move" will either not affect the position of the ith card, or that it will be replaced by one of its neighbors. Another way of viewing this is that the chain moves "locally" in the state space; it does not allow for radical changes.

(4) *Speed of convergence*. Some MCMC moves are better than others. To shuffle the card, a more radical strategy consists in throwing them down the stairs and picking them up again in the order you find them. We may start from a fully ordered set as before but after just one of these shuffling moves it is

clear that I won't do a very good job of predicting which card is on top of the stack. If the cards are sticky, there will still be some dependence on the previous step but is clear that convergence to the uniform distribution will happen a lot faster. Viewed another way, our first method (using three cards) couldn't go from state (1,2,3) to state (3,2,1) in one step. Our second method – throwing them down the stairs - can and so will produce states that are less dependent on one another.

(5)*Estimating parameters of the distribution from samples*. In MCMC we estimate some aspects of the target distribution from the samples. For example, the mean of the target distribution is estimated from the mean of the samples. In our case let's say that we want to estimate the average label of the ith card, which should be (1 + 2 + ... + n)/n). We could do this by noting the value of the ith card at each iteration of the process and averaging afterwards. However, over many iterations no particular card will have more of a chance to be in the ith spot than the other, so that the sample average will be approximately correct.

The next step is to make a chain that converges to any possible distribution—exactly what generic MCMC methods achieve.

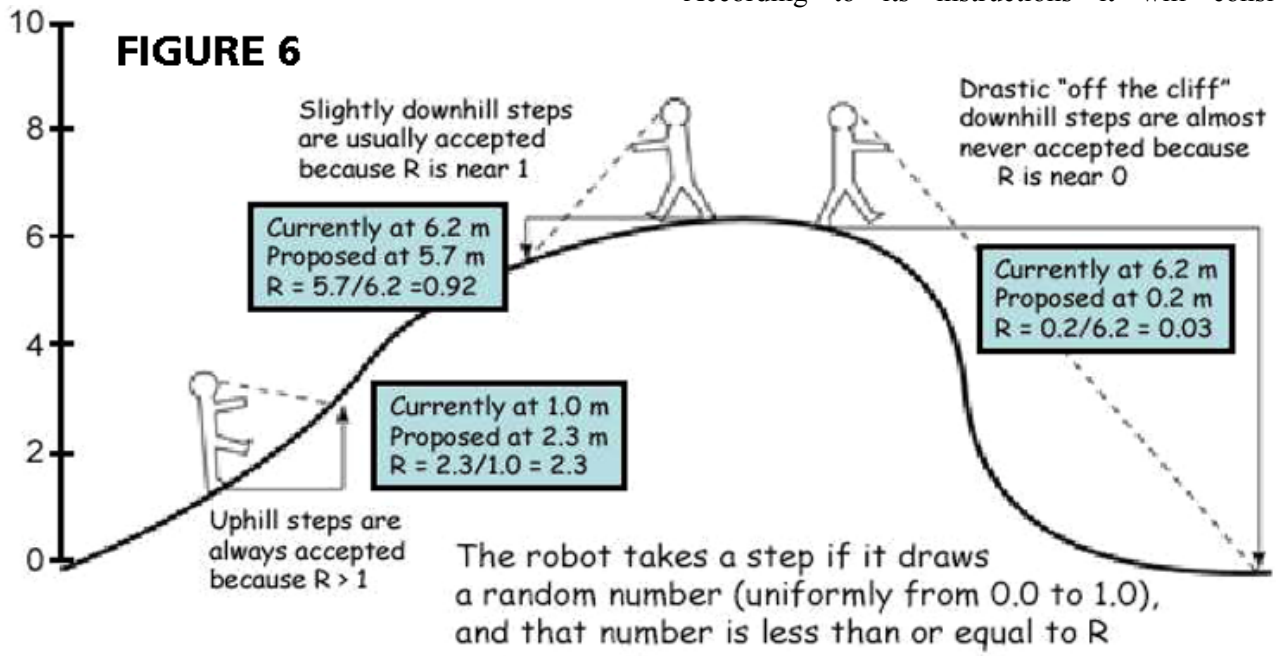
THE METROPOLIS-HASTINGS ALGORITHM

We start by constructing a Markov chain such that its equilibrium probability distribution is our target distribution. Then we arbitrarily start from some point and iterate the Markov chain many times (like how we forecasted the weather n times). Eventually, the draws we generate after discarding a few initial draws would seem as if they were coming from our target distribution.

To design the Markov chain properly, it is sufficient to manipulate the transition matrix. This is done using the Metropolis-Hastings algorithm:

(1) Start with a random tree and parameters.
(2) In each generation, randomly propose either
    a new tree topology or
    a new value for a model parameter.
(3) If the proposed tree has a higher posterior probability, $P_{proposed}$, than the current tree, $P_{current,}$ the transition is accepted.
(4) If the proposed tree has lower posterior probability than the current tree, the transition is accepted with probability $P_{proposed}$ /$P_{current}$.
(5) Every k generations, save the current tree.
(6) After n generations, end the Markov chain and use the saved trees to draw conclusions, using histograms, credibility intervals, etc.

This algorithm can be visualized as a robot walking around in a multidimensional landscape (Figure 6). According to its instructions it will consider



randomly chosen steps, always accepting up-hill steps and sometimes accepting down-hill steps, In Figure 6, R is the ratio, $P_{proposed}$ /$P_{current}$. (Note: m, the probabilities in this diagram, are logs since sums of logs are easier to use in algorithms than products.)

Note that, unlike in the Maximum likelihood method, in Bayesian Inference we are not just interested in the elevation of the very tip of the absolute peak of the posterior probability surface, but rather are interested in topographical map of the entire posterior probability, not the elevation of the tip of the very highest peak in parameter space.

DRAWING CONCLUSIONS

How do we derive phylogenetic conclusions from the posterior probability distribution of trees? One possibility is to use the most probable tree as a point estimate of phylogeny. This is called the maximum a posteriori probability (MAP) estimate of phylogeny.

A standard Bayesian approach to summarize results is to form a 95% credibility interval for the parameter of interest based on the posterior distribution. The Bayesian use of the term "credibility interval" for an entity is similar, at least in some ways, to the "confidence interval of" classical statistics. In phylogeny construction, a 95% credible set of trees can be constructed by starting with the MAP tree and adding trees in order of decreasing probability until the cumulative probability is 0.95.

The most powerful approach is to summarize the results of a Bayesian analysis on a majority rule consensus tree or on the MAP tree, as is typically done when summarizing the results of a bootstrap analysis. However, the numbers on the branches of the tree now represent the posterior probability that the clade is true. Although the MAP, credible set and majority rule consensus tree are the usual ways to summarize the results of a Bayesian analysis of phylogeny, other methods, equally valid, also are used.

BAYESIAN INFERENCE COMPUTER METHODS

There are a host of Bayesian inference computer programs but the one I am familiar with (and have on my computer) is MrBayes, written by John Huelsenbeck of the Department of Integrative Biology of the University of California, Berkeley, and Fredrik Ronquist of the Naturhistoriska Riksmuseet, Stockholm, Sweden.

An example of an input to this program is shown in Figure 7 where a phylogenetic tree of *Homo sapiens*, *Pan* (chimpanzee), *Gorilla*, *Pongo* (orangutan), *Hylobates* (gibbon), *Macaca fuscata* (macaque, a New

World monkey), *Macaca mulatta, Macaca fascicularis, Macaca Sylvanus* and *Saimiri sciureus* (squirrel monkey, a New World monkey) is to be constructed, with *Tarsius syrichta* (tarsier) and *Lemur* (lemur) used as outgroups. The data consists of 898 characters of DNA base information for 12 taxa. (I have truncated the input on the right at 74 characters in order to save space.)

After the data is inputted to the program, the first order of business is to specify a substitution model. There are dozens of models available, including the Jukes & Cantor and Kimura models shown in Figure 5. The one used in this analysis used the General Time Reversal (GTR) model which allows the four nucleotides to occur at different frequencies (the Jukes & Cantor and Kimura models assume that all four nucleotides occur at the same frequencies).

Next, one sets the prior probabilities for the model. There are six types of parameters in the model: the tree topology, the branch lengths, the four stationary frequencies of the nucleotides, the six different nucleotide substitution rates, the proportion of invariable sites, and the shape parameter of the gamma distribution of rate variation but the default priors work well for most analyses.

Before starting the analysis, certain settings must be entered, such as the number of sampling generations, sampling frequency and other constants in the simulation.

Recall, that the idea in MCMC sampling is to move around in parameter space in such a way that the points will be visited according to their posterior probability (i.e., a region with very high posterior probability will be visited frequently). It takes a while after starting such a process before the sampling gets "out of the foot-hills and into the mountains" of the distribution, and only after this "burnin" period can the sample points be trusted.

After the analysis is started the program will print the state of the chains every 100th generation and predict the time to completion. A majority rule consensus tree is calculated and is the first tree plotted to the screen. Below the consensus cladogram (Figure 8), a consensus phylogram (Figure 9) is plotted. The branch

lengths in this have been averaged over the trees in which that branch was present (a particular branch corresponds to a partition of the data, and will typically not be present in every sampled tree). The cladogram also has “clade credibility" values” are in fact the posterior probability that the clade is real (based on the present data set). These numbers are different from bootstrap values: unlike bootstrap support (which have no clear statistical meaning) these are actual probabilities.

A list of trees is printed after the phylogram. These trees are sorted according to their posterior probability and highlights how Bayesian phylogenetic analysis is different from maximum likelihood: Instead of finding the best tree(s), we now get a full list of how probable any possible tree is. Estimates of all the parameters, including their credibility intervals, is also printed out (Figure 10).

In this analysis there is overwhelming support for a single tree, so all forks have a posterior probability of 100%. The phylogram is as expected. The Old World macaque species and the New World squirrel monkey clades are clearly separated from each other and they in turn are clearly separated from the great apes - man, chimpanzee (*Pan*), gorilla and orangutan (*Pongo*) - and from the lesser ape, the gibbon (*Hylobates*).

SUMMARY

Bayesian phylogenetics using Markov chain Monte Carlo technology has unquestionably revolutionized the field of phylogenetic systematics, and represents the first treatment of tree topology as a random variable. Bayesian inference has allowed successful analysis of some of the largest and most complex empirical data sets ever compiled. These data sets could not have been analyzed a scant five years ago, and, though computer processor speeds have advanced considerably since then, it is due chiefly to Bayesian methodologies that they can be analyzed today. True, such data sets could be analyzed using maximum likelihood methods, but it would require enormous computer facilities that the average researcher does not have access to. Part of the appeal of Bayesian phylogenetics, then, is that reconstructions can be performed on conventional desktop computers in a reasonable amount of time.

The simultaneous estimation of parameter values and support gives not only a speed benefit to Bayesian Inference, but also provides the investigator with more information than in a maximum likelihood search (i.e. the shape of the posterior probability distribution, rather than just a point estimate). Systematists should be more concerned with identifying the total set of trees that can be reasonably supported by the data, rather than focusing on point estimates of topology.

Bayesian inference is the first methodology in phylogenetics that generates probabilistic calculations of such sets, and the probabilistic properties involved allow for direct interpretation that has until now been sorely missing from phylogenetic systematics. A major benefit of using Bayesian inference is that it explicitly accounts for uncertainty in phylogeny when estimating parameters of interest, rather than assuming the phylogeny is known without error.

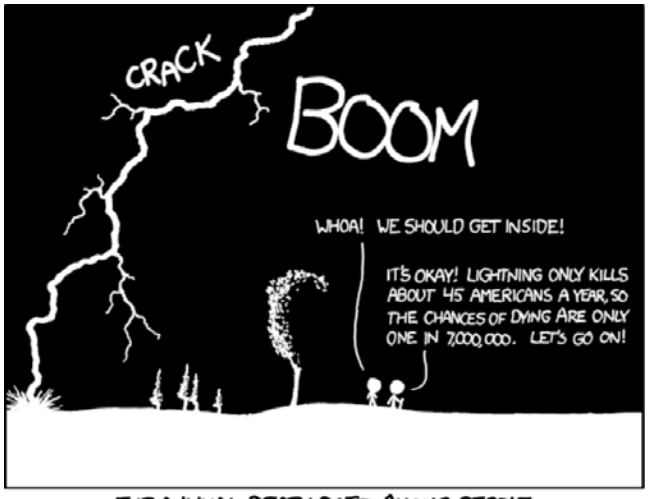
There are, however, some controversies over the method. It has been observed that bootstrap values, calculated under parsimony or maximum likelihood, tend to be lower than the posterior probabilities obtained by Bayesian inference. This fact leads to a number of questions such as: Do posterior probabilities lead to overconfidence in the results? Are bootstrap values more robust than posterior probabilities?

However, a bootstrap proportion is an index of repeatability, *not* of the accuracy of the results. A Bayesian posterior probability, conversely, is a direct probability statement that the results reached are true, given the data. On the matter of interpretation of results, then, a Bayesian approach is undoubtedly ideal.

Using prior probabilities for Bayesian analysis has been seen by many as an advantage as it will provide a hypothesis a more realistic view of the real world. However, some biologists argue about the subjectivity of Bayesian posterior probabilities after the incorporation of these priors. Also, the results of the Bayesian analysis of a phylogeny are directly correlated to the model of evolution chosen, so it is important to choose a model that fits the observed data, otherwise inferences in the phylogeny will be erroneous. However, there are programs that are specifically designed for the purpose of finding models of evolution that best fit the data and those that evaluate the adequacy of different models.

ENTER HAMLET

The last thing that I'd like to mention is that although in the card example I used to explain MCMC it can take us from a probability distribution that's fully concentrated (we know the cards are sorted) to one that's maximally uncertain (the uniform distribution over possible permutations), it's just as easy to do the reverse by having sorting moves instead of shuffling moves. A good example is the following that was devised by Marc Corum, a student at



THE ANNUAL DEATH RATE AMONG PEOPLE WHO KNOW THAT STATISTIC IS ONE IN SIX.

Stanford University. To investigate this he tried the algorithm out on a problem for which he knew the answer.

The following is a well-known section of Shakespeare's Hamlet:

ENTERHAMLETHAMTOBEORNOTTOBETHATIS
THEQUESTIONWHETHERTISNOBLERINTHEMI
NDTOSUFFERTHESLINGSANDARROWSOFOUT
RAGEOUSFORTUNEORTOTAKEARMSAGAINST
ASEAOFTROUBLESANDBYOPPOSINGEND

The text was scrambled at random and the MCMC algorithm was run. Figure 11 shows the sample output. After 100 steps, the message is a mess. After two thousand steps, the decrypted message makes sense. It stays essentially the same as further steps are tried. I find it remarkable that a few thousand steps worked so well. It also shows that the method has a wide application in other areas, including cryptology and forensics.

FIGURE 11

A FEW WORDS ON THE ORIGIN OF THE WORD "AQUARIUM"

by Albert J. Klee, PhD

(Aquarium Hobby Historical Society, Yahoo Post # 13052, April 3, 2015)

János Reisinger (born in Győr, Hungary in 1784 and died in Pest, 1852) received his medical degree in 1806 and a year later his degree in surgery. He practiced medicine in Szeged (the fourth largest city in Hungary) for a short time and in 1807 returned to Pest where he was a senior lecturer at the Department of Natural History of the university. From 1810 until his retirement in 1848 he was a professor of zoology and mineralogy at the Faculty of Medicine in Pest.

In 1830 he wrote a book titled *Specimen ichthyologiæ-sistens pisces aquarium dulcium Hungariæ*. As this was the earliest reference in which I saw the word "aquarium" and "fish" (i.e., "pisces") together, it got me wondering what exactly the word "aquarium" had meant in those days and also who came up with the word in the first place.

I had come across the term "dulcium aquarium" in many texts published later in the Nineteenth Century and there also, as it did in Reisinger's text, it always meant "fresh water." For example, Mercator drew a marine chart in 1569 that portrayed the Great Lakes as accurately as could be drawn at the time. It was noted that river running into the St. Lawrence Gulf had two large branches and at the head of the northern branch was grouped three small lakes just west of which is a very large lake. Beside this lake is written (the boldfacing in this essay is mine): "hic mare est **dulcium aquarium**, cujus terminum ignorari Canadenses ex relatu Saguenaiensium aiunt" ("this sea is of **fresh water**; the Canadians do not know its bounds, according to the report of the people of Saguenay"). The "sea" that Mercator was talking about, by the way, is what is now known as Lake Huron.

The earliest reference I found to "**dulcium aquarium**" was in Pliny the Elder's *Naturalis Historia*, published circa AD 77–79. In Book 59, Volume 19, he talks about directions for watering certain plants:

Peculiaris medicina raphano, betae, rutae, cunilae in **salsis aquis**, quae et alioqui plurimum suavitati et fertilitati conferunt. Ceteris **dulcium aquarum** rigua prosunt. Utilissimae ex his quae frigidissimae et quae potu suavissimae.

"There is a curative property especially effective for radish, beet, rue and savory in **salt waters**, which moreover also contributes a great deal to their sweetness and to their fertility. All other plants are benefited by being watered with **fresh water**, the most useful for the purpose being water from streams, which is extremely cool and very sweet to drink."

Note: In Latin, adjectives and nouns agree in case, number, and gender. Aquis is the plural of water. To make things more difficult, aquarium can be an adjective meaning "pertaining to water" or a noun, 2nd declension, neuter meaning "a source of water," "a watering place" or "a water hole (for cattle)."

Marcus Porcius Cato, byname Cato the Censor, or Cato the Elder (born 234 BC in Tusculum, Latium [Italy] and died in 149 BC), was a Roman statesman, orator and the first Latin prose writer of importance. The earliest mention of the word "aquarium" is found in Cato's *De agricultura* ("On Farming" sometimes referred to as *De re rustica*), written about 160 BC. It is his only surviving work and the oldest remaining complete prose work in Latin. It is a practical handbook dealing with the cultivation of grape vines and olives and the grazing of livestock, but it also contains many details of old customs and superstitions.

As mentioned, Cato was the first author of record to use the word aquarium. Examples from his book include the following: **situlum aquarium** ("water bucket"), **urceum aquarium** ("water vessel") and **bonumque aquarium** ("well-watered"). Note, however, that aquarium here did NOT mean a container of water.

With regard to the term, "watering place," in Cicero's *Three Books of Offices and Other moral Works*, written in 44 BC, we find the following:

Tum Canius inquit, quæ, Pythi, quid est hoc? Hic, ne, tantum piscium, ne tantum cymbarum? Et ille inquit, quid mirum? Quidquid piscium est Syacusis est hoc poco, **hic aquatio**…

"Then Canius says, 'What is this, pray, Pythias – so many fish – so many boats?' And he answers, 'What's the wonder? Whatever fish there are at Syracuse are taken at this place; **here is their water-place**…'"

"Aquationis" is the genitive (possessive) form of a Latin word that was used by Julius Caesar, Palladius, Columella, Pliny and Cicero with regard to water that had several different meanings but Cicero uses the nominative form "aquatio" here to mean "watering-place; it was not used in the sense of a container to hold fish (or anything else for that matter).

Thus at no time did the Romans use aquarium or its cousins in the sense of a container; rather, it was either meant as water or a place (but not a vessel) that held water.

The one who DID use the word aquarium as a vessel to hold water was Linnaeus. In his 1742 prologue to his *Hortus Upsaliensis*, he defined the following terms under the heading of "Aquaria:" Aquarium fluviatile, Aquarium lacustre and Aquarium palustre, denoting respectively a river pond aquarium, a lake pond aquarium and a marsh pond aquarium. Here is how Linnaeus described the last-named:

Aquarium palustre ad latera truncos horizontales seu parietes habet, aquam a solo separantes, inter illos vero & ipsam humum repletum est spatium humo limosa e paludibus desumta, cui insertae plantae palustres.

"The marsh aquarium has horizontal sides of tree trunks or walls that separate the water from the surrounding soil; the ground between them is filled with soil from muddy swamps, into which is inserted marsh plants."

Clearly Linnaeus was describing the construction of an artificial container and was not using the word aquarium merely as a synonym for water. Linnaeus, of course, was not concerned with fish but with aquatic plants but, as we all know, by the beginning of the 1800s the gardener's aquarium morphed into that of the aquarist's well.

Watering place near Cervara, a municipality in the province of Rome in the Italian region Latium, located about 31 miles east of Rome.

EXPLAINING AWAY THE NON-EXISTENT

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, May 21, 2015)

Much of my career - both as an engineer and as a scientist - has been involved with mathematics and one of these areas includes experimentation. Now in addition to requiring some technical knowledge, bona fide experimentation is both expensive and time-consuming. The last two affected my ability to do much experimentation in the aquarium hobby and thus I can list them here very quickly with regard to their topics: the effects of salt on catfish, beef heart versus snail meat in the feeding of bettas, the effect of various dyes on the prevention of fungus in the development of killifish eggs, and electrophoresis in differentiating strains and species of *Aphyosemion*.

With regard to the last, I had hoped that after it had taken a breather from the hectic days of getting started in earnest, the American Killifish Association would establish a committee that conducted experiments relevant to killifishes. I would have taken on the job myself but my limited time was required in the area of Association publications; unfortunately, no one volunteered for the job and so the committee never saw the light of day.

Now if one is averse to expending the time and expense it would take to conduct experiments that produce reliable conclusions, we are reduced to opinions or beliefs based upon little or no evidence. This not to say that they are worthless; indeed, the opinions and beliefs of those with experience and other qualifications are often highly regarded. Unfortunately, they are also often highly in error.

When Sam Wineberg and I were publishing *The Aquarist's Notebook*, the publication was sent to several thousand pet stores across the country and we got to be on very friendly terms with most of them. I was interested in the incidence of *Ichthyophthirius* in their stores and after agreeing that their store name would not be mentioned in any article that I might write (I mentioned *Pet Shop Management* as one possibility), a good many of them provided me with the information I had requested.

I was mostly interested in whether the incidence of *Ichthyophthirius* was greater or larger in small stores than in larger ones and found that it indeed was greater in the small stores. As I was putting this into an article I was writing, along with a discussion as to why this might be so, I decided to check my calculations by looking at the smallest incidence of *Ichthyophthirius* and found that it also occurred in the small stores! How could this be? The answer was in the Law of Small Numbers, which is based upon the fact that smaller samples have more extreme values than large ones.

The Law of Small Numbers is the judgmental bias which occurs when it is assumed that the characteristics of a sample population can be estimated from a small number of observations or data points. My mistake was in computing simple percentages without also calculating their standard error. When I did do this, the ranges for the incidence of *Ichthyophthirius* overlapped, indicating that there was no difference between the large and small stores.

To show how an increase in sample size diminishes the probability of the occurrence of a rare event, consider a tank full of platys, half of which are red and the other half are blue. Two aquarists, Sam and Betty, are asked to dip into the tank and remove some fish. Sam is instructed to draw out three fish while Betty is allowed six. The tank has opaque sides and is high enough so that neither can see the fish before drawing them out. They both record each time they observe a sample that is either all red or all blue. The sampled fish are returned to the tank and the sampling is renewed for many times. If they go on long enough, Sam will observe such extreme outcomes more often than Betty – by a factor of 8 (the expected percentages are 25% and 3.125%, respectively).

Fortunately for me, I caught my mistake and discarded the article before it ever got to the publisher. My "explanation" for the difference being that large stores were more careful in handling their fish would have been an embarrassment indeed had it been published!

Our minds are drawn to causal explanations and when our attention is called to an event, our associative memory will look for a cause; more precisely, activation will automatically spread to any cause that is already restored in memory. However, random events do not, by definition, have a cause and so such causal explanations will be wrong.

Another area where causal explanations try to explain events that have no explanation is the concept of "Regression to the Mean." The statistician, David Freeman (a professor of statistics at the University of California, Berkeley who transformed the practice of

applied statistics as it is directed toward litigation, Congressional action and public policy), used to say that if the topic of regression comes up in trial, the side that must explain it to the jury will lose the case. I'll give it a try here.

In statistics, regression to the mean is the phenomenon that if a variable is extreme on its first measurement, it will tend to be closer to the average on its second measurement In other words, an extreme event is likely to be followed by a less extreme event.

The concept of regression comes from genetics and was popularized by the polymath Sir Francis Galton (Charles Darwin's cousin) during the late 19th century with the publication in 1886 of his *Regression towards mediocrity in hereditary stature*. For example, the children of tall parents tend to be tall themselves but not as tall as their parents. The fact that the children tend to be taller than average is probably the result of genetics, but the fact that they tend not to be as tall as their parents is the result of regression to the mean. (I should note that the word "mediocrity" was neutral at first – it was based upon the Latin mediocris, meaning halfway up a mountain, and merely designated a middle state. Its disparaging sense began to predominate from the late 1600s but was replaced by the mean by later day statisticians.)

Here is why it happens. In the figure suppose you sample a point (point 1) and it falls where the red region and the yellow region meet. If you sample another point is it more likely to be closer to the mean (yellow region B) or further from the mean (red region A)? Obviously it is more likely to be closer to the mean because there is more probability there. Now suppose you sample another point (point 2) and it falls where the green region D and the white region C meet. If you sample another point, once again it is more likely to be closer to the mean because there is more probability there.

A fallacy occurs when one mistakes regression to the mean, which is a statistical phenomenon, for a causal relationship. For example, if a tall father were to conclude that his tall wife committed adultery because their children were shorter, he would be committing a regression fallacy.

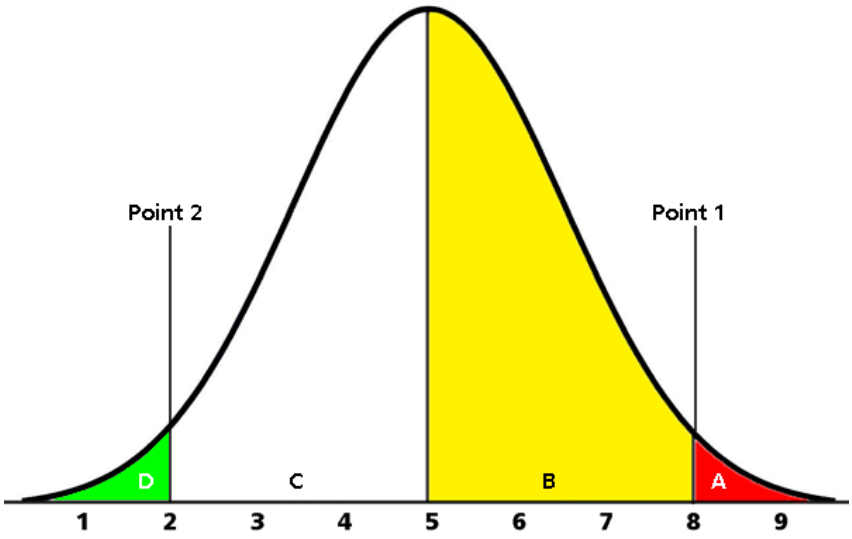
Now consider a guppy breeder who has a tank containing a strain of fish, each with the same genetic background and kept under identical environmental conditions. He wants to increase their size by using the largest of the fish in the tank. However, he finds that the offspring generally are smaller than the parents and he has a causal explanation, i.e., that the strain is deteriorating and so he feels that he must introduce some large fish from some other strain into his breeding program. This is another example of the regression fallacy, i.e., explaining away the non-existent.

You can get a good conversation started at a party by asking for an explanation of the following assertion - which is true, by the way - offered by Daniel Kahneman (he received the Nobel Prize in Economic Science in 2002 for his pioneering work on decision making):

Highly intelligent women tend to marry men who are less intelligent than they are.

Some may think of highly intelligent women wanting to avoid the competition of equally intelligent men, or being forced to compromise in their choice of spouse because intelligent men do not want to compete with intelligent women. More far-fetched explanations will come up at a really good party, especially if alcohol is readily available! The bottom line is that it is a mathematical inevitability that highly intelligent women will be married to husbands who are on average less intelligent than they are (and vice versa, of course).

In any event, those aquarists who take shortcuts to experimentation should beware of these two hidden traps, The Law of Small Numbers and Regression to the mean.



A HISTORY OF ZOOLOGICAL NOMENCLATURE

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, June 28, 2015)

Experienced aquarists generally have more than just a passing acquaintance with the International Code of Zoological Nomenclature (ICZN). The Code's fundamental aim is to provide the maximum universality and continuity in the scientific names of animals compatible with the freedom of scientists to classify animals according to judgments made with regard to the description, identification, naming and classification of animals. It is designed to enable zoologists to arrive at names for taxa - such as genus and species - that are correct under particular taxonomic circumstances. The use of the Code enables a zoologist to determine the valid name for a taxon to which an animal belongs at any rank in the hierarchy of species, genus, and family, and it is these names that are passed down to aquarists as a fish's "scientific name." However, it is not my intention here to discuss the working of the Code - which I have done in some detail (see "The Name Game" in my *Essays on Aquarium Hobby History*) - but rather to examine its development from an historical perspective. It is also neither my intention to discuss all the historical details of the problems faced by its trustees and Secretaries as the Code was developed and changes made over the years, as this would result in a small book rather than an essay, but I will comment on a limited number some of the thornier problems experienced during the Code's development.

PART I: THE PRE-LINNAEAN ERA

To a large extent, the study of the natural sciences up to the Eighteenth Century was not differentiated into separate realms, or at least far less so than at any time since. Every educated person could communicate in Latin more easily than between one modern language and another, and biologists could feel themselves to be, as it were, members of a club. There was a measure of understanding where names were concerned that rendered formal rules of nomenclature superfluous.

However, as more and more undescribed material was sent back from all corners of the world, so the number of biologists increased and the need for a more organized approach to describing and naming plants and animals became clear. The first step in that direction was the recognition of two categories of biological units that we now term "taxa" - the genus and the species. The second step was the reduction of the generic name to one word. Pliny the Elder in his *Naturalis Historia* (begun in 77 AD and comprised of 37 books) had already supplied many familiar words of that sort for the European, Middle Eastern and African animals known to the Romans. Species, however, were still denoted by descriptive phrases. The full name thus indicated its generic placing but employed a sentence instead of a word to designate a species.

This formed a system of polynomial nomenclature with the names having two separate functions. First, to designate or label the species, and second, to be a

Pliny the Elder (AD 23-AD 79), Roman naturalist.

Joseph Pitton de *Tournefort* (1656 – 1708), French botanist.

diagnosis or description; however these two goals were eventually found to be incompatible. Many biologists gave the species they described long, unwieldy Latin names that could be altered at will and a scientist comparing two descriptions of species might not be able to tell which organisms were being referred to. For instance, the common wild briar rose was referred to by different botanists as *Rosa sylvestris inodora seu canina* and as *Rosa sylvestris alba cum rubore, folio glabro*.

The French botanist, Joseph Pitton de Tournefort (1656-1708), is often credited with being the first to make a clear distinction between genus and species. Though he did indeed cluster the 7,000 plant species that he described into around 700 genera, this was not particularly original. Concepts of genus and species had been framed as early as the 16th century; Caspar Bauhin (1560–1624), a Swiss botanist, in particular consistently distinguished genera and species and took some important steps towards the binomial system, by pruning the Latin descriptions, in many cases to two words. Linnaeus honored the Bauhin brothers, Caspar and Jean, in the genus name *Bauhinia*.

Augustus Quirinus Rivinus (1652-1723), a German physician and botanist (he was also known as August Bachmann) had even advocated the use of binary nomenclature shortly before Tournefort's work was published in 1700. Rivinus was the first to apply consistently the rule that the names of all species in a genus should start with the same word (generic name). If a genus contained just one species, the generic name would be its only name. If there were more than one species in the genus, their names should consist of the generic name followed by a brief diagnostic phrase. His nomenclature differed from de Tournefort's in not using a diagnostic phrase with the first plant of a genus, adding differentiae (i.e., characters differentiating the species) only to the second and subsequent plant species.

Caspar Bauhin (1560–1624), Swiss botanist.

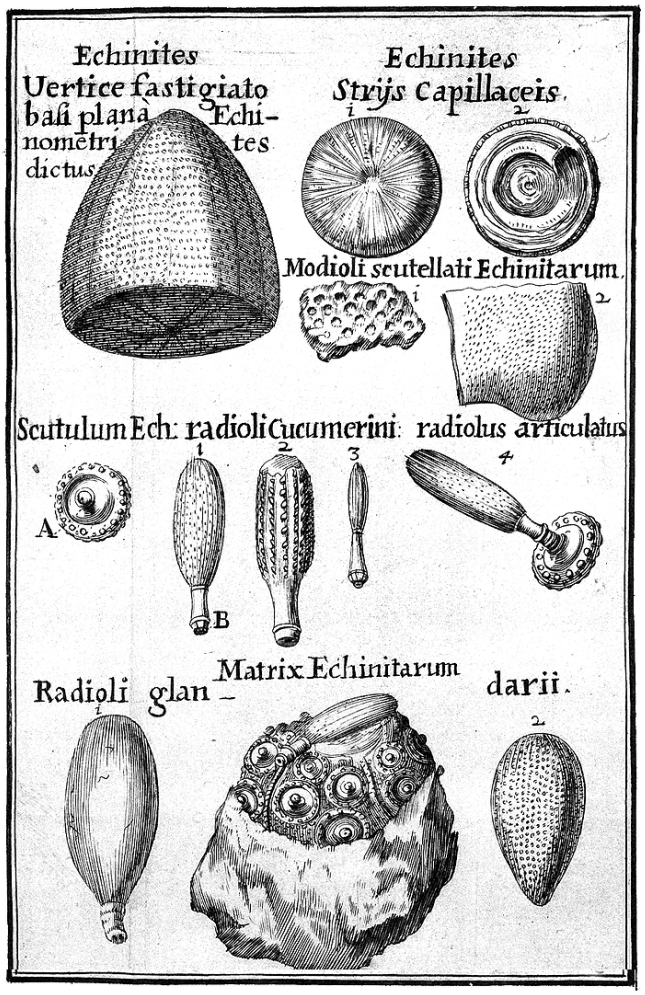
Augustus Quirinus Rivinus (1652-1723), German botanist.

Tournefort's work was quickly adopted by other predecessors of Linnaeus, for example in zoology in 1722 by Carl Nicolaus Lange (1670-1741), a Swiss medical doctor interested in fossils. The function of the specific name, however, was still to describe rather than to label; it was only intended to provide differentiae.

PART II: ENTER LINNAEUS

Biological nomenclature can be said to have begun with the first attempt to give it formal shape and structure. That this was done first in botany is due only to the fact that the man who did it was primarily a botanist, Carl Linnaeus, who held the Chair of Botany at Uppsala University in Sweden from 1742 to 1777.

The essence of the Linnaean revolution was the recognition that the function of the specific name was merely to label a concept rather than to describe an entity; the name could, therefore, be reduced to a single word. In 1751 Linnaeus enunciated 43 rules for botanical nomenclature which, by implication, were taken to apply also to zoology. Of these precepts, 23 are concerned with stating which sorts of words were eligible as generic names and with the formation of such names - matters with which all draftsmen of codes of nomenclature have been much preoccupied. His other precepts state that every plant must have a generic and a specific name, but none deals with specific names; each genus must have only one name which is universally to be used; names are not to be changed for impropriety; synonyms must be used for subdivisions of genera; names are not to be transferred from one genus to another;



A page from Carl Nicolaus Lange 's *Historia lapidum figuratorum*, 1705. Lange adopted Tournefort's nomenclature but it still was not binominal.

Carl Linnaeus (1707-1778), Swedish botanist.

if a genus is divided, the original name must be retained for the commonest or the medicinal plant.

It was in his 1753 *Species Plantarum* that he first began consistently using a one-word "trivial name" together with a generic name in a system of binomial nomenclature and this was followed in the 10th edition of his *Systema Naturae* (1758). This trivial name is what is now known as a specific name

It has often been pointed out that Linnaeus had no idea of a principle of priority. Indeed, he was in no moral position to hold any such idea, engaged as he was in rejecting nearly all existing names of species. His intention must have been not so much to replace the earlier names as to provide a set of labels by which to trace and identify them. The uninominal specific names that he provided were thus of very small importance and he naturally regarded them as trivia.

Nevertheless, Linnaeus's trivial names introduced an important new idea, namely that the function of a name could simply be to give a species a unique label. This meant that the name no longer need be descriptive; for example both parts could be derived from the names of people. Thus Gerard's *phalangium ephemerum virginianum* became *Tradescantia virginiana*, where the genus name honored John Tradescant the younger, an English botanist and gardener. A bird in the parrot family was named *Psittacus alexandri*, meaning "Alexander's parrot," after Alexander the Great whose armies introduced eastern parakeets to Greece. Linnaeus' trivial names were much easier to remember and use than the parallel polynomial names and eventually replaced them.

In 1778 Johan Christian Fabricius (1745-1808), a Danish zoologist considered one of the most important entomologists of the 18th century, having named nearly 10,000 species of animals and established the basis for the modern insect classification, published a set of precepts on entomological nomen-

clature. Like the Linnaean ones, these were little more than a guide to good manners but he gave more attention to specific names. Later biologists gave these names much greater importance, both for their convenience and because they allowed descriptions to be modified without changing names.

After Fabricius's publication more than 60 years elapsed before any further attempt was made to provide regulations for zoological nomenclature. During this period the number of names in circulation increased enormously, and many of these were felt to be unfortunate or even offensive to good taste and good science. To a generation in which all educated persons knew Latin and to whom the Latin influence on scientific literature was very strong, the formation of non-Latin or barbarous names, or the combining of Latin and non-Latin elements in compound names, was strongly objectionable. "Oh barbariem!" exclaimed Louis Agassiz in the long and detailed preface to his 1846 *Nomenclator Zoologicus,* in which his pursuit of classical purity led to the coining of hundreds of replacement generic names.

PART III: 1842-1895: CODES AND CONTROVERSIES

The Stricklandian Code (1843)

By the 1840s the growth of taxonomy without the control of a structured and hierarchical nomenclature was a cause of increasing confusion. In 1841, Hugh Edwin Strickland , a young Englishman who was primarily a paleontologist but with very wide zoological interests, wrote of the need for "the establishment of a uniform and permanent language among naturalists of all nations." Taking the initiative, he proposed to the British Association for the Advancement of Science that a committee should draft a Code of rules (among others, the Committee included two men well-known to aquarists: Charles Darwin, and the Rev. Leonard Jenyns who named the Chanchito) . The resulting rules were published in 1843 in the *Proceedings* of the Association meeting held at Manchester the previous June. It is clear that Strickland must have thoroughly prepared the ground in advance, for over 200 eminent men and learned societies were consulted in Britain, Europe, North America and Australia.

Hugh E. Strickland (1811-1853), English paleontologist.

The Stricklandian or British Association Code went much further than Linnaeus or Fabricius had gone with their mild recommendations for good manners. It is not the object here to analyze all the rules of the Strickland Code. However, the treatment of priority, as well as rules related to it, are commented on. The law of priority, the fundamental basis of the entire code, was defined as follows: "The name originally given by the founder of a group or the describer of a species should be permanently retained, to the exclusion of all subsequent synonyms (with the exceptions about to be noticed)."

Although priority had been adopted as a guiding principle by some naturalists for at least 30 years, no starting point had been proposed so far. In his personal draft, Strickland had already indicated that the starting point should be the *Systema Naturae*, but had not indicated which edition. The Committee decided that the starting point was the 12th edition and gave the date 1766 for a starting point. An alternative was the 10th edition, in which Linnaeus (1758) consistently applied the binominal nomenclature to all animals for the first time. However, the 12th edition was favored because Linnaeus changed quite a few names between the 10th and 12th editions of the *Systema Naturae*; selecting the 12th edition guaranteed that Linnaeus's last and supposedly preferred names would have precedence over former names that he discarded.

The starting point of zoological nomenclature, which clearly is central in the application of the principle of priority, remained discussed extensively until the end of the 19th century, when a decision was finally made to select the 10th edition of the *Systema Naturae*. Even though the British Association committee selected the 12th edition as a starting point, we owe to Strickland and the rest of the Committee to have pointed out the critical importance of a starting point for the application of priority.

The Strickland Code is divided in two parts. The first includes "rules for rectifying the present nomenclature" and deals with names that have already been created. It contains only 14 articles (rules), most of which deal with the application of the Principle of Priority. The second part includes "recommendations (not rules) for improving the nomenclature in future" and deals with the formation of new generic and specific names.

In zoological nomenclature, a type species is the species to which the name of a genus or subgenus is permanently linked, i.e., the species that contains the biological type specimen(s). A similar concept is used for suprageneric groups, the concept of a type genus. Several articles of the first part of the Strickland Code set the stage for typification within genera. In particular, the Strickland Code provided ways of determining which is the type species in case no typical species was designated originally, especially when a genus is split into several genera. The Stricklandian Code had a widespread influence on nomenclatural practice, however, and not many years elapsed before attempts began to improve on it.

Helmuth von Kiesenwetter (1820-1880), German entomologist.

The Kiesenwetter Code (1858)

The first Code published subsequent to the Stricklandian Code is *Die Gesetze der entomologischen Nomenclatur* by Helmuth von Kiesenwetter, with a French translation and comments in 1860. This makes no mention of the Stricklandian Code and might have been drafted as though that did not exist. It was adopted by a congress of German entomologists in Dresden in 1858. This Code states that a specific name consists of a combination of the name of the genus (taken as a noun) with the name of the species itself (taken as an adjective); that species and genera of insects must only be named when their existence in nature has been scientifically demonstrated; that publication must be in a language of Latin or Germanic origin and must be in a work that can be bought by way of trade or in a learned periodical; that a genus or species is named only when its publication renders it recognizable; that the addition of a diagnosis in Latin to make the taxon recognizable is absolutely necessary. In all these points the German Code clearly complements the Stricklandian. But in Article 15 it reads: "the principle of conserving the oldest of several names given to the same insect is not absolute; the choice between them is free according to greater or less convenience. This was perhaps the first formal attack on the sanctity of the principle of priority and was the opening shot of a campaign not yet concluded.

The Stricklandian Code (1866 version)

In 1865 the Strickland committee was resurrected by the British Association, although without the eponym. Strickland had died tragically at the early age of 42 when run down by a train while studying the geology of a railway cutting on his way home from the 1853 British Association meeting. There was only one significant emendation: when a species was raised to generic rank it was not the specific name but the generic name that was to be changed to avoid tautonymy, i.e., the situation where the generic and specific names are the same, as in *Danio danio;* this rule, however, is not used in zoology. The committee emphasized the importance of the recommendation that great restraint be used in naming taxa after persons, and proposed to omit the recommendation that specific names be written with a small initial letter.

The 1865 committee explicitly fixed the 12th edition of Linnaeus's *Systema Naturae* (1766) as the starting point of nomenclature, with special exceptions for generic names of Scopoli in insects, Artedi in fishes and Brisson in birds. This gave a legitimacy to binary nomenclature with unfortunate results. Binary, it should be noted, technically meant two similar or related things or concepts, and binominal meant the same except that it specifically denoted that the two similar things were names. Binary nomenclature therefore could mean either that the name of the species embodied two concepts (the genus and the species) or that the name consisted of two words.

William Arnold Lewis and David Sharp (1872-1875)

Three important pamphlets were published in London by Lewis (1872, 1875) and Sharp (1873). W.A. Lewis was a professional lawyer and an amateur lepidopterist. He deployed all the skills of the advocate and of the salesman, his mission being to attack, and if possible, destroy the law of priority as expressed in the Stricklandian Code.

Lewis repeatedly criticized attempts to use the names proposed by early authors (including Linnaeus and Fabricius) because their descriptions, while adequate when they wrote, might now cover half a dozen or more closely related species. He proposed that no name published before 1842 should ever be "used again unless it had "been kept alive by quotation as the true name in some work since 1842."

This issue could have been partly solved by going back to type specimens. However, as most authors in that period, Lewis paid much more attention to written descriptions, necessarily incomplete, than to types. In fact, he agreed with Sharp, a strong defender of the strict priority rule, that "it is clear that [types] must not be exclusively or even strongly relied on," when one wishes to determine which species is referred to by a species name.

This opinion was widely shared at the time. However, even though many of the genera named by the early authors had been subdivided, they nevertheless provided (and still provide) the main points of refer-

ence for the whole taxonomic system; their type species must perforce be found among their originally included species. But unfortunately, only primitive ideas about the type species of genera then prevailed.

According to Lewis then, some names would have to be rejected, but he offered no suggestions as to how or on what authority these were to be chosen. He rejected all appeals to type specimens because those of the early authors were in many cases damaged or of doubtful authenticity, but did not envisage any way in which they might be substituted. He failed to realize that going back to the type specimens is critical when determining the entity a name refers to, which cannot be answered if only written descriptions are considered.

David Sharp was an explorer and eminent coleopterist who wrote extensively on the fauna of the southern hemisphere. His 1873 pamphlet, by contrast with Lewis's views, is a defense of the law of priority. It makes an important point for the first time - that any system of nomenclature for species must conserve on a permanent basis the concept represented by the original binomen (i.e., a scientific name at the rank of species with two terms: a generic name and a specific name) as first established. It takes both terms of a binomen to express the concept and only the original binomen can express the original concept of its author. This was too metaphysical and neutral an idea to have impressed the one-sided mind of the advocate Lewis.

Maurice Chaper and Henri Douville

The pioneer of the sustained French initiative in matters of zoological nomenclature was Maurice Chaper, a graduate of the École Polytechnique and a railway and metallurgical engineer. He was an enthusiastic student of living and fossil mollusca and an associate of the much more eminent paleontologist Henri Douville, who was a mining engineer and Professor at the École des Mines in Paris and active in the first International Geological Congress held at Paris in 1878. This Congress set up a committee to study "the rules to be followed in the naming of species" and to report to the second Congress. Wishing to make sure that zoologists influenced the code that paleontologists intended to develop, Chaper alerted the Societé Zoologique de France and said that it would surely be wrong for the zoologists to have their rules laid down for them by the paleontologists, since the same nomenclature covered both. The reports by Douville for the Geological Congress and by Chaper for the Societé Zoologique were both presented in 1881. It is clear that Chaper was kept in touch by Douville with developments in his committee, but the two reports differ widely; these differences are of some interest and are much to the credit of Chaper.

Douville's report contained a set of 11 rules and was unremarkable except for its expression of the law of priority. It saw no need to set a backward limit to the application of this law. Any name that conformed to the law of binominal nomenclature and that was published with a clear definition of its taxon was acceptable, even if published before the time of Lin-

Henri Douville, (1846-1937), French paleontologist.

Maurice A. Chaper (1834-1896), French collector of zoological and botanical specimens.

naeus. It also insisted that no name was available unless accompanied by an illustration, but this requirement has not survived although it would be of great practical importance, especially in paleontology. The remaining Articles are unexceptionable and follow lines already well established. The accompanying report is entirely historical and deals with nomenclature from Aristotle onwards.

The committee of seven members of the Societé Zoologique de France included the Secretary-General of the Society, Raphaël Blanchard, then aged 34 but destined to acquire a towering importance in the affairs of the International Congress of Zoology and in nomenclature, and also in his chosen discipline of parasitology. Clearly, however, Chaper was the prime mover in the committee. That he was probably the sole author of the report is indicated by its completion in five months, which would have been unlikely for a group of seven if each had taken an active part, and by the numerous examples in the report taken from recent and fossil mollusca and none from the specialties of the other members. Furthermore, none of the other members had up to that time shown much interest in nomenclatural matters. Chaper's contribution attracted tributes from Douville for his "clarity and precision and extremely rigorous reasoning" and from Blanchard for his "inescapable logic communicated with great charm, and the marvelous lucidity of his thinking." Chaper's role in setting the foundations of nomenclatural rules in zoology is little recognized today, yet his influence persisted after his death into the 1905 *Règles (Rules)* and can still be detected in the present ICZN Code.

The Chaper report consisted of 17 Articles and an essay on the work of the committee and on the underlying principles of nomenclatural rules. The rules are all expressed with admirable brevity and clarity. A few points deserve mention. One detail in Chaper's (1881) rules is intriguing. Indeed, the first Article reads:

Raphaël Blanchard, (1857-1919), French parasitologist, Commissioner and President, 1895-1919.

"The nomenclature adopted for all organized beings is binary and binominal [*binaire et binominale*]. It is essentially Latin. Each being is distinguished by a genus name followed by a species name." Chaper's ideas on the meaning of binary and binominal have remained unclear, especially because both adjectives were used interchangeably in the 19th century to refer to the Linnaean nomenclature. As Melville (1995 pointed out: "It is not clear why he used both adjectives when one would have sufficed." Blanchard (1889), whose rules were deeply inspired from Chaper's rules, also used both adjectives without giving a clear distinction between them. At all events, that expression gave rise to furious disputes for some 40 years and was not officially eliminated from the Code until 1961.

All the remaining Articles are found in the 1905 *Règles* with little or no modification, except for Articles 16 - "Any barbarism, any word formed contrary to the rules of spelling, of grammar and of composition must be corrected' - and 17 - "When generic and specific names have a Latin pronunciation so nearly alike that confusion would result, only the first is to be retained." The latter Article was reduced to the status of a recommendation in the 1905 *Règles* and eliminated in later Codes.

The accompanying essay by Chaper is also admirable in attempting to set out the underlying principles in a clear, coherent and collected statement. He insisted on the committee providing a practical means to meet existing needs and avoid confusion, rather than a nomenclatural system theoretically better than any other. The committee accepted a number of points that might have been rejected on philosophical grounds; they would have preferred a single law of homonymy (the state or quality of a given word's having the same spelling and the same sound or pronunciation as another word, but with a different meaning such as race "tribe" and race "running contest") for both the plant and animal kingdoms, but practical considerations demanded their separation. The essay analyzed the importance of giving a Latin form to names since natural history was originally taught in Latin and Latin was the only medium of communication between people with different national languages: its use obviated the need to learn several languages in order to read the scientific literature. The essay stressed the cardinal importance of fixing the type species of each new genus as an integral part of its first establishment; this did not become part of the *Règles* until 1931. It closed with a disclaimer to have offered anything doctrinal or authoritative: the report merely provided, for general convenience, the rules and usages sanctioned by common sense and long practice, collected and coordinated.

The year 1889 was of special importance for France because of the International Exhibition held in Paris, which gave rise to no fewer than 70 congresses. One of these was the first International Congress of Zoology, initiated and presided over by Alphonse Milne Edwards. In addition to being the foremost French zoologist of his day he had important friends in political circles and the Congress received government support channeled through the Societé Zoologique de France. The opportunity to establish France as the leader in the international regulation of zoological nomenclature was too good to miss and Blanchard, as Secretary of the Societé, was not the man to let it slip.

The Blanchard Code (1889)

The draft Code presented to the first International Congress of Zoology by Blanchard is preceded by a lengthy report in which Chaper's 17 Articles are reprinted verbatim. Blanchard's own Code, which terminates the report, consists of 53 Articles and includes virtually all Chaper's Articles, somewhat reorganized. A large part of the remainder is concerned with the choice and formation of names. Discussion of this draft could not be completed at Paris and was accordingly deferred to the second Congress to be held at Moscow in 1892. Blanchard's second report, republished in 1895, contains the following significant passage on the application of the Articles expressing the Law of Priority: "A certain reserve is recommended to authors in applying the above rules. In particular, special cases should be taken into account where the replacement of a known name by a new name would cause a real disturbance of nomenclature recompensed by very slight advantages."

The Third International Congress of Zoology (1895): The Creation of the International Commission on Zoological Nomenclature

The achievement of the French in only six years (1889-1895) was considerable in the creation of an international framework - an ongoing Congress - in which nomenclature could be discussed. The regulation of nomenclature could be regularly examined as an integral part of zoology as a whole, thus countering a tendency for nomenclature to be discussed in isolation from other aspects. At the time of the third International Congress of Zoology at Leiden in 1895 there were three recent and partly incompatible sets of rules, from America (the American Ornithologists' Union Code), from France (the Blanchard report) and another from Germany (Deutsche Zoologische Gesellschaft Code. This Congress provided the opportunity for harmonization.

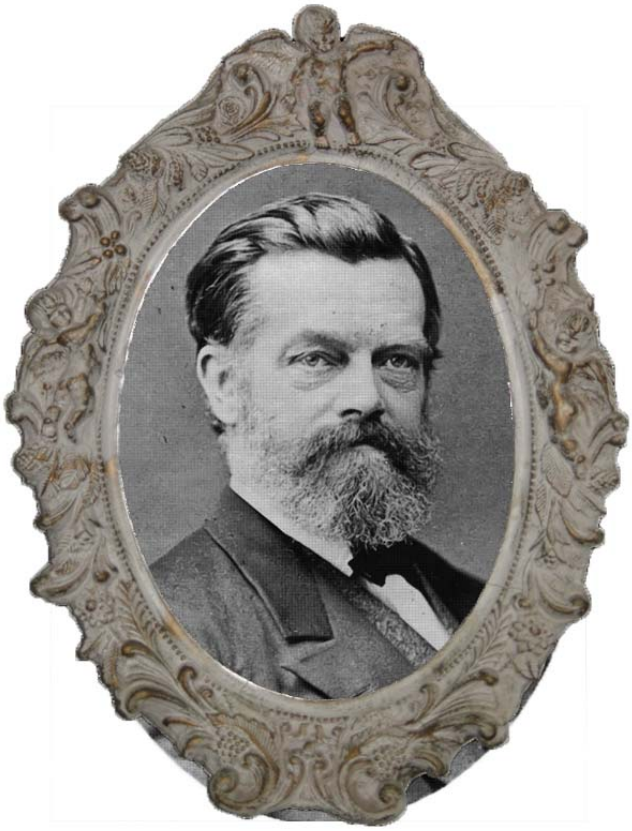
The initiative in this was taken by F.E. Schulze of Berlin with Blanchard's support. Blanchard must have realized that, if the international treatment of the subject remained in exclusively French hands, other zoologists would dissent; in that case all his and Chaper's hard work would be lost. Schulze would propose to the Congress that a commission of three members be nominated to produce one single code that could be recommended in different countries and be written in three languages, French, English and German. The accompanying image of the *Bulletin* of the Third International Congress of Zoology shows this proposal in two languages, German and French. (The German version refers to "Tierformen" or "animal forms" while the French version refers to "êtres organisés " or "organized beings" and meant plants and animals.) This proposal, with the noteworthy difference that there should be five members, was presented at the Congress's second plenary session on September 18th. It was carried unanimously and the International Commission on Zoological Nomenclature was born.

The five members appointed by the Congress were Raphaël Blanchard from Paris, one of the founders of medical parasitology; Julius V. Carus from Leipzig, pioneer in the development of comparative animal morphology and translator of Darwin's books into German; F.A. Jentink, mammalogist and Director of the Leiden Natural History Museum and also President of the Congress; Philip L. Sclater, ornithologist and Secretary of the Zoological Society of London; and Charles W. Stiles, principal zoologist of the U.S. Department of Agriculture Bureau of Animal Industry in Washington and at the age of 28 already well known both in Europe and America for his contribution to helminthology and public health.

The Commission immediately began work by correspondence and their first action was to ask Blanchard to be their President. With the exception of Jentink, the Commissioners met at Baden-Baden, Germany in August 1897 and appointed Stiles as their Secretary. They resolved to propose to the fourth Congress to be held at Cambridge in 1898 that the Commission should be enlarged to at least seven members and made permanent, with a remit to report to successive Congresses on "toutes les propositions relatives a la Nomenclature." They agreed on "un corps de *règles*" with unanimity except (ominously) on "questions secondaires." These rules were presented in French, English and German. Now, the destiny of the Code would remain in the hands of both the Commission and the Congress. It would still be ten long years before the first Code would be published, as the *Règles internationales de la nomenclature zoologique* (ICZN 1905).

The Fourth International Congress of Zoology, Cambridge (1898)

The Commission did not have an easy time. When the members arrived in Cambridge they were refused a place on the agenda to present their proposed rules. The General Secretary of the Congress, Jeffrey Bell of London, gave as the reason that their report was not in all respects unanimous. A large part of the time and energy of the three previous Congresses had been spent in discussions of nomenclature, and Bell may have thought that zoologists would stop coming if that continued. Sclater proposed that the report should be referred back to the Commission for further consideration, with power to add to its number, that all questions on zoological nomenclature should be referred to the Commission and that it



Julius Victor Carus (1823-1903), German zoologist, Commissioner 1895-1903.

Charles Wardell Stiles (1867-1941), American parasitologist, Commissioner 1895-1941, Secretary 1897-1936.

Philip Lutley Sclater (1829-1913), English zoologist, Commissioner 1895-1901.

Fredericus Anna Jentick (*1844-1913),* Dutch zoologist, Commissioner 1895-1913.

should be invited to present a final report on the Code to the next Congress. Ten additional members were elected to the Commission and the Commission approved the description of its functions as prepared by Blanchard: "This Commission of 15 members is responsible for bringing together, discussing and working out all questions relating to zoological nomenclature."

The effect of Bell's refusal to have the Commission's report discussed at the 1898 Congress was to segregate nomenclatural business from other topics in zoology and to define the Commission's status as an independent agency of the Congress as a whole. Once its reports reached the floor of the Congress they could be accepted or rejected but not discussed or amended. There was no Section on Nomenclature in which the Commission's reports could be discussed by other zoologists in advance of the general sessions of the Congress.

The Cambridge Congress adopted two resolutions of great consequence for the Commission. One ruled that no nomenclatural business could be brought before the Congress except through the Commission and having been in its hands for at least a year. This latter requirement is still in effect so far as changes to the Code are concerned and was valuable in allowing the Commission - which could work between Congresses only by correspondence - to present an orderly and considered report. The other resolution confirmed Bell's requirement for a unanimous vote on all matters concerning the rules of nomenclature and was to be a source of great difficulty for the Commission and its Secretary.

Charles Wardell Stiles, Commissioner 1895-1941, Secretary 1897-1936

The Commission's welfare, development and success were the responsibility of Stiles, who remained Secretary until 1936. Stiles (1867-1941) was an American parasitologist of immense distinction as well as a successful social engineer. He went to Europe in 1886 for five years to study at the universities of Paris, Gottingen and Berlin before taking a Ph.D. at Leipzig with the eminent parasitologist Rudolf Leuckart. As a result of this background he was well known to European zoologists. In 1898-1899 he served as agricultural attaché in the US Embassy at Berlin. Here he showed that American pig meat was not infected with worms, on which supposition its import had been banned, and this led to lifting the embargo. Among his many gifts was the capacity to move authorities to action, for example in the application of his research on hookworm *(Necator americanus)* in the southern United States and on pollution by sewage to the establishment and improvement of public sanitation.

Stiles was interested in nomenclature from an early age. In an early paper on cestodes in man, he stated that "the only way to establish an international nomenclature in medical zoology…is to enforce the law of priority." He attended the first and second International Congresses of Zoology at Paris (1889) and Moscow (1892), which had devoted much of their time to discussion of Blanchard's draft Code of nomenclature. When the Commission was set up he must have seemed the natural candidate for its Secretaryship. The other four members were all senior figures and all Europeans. Stiles had already demonstrated an immense capacity for work as well as shrewd political sense. Perhaps the other four hoped much from "calling the New World into existence to redress the balance of the Old"; such hopes were more than fulfilled.

PART IV: THE RÈGLES ARE PUBLISHED (1905)

Much detailed editing of the *Règles* was still needed after the Berlin Congress and this was entrusted to a committee of three: Blanchard, von Maehrenthal and Stiles. The committee was unable to meet until the sixth Congress (Berne, 1904). In order to finalize the text it met daily for a week after this Congress had closed. The resulting *Règles Internationales* were published in 1905 in three languages — French, English and German, the French text to be taken as decisive in case of divergence of interpretation. In the Preface Blanchard noted that it was impossible to force anybody to obey the rules, but that the Commission appealed "au bon sens des zoologists" to follow them. Although they had been "longuement

deliberees par des savants de tous pays" they would not be definitive for all time — da Science marche."

It might have been thought that what the zoological world was looking for was a strong, clear code of rules that would provide a workable compromise between the adherents of rigid priority and those who favored some relaxation in the interests of practical convenience and continuity. In 1960 Stiles's successor Hemming gave a colorful account of the actual situation — "After twelve years [i.e. since the 1889 Paris Congress] of embittered debate an International Code of Zoological Nomenclature had been adopted at Berlin…but only at the cost of painful compromises only half accepted by the groups concerned. The fact that any agreement, however defective, should have been reached, came as a great relief to those zoologists, the great majority, who were less interested in polemics than in the pursuit of their zoological studies. The appearance of this document gave rise to painful surprise in many quarters."

Those who had not been at Berlin in 1901 were shocked to see the rigid form given to the Law of Priority; those who had attended found it a highly distasteful reminder of the compromises which had been entered into. The implementation of strict priority introduced instability rather than stability in nomenclature. The Commission, as an official agency of the Congress, could have given a strong lead to almost any imaginative and courageous move in response to public opinion, but it was too divided to do so. It was also laboring under the refusal of successive Congress Presidents to permit even a discussion of proposed amendments of any rules which did not have the unanimous support of those Commissioners present. The principle of international cooperation in areas of science other than pure research was novel, whereas the notion of priority in the framing of concepts was deeply rooted. Nevertheless, Stiles, although relatively young, could perhaps have used his position to further progress and harmony in nomenclature and promote the status of the Commission. The fact that he did not do so is perhaps not surprising in the light of the working methods that he adopted over the many years of his Secretaryship. In spite of these unhappy auspices, the *Règles Internationales*, with the support of the Congress, gained acceptance to the extent that only two alternative Codes have been put forward.

PART V: PROBLEMS FACED BY THE COMMISSION

Toward a Limitation of Priority

Early on, it was realized by the International Congress of Zoology and the International Commission on Zoological Nomenclature that, in some specific cases, the application of some of the 1905 *Règles* might need to be suspended to avoid nomenclatural confusion and promote stability. It is the reason that, in 1913, the International Congress of Zoology (Monaco) conferred upon the ICZN the plenary powers to limit the application of the 1905 rules. One of the purposes of those plenary powers was that zoologists could submit requests to the Commission to protect a junior synonym over a senior name (implying a reversal of precedence). That is the reason that, when Chapman (1923) argued that a strict

application of priority generated confusion in nomenclature by resurrecting earlier and forgotten names, ICZN commissioner Bather promptly replied:

"Mr. Chapman's letter overflows with good sense; but it has all been said before. His laments, however, will not have been entirely wasted if you will permit this consolatory reply - namely, that in the year 1913, at the International Congress of Zoologists in Monaco, an agreement was reached in the largely attended section on nomenclature and confirmed in plenary session, by which the International Commission on Zoological Nomenclature was given power, on certain conditions, to suspend the rules in those cases where their operation was contrary to the general convenience. The Commission has, on the request of various zoologists, already taken action in several cases."

The possibility of submitting requests for limiting the application of priority was not enough for some authors, who thought, as did some taxonomists from the 1870s, that the Principle of Priority should be abandoned in favor of a principle of "continuity" (i.e., junior synonyms that were widely used should be conserved over earlier names). In the first half of the 20th century, debates about priority continued among zoologists as well as botanists. Beyond the Principle of Priority, it was the notion of stability that was discussed, i.e., whether it was realistic to think that nomenclature could reach absolute and permanent stability. Against authors who argued that favoring usage over priority was the best way to build a stable nomenclature, others replied that instability could not and should not be avoided:

A major step toward a limitation of priority was the recognition (not the adoption) of the "principle of conservation" (of junior synonyms over senior synonyms) at the 14th International Congress of Zoology, Copenhagen, in 1953. Discussions that took place at the Colloquium on Zoological Nomenclature, in Copenhagen, are mentioned in the detailed Report edited by Hemming (1953), then secretary to the International Commission: "After considerable discussion, the Colloquium agreed, by a majority, to recommend the inclusion in the forthcoming edition of the *Règles*, of a provision recognizing the Principle of Conservation to a limited extent." (Hemming, 1953,) Several drafts for an article governing the application of the principle of conservation were then presented. However, "…it was unfortunately found impossible to secure agreement upon any of these drafts" (Hemming 1953) and the precise wording was left to the responsibility of the International Commission.

Another issue related to the application of nomenclatural rules and stability of names: the enormous amounts of time it takes to get acquainted with the entire literature on a given taxon. Taxonomic work is poorly rewarded, and nomenclatural work is even more poorly rewarded. What people often do not understand, however, is that sound taxonomic work requires detailed nomenclatural knowledge. Regardless of the kind of rules supported by the Code (absolute priority versus priority and possible conservation of junior names), people talking about the "stability" of zoological nomenclature need to understand that: (1) dealing with all nomenclatural situations requires valuable expertise; (2) in order to reach that level of expertise, taxonomists need to spend a great deal of time working on basic nomenclatural data (lists of names, type availability, etc.); (3) more importantly, this kind of work by taxonomists should be highly respected and regarded as a direct part of their mission and duties. Indeed, one of the reasons that nomenclature is unstable is that the history of taxon names is highly complex in all taxa; experts of that history are needed, regardless of our rules.

The Type Species Problem

As surprising as it might seem, a historical review of the type concept and the terms related to typification, as well as their practical and philosophical implications, still needs to be written. In particular, it is unclear when type specimens started being used by zoologists (and botanists for that matter). Although detailed studies clearly are needed on this topic, it seems that it was only in the 1890s that zoologists realized the critical importance of type specimens in relation to the application of the Principle of Priority for species names: in fact, many papers addressed

that particular issue as far back as 1890. Blanchard's early rules included articles on type species (because of the abundant literature on this topic published in the second half of the 19th century) but did not include anything on type specimens. Because of the literature published in the late 1890s on type specimens, the first *Règles* (ICZN 1905) provided a brief recommendation on type specimens in the appendix: "This diagnosis should state in what museum the type specimen has been deposited and should give the museum number of said specimen." Terms such as holotype, paratype, syntype, and neotype, became more widely used only later.

One important challenge at the beginning of the 20th century was to go through all the terms that had been proposed so far for types and select those appropriate for the Code. This was not an easy process as there were inventoried no fewer than 233 terms available in the literature, most of which have been completely forgotten, such as: aedoeotypus, agriotype, chorotype, graphotype, hypotype, ideotype, and tautogenotype. This long list of terms shows that taxonomists, especially those interested in nomenclature, have always been profusely creative. More importantly, it also shows that the terminology related to types was abundantly discussed before terms were chosen for the Code (as always in nomenclature).

The first Opinions and the Official List of Names

At the seventh Congress (Boston, 1907) the Commission included in its report five "Opinions" on the application of the principle of priority; these were published in *Science* in October 1907. Subsequent Opinions were until 1936 published by, and at the expense of, the Smithsonian Institution in Washington. Stiles's administrative difficulties were formidable. The Commission had neither legislative nor executive powers except to issue Opinions. To an American that term suggested a judicial verdict by the highest court in the land; to a European it would more probably indicate advice provided by an advocate and still subject to the risks of a trial in court. Stiles may have thought both to have his cake (in adopting a term familiar to American zoologists in their sense of the word) and eat it (in that by issuing mere "opinions" he could not be accused of stepping on the forbidden ground of "decisions"). His successor, Hemming, met this problem by retaining the familiar term "Opinion" but by labelling the most important part of it the "Ruling"; no objection was raised to this.

At the Boston Congress the Commission announced its intention to apply 'the provisions of the Code to the names of the more common and better known animals of the world, and of publishing results in the form of a list of several thousand such approved names, with a request to zoologists that no proposition for change of any name in said list be published until such proposition together with the reasons therefor shall have been submitted to the Commission, and shall have received its sanction under the Code. This was the germ of the present *Official Lists of Names and Works in Zoology*.

An example of an opinion that affected a fish name is Opinion 14, "The Type Species of *Etheostoma Rafinesque, 1819."* David Starr Jordan submitted a case to the Commission for an opinion on *Etheostoma* vs. *Catonotus* and *Diplesion* (all genera of darters). The Commission's ruling was as follows (in part): **"**The designation of *E. blennioides* Rafinesque, 1819, as type of *Etheostoma* Rafinesque, 1819, by Agassiz, 1854, is not invalidated by the fact that Agassiz used as basis for his generic diagnosis characters taken from an erroneous specific determination of 1839."

Funding: The Eighth Congress of Zoology, Graz (1910)

Up till 1910 there had been no method of funding the Commission's work. The most important administrative development at Graz was the announcement of a three-year grant by the Smithsonian Institution of $2700 for clerical expenses and $500 to meet the costs of publication. The Commission's work would then be published by the Institution and sent to 1100 libraries, to members of the International Congress and to a limited number of specialists. This grant must have lifted a weight of anxiety from Stiles' mind, and when his secretary was put on the established payroll of the Smithsonian and treated as one

of its regular employees he was as independent as he could have expected.

The availability of funds immediately transformed the Commission's public face. The placing of funds at the Commission's disposal in 1910 led to the republication of Opinions 1 to 5 together with Opinions 6 to 25 in the *Smithsonian Publications* in July of that year, and by the 1913 Congress 51 Opinions had been published. This was certainly remarkable given the conditions of the time.

However, considering that Stiles' secretaryship lasted until 1936, it is perhaps surprising that he produced only 133 Opinions in all and transferred a backlog of some hundreds of unfinished cases to his successor. His working methods and philosophy - in his own word, conservatism - may have had something to do with this. Moreover, it is possible that the atmosphere among American zoologists and paleontologists was not very favorable to him. There was undoubtedly a strongly individualistic spirit in the United States with perhaps the signs of an isolationist attitude as the young country felt the burgeoning of its enormous strength. Biologists there may not have seen the necessity for a worldwide Code of rules and may have been quite satisfied with the Codes such as the American Ornithologists' Union. The strongest feature of Stiles' position must have been the Commission's power to issue Opinions on nomenclatural problems, to put the authority of the International Congress behind them, and to be the only body with that power and with neutral status. The view gradually gained ground that only an Opinion by the Commission had any value in such matters.

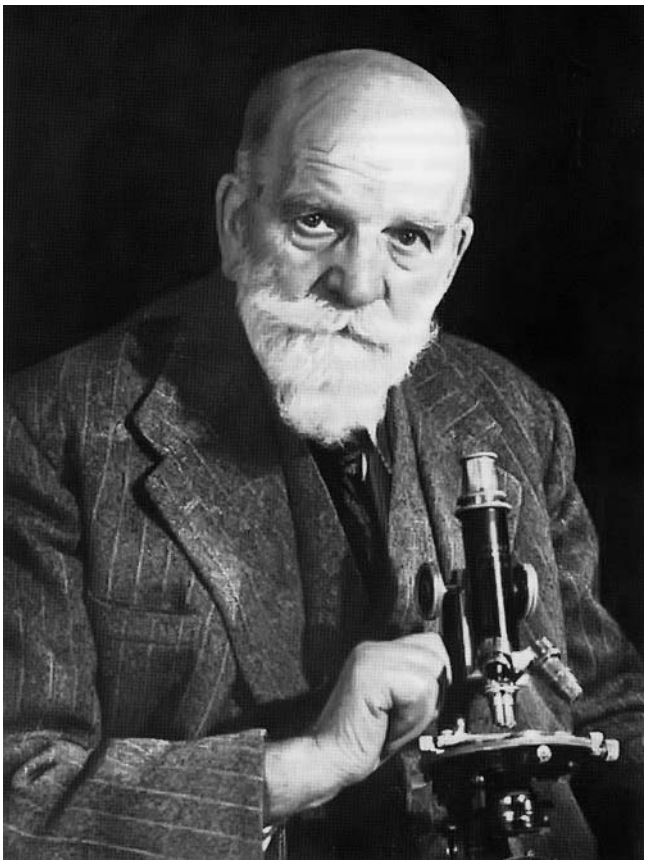
PART VI: TOWARDS A NEW CODE

Francis Hemming (Secretary 1936-1958)

Francis Hemming (1893—1964) was a high-ranking British civil servant with a flair for organization and wide administrative and political experience. He was secretary to ministers and to the International Board for Non-Intervention in the Spanish Civil War (1936—1939). At the same time, he was an international authority on the taxonomy and literature of the Palaearctic butterflies.

For the first ten years of his Secretaryship he had the active and enthusiastic support of the President of the Commission. Karl Jordan, President since 1929, was 75 when Hemming became Secretary; increasing deafness was beginning to limit his activity but, despite this, his wise governance played a major part in forming the new and more energetic arrangements that Hemming felt to be necessary.

Hemming had little to start with apart from two truckloads of unsorted papers, and it took him two years of spare-time work to sort, index and bind these (at a cost of £16). There was no money, the Commission having never had or controlled funds of



Heinrich Ernst Karl Jordan (1861-1959), German entomologist, Commissioner 1913-1950, President 1929-1948.

its own, no staff and, with the Secretary no longer in the Smithsonian Institution, no medium for publishing cases and the Commission's decisions. Yet the need for action to move affairs forward was urgent. The only official edition of the *Règles* was long out of date and out of print, and none of the amendments made by successive Congresses had ever appeared in the substantive language, French. The Official Lists of Names had never been published in a consolidated form and, like the *Règles*, the early Opinions were unobtainable.

Whoever had been elected Secretary to the Commission after Stiles's resignation would have been faced with the same problems and would have had to find his own solutions to them. Hemming's eventual solutions were fortunately successful and, in the administrative and financial arrangements that he made, exceptionally durable - the system that he set up still works today with little alteration.

The "Binaire" Conundrum

This was resolved by Francis Hemming, who defined the task before the Commission as being to determine, not what the draftsmen intended in 1901 but what, "on a due and proper construction,", the expression "nomenclature binaire" meant in the Code, for that provision demanded that the author of an available name, whether generic or specific, must have applied "les principes de la nomenclature binaire," There being nothing in the Code that defines the meaning of the expression, it was necessary to examine other passages in the Code to see if any light was thrown on the problem. This examination had to bear in mind that, in the absence of contrary evidence, the same meaning must be attached to any expression wherever it is used in a statute.

The only other use of "nomenclature binaire" was in an Article which read: "La dixieme edition du *Sys-*

Arthur Francis Hemming (*1893-1964*), British entomologist, Commissioner 1935-1964, Secretary 1936-1958.

terna naturae de Linne (1758) est l'ouvrage qui a inaugure l'application generale de la Nomenclature binaire en zoologie" ("The tenth edition of naturae Systerna Linne (1758) is the work that inaugurates the general application of the binary nomenclature in zoology"). But the one distinctive feature of the 10th edition is that it inaugurates the general application of a binominal nomenclature, i.e. species were denoted by two words only. It thus followed that "binary" and "binominal" were completely synonymous; and if this was true for one Article, it had to be true also for all the others.

The International Trust for Zoological Nomenclature

Hemming faced an invidious problem concerning the finances of the Commission, for by the end of the war in 1945 he found himself holding over £ 1000 in a bank account in his own name. This money was not his nor was there anybody else who could own it. The Commission had no corporate existence in any place and, were Hemming to have died, the money could not readily have been claimed from his estate. After obtaining the agreement of all the Commissioners who could be contacted, in February 1947 he and Jordan set up the International Trust for Zoological Nomenclature as a registered company. The Trust was (and is) a charity under United Kingdom law, meaning that it would pay no taxes on its income from subscriptions, the sale of publications or any other activities. The Trust's purpose was to hold and manage funds and apply them to the activities of the Commission, notably the expenses of publications and the salaries of the Secretariat. With regard to the latter, Hemming himself was precluded as a British civil servant from taking any payment for his work as Secretary. In the first few years of its existence the Trust recorded small surpluses of income over expenditure.

The Bulletin of Zoological Nomenclature

By June 1942 Hemming was able to give zoological nomenclature some renewed attention, but without money not even a man of his extraordinary energy and experience could do anything. Fortunately the Opinions adopted by the Lisbon Congress awaited publication and, by being put on sale in 1942, yielded a small profit over their cost of production. An appeal for funds provided a small amount (£297 by 1943) for office expenses. Hemming felt that applications to the Commission on particular problems in nomenclature ought to have wider publicity by being put within reach of the zoological public in general, rather than being distributed by the somewhat arbitrary and limited method of Circular Letters. In 1942 he and Jordan initiated the *Bulletin of Zoological Nomenclature* in wartime conditions when miracles were needed to obtain supplies of paper. Publication of the *Bulletin* began in May 1943 and generated the lifeblood of a subscription income; this enabled a revival of the Commission's activities although no new cases were voted upon until 1948.

From the inception of the *Bulletin of Zoological Nomenclature* in 1943, Hemming began to receive, and himself conceive, proposals for the correction, modification or extension of the *Règles.* To his work on this he brought the drafting skills of a trained civil servant and an extreme, some would say an exaggerated, respect for correct form. To a mind as highly organized as his, the spectacle of the 1905 *Règles* and the additions and alterations that had been made to them by various Congresses was a shambles. The additions and alterations to the original *Regies* had never even been put into French, the substantive language, so an objector could have claimed that they had no official existence and no authority. Unofficial texts had appeared at various times, such as that of the Biological Society of Washington in 1926 and the German text by Richter in 1927. Even when these defects had been cleared out of the way, there was a need to extend and develop the *Règles* in various directions to cover issues whose significance had only emerged over time.

Preparation for the new Code

The Fourteenth Congress of Zoology held in Copenhagen in 1953 finished the work of completing and developing the *Règles* that Hemming thought to be necessary. There remained the task of collating the old provisions of 1905 with all the decisions of subsequent Congresses, and with the Declarations that the Commission had adopted under Hemming's leadership, and the decisions taken at the Thirteenth

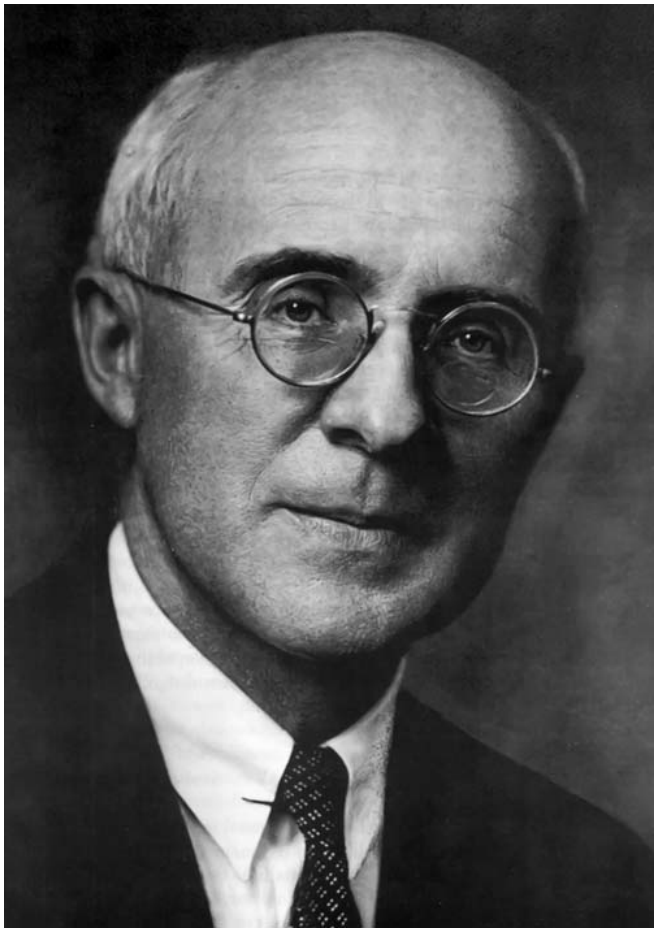
Congress of Zoology in Paris in 1948 and the following one in in Copenhagen, a modern Code could at last be produced. It would have been quite unrealistic to have expected Hemming to have added all this to the demands already made upon him by the normal work of the Commission, quite apart from the fact that he had now reached the age of 60 and was aware that he was beginning to slow down. The task of drafting the Code was therefore entrusted to J. Chester Bradley, of Cornell University, New York State, who had been at the 1948 discussions in Paris and had been elected President of the Commission in 1952. To stabilize the situation in the interim before the new Code could be adopted and published the Copenhagen Congress adopted two resolutions. The first "advised taxonomists to guide themselves ... by the decisions taken by the Congress in the light of the recommendations" by the Colloquium and Commission; the second "directed the International Commission to guide itself during this period by the decisions . . . and should treat them as binding upon it."

Parlez-vous Français?

As the close of the Copenhagen Congress drew near, it was obvious that a decision had to be taken on the substantive language of the Code that was to be put together by Chester Bradley out of the materials just enumerated. Although the 1905 *Règles* had been published in French, English and German it was the first of these texts that was to be decisive in any case of ambiguity. There were two reasons for this: the *Règles* were entirely of French inspiration and had been prepared by Raphaël Blanchard, and French was the language of international diplomacy and congresses. However, all the work done since 1905 had been in English and there was a widespread wish that the new Code should have this as the prime language. Hemming consulted zoologists from Brazil, Denmark, Germany and the Netherlands on the subject and all expressed a preference for English as the substantive language, with an official French translation; the earlier German text was not considered. Taken with those of the English-speaking countries, these made up a substantial part of the attendance at the Congress.

However, immediately before the closing plenary session objections were raised by the French zoologists present, who included both the President and the Secretary of the *Comite Permanent des Congres internationaux de Zoologie*. In view of these objections, the President of the Congress (Ragnar Sparck of Copenhagen) and Hemming took the instant decision not to proceed with the proposal to change the substantive language of the *Règles.* It has to be remembered that the Commission was not an independent organization. It was a body created by and within the Congress and was obliged to submit all its work for formal approval by a plenary session of the Congress.

Strong expressions of regret at what had occurred were immediately made. As Congress President, Sparck then directed that the English text of the Code should rank with the French as a joint substan-



James Chester Bradley (1884-1975), American entomologist, Commissioner 1944-1963, President 952-1963.

Richard Valentine Melville (1914-1993), British paleontologist, Commissioner 1968-1989, Assistant Secretary1958-1959, Secretary 1968-1985.

tive language. The reason for his decision was given as the need to avoid the delay which would be caused if the English text which Chester Bradley would produce had to be translated into French, and the equivalence of the two texts agreed, before any official Code could appear. Once it was accepted that the English text was of equal status with the French, there was no reason why the one that was the quicker in preparation should have to wait for the slower. The Trust undertook to publish the French version "at the earliest possible moment and at the same price as that proposed to be fixed for the English text"; they eventually appeared together in the 1961 Code.

The Official Lists are Finally Published

In 1958 Hemming was at last able to publish the first instalments of the Official Lists of those names and works which had been explicitly accepted by the Commission as being available, and of the Official Indexes of those which had been rejected or suppressed. This project had been initiated at Boston half a century earlier, but the Lists had never been published. The 1958 Lists and Indexes in eight separate volumes comprised 509 family-group, 2443 generic and 2052 specific names and 96 works. Some names were "withdrawn for further consideration," but most of these have since been restored to the Lists. The introduction to the Lists recorded that the 1948 Paris Congress had introduced into the *Regies* a provision that "a name on the Official List ... is not to be discarded in favor of some other name or used in a sense different. . . unless and until the Commission . . . shall so direct," the listed names were thus conserved.

Although Hemming had planned to pilot the Code through the London Congress, he was obliged on medical advice to retire at the end of April 1958, less than three months before the opening of the Congress. Fortunately, the Trust's finances enabled it to deal with this crisis by appointing Richard V Melville, a paleontologist on secondment from the Geological Survey of Great Britain, as Assistant Secretary. Melville had greatly helped Hemming at the 1953 Copenhagen Colloquium and was familiar both with the proposed nomenclatural rules and with many of the zoologists expected to participate in London.

Problems with the International Trust for Zoological Nomenclature

One major problem that came to a head in Copenhagen in 1953 concerned Hemming's publication policy and his management of the International Trust for Zoological Nomenclature. By the time of the Copenhagen Congress no regular source of income other than profit on the sale of publications had been found. A committee was proposed to examine the problems of finding an adequate financial basis for the work of the Commission and to make recommendations to the Congresses. It had also to consider the finding of a replacement for Hemming as Secretary to the Commission, for he had announced his inten-

tion of retiring as soon as the new Code could be published and this was expected before the next Congress.

The committee proposed a plan as follows: a new financial structure would be set up on the basis of an International Association for Zoological Nomenclature whose members, both individual and institutional, would subscribe to the support of the Commission; until that arrangement was in place, the existing structure of the Trust would continue and a grant-in-aid would be sought to meet expenses; financial matters would be handled by the officers of the new international society; and the work of the Secretary would be shared between an Interim Secretary and an Interim Editor, both honorary posts.

In May 1954, however, Hemming wrote to the committee to say that for various reasons the new Code ought not to be promulgated in the form proposed at Copenhagen but should first be considered by a Colloquium to be convened as a prelude to the 15th International Congress of Zoology to be held in London in 1958, and that he therefore proposed to defer his retirement to the close of that Congress. The Committee saw some advantage in this proposal and replied that they proposed to lay their report before the London Congress, at the close of which the International Association for Zoological Nomenclature could be instituted.

The report was completed in 1958 and proposed to institute drastic economies, hoping that the new source of income from subscriptions to the International Association would lessen dependence on profit from the sale of publications. The length and number of the publications and hence their price would be reduced by eliminating duplication between the *Bulletin* and the *Opinions*. The Committee proposed a structured scheme for subscriptions to the International Association, as well as measures for its organization and governance. A proposed budget showed that expenses could be matched by an equivalent income. Sufficient funds had been accumulated to ensure the transfer of work to Hemming's successor without interruption. There can be no doubt that the report of the Committee contained many excellent proposals. The Trust immediately economized by reducing the number of salaried staff. The position of Lord Hurcomb's - the Chairman of the Trust - as a Trustee of the British Museum (Natural History) facilitated the Secretariat's move into free accommodation in the Museum with its unrivalled libraries. This arrangement has continued ever since, to the great advantage not merely of the Commission but of zoology everywhere. The Trust's serial publications were confined to the *Bulletin of Zoological Nomenclature* alone by eliminating the separate *Opinions and Declarations.* However, the International Association for Zoological Nomenclature was not formed and the proposed distribution of the roles of Commission Secretary and of Editor to two honorary officers was not pursued.

The Chester Bradley Draft Code

Chester Bradley's draft of the Code was published in 1957 as volume 14 of the *Bulletin.* It was immediately seen to be a completely new Code and the thoroughness of the new document was remarkable. The structure of the Code had been carefully thought out. It was divided into three sections - one for the "Rules, Nomenclatural Regulations and their interrelations with Taxonomy," one for "Linguistic Regulations' and one for 'Regulations pertaining to this Code and to the Commission."

In spite of the enormous elaboration of the old *Règles*, this was all set out in 30 Articles compared with the 35 Articles of the *Regies.* Each Article was divided into numbered sections and lettered subsections. Recommendations were inserted as close as possible to their relevant mandatory provisions and numbered in sequence within each Article. All this is still reflected in the current Code.

The outstanding characteristics of the Chester Bradley draft were its clarity and balance. The language was plain and shorn of complexities except occasionally where the author was at pains to demonstrate the logical basis of his drafting; with perhaps a private wish to show where he thought Hemming had missed a point. He was careful to provide explanations of points that he found obscure and suggestions for dealing with defects that he thought beyond his

own authority. He also took care to give the authority for each provision - whether in the *Règles* or in the proceedings of the Paris and Copenhagen Congresses, or in a Declaration by the Commission. It is difficult to see how a plainer basis could have been provided for final decisions on the shape and content of the Code to be taken by the London Congress. The Commission later formally recorded that Chester Bradley's "occupancy of the Presidency was one of exceptional importance, comparable only with that of Professor Raphaël Blanchard fifty years earlier. Both men devoted their main attention to the international regulation of zoological nomenclature, Professor Blanchard being the principal author of the Code ultimately adopted in Berlin in 1901, Professor Chester Bradley playing a similar role in the preparation of the draft of the revised Code adopted by the London Congress in 1958."

Norman R. Stoll (1892-1976), American parasitologist.

International Code of Zoological Nomenclature (1961)

The final work on the London Code was entrusted to an Editorial Committee of two Americans (Norman R. Stoll and Curtis W. Sabrosky), two French and two English zoologists, with Stoll as Chairman and Richard V. Melville as Secretary. The task of drafting a coherent Code was demanding, and Stoll and Sabrosky spent many weekends together working on it. The Committee met in London in May 1959 and worked for over a week, "almost literally around the clock" according to Stoll. During the period 1958-1960 almost all the normal work on individual cases and production of the *Bulletin* was done by the Secretariat assistant, Miss Margaret Spillane. Joseph H. Riley saw the London Code through to publication in November 1961, with a preface by Chester Bradley giving a masterly expose of the principles of nomenclature and an introduction by Stoll describing the work of the Editorial Committee. Within 18 months 3750 copies of the Code had been sold at one £ each. Translations accepted as authorized texts soon appeared in Bulgarian, Czech, German, Japanese, Polish, Russian and Spanish, the German translation being by Otto Kraus, appointed to the Commission in 1963 and its President in the centenary year. Amendments made to the 1961 Code by the 16th

Curtis Williams Sabrosky (1910-1997), American entomologist.

Congress meeting at Washington in 1963 were incorporated in a second edition published in 1964.

CONCLUSIONS

An important aspect of nomenclature that one should keep in mind when potential changes of nomenclatural practices are discussed is that nomenclature is a means of facilitating, not an end result, of taxonomy. In fact, one can read on the front page of the American Ornithologists' Union Code of 1886: "Zoölogical nomenclature is a means, not an end, of zoölogical science." This implies that nomenclature should remain open to changes that facilitate the work of taxonomists. This is exactly why numerical taxonomists argued in the 1960s that nomenclature should be changed so that it could serve better the modern context of numerical taxonomy. This also is why it has been more recently argued that nomenclature should be changed to better serve the modern context of phylogenetic systematics.

New nomenclatural questions may arise from new techniques too. Early writers (e.g., Strickland 1835, 1843) rightly argued that names should be eligible for priority only if the species designated by that name had been properly described. What constituted a "good" description was actively discussed throughout the 19th century in relation to the Principle of Priority, but basically descriptions should include as much information as possible so that species can be re-identified.

However, standards of species description change over time because new techniques are available. For instance, when Blanchard and the other members of the International Commission devised the first *International Rules of Zoological Nomenclature* in the late 19th century, the ability of comparing nucleotide sequences for taxonomic purposes did not exist. Should the Code recommend that DNA sequences of a few standard markers be included in species descriptions as, in the 19th century, some authors thought that illustrations of specimens should be mandatory when creating a new name?

It seems that the future of nomenclature is going to be fascinating. However, taxonomists should not fear that changes may be needed in nomenclature, as long as those changes can help to better serve modern needs in systematics. Nomenclature has remained dynamic for the last 250 years, and will be dynamic for the next 250.

THE CLASSIFICATION OF FISHES: FROM ARISTOTLE TO LINNAEUS

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, July 25, 2015)

Although I have written about nomenclature, classification is also of interest to serious aquarists. Classification is a way of categorizing animals based on their physical and genetic characteristics into groups and subgroups. As most aquarists know, the most common are (in descending order of complexity) order, family, genus and species. As Gaylord Simpson put it, "This is, as I see it, the primary purpose of classification: simply to provide a convenient, practical means by which zoologists may know what they are talking about and others may find out." Replace the word "zoologists" with "aquarists" and a simpler reason for why classification is important cannot be found. Classification is one part of taxonomy, which includes the identification, description, classification and naming of fishes.

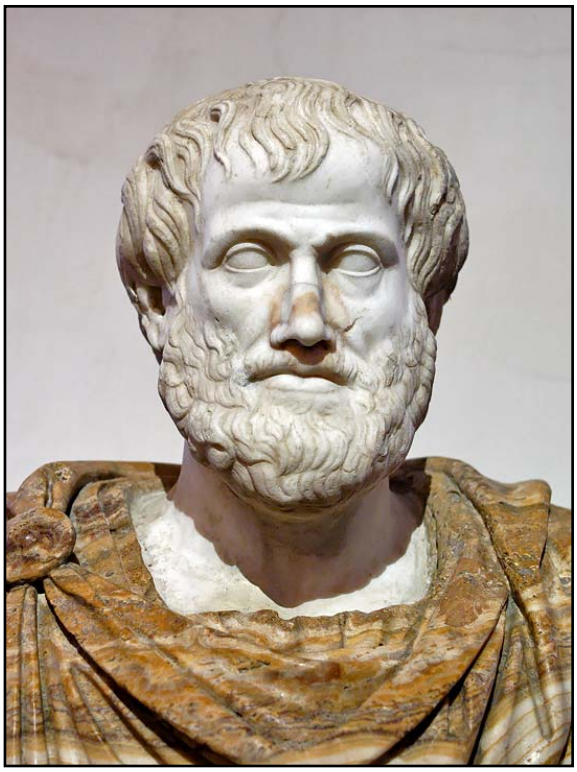
THE ANCIENTS

Aristotle

It is necessary to start with Aristotle since his views on the classification of animals lasted for thousands of years, extending into the Renaissance and even after. Aristotle (384–322 BC), the pupil of Plato, is generally considered as the real founder of zoology, though not necessarily of ichthyology as he never wrote a monograph on fishes. However, the advances he made both in practical observations of fishes and in theoretical considerations about their nature are just overwhelming, such as why bony fishes are so prolific or how the Chondrichthyes (cartilaginous fishes) and Osteichthyes (bony fishes) differ in their reproductive biology. Aristotle's zoological definition of a fish was the first clear and correct one. The following is taken from his *Historia Animalium* (*History of Animals* - written in 350 BC): **"…the tribe of fishes is a unified group, distinct from other water-animals, and includes many sorts of various appearances …they have two peculiarities, gills and fins."**

Aristotle's classification of species was his greatest contribution to the history of zoology as it was the first known attempt to classify animals into groups according to their behavior and, most importantly, by the similarities and differences among their physiologies. Using observation and dissection, he categorized species. Although his broad classifications might seem strange to modern zoologists, considering the limited equipment and store of knowledge he had access to, his zoology stands as a tribute to his systematic methods and empirical approach to acquiring knowledge.

While Aristotle's zoology and classifications were broad and often inaccurate, the sheer scale and the thorough documentation sets apart his *Historia Animalium* as one of the landmark scientific texts in the history of biology. Aristotle's work was the beginning of the science of zoology, with many of his observations preempting the studies of great naturalists such as Darwin, Linnaeus and Wallace. Sadly, the observations were spread across nine books that deal with his history of animals, and much of this work was lost.



Aristotle (384-322 BC)

An Aristotelian classification works according to a set of binary characteristics in which the object being classified is either present or present. At each level of classification, enough binary features are used to place any member of a given population into one, and only one, class. For example, Aristotle described features in binary terms: **"Some are nocturnal, as the owl and the bat, others live in the daylight."**

This system of classification is commonly called morphological, its basis being the grouping of animals according to the number, and to some extent the kind, of structural characteristics that they have in common. Each grade in a hierarchy corresponds with certain fixed characters possessed by all the animals included at a particular level. The lower the hierarchic rank, the more characters are held in common by the included animals. For instance, such a classification based on these premises might be:

A. Dorsal & anal fin same size
  a. 10 or more dorsal spines (White Crappie)
  b. 5-6 dorsal spines (Black Crappie)
B. Dorsal longer than anal fin
  a. Black corner of mouth extends to back of eye (Largemouth Bass)
  b. Black corner of mouth does not extend to back of eye (Smallmouth Bass)

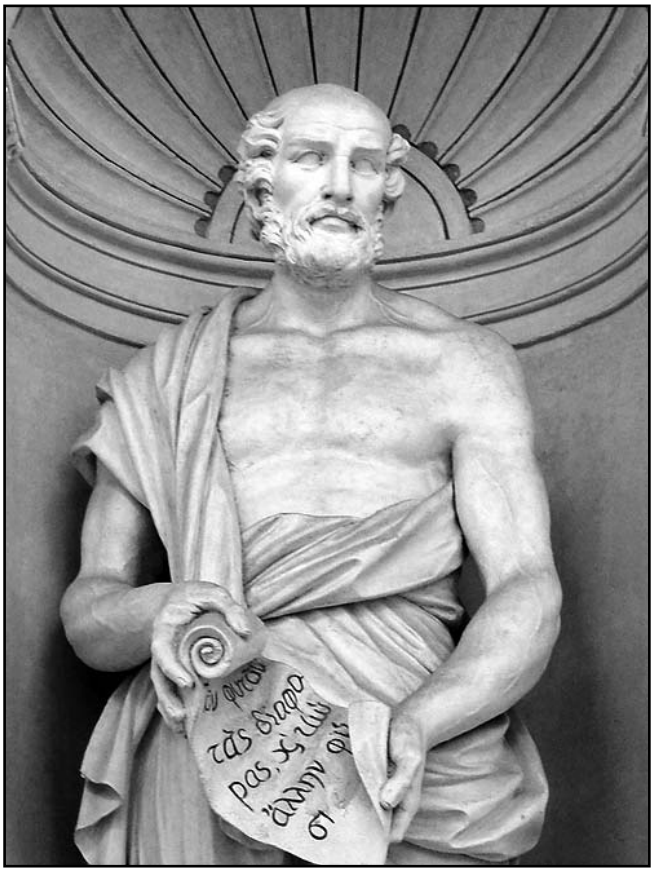
This was the sort of classification adopted by almost all early naturalists, including Linnaeus and most of his successors before Darwin.

For aid in the easier identification of specimens, classifications wholly morphological in principle are still in common use. They are entirely valid and are often more practical than any others, but they are not now accepted as the standard or ideal of zoological classification. In fact, they are not, as a rule, called classifications but keys. Keys of course are known to and are used by aquarists.

A "true" or "natural" classification on the other hand has, by intention, quite a different basis that came with the general acceptance of the theory of evolution. The belief that different animals, even very unlike animals, were actual flesh-and-blood relatives and had common ancestors suggested that it would be more natural, or philosophically preferable, to define groups by community of origin, i.e., by phylogeny. This radical change, much the most revolutionary in the whole history of taxonomy, had extraordinarily little immediate effect on the general nature and aspect of formal classifications. From their classifications alone, it is practically impossible to tell, for example, whether the zoologists of the middle decades of the nineteenth century were evolutionists or not, and classifications that were intended to be phylogenetic differed as much among themselves as they did from frankly morphological classifications.

Theophrastus

One cannot leave Aristotle without mentioning his favorite pupil, Theophrastus, who he named as his



Theophrastus (371-287 BC)

successor, bequeathing to him his library and manuscripts of his own writings. Theophrastus (371 or 372 -287/286 BC) was born in Eresos on Lesbos. He was a student of Aristotle and succeeded him as a director of the Lyceum in Athens. He held this positon for about 35 years and was a teacher of about 2000 students. He took over the philosophy of Aristotle in parts, reshaping, commenting and developing it in an original way. His thinking lead to an empirical approach that included observation, collection and classification.

If Aristotle goes down in history as the Father of Biology and Zoology, Theophrastus certainly earns the title of "Father of Botany" and perhaps of Ecology as well. He began the science of botany with his books , *De causis plantarum* (*The Causes of Plants*) and *De historia plantarum* (*The History of Plants*). He described the origin of plants from seeds, carried out germination experiments, discussed the influence of abiotic habitat factors on plants, the ecology of domestic plants and the pollination of plants. Using the example of the fig, he invented a growth form terminology which is still valid (root, shoot). He described more than 500 species and varieties of plants from lands bordering the Atlantic and Mediterranean. He classified plants into trees, shrubs, under shrubs, and herbs. He noted that some flowers bear petals whereas others do not, and observed the different relative positions of the petals and ovary. In his work on propagation and germination, Theophrastus described the various ways in which specific plants and trees can grow: from seeds, from roots, from pieces torn off, from a branch or twig, or from a small piece of cleft wood.

Note: After Aristotle observed that "one swallow doth not a Spring make," Theophrastus set to work on a treatise entitled, "On the Number of Swallows Needed to Make a Spring."

Pliny The Elder

Pliny the Elder was the son of an equestrian (the lower of the two aristocratic classes in Rome) and was educated in that city. After serving in the military he became a lawyer and then a government bureaucrat. In these positions he traveled not only throughout what is Italy today, but also what would later become Germany, France and Spain as well as North Africa. He wrote a 37-volume, *Naturalis Historia* (ca. 77-79), in which he claimed that he had compiled "20,000 important facts, extracted from about 2000 volumes by 100 authors" and was written for "the common people, the mass of peasants and artisans, and only then for those who devote themselves to their studies at leisure." This is the earliest known encyclopedia of any kind, and has been interpreted as a Roman invention intended to compile information about the empire. However, it was a rather disorganized book, whose prose has been criticized by many. Pliny seemed to be more interested in what appeared to be curiosities than what were facts. Thus, this is a large collection of fact and fiction, based mostly upon what others said.

He devoted nine of the thirty seven volumes to animals and ordered them according to where they live. Volume IX (*Historia Aquatilium*) of *Naturalis Historia* is devoted to aquatic creatures, whether living in oceans, rivers or lakes, whether vertebrate or invertebrate, real or mythical. Based on their size he catego-

Pliny the Elder (23- 79 AD)

rized as “monster” anything big, whether it was a whale, sawfish or tuna.

He grouped together all known species of cetaceans but constantly mixed their descriptions with those of other marine mammals such as seals as well as with cartilaginous fishes such as sharks. Pliny did recognize that neither whales nor dolphins have gills, that they suckle from the teats of their mothers, and that they are viviparous. In addition to these true facts copied from Aristotle, he mentioned exaggerations such as whales of four jugera (about 1000 feet) in length that because of their large size “are quite unable to move.” In addition to some of the biological facts mentioned by Aristotle, Pliny adorned his narrative with various tales about interactions between cetaceans and humans.

By lumping together all kinds of aquatic organisms, it is hard to distinguish what he called a “fish” and what he did not. His classification took a step back from Aristotle because he did not try for a comprehensive classification of animals. He failed to compare organisms based on shared or divergent characters. Many times he ordered creatures based on size, from the largest to the smallest. Yet, his work had great influence for 1700 years, which was unfortunate because he was an uncritical compiler of other people’s writings even if they were contradictory. Pliny also created a number of unfounded impressions about the reality of nature. His only positive contribution was that he established the norm of always citing the sources of his information (in actuality 437 authors, whose works, in some cases, are no longer available).

THE THIRTEENTH CENTURY

The jump to this date from the time of Aristotle and Theophrastus is enormous, but with regard to fishes no significant advances took place during this interval. To start, the Middle Ages should be judged from an ichthyological point of view mainly from their ecological aspects. The economy that expanded considerably in medieval Europe was fraught with severe environmental impacts and with complex interactions between human societies and the ecosystems in which they lived.

The hydrological conditions in many European countries changed drastically and basically. Deforestation, aggregation of people in steadily growing cities, intensification of agriculture and the proliferation of water-powered grain and saw mills caused a great change in the hydrographic balance and in the ecological conditions of aquatic habitats. Floods as well as the dewatering of streams, pollution and the cutting off of the migration routes of fish had deleterious consequences and with these, a severe impact on fish stocks resulted. Interesting social responses of medieval Europeans to rising pressures against the fish resources of inland waters included privatization, commercialization, public regulation of fish exploitation and the pond culture of fish. The Middle Ages were also the beginning of increased exploration and seafaring and with it, an interest in foreign populations, animals, plants and riches.

Though in the course of the Middle Ages Aristotle became important for his rational and logical approach to knowledge and thus influenced the scholars at the newly forming universities during the 12th Century Renaissance, his natural science gained far less interest. Scientific literature about fish did not exist except that clergymen, either by ignoring or happily accepting the findings of Aristotle, found some animals living in rivers, such as beaver, otter and some birds, to be “fishy” enough to make good eating during fasting days.

Albertus Magnus

The learned German bishop and scholar Albert the Great or Albertus Magnus (1193-1280) was known during his lifetime as *doctor universalis* and *doctor expertus* and, late in his life, the term *magnus* was appended to his name). He was born at Lavingen in Swabia, Germany in 1205 and received his education at Pavia, Italy, where he entered the order of Dominicans. Sometime later he went to Paris and delivered public lectures to great acclaim. In 1248, he was invited to Rome by Pope Alexander III., who appointed him to the office of Master of the Holy Palace, and bestowed on him the bishopric of Ratis-

Albertus Magnus (1206-1280)

bon, Germany, which he soon after resigned. Returning to Cologne, he resumed his very popular lectures.

Albertus was the greatest German philosopher and theologian of the Middle Ages. Pope Gregory X called upon him to assist at the general council, held at Lyons in 1274, where the conclave of cardinals for the election of the successor of St. Peter was first instituted. In Cologne he is not only known for being the founder of Germany's oldest university there, but also for "the big verdict" (der Große Schied) of 1258, which brought an end to the long-smoldering conflict between the citizens of Cologne and the archbishop, a matter of jurisdiction between the city and the township. Among the last of his labors was the defense of the orthodoxy of his former pupil, Thomas Aquinas, whose death in 1274 grieved him greatly.

Albertus was the first to comment on virtually all of the writings of Aristotle, thus making them accessible to wider academic debate. He wrote so many works that, when collected for a general edition at Lyons in 1651, they filled twenty one thick folios. His character was highly respectable and his treatise *De animalibus* (*On the animals*), published circa the 1260's, is certainly a remarkable production for the age in which he lived. In this book Albertus describes the common torpedo or eyed electric ray (*Torpedo torpedo*) thusly:

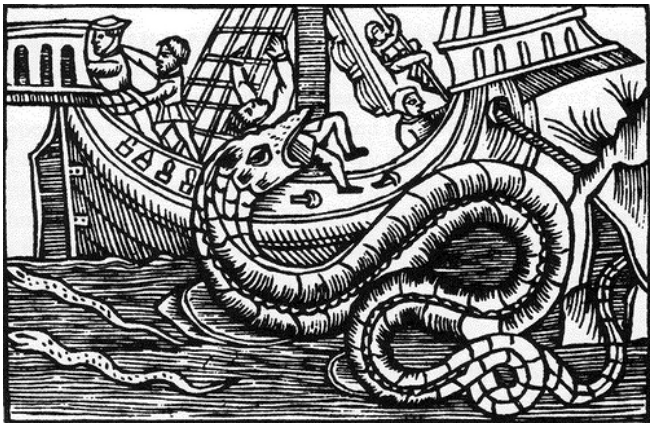
"There is, moreover, sometimes a given operation of the fish, which derives from the necessity of nature. But this operation is also carried out in an artful way, as it appears in the case of the fish that Greeks call barkis and we call torporific (stupefactorem*),* because it induces torpor in the hands of those who touch it. It is by inducing torpor that this fish captures animals that pass near it and instantly eats them. So great is its virtue in inducing torpor that a trustworthy man who touched the fish with the extremity of his finger for the sake of experience had his arm so numbed that he had to undergo treatments for more than a month with hot baths, applications of warm ointments and with friction (rubbing), in order to recover his sensibility and movement."

A page from Magnus' de animalibus, circa 1260, showing fish and other marine creatures.

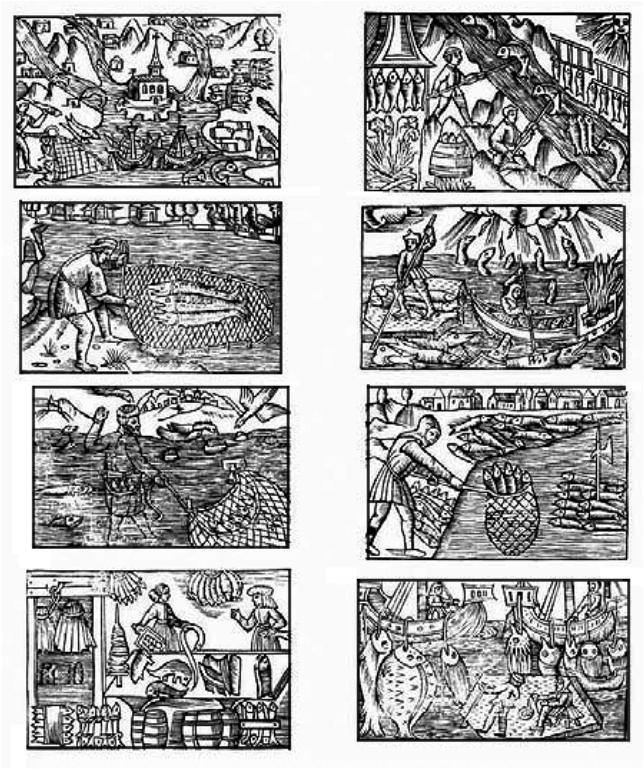
However, a limited knowledge of the actual relationships between groups is evident in these old zoological classifications. For example, in *De animalibus* Magnus classified the bats with birds, and the whales with fishes.

It is recorded that he had constructed a brazen head (among the people reputed to have one were Roger Bacon, Faust, Pope Sylvester II and Virgil). This was a legendary automaton that often appeared in literature, reputed to be able to answer any question. It was said to have been owned by medieval scholars who were believed to be wizards, or who were reputed to be able to answer any question. The device was always in the form of a man's head, and it could correctly answer any question asked of it. Mechanical variations appear in fictional literature: the head might be cast in brass or bronze, it could be mechanical or magical, and it could answer freely or it could be restricted to "yes" or "no" answers. However, these brass heads were so common that people began to believe that there was nothing supernatural about them. However, Thomas Aquinas, his pupil at the time, is reported to have broken it in a fit of terror.

Albertus died at Cologne at the age of 77 and was declared a saint by the Church in 1622. If we relax the definition a bit, we might say, tongue in cheek, that he was the only ichthyologist so beatified. The Albertus typeface, by the way, is named after him.



Woodcut of a sea serpent by Olaus Magnus (from Historia *de Gentibus Septentrionalibus,* 1555)



Pictures from Olaus Magnus' *History of the Northern people*, 1555.

THE SIXTEENTH CENTURY

Olaus Magnus

Olaus Magnus ((1490-1557) or Olaf Mansson before his name was Latinized was a Swedish historian and geographer. He first had been taken into the higher ecclesiastical service and made cathedral provost at Strengnas, and later he became the last archbishop of Uppsala. Afterwards he traveled on behalf of the king of Sweden to gather information on the very little known region of the Northern Scandinavian Peninsula and its bordering seas. His travel reports are a mixture of reliable observations and credulity. Among other things, he gained knowledge on the tremendous richness of fish thriving in these regions. Though these resources were used by the people living along the shores of the Gulf of Bothnia and the North Sea for some time already, the North and the North Sea were still largely unknown to the civilized world.

Not surprisingly, Olaus' reports contain much new information on fish, fishing, fish behavior, fish trade

and mysterious aquatic beasts as well. In his famous *Carta marina* of 1555 (the earliest detailed map of the Nordic countries) as well as his 1555 *Historia de Gentibus Septentrionalibus* (*History of the Northern People*), Magnus tells about river migration and catch of salmon at the Baltic, fishing with light, salting of fish and the rich herring fisheries near Bohuslän in Western Sweden and at the coast of Skåne (Schonen). Much of this was seen by him, but he regarded strange fishes and sea monsters of the North Sea as real, trusting in the reports of others.

Gregor Mangolt

The first book of modern age addressing entirely fishes was written in 1557 by Gregor Mangolt (1498-1576), a German chronicler, former priest, bookseller and publisher. It deals with the fishes of Lake Constance and may be called the first ichthyological book on the whole. It is the first treatise on this subject not written in Latin but rather in a native language. Its title reads: *Fischbuch von der Natur und Eigenschaft der Vischen, insbesondere derer so gefangen werden im Bodensee und gemeinlich auch in anderen Seen und Wassern, durch den wohlgeleerten Gregorium Mangolt beschrieben vormals nie gesähen* (*The fish book of the nature and characteristics of fishes previously never seen, especially those caught in Lake Constance and commonly described from other lakes and waters, by the highly qualified Gregorium Mangolt*).

Fischbuch
Von der Natur vnd
Eygenschafft der Fischen / Insonderheit deren so gefangen werden im Bodensee/ vnd gemeinlich auch in andern Seen vnd Wassern / Durch den wolgelehrten Gregorium Mangolt beschrieben / vormals nie gesehen.
Item / ein ander Büchlein / wie man Fisch vnd Vogel fahen solle / mit dreissig newen vnd bewehrten Recepten. Auch zu was Zeiten im gantzen Jahr ein jeder Fisch am besten sey.
Jetzo auffs newe gedruckt.

Title page of Gregor Mangolt's Fish Book, 1557.

His simple descriptions relate to the reproduction and food of fishes, their value as human food and, in detail, to the nature and characteristics of many of them. The book surely was intended to inform local people of "their" fish as well. Mangolt mentions 76 fish names which were commonly used only by people of Konstanz. This high number of common names is partly to be explained by the fact that for some of the fish more than one name was in use and it cannot be decided in each of the case whether some of the species Mangolt mentioned are just duplicates of others.

THE RENAISSANCE

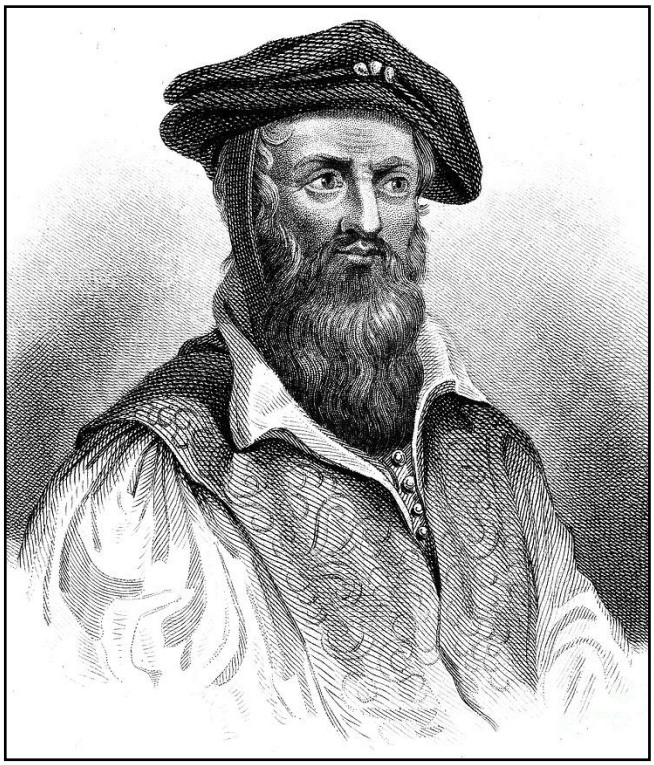
For nearly 2000 years after Aristotle, few original observations about fish were recorded because Aristotle was considered to have completely covered all areas of natural history. In the 16th century, however, a general interest in fishes (especially marine species) increased and interest in fishes gained a deeper and newer scientific interest once again. Aristotle's grip on ichthyology (and science) was finally broken.

Within the short period of 15 years, five men were born in the first quarter of the 16th century who were destined to revolutionize the study of natural history in southwestern Europe and to lay a broad, deep and solid new foundation of ichthyology. These scientists were in order of birth: Guillaume Rondolet (French) (1507-1566), Ippolyto Salviani (Italian) (1514-1572),

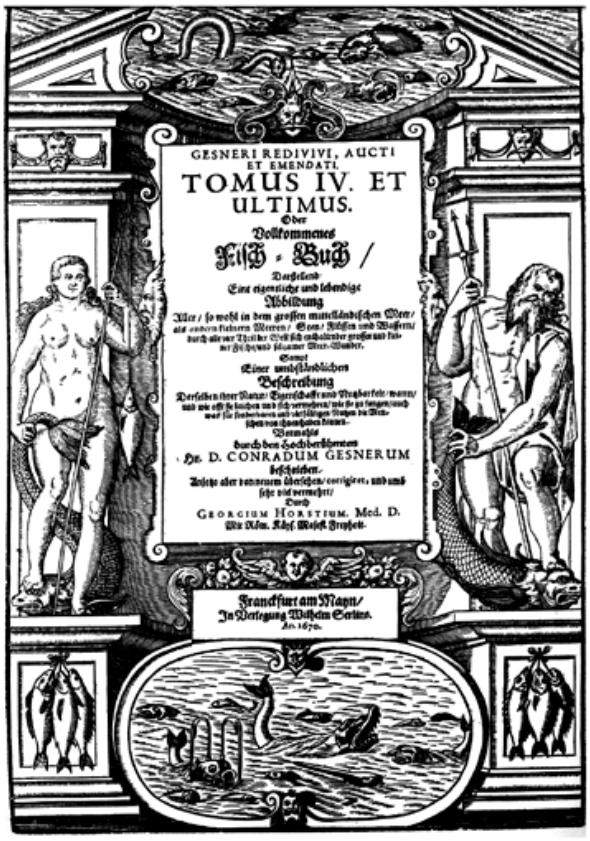
Conrad Gesner (German-Swiss) (1516-1565), Pierre Belon (French) (1517-1564) and Ulysse Aldrovandi (Italian) (1522-1605). They can be considered as a product of the Renaissance, the time of intense mental ferment which had as its precursor the "Revival of Learning" stirred on by the resurrection of Greek and Roman art and literature, and the development of humanism by Dante, Petrarch, Boccaccio and others who led the way to overcome the Dark and Middle ages.

Conrad Gesner

A scientific interest in the diversity of life on Earth was awakened in the publication of encyclopedic works, such as those devoted to the animal world by the Swiss Conrad Gesner and the Italian Ulisse Aldrovandi. Their bulky compilations (Aldrovandi's books sum up to some 7000 large-size pages) recorded everything that had been written on zoological matters up to that time. Their value, however, was severely limited by the authors' limited critical attitude, so that reliable behavioral or anatomical observations were presented on the same footing as folk legends or purely literary, fanciful accounts.



Konrad Gessner 1516-1565)



Title page of Gesner's *Fischbuch*.

Conrad Gessner 1516-1565) was a Swiss naturalist and bibliographer. He was well known as a botanist, physician and classical linguist. His five-volume *Historiae animalium* (1551–1558) is considered the beginning of modern zoology, and the flowering plant genus *Gesneria* and its family Gesneriaceae are named after him. A genus of moths, *Gesneria*, is also named after him. Gesner was an encyclopedist of the early modern age, the first one after Aristotle and 1800 years later. One of the six volumes of Gesner's *Historia Animalium* is on fishes and in contrast to Aristotle some of his work is ichthyology in the strict sense. This part was translated into German in 1598; it became extremely popular and many reprints followed. As its subtitle stated, the author had intended to describe all the fishes of the world: those from the Mediterranean, from lakes, rivers, and from waters not only of Europe but also of Asia, Africa, America, and the East and West Indies.

Gesner labeled imaginary groups with names and regarded water mammals and invertebrates as fish.

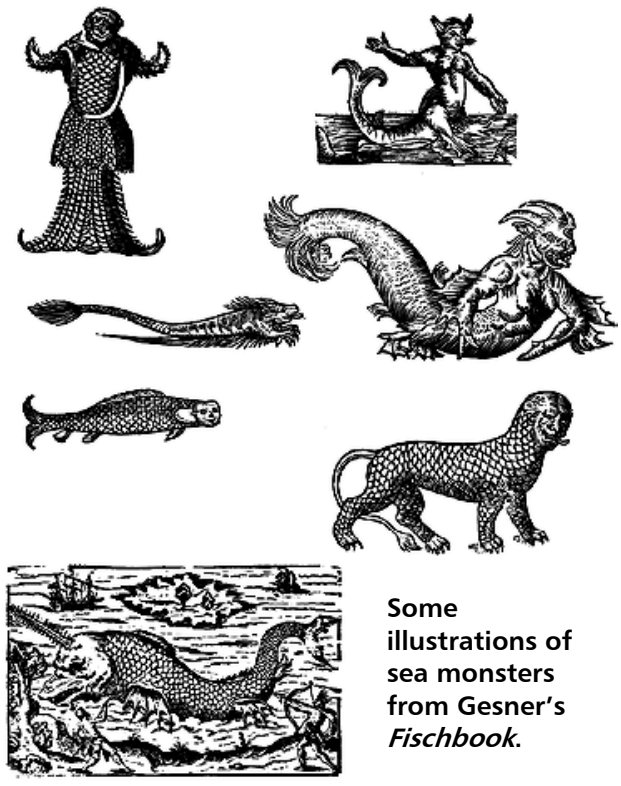
Some illustrations of marine fishes frtom Gesner's Fischbuch.



Some illustrations of sea monsters from Gesner's *Fischbook*.

Even more uncritical, he included each of the sea monsters he ever heard about into his book, many of them copied from Olaus Magnus. It is obvious that many of the fishes in Gesner's book were illustrated just by hearsay or copied from others and not collected or seen alive or as fresh specimens by the author himself. Nevertheless, it became a standard work in the Europe of the 16th and 17th centuries.

Several of the woodcut figures were quite acceptable and allowed a rough identification of certain species. Many pictures were poorly drawn, surprisingly even those showing domestic fresh water fishes. But the figures of monsters, "Wallfischen" (whales, sea monsters, and other "sea miracles"), are well-done. A classificatory effort is evident as he distinguished 17 orders of aquatic animals. Eleven of these included different kinds of fishes, mostly distinguished on the basis of body shape, rather than their habitat (as was fashionable at the time) or skeletal peculiarities (as would become general practice a couple of centuries later). The other orders were those of cetaceans (including, however, seals and sea turtles), cephalopods, crustaceans, "testaceans" (i.e., molluscs with shells), "insects" (which included several kinds of marine worms, plus isopod crustaceans and even the sea horse!) and zoophytes (i.e., corals and the like).

Ulisse Aldrovandi

Aldrovandi was born in Bologna to a noble family and sent him to apprentice with merchants. However, after studying humanities and law at the universities of Bologna and Padua and becoming a notary, he found his vocation. Successively his interests extended to philosophy and logic, which he combined with the study of medicine. He obtained a degree in medicine and philosophy in 1553 and started teaching logic and philosophy in 1554 at the University of

Ulisse Aldrovandi (1522–1605)

Bologna. In 1559 he became professor of philosophy and in 1561 he became the first professor of natural sciences at Bologna.

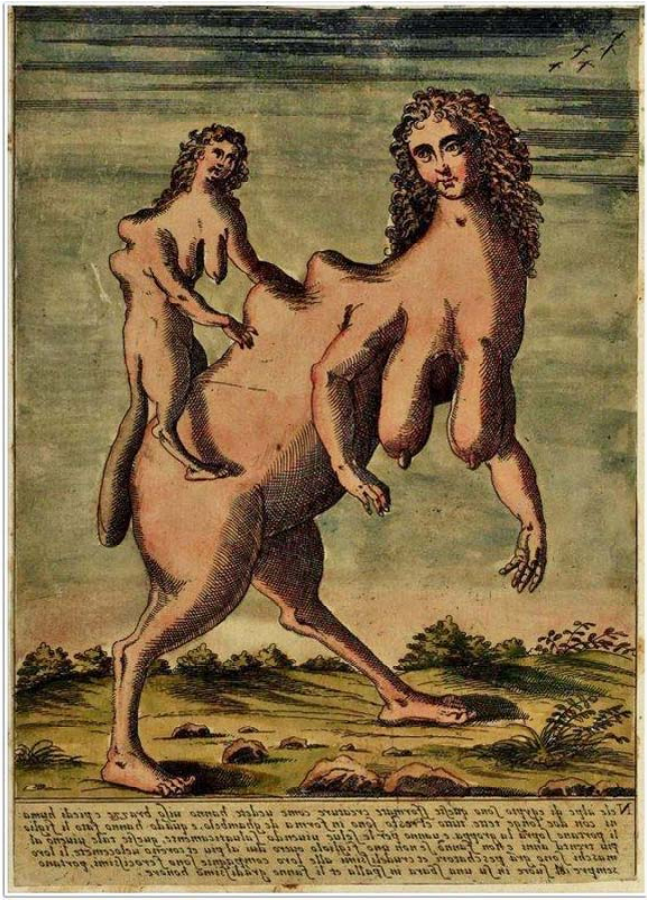
Aldrovandi was also a naturalist and the moving force behind Bologna's botanical garden, one of the first in Europe. Carolus Linnaeus and the Comte de Buffon reckoned him the father of natural history studies. Aldrovandi taught for many years at the University of Bologna during the latter half of the sixteenth century. He was of a well-off family and his fortune enabled him to travel extensively to collect materials for his books and to employ artists in painting and engraving suitable illustrations. A contemporary of Shakespeare, he was one of the first great specimen collectors and regularly organized expeditions for that purpose.

Aldrovandi was nicknamed both the "Bolognese Aristotle" and the "Second Pliny." Like Pliny, much of his life was devoted to compiling an enormous encyclopedia. Moreover, it had the same name as Pliny's work. Aldrovandi's *Storia Naturale* (*Natural History*) was many thousands of pages long. It filled 14 folio volumes (10 published posthumously between 1606 and 1668). It had fine illustrations, and to a large extent, the descriptions were based on direct observations, unlike those of so many of his predecessors. The only comparable work of the era was Gesner's *Historiae animalium*.

Of Aldrovandi's innumerable books and papers, relatively few were published in his lifetime. One of the many books he wrote was *Monstrorum Historia* (*A History of Monsters*), a compendium of reported human and animal monstrosities. The book included accounts not only of monstrous natural births but also of what now seem to be extremely far-fetched monsters. This sort of juxtaposition was common at the time, since there was not as yet a distinction between the literary and the scientific. If a given monster had been described by previous authors it was considered proper to mention it, whether or not it was fabulous. Another of his books mixing fable with reality was *Historia serpentum et draconum* (*The History of Serpents and Dragons*), published in 1640. It pictured real snakes alongside fanciful creatures.

Aldrovandi was certainly one of the most zealous naturalists of his time but although he added considerably to the stock of information, he can only be considered as a laborious collector of materials. Cu-

A drawing from Aldrovandi's Natural History.



From Ulisse Aldrovandi's Monstrorum historia: human monsters.

vier pronounceg his works "an enormous compilation without taste or genius," and agrees with Buffon in thinking, that were the useless parts removed, they would be reduced to a tenth of their bulk. Moreover, his materials were to a great extent borrowed from Gesner. However, in all ages writers on natural history have been so much addicted to the practice of borrowing that Aldrovandi is hardly to be censured on this account.

Some portions of his museum have successfully struggled with the destructive energies of time, and are still to be seen in the collection of the Institute of Bologna. His manuscripts, of which there is an immense mass, are preserved in the public library of the same city and the drawings from which the engravings for his work were taken were carried, at the time of the Italian Revolution, to the Museum of Natural History at Paris.

The Three Magi

Of more limited scope, but of much greater scientific value, were the monographs and books on fishes and other aquatic animals written by the French Pierre Belon - *Histoire naturelle des estranges poisons*, 1551 and *De aquatilibus*,1553 - the Italian Ippolito Salviani - *Aquatilium animalium historiae*, 1554 to 1558 and the French Guillaume Rondelet - *Libri de piscibus marinis in quibus verae piscium effigies expressae sunt*, 1554. In short, it can be said that essentially Belon published the first modern systematic treatise on fishes, Salviani created the first regional work on an ichthyofauna and Rondelet wrote the first text on ichthyology.

Each of their works is complemented by rich illustrations of fishes; those by Rondelet and Belon are quite simple to naïve although a few of them are just fantastic. The ninety-nine copperplate engravings Salviani had added to his book, however, are not only very well done but also especially famous because of their accuracy. Salviani had been a private physician to three popes and according to his social status became acquainted with several well-known artists who helped him with his drawings.

Unlike the others who came after Aristotle, these three saw and examined for themselves the fishes of which they spoke. Too faithful, however, to the spirit of their time, they took more pains to find out the names which these fishes bore among the ancients and in selecting fragments for their history, rather than in describing them in a distinct manner so that, were it not for the figures, it would in many instances be almost impossible to determine their species.

Pierre Belon

Belon was typical of the renaissance scholar and took an interest in "all kinds of good disciplines" in his lifetime. He was interested in zoology, botany and classical Antiquity. He was born at Souletière, in the parish of Oisé, in Le Maine, about the year 1518. It is supposed that his parents were poor and we accordingly find that he was indebted for his education to René du Bellay, bishop of Mans, William Duprat, bishop of Clermont, and the Cardinals of Tournon and Lorraine. At an early age he began the study of

Pierre Belon (1517–1564)

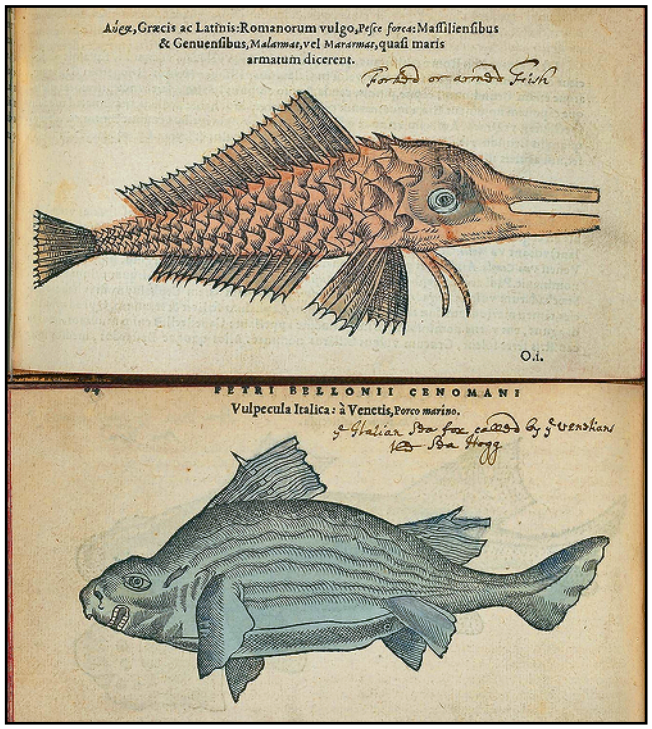
medicine and botany, and having distinguished himself among the pupils of Valerius Cordus, the professor of natural history at Wirtemberg, was allowed to accompany his master on the excursions that he was in the habit of making into Germany and Bohemia for the purpose of obtaining specimens.

On finishing his education he traveled through Greece, Egypt, Palestine and Asia Minor, whence he returned to Paris in 1550, with a valuable collection, after an absence of three years. He now arranged the materials which he had thus procured and published several interesting works. Notwithstanding the merit of which, he experienced great difficulty in obtaining admission into the medical faculty of Paris. In 1557, he undertook another journey into Italy, Savoy, Dauphiny and Auvergne. On his return, he engaged in a translation of Dioscorides and Theophrastus, and was preparing an important work on agriculture, when he was murdered in the wood of Boulogne, as he was proceeding from Paris to his place of residence at the Chateau de Madrid. This happened in 1564, when he was about forty-five years of age.

Besides the narrative of his travels he wrote several scientific works of considerable value, particularly the *Histoire naturelle des estranges poissons* (1551) and *De aquatilibus* (1553). At that time the concept of fishes included all aquatic animals including mammals and *De aquatilibus* included the first French illustration of a hippopotamus. A French translation of this treatise on fishes, a foundation of modern ichthyology, was published in three editions at Paris and the volume was reprinted in Frankfurt and Zurich. His works were held in high authority by Aldrovandi. As a botanist, Belon ranks not less highly than as a zoologist and, to do honor to him in the former capacity, an American genus of lichen was given the name of *Belonia.*

Ippolito Salviani.

Ippolito Salviani was born in the year 1514, in La Citta di Castello, situated on the Tiber, twenty seven miles from Urbino, the capital of the Duchy of that name. He was of noble descent and after having finished his general education, he studied medicine and having visited the cities of Italy, he finally settled at Rome, where he long practiced the healing art with great celebrity, and taught the science of medicine in



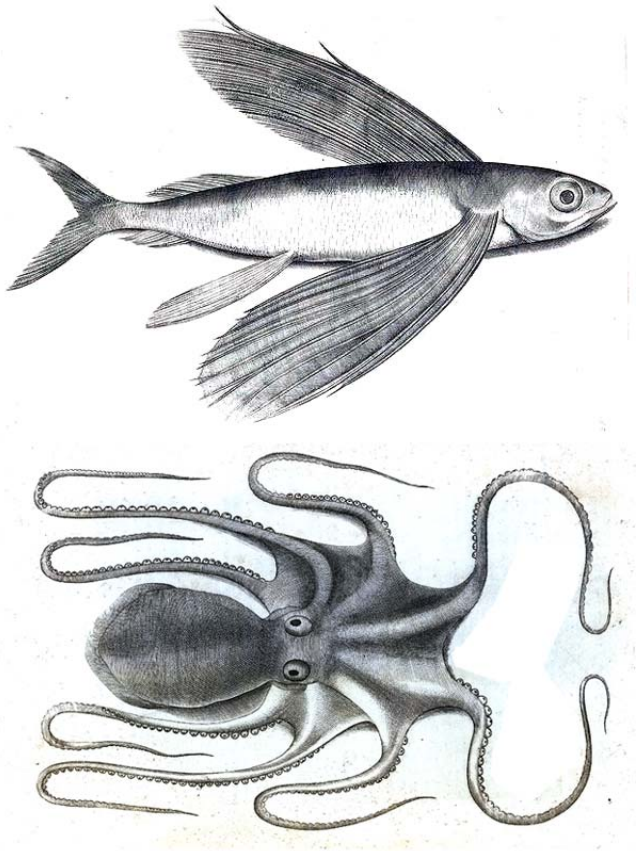
Illustrations from Pierre Belon's *De aquatilibus*.

Hippolito Salviani (1514-1572)

its University with much success. His varied talents, and peculiar taste for natural history, obtained for him the friendship of Cardinal Cervini, who procured for him the situation of Physician to Pope Julius III.

Salviani selected the class of fishes as the chief object of his researches, and used every effort to collect such as he could procure in Italy, while he extended the range of his knowledge by obtaining, with the help of his protector, accurate drawings of those which were known in Greece, France, Germany and Britain. He established in his own dwelling a regular printing establishment, from where he issued his lesser treatises and corrected his great work, entitled *Aquatilium Animalium Historia*. The author had first dedicated his work to his benefactor Cardinal Cervini but this prelate, one of the presidents of the Council of Trent, having become Pope, under the title of Marcellus II, having died of apoplexy twenty one days after his election, he substituted another dedication to his successor, Pope Paul IV.

In general, he was regarded as the principal and most distinguished naturalist of his day in the Great City. Thus we learn, that when anything curious in animated nature found its way to Rome, he was almost invariably and immediately apprised of it and he, in his turn, lost no time in informing ail his scientific friends, who immediately resorted to him, to inquire and examine for themselves. “I communicate the tidings (he remarks), not only that I may not deprive them of the gratification which I myself enjoy, but also that from our mutual conversations on these new and strange objects, we may be able more satisfactorily to arrive at correct conclusions.” After all were in this way satisfied, Salviani was in the habit of examining the internal parts of the animal, and of making preparations, always retaining the skin, and preparing, when possible, a stuffed specimen, together with accurate drawings.



Images from Salviani’s *Aquatilium Animalium Historia.*

The *Aquatilium Animalium Historia* of Salviani is chiefly remarkable for the beauty of its engravings, some of which have scarcely been surpassed by the efforts of modern art. The title page bears the date of 1554, but the work was not completed till 1558. It contains descriptions of ninety-nine species of fishes, each including the synonymy, the extremal appearance of the animal, the places in which it occurs, its habits, the manner in which it is caught and prepared, and its medical properties. He also points out the passages in Aristotle, Pliny and other ancient writers, who have spoken of them, and to the observations of these authors adds many excellent ones of his own. Consequently, the work, on account of the general accuracy of the plates and descriptions, is one that may be considered indispensable to the modem ichthyologist.

Guillaume Rondelet

Rondelet, the son of an apothecary, was born at Montpellier on the 27th September 1507. Being originally of a very infirm constitution, he was judged incapable of performing a part in active life, and, accordingly, when his father's fortune was distributed, he received a sum merely sufficient to procure his admittance into a monastery. As he grew up, however, he improved in strength, and having no affection for a monastic life, he commenced his studies at the age of eighteen, and finished his general education at Paris, where he was supported by his elder brother. Having resolved to embrace the medical profession, he returned in 1529 to his native city, and afterwards settling at Pertuis, a small village in Provence, he began to practice. However, not meeting with success in the healing art, he endeavored to earn a living by setting up a grammar school.

Guillaume Rondelet (1507-1566)

This expedient also failing, he went again to Paris in order to improve his knowledge of the Greek language, and, being unwilling to burden his brother any longer, became tutor to a young nobleman. Sometime after, he removed to Maringues, in Auvergne, where he again entered the medical practice and, in 1537, received a medical degree at Montpellier. The following year he married a young lady endowed with many estimable qualities, but destitute of fortune. As his brother at this time was dead, this alliance increased his difficulties. However, he settled finally at the place of his birth and, being assisted by his wife's sister, began to extend his acquaintances and succeeded so well in his profession, that, in 1545, he was appointed professor of medicine in the university.

He also obtained the office of physician to the Cardinal of Tournon, whom he accompanied on his missions in France, Italy and the Low Countries. O these occasions he eagerly availed himself to increase his knowledge of natural history. Returning once more to his usual place of residence he established an anatomical theatre, at which he lectured several hours daily to large audiences. His passion for dissection was so strong, that he opened one of his own children after death, and this circumstance has naturally enough given rise to the opinion that he must have been a man destitute of sensibility. However, this does not appear to have been the case. His wife having died in 1560, he soon remarried another, a poor and handsome woman like the first. While on a journey to Toulouse he was attacked by dysentery, occasioned by eating too many figs, and he died at

De Solea parua siue lingula.

CAPVT XV.

HANC Buglosi parui speciem diminutiuo nomine lingulam appellamus, quod sit buglossorũ omnium, quæ à linguæ figura nomen traxerunt, minima. Neq; debet existimare aliquis maiorum fœturam esse. Certa enim nota à buglosis omnibus discernitur. Est enim

LYBER XI. 325

enim piscis planus buglosis reliquis specie quidem similis, sed semper paruus, dodrantalem magnitudinem nunquam excedens. Linea quæ corpus dirimit, spinámque firmat vel tuetur, ex squamis contexta est longè eminentioribus quàm in toto corpore, dempta ea parte quæ circa maxillam inferiorem est. Duriore est carne quàm buglossus lævis, glutinosíque nonnihil habet. Saris rarus est piscis, & ob corporis tenuitatem vilis. Solent enim magni corpulentíque pisces probari, parui verò reiici, nisi ex Aphyarum sint genere, vt vna cum spinis edantur. Exigui alij quibus eximendæ sunt spinæ molesti.

De Hippoglosso.

CAPVT XVI.

HIPPOGLOSSVM vocamus buglosi speciem, quam Galli *flettan* appellant, quòd fluitando natet, vt opinor. Huius nomen nullus apud Aristot. Plin. Oppianum requirat: veteribus enim incognitus fuit, Oceani tãtùm accolis notus. Quare huic pro ipsius natura nouum nomen imposuimus, quod faciendũ esse cẽsent Plato & Galen. Hippoglossum igitur à nobis vocatur, quòd buglossa omnia magnitudine superet. Græci enim rei magnitudinem indicant βυ & ιππο particulis, vt in ιππο(ελινο, ιππομυρμηκο. Sic hippoglossum dicimus à magnitudine non à similitudine cũ hippoglosso herba. Quod autem buglosi species sit hippoglossum nostrũ, nemo est qui non statim primo aspectu iudicet: oblongo enim cõtracto{q; est corpore, altera parte candido, altera nigricãte, in qua oculi siti sunt. Ore est cõtorto, dentibus munito cithari modo, quibus buglosi carent. Pinnæ corpus ambiunt, vt breuiter dicam. Buglossus est cetaceus. Vidimus enim hippoglossum quatuor cubitos longũ. Carne est dura sed suaui, ad rhombi naturã proximè accedente. Ossa spongiosa habet, qui-

Pages from Rondelet's *De Piscibus Marinis Libri .*

Realmont, where he had gone to visit a patient. His death happened on 30th July 1566, in the fifty-ninth year of his age.

Rondelet greatly surpassed Gesner, Belon and Salviani in the extent of his knowledge as an ichthyologist, and although his figures, being only woodcuts, are inferior in beauty to the copperplate engravings of the last of these authors, they are yet more correct in characteristic details. His work is entitled *De Piscibus Marinis Libri XVIII, in qui bus vivæ piscium imagines expositae sunt* (*Book of the fish of the sea in which they are shown in their true images*), and was published at Lyons in 1554. A second part appeared in 1555, under the name of *Universae Aquatilium Historiae Pars Altéra, cum veris ipsorum Imaginibus* (*The entire history of aquatic animals with true images*). The first part treats of marine animals, including the cetacea, turtles and seals, mollusks and crustacea.

In the second part, shells, insects, zoophytes, and freshwater fishes, are described. These objects, although not methodically arranged, are often placed in such a manner as to indicate that the author had some idea of generic affinity. The anatomical details which he presents were pronounced by Cuvier to be frequently correct, but his descriptions, it must be granted, are inferior to the figures which are truly surprising for the period in which he lived. In reference to the fishes of the Mediterranean this work is indispensable, and indeed, to the ichthyologist generally it is one of the most important that exists. The descriptions and figures were copied by Gesner, in his work *De Aquatilibus*, while Ray, Artedi and Linnaeus, have also obviously profited by them.

He was a man of very small stature, but robust and active. At the age of twenty-five from an apprehension of gout he gave up the use of wine and spirits, but he compensated for his abstemiousness in these articles by indulging his appetite for fruit and pastry. Although he had acquired considerable sums of money in the practice of his profession, he expended them in the gratification of his taste for building and in various acts of generosity so that he left very little behind him.

THE SEVENTEETH CENTURY

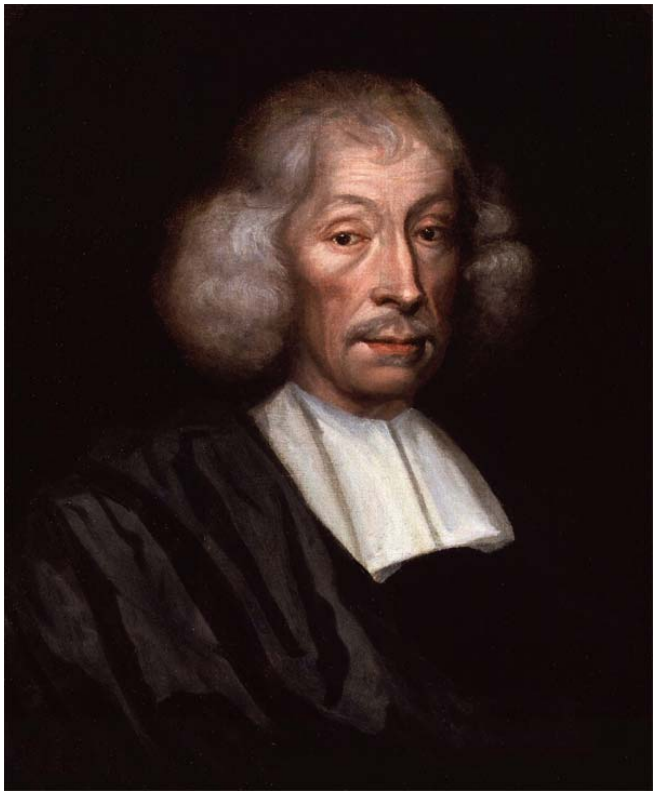
The authors of these times looked less to nature than to the writings of Aristotle, Pliny and their other predecessors so that in their works we find little more than a repetition of what had been previously said. Their descriptions are rude, frequently incorrect, and in few cases characteristic. The alphabetical arrangement was followed by some, while others possessed a rude notion of the affinity of species. But although attempts were made to separate the animals into classic groups, yet from the days of Aristotle to those of John Ray, we find no traces of the anatomical knowledge necessary for the accomplishment of such an undertaking. We have, indeed, little reason to expect in the writings of the ancients, or in those of the succeeding naturalists, any example of a just classification.

Still we cannot but marvel when we find, that very few of them endeavored to represent objects as they might have seen them with their own eyes. Whatever may be the causes of this defect, those who are extensively conversant with the publications of our own times must be aware, that the practice of copying from books, instead of having recourse to Nature herself, has not yet been relinquished, though nothing is more clear than that there can be no real progress in natural history without authenticating the observations of preceding writers by examining the objects which they have described, and by noting the particulars in which they are erroneous.

John Ray

John Ray (1623–1705) was the greatest naturalist and natural theologian of his time. He was the first naturalist to emphasize that natural history must be founded on an ability to identify plant and animal species, yet systematics was never the goal of his studies. His interest in natural theology encouraged his investigation into how nature works and although his adult life was something of a struggle, he was nevertheless a constantly productive naturalist who produced numerous publications. The cumulative impact of his work was a major contribution to the Scientific Revolution during the 1600s.

Ray (until 1670, he wrote his name as John Wray; from then on he used "Ray" after having ascertained that such had been the practice of his family before him) came from modest circumstances. His father was a blacksmith and his mother was an herbal healer. He studied at the University of Cambridge, pursuing comparative anatomy although initially his main interest was botany. He taught Greek, mathematics and humanities at Cambridge but abandoned his teaching position after refusing to comply with the Act of Uniformity of 1662, an Act of the Parliament of England. It prescribed the form of public prayers,



John Ray (1628-1705)

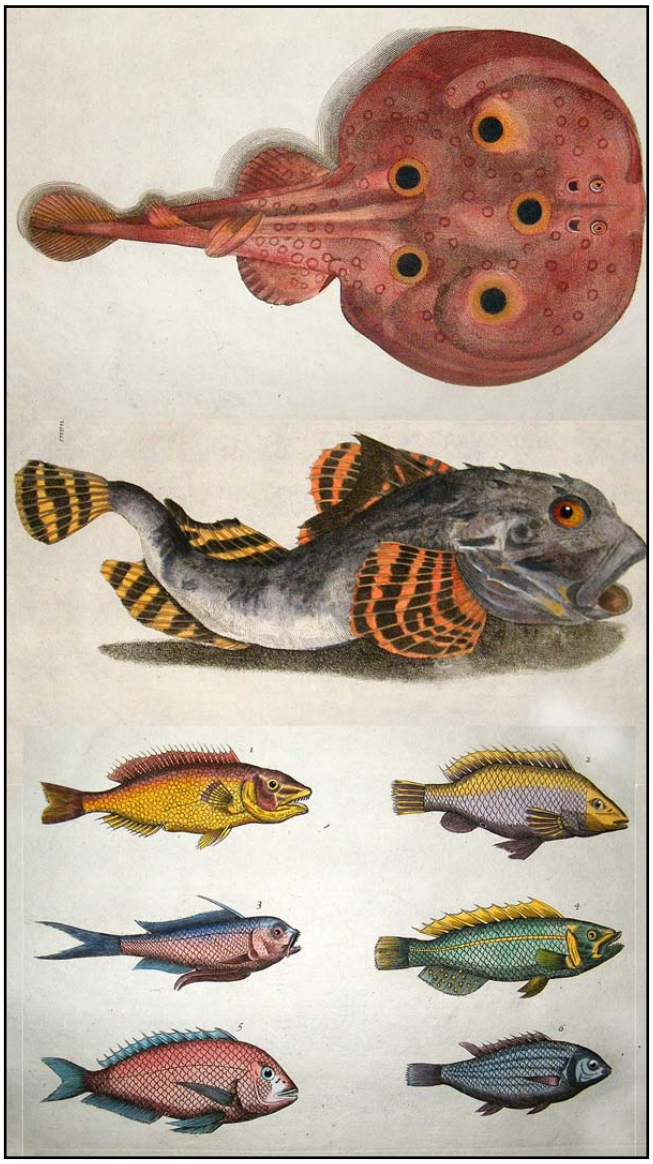
administration of sacraments and other rites of the Established Church of England, following all the rites and ceremonies and doctrines prescribed in the Book of Common Prayer. Adherence to this was required in order to hold any office in government or the church. In spite of this, Ray was a very religious person who undertook the study of nature to understand God's creation.

Fairly early on he developed a plan with his student and patron, Francis Willughby to produce a joint general natural history. To that end they went on an extended tour of England and Europe (1662-1666), including the medical school at Montpellier. Although they did not always travel together, both collected specimens, got involved in dissections and acquired books and illustrations, the endeavor bankrolled by Willughby.

When Willughby died, Ray took over his parts of the general natural history. Willughby left him an annuity of £60 and Ray stayed on as tutor to Willughby's children until 1675, when Willughby's mother, also his patron, died, and the widow immediately terminated the relationship. Ray inherited a small farm that also contributed to the family's maintenance while he earned money from his productive publishing. Therefore Ray had the financial freedom to pursue his intellectual interests.

Ray's first published work on cetaceans was *Dissection of a Porpess* (1671). He does a much better job in describing the internal anatomy of this animal when compared with Rondelet but does not get into the detail that Tyson (Edward Tyson, 1651-1708, was a British scientist and physician, commonly regarded as the founder of modern comparative anatomy) achieved later. During the narrative of his findings he keeps noticing that a porpoise has a lot in common with the "quadrupeds," yet he persisted calling them "fishes."

Ray published *Historia piscium* (1686), under Willughby's name fourteen years after his patron's death, though Ray himself contributed the vast majority of the content. He carried out the first serious attempt to achieve a systematic arrangement, the success of which can be attributed by the fact that it served as a basis for the systematics work of the following century. His approach was based on direct observation, collaboration with other researchers, and critical reading of previous authors.



Images from Ray's *Historia Piscium.*

Historia Piscium is divided into two parts that were printed separately: the first is the narrative and the second, titled *Ichthyographia,* were the illustrations. Many libraries today have both bound together. As sources Ray used authors mentioned earlier in this essay: Rondelet, Salviani, Gessner, Aldrovandi and Belon, among others. Yet, far from merely compiling

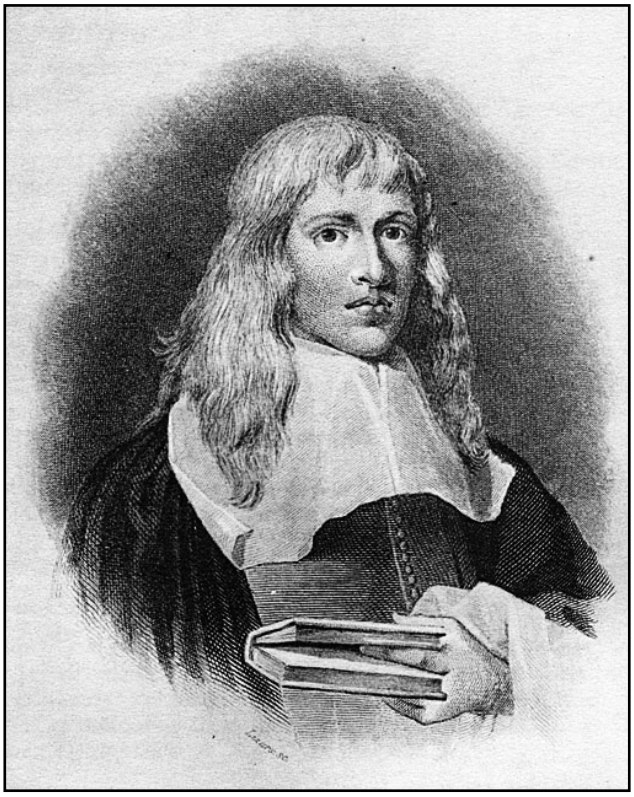
information from them, Ray insisted in very comprehensive descriptions of species and discarded all monsters and mythical creatures mentioned by his predecessors. Ray not only removed narratives of marine invertebrates but also other aquatic animals such as the crocodile and the hippopotamus. He divided his subject matter into three groups: cetaceans, cartilaginous fishes and bony fishes. He recognized that when it comes to reproduction and internal anatomy cetaceans are identical to the "viviparous quadrupeds." Still, he kept cetaceans within the "piscium" despite the fact that he was well aware that they were biologically distinct from fishes.

In his narrative of species Ray moved away from in the practical aspects related to these animals. Aspects such as usage for medical purposes were very common among previous authors because of their medical background. Yet, Ray was very keen at compiling names on the belief that a universal language could be constructed based on the knowledge of nature. Ray believed that there was a need for "a construction of a universal language based on a table that properly expressed the natural order and relations between things." Hence a precise description and classification was the route to achieve that goal. The final product counted not only on the intellectual support of the Royal Society's members who provided constructive criticism and moral support but also their financial support.

Ray's third publication related to marine mammals was *Synopsis Methodica Animalium Quadrupedum et Serpentini Generis* (1693). By then he was totally convinced that cetaceans were not fishes: "For except as to the place on which they live, the external form of the body, the hairless skin and progressive swimming motion, they have almost nothing in common with fishes, but remaining characters agree with the viviparous quadrupeds." He placed today's terrestrial mammals (including the manatee) among the "hairy animals" very close to the *Cetaceum* genus (cetaceans).

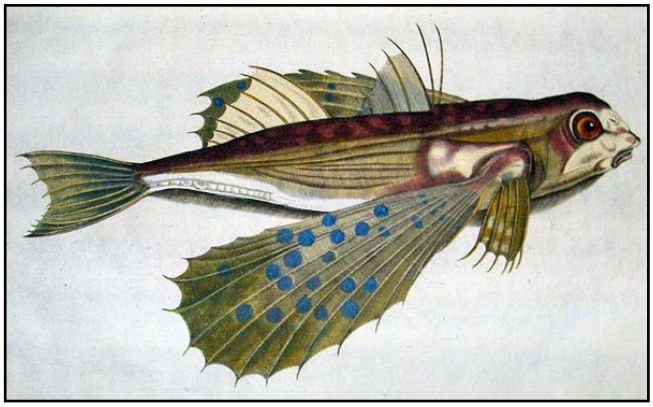
In *Synopsis* Ray included a section called *Pisces Cetacei seu Belluae marinae* where he expressed that these animals breathe and give birth like the "oviparous quadrupeds." He grouped them into two categories according to the presence of teeth much as we do today separating odontocetes (toothed whales) from mysticetes (finback and humpback whales). Ray was the first in doing so. The species he cited were *Balaena vulgaris* (Rondelet), *Balaena* (Fin-Fish), *Physeter* or *Balaena physeteris*, *Orca* (Rondelet & Belon), *Cete* (Sperm whale), Pot Walfish, *Albus piscis cetaceus* (white fish), *Monoceros cetaceo* (*Narhual islandis*), *Delphino antiquorum* (dolphin, from Rondelet), *Phocaeno* (Rondelet & Belon), dissecting a specimen of the latter in 1669.

Clearly the fish volume depended heavily upon previous books by Rondelelt, Belon, Salviani and Gesner. Even the observation from *Historia Piscium* about sharks having the mouth on their bottom side as a provision of nature to ensure safety of other fish and to prevent sharks from dying from gluttony, is actually repeated from Aristotle's *De Partibus Animalium*. Thus it came under some criticism and as one critic stated: **"It cannot be said that this is a very important contribution to natural history."**



Francis Willughby (1635-1672)

Nevertheless, two historians of ichthyology thought highly of this work. Cuvier in 1828 wrote: **"Ray and Willughby had the honor of being the first to write an ichthyology in which the fishes were clearly described according to nature and classified based on characteristics drawn only from their structure, and in which their natural history was finally rid of all passages from ancient writings…"** Later (1905), David Starr Jordan (the "Dean" of American iconologists) wrote that **"The basis of classification was first fairly recognized by Ray and Willughby in *Historia Piscium*, which brought "order out of the confusion left by their predecessors."**



Lavish engravings in *Historia Piscium* nearly did in the publication of Isaac Newton's great work, *Principia Mathematica*

Ray's classification of plants in his *Historia Plantarum*, was an important step towards modern taxonomy. He remarked, in particular, that classification must proceed upwards, beginning with the description of species, to proceed then with the comparisons upon which the species may be grouped into genera, the genera into families, and so on. This was a basic upside down revolution in respect to Cesalpino's method (Andrea Cesalpino (1519-1603) was an Italian physician, philosopher and botanist; in his works he classified plants according to their fruits and seeds, rather than alphabetically or by medicinal properties), in which Aristotle's logic was applied by dividing the whole of the plant kingdom into progressively smaller subgroups, down to the individual species.

Ray rejected the system of dichotomous division by which species were classified according to a preconceived, either/or type system, and instead classified plants according to similarities and differences that emerged from observation. Thus he advanced scientific empiricism against the deductive rationalism of the scholastics. He was the first to give a biological definition of the term species. In his 1686 *Historia Plantarum* he wrote:

"… no surer criterion for determining species has occurred to me than the distinguishing features that perpetuate themselves in propagation from seed. Thus, no matter what variations occur in the individuals or the species, if they spring from the seed of one and the same plant, they are accidental variations and not such as to distinguish a species…Animals likewise that differ specifically preserve their distinct species permanently; one species never springs from the seed of another nor vice versa."

The lavish engravings in *Historia Piscium* were so expensive to publish that they nearly bankrupted the young Royal Society, at that time only 26 years old. Short of cash, the Society had to rescind its promise to help pay for the production of Newton's masterpiece, *Philosophiae Naturalis Principia Mathematica* (*Mathematical Principles of Natural Philosophy*).

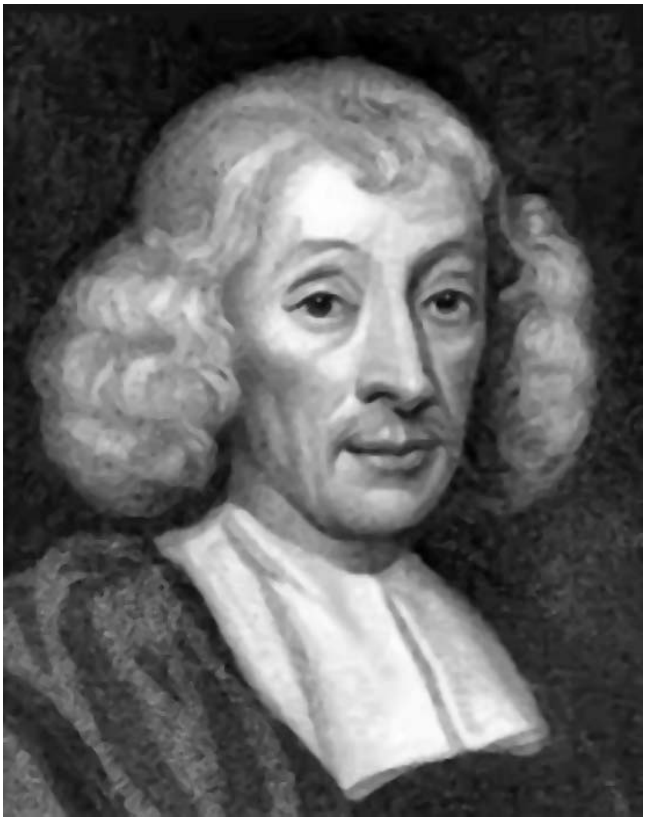
Fortunately for Newton (and for science), his *Principia* caught astronomer Edmond Halley's eye. Halley is remembered mainly for computing the orbit of the comet that bears his name, but at the time he was a young Royal Society clerk. Halley took on the *Principia* as a personal project, raising funds (many from his own pocket) to get the work published in 1687. Newton's book included his three laws of motion, which along with his law of universal gravitation, was able to explain the orbits of planets. In fact, his book is still widely considered to be one of the most important scientific works of all time, covering physics and mathematics.

Finally, Ray had a sense of humor. The following is one of his aphorisms: **"Fish must swim thrice - once in the water, once in the sauce, and a third time in wine in the stomach."**

Peter Artedi

Before examining Linnaeus' contribution to classification, it is necessary to say a few words about his good friend, Peter Artedi. Artedi was the son of a parish priest who developed an interest in fishes from an early age. He studied medicine at the University of Uppsala, devoting most of his time at studying natural history. At 29 years of age he went to London for a year to study natural history collections and described the sighting of a whale in November 1734, probably downstream of the London Bridge. He then moved to Leiden, The Netherlands, to complete his medical studies and there he met Linnaeus, whom he knew from their native Sweden, forging a lifelong personal and professional relationship.

They took an immediate liking to each other and soon formed an intense intellectual bond. Sharing their revolutionary ideas about order and hierarchy in nature, the pair developed elaborate plans to classify plants and animals in ways never seen before - Linnaeus focusing on plants and Artedi concentrating on fishes. In September 1735, though, just as Artedi was set to publish his work, he drowned under puzzling circumstances. Following up on a pledge to his lost friend, Linnaeus recovered his manuscripts and published *Ichthyologia* (1738) without amending Artedi's original work.



Peter Artedi (1705-1735)

Despite the fact that this was an unfinished work, it was a fundamental publication that marked the origin of ichthyology as we know it today. After a long (96 pages) introduction describing previous authorities on ichthyology the second part deals with the taxonomic terminology he used, particularly regarding the concept of genus and distinguishing between species and varieties. His system set the basis for the modern systematic classification of living organisms later established by Linnaeus. In part three he went into the classification of species including detailed description of them, some of which he had dissected himself. For this Artedi is considered the father of ichthyology.

Artedi established the basic classification of fishes that lasted for about 200 years and separated cetaceans into a totally different order than fishes; he apparently knew that they were different, but still tradition was difficult to break and thus he included them into his ichthyological treatise. He also established the basic branching of animal groups into Class, Maniples (Families), Genera, and Species, a system that was to be closely followed by Linnaeus. His work set the foundations for what Linnaeus would culminate as the definitely recognition of cetaceans as distinct group within mammals. Iit should be remembered that Ray's contribution is the first scientifically valid introduction to a zoological system using the concepts of genera, families, orders and classes based on thorough morphological investigations.

After defining what was to be understood by genus and subjected genus-names to a severe scrutiny, Artedi discussed species in general and went on to critically examine the names in use for them:

"A species name," he stated, "is the epithet, consisting of some few words, which is append-

ed to the genus-name, in order to distinguish one fish species from the others in the same genus. These epithets must be effective for the function they are thus required to perform; if they only state the more or less general occurrence of the species, its assumed sequence in the genus, home, mode of occurrence, size, varying color or markings, etc., they are, as being of no use to the reader, spurious and reputable. Genuine species-names, on the other hand, are those which serve to mark off at a glance, or with a minimum of effort, one species from the others in the same genus. They must, in other words, state such genuine species-characters as have been mentioned in the foregoing."

In having solved the question of genus-names so excellently, by enunciating such clear and definite rules for their use, Artedi was on the very threshold of a complete solution of the nomenclature problem; there would seem to have been but one simple step for him to take, to arrive at binominal nomenclature; however, in treating species-names he drifted away from the right track, owing to the exacting demands he made upon them. He transformed generic names, into real names, but in dealing with species names he confused the two ideas of name and diagnosis. In demanding of species-designations that they should express the differences existing among the several species, it was no longer possible for him to insist on unity in a species-name which was to fulfil those conditions, and still less possible as time went on and more and more forms became known and had to be scientifically treated. Consequently it was reserved for Linnaeus**,** 20 years later, to publish to the world the system of binominal nomenclature, and so to arrive at the final solution of the problem of how successfully to name natural history objects. The foundation laid by Artedi should not, however, on that account be forgotten or discredited.

Further, Artedi set a positive example in taking the earlier literature into consideration most comprehensively. Artedi's species characterizations **"are even now models of exactitude and method"** as Günther put it in 1880. In the year of Linnaeus' 300 anniversary (2007) it should be recalled that Artedi (if he would have survived for some more years) would likely be named always together with Linnaeus and many fish species might have carried a capital A. instead a L. behind their scientific names.

Artedi was buried in a pauper's grave in St Anthony's churchyard in Amsterdam on October 2, 1735. His grave was never marked and the churchyard site has since been appropriated for other purposes. An epitaph, written in Latin by Anders Celsius (he proposed the Celsius temperature scale which bears his name), and translated into English by George Bernard Shaw, is known because it was inscribed on the back flyleaf of Linnaeus's own copy of *Ichthyologia*:

Here lies poor Artedi, in foreign land pyx'd
Not a man nor a fish, but something betwixt,
Not a man, for his life among fishes he past,
Not a fish, for he perished by water at last.

Linnaeus

Born Carl Linné (or Carolus Linnaeus; he loved Latin and used it for everything, including changing his name to the Latin version) in 1707 in Rashult, Swe-

Carl Linnaeus (1707-1778)

den, Linnaeus had as a father a country person who loved plants. Linnaeus followed a medical career but was actually more interested in botany than in anything else. What Linnaeus learned from Artedi set the basis for a better classification not only of plants but also animals in general. Linnaeus is often called the Father of Taxonomy and his system for naming, ranking, and classifying organisms is still in wide use today (albeit with many changes). His ideas on classification have influenced generations of biologists during and after his own lifetime, even those opposed to the philosophical and theological roots of his work.

With all of this background, the botanist Linnaeus was ready to revolutionize biological classification and in the 10th Edition (1758) of his fundamental work *Systema Naturae*, he introduced the term Mammalia, and included *Cete* (whales and dolphins) among them. For Linnaeus, mammals were united by having hair, being viviparous and producing milk. He coined the term *cetacea* and separated them from fishes and grouped them with the rest of the viviparous quadrupeds based on the following characteristics: two-chamber heart, breathing by lungs, hollow ears, internal fertilization and production of milk.

However, even some of Linnaeus students were in the process of developing a better understanding of cetaceans as being really close to "viviparous quadrupeds." That was the case of Pehr Löfling, one of Linnaeus' students who came very close to making major contributions to the true nature of dolphins and manatees based on his observations of these animals in South America. In his description of Amazon freshwater dolphin or boto, Löfling was clear about when writing that whales and dolphins were different from fishes: "Pisces per pulmonibus spirantibus (fish breathing through the lungs)." However, his early death and the fact that his manuscripts were never published prevented him from gaining recognition in the scientific community.

Linnaeus revolutionized the science of systematics by developing a fully natural system of classification, consistently using binomial nomenclature and designing species with Latinized names (genus and species). He developed a hierarchy (class, order, genus, species) as proposed by Artedi, with species defined as similar individuals bound together by reproduction, which also set the basis of the biological species concept. The use of telegraphic speech-like (very short sentences) diagnosis for species descriptions and the standardization of synonymies (same species with different names) in order to reach a taxonomic consensus made his classification even more useful since from now on one could find clarity on what a particular species was tracing its description to other authors. He also doubled the number of species described by Ray. Thus, despite the fact that he was not a zoologist *per se* nor was he involved in dissection of animals, he was far from a compiler in that he applied critical thinking to the way he ordered nature.

This progress is even more remarkable when considering that Linnaeus was also far from being an evolutionist. For him species were fixed except for small variations due to climatic and/or local conditions. Yet, Linnaeus was, without question, the founder of systematics and the one who laid the foundations for the naturalists to become specialists and, therefore,

"Heaven welcomes ichthyologists - we've millions of fishes that need classifying!"

opened the door for the first group of marine mammal specialists, now that these creatures were no longer considered "fishes." It was not until Linnaeus that the science of taxonomy made the strides that have lead us to where we are today in our understanding of the natural world. Linnaeus understood biological principles and placed animals in groups based on existence of shared ancestry between a pair of structures, or genes, in different species rather than using environment to drive classification, and this was what allowed him to recognized cetaceans as a distinct group within mammals.

COMMENTS ON THE TWENTIETH CENTURY TO THE PRESENT

Phenetics

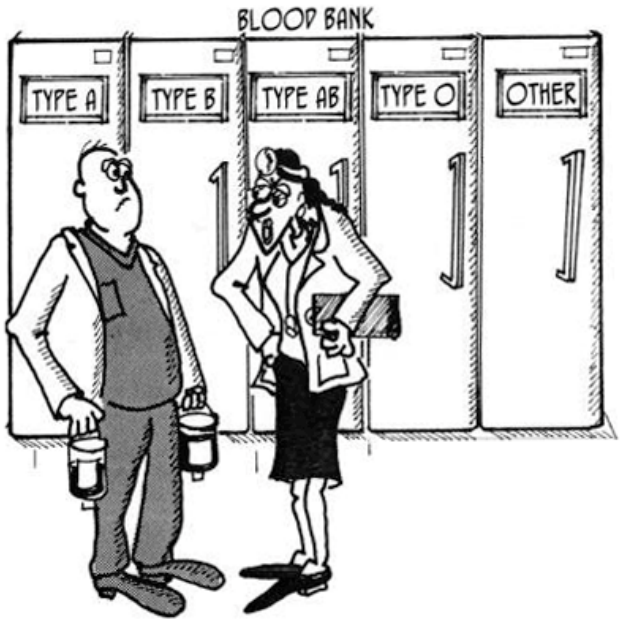
From Linnaeus up to the twentieth century, classification was largely carried out by "gentlemen" scientists who based their identifications of organisms upon a few "important" characteristics and a "gut feeling" developed during many years of experience. This was followed by phenetic classification methods, invented by those who thought that this type of classification scheme was too subjective. They argued that taxonomy should not be based on a few characteristics arbitrarily judged to be "important," but rather upon the degree of overall similarity between organisms. Thus they collected data on as many characteristics of the organisms being classified as possible. Each organism was then compared with every other for all the characters measured, and the number of similarities (or differences) was calculated. The organisms were then clustered in such a way that the most similar were grouped close together and the more different ones were linked more distantly.

Because of the enormous amount of data involved in this process, these calculations were usually made using specially programmed computers (desktop computers were not available at the time). The dependence of phenetics on the use of computers made it particularly unpopular with some "old-school" biologists. Paul Ehrlich, one of the early converts to phenetics, was reportedly once asked by an irate taxonomist at a conference, **"You mean to tell me that taxonomists can be replaced by computers?"** Ehrlich responded, **"No, some of you can be replaced by an abacus!"**

The clusters that resulted from such an analysis did not necessarily reflect genetic similarity or evolutionary relatedness. Pheneticists argued that this was acceptable because nobody really knew the true evolutionary histories of these organisms and at least this system was objective. However, the lack of evolutionary significance in phenetics has meant that this system has had little impact on animal classification and, as a consequence, interest in and use of phenetics has been declining in recent years.

Cladistics

An alternative approach to diagramming relationships between taxa was developed, called cladistics. The basic assumption behind cladistics is that members of a group share a common evolutionary history, and are thus more "closely related" to one another than they are to other groups of organisms. Related groups of organisms are recognized because they share a set of unique features which were not present in distant ancestors, but which are shared by most or all of the organisms within the group.

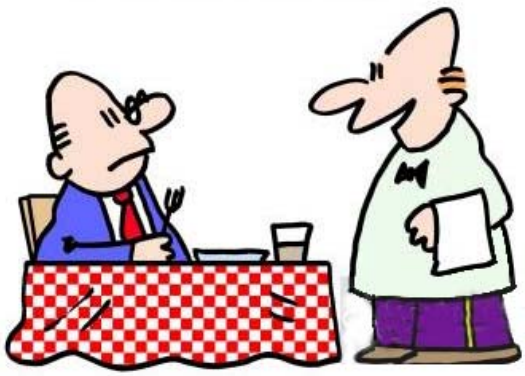


"McWit, I'd like to talk to you about your blood clsification system."

In contrast to phenetics, cladistics groupings do not depend on whether organisms share physical traits, but on their evolutionary relationships. Indeed, in cladistic analyses two organisms may share numerous characteristics but still be considered members of different groups. For example, consider a jellyfish, a sea star, and a human: jellyfish and sea stars both live in the ocean, have radial symmetry and are invertebrates, so phenetic analysis might place them together in a group. However, this would not reflect evolutionary relationships, as sea stars are actually more closely related to humans than they are to jellyfish. Thus in cladistics, the emphasis is not upon the presence of all shared traits, but upon the presence of shared derived traits. In the example above radial symmetry, aquatic habitat and invertebrate structure are all traits that are believed to have been present in the common ancestor of all animals, and so such traits are not considered to be very useful in determining relationships using cladistic analysis.

Evolutionary Systematics

Like cladistics, evolutionary systematics is based strongly on evolutionary relationships. However, its supporters suggest that the degree of genetic differences between lineages should be used in addition to their genealogical (evolutionary) similarities when developing taxonomic classifications. Among other ways in which evolutionary systematics and a cladistic analyses differ are that evolutionary taxonomists are more tolerant of multiple branches developing from an ancestral line, rather than just two as in cladistics, and they tend to treat organisms that are unchanged when a new branch arises from their lineage as the same species that existed before the branching event (i.e., the original species is not always believed to become extinct every time a branching event occurs).



It's nice of you to ask, but the recipe is classified."

U.S. Postal Service classification system.

However, the biggest difference between the two approaches is that, when creating groupings, evolutionary taxonomists seek to maximize the way in which the groupings they create communicate information about the group (in the way the word "mammal" or "reptile" does for an untrained person). This type of division is also intended to increase the ease with which a field biologist, or even someone coming in from the outside, can retrieve information about a group of organisms of interest to him using the taxonomic divisions formed.

An example of the differences between cladistics and evolutionary systematics is the following involving birds and crocodilians. It has been shown that these two groups diverged from the same ancestral reptilian line. A cladist would insist that these "sister groups" be placed in the same taxon, even though the amount of change from the common ancestor is much greater for the birds than it is for the crocodiles. An evolutionary taxonomist would suggest that the large number of similarities between crocodilians and reptiles would

justify grouping them within the same general taxon, while placing birds in a separate taxon due to the large number of unique characters possessed by members of this group.

THE CLASSIFICATION OF FISHES: THREE CONFLICTING APPROACHES

by Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society, Yahoo Files, August 8, 2015)

The task of systematics is to find the best possible general reference system, but finding it is not so easy since it turns out that there are several approaches or ways to go about performing this task.

During the 1950s, and much more so during the 60s and early 70s, there was much confusion and debate over the principles of systematics. Reflecting this basic uncertainty about the methods and goals of systematics is the fact that during a fifteen-year period from 1960 to 1975 over a dozen books were published in which the methods and goals of systematics were argued back and forth. From all this intellectual fervor came three competing theories of classification, each claiming to be more objective than the other two and each claiming to produce a better general reference system than the other two:

1. Phenetics or Numerical Taxonomy
2. Cladistics or Phylogenetic Systematics
3. Evolutionary Systematics

PHENETICS

The major criteria are:

1. It is based on overall similarity;
2. Numerous characters are used (as many as can be found);
3. All are given equal weight;
4. The resulting branching diagram (tree) is computer generated;
5. The branching diagram (tree) that is produced is called a phenogram (from the Greek "phenomen," that which is seen), a branching diagram that links organisms by estimates of overall similarity as evidenced by an analysis of characters (see Figure 1).

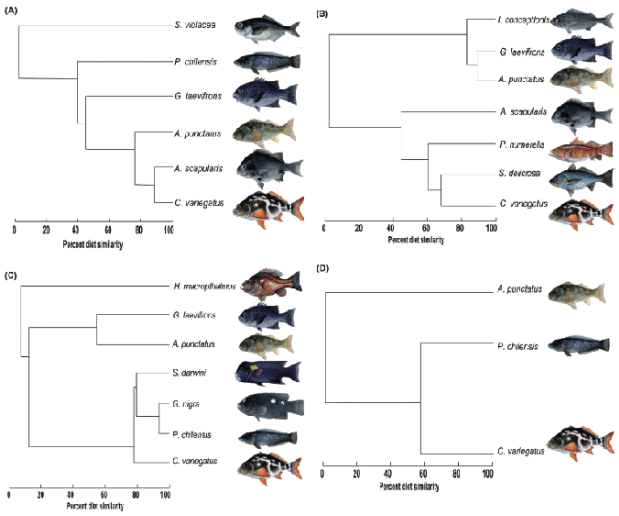

Figure 1: Phenograms of Fishes from Northern Chile.

The phenetic method was all the rage in the early and mid-sixties, popularized primarily by Robert R. Sokal and Peter H. A. Sneath.

CLADISTICS

Sometimes called phylogenetic systematics, the major criteria are:

1. One criterion for classification, i.e., the recency (i.e., of late occurrence, appearance or origin) of common descent;
2. The method allows only the use of specialized or derived character states, character states that we call apomorphic (primitive characters states are called plesiomorphic). So, in this sense, characters, or more precisely, character states, are more heavily weighted over others;
3. Taxa that share derived or apomorphic characters states are said to be related. Shared apomorphic character states are called synapomorphic, whereas shared plesiomorphic character states are called symplesiomorphic;

4. Grouping and ranking are given simultaneously by branching points in a diagram called a cladogram (from the Greek "clad" or "klados," meaning to branch' see Figure 2).

This concept of primitive versus derived character states can best be illustrated by examples. Picking an example from fishes, let's take a simple one like the skeleton. Skeleton is the character, but thinking about it you realize that skeletons among fishes consist of at least two states, a bony skeleton and a cartilaginous skeleton. We know that a skeleton of bone evolved very early in vertebrate history and that those vertebrates with a skeleton of cartilage are the result of a loss of the ability to ossify the skeleton. A bony skeleton is thus the primitive or plesiomorphic character state, while a cartilaginous skeleton is clearly the derived or apomorphic character state.

Let's pick another, slightly more complicated example, forelimbs. Thinking about forelimbs among fishes and other vertebrates, we can list at least three character states: pectoral fins, arms and wings. We know that pectoral fins evolved early on in vertebrate history and that these structures are the evolutionary forerunners of arms and wings. Thus pectoral fins represent the primitive character state of a character called forelimbs. What about arms and wings? We know that arms evolved in the earliest four-legged vertebrates (i.e., the first amphibians) long before wings first appeared in birds or mammals (bats), so we conclude that arms are a derived character state relative to pectoral fins, but a primitive state relative to wings. Wings clearly represent the derived character state relative to both pectoral fins and arms.

Cladistic systematics, or cladistics for short, was first articulated in a formal way by a German

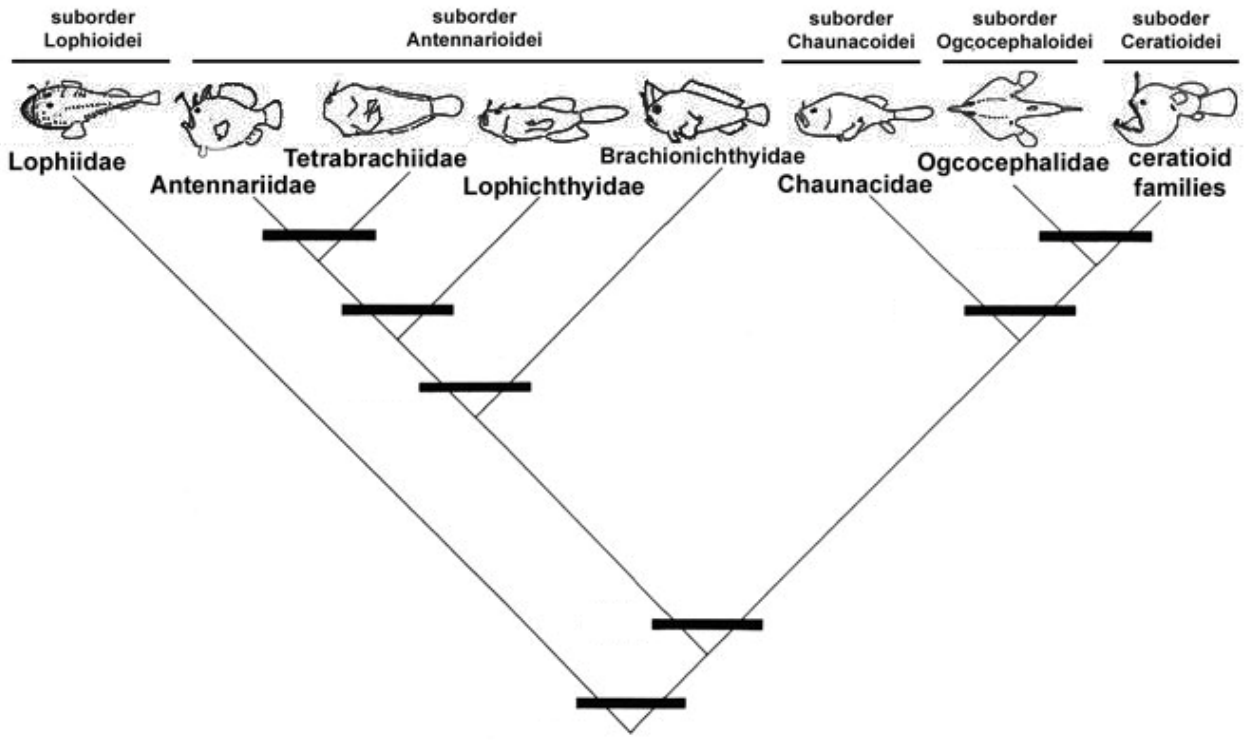

Figure 2: A Cladogram Showing the Phylogenetic Relationships of Families of Anglerfishes. The black bars indicate a change of character states

entomologist named Willi Hennig, a world's authority on the systematics of flies (order Diptera). He wrote a book, first published in German and later translated into English.

The cladistic method immediately became popular among entomologists and quickly spread to systematists working on other groups, particularly ichthyologists. The primary proponents of cladistics in the fish world were Donn E. Rosen and Gareth Nelson, both formerly working in the Department of Ichthyology at the American Museum of Natural History in New York. They, and a host of followers, beginning in about 1970, began publishing theoretical as well as applied papers in a number of prestigious scientific journals, most important among them being *Systematic Zoology* (since then renamed *Systematic Biology*).

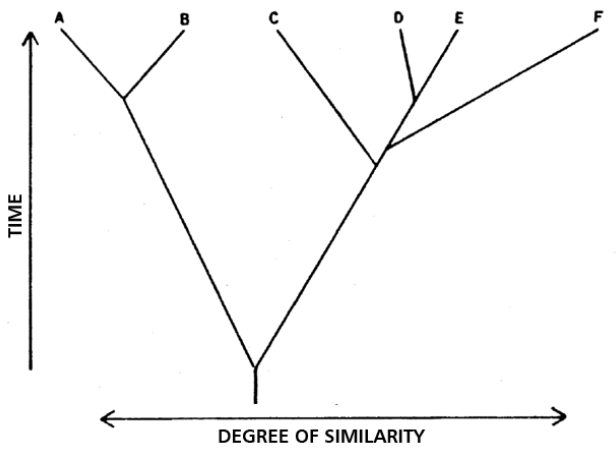

Figure 3. A hypothetical evolutionary tree showing the relationships of terminal taxa A through F. In contrast to a phenogram and a cladogram, which give only two kinds of information (geological time on the vertical and a measure of similarity on the horizontal), this diagram provides three kinds of information: geological times on the vertical, degree of similarity on the horizontal, and degree of divergence by the angle of divergence.

EVOLUTIONARY SYSTEMATICS

This is sometimes called the synthetic method, because in some ways it combines the criteria of phenetics and cladistics.

Evolutionary systematics relies on:

1. Two criteria for classifying and ranking organisms: recency of common descent and the amount and nature of evolutionary change between branching points;
2. The method allows the use of plesiomorphic (primitive) character states as well as apomorphic (derived) character states;
3. Character states thought to be more evolutionarily or functionally significant are often heavily weighted over others;
4. Grouping and ranking are given simultaneously by branching points in a diagram called a phylogenetic tree (Figure 3).

The major proponents or defenders of evolutionary systematics were George Gaylord Simpson and Ernst Mayr, each of whom wrote classic texts on this subject.

THE PROBLEMS WITH PHENETICS

Today, very few if any systematists employ phenetics or numerical taxonomy. When first proposed, the methodology seemed to resolve the problem of the lack of objectivity in evaluating characters for purposes of determining evolutionary characters. But early on, detractors pointed out serious deficiencies. According to Ernst Mayr ("Evolution and the Diversity of Life," p. 429, Belknap Press, 1976), "the phenetic approach…has been largely a failure when applied to higher organisms." One of the criticisms is that it totally ignores the possibility of evolutionary convergence, i.e., the process whereby organisms not closely related independently evolve similar traits as a result of having to adapt to similar environments or ecological niches.

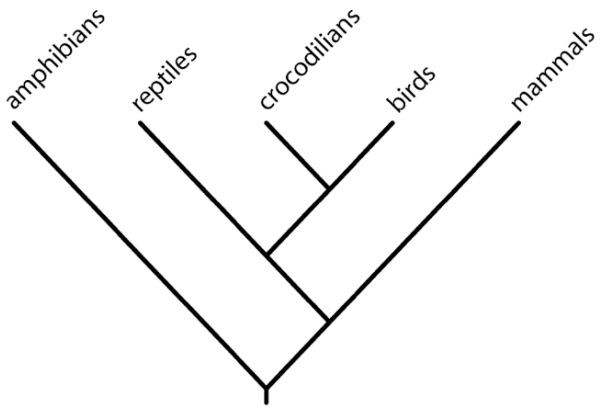

Figure 4: A cladogram showing the evolutionary relationships of five kinds of vertebrates. Each level in the hierarchy is defined by one or more similarities interpreted as derived character states.

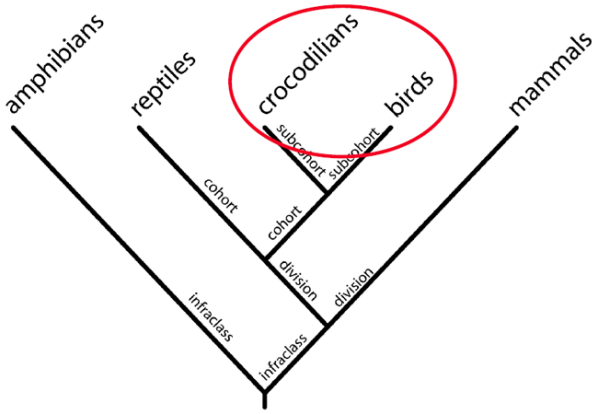

Figure 5. Cladists lump birds and crocodiles (the latter usually thought of as a subgroup of reptiles) together in a taxonomic category called Archosauria, which is given equal rank with reptiles. Ranking and classifying are based solely on a single criterion, recency of common descent.

CLADISTICS VERSUS EVOLUTIONARY SYSTEMATICS

The primary controversy is between those who support cladistics and those who back evolutionary systematics. The proponents on both sides declare that their method provides the greatest number of conclusions and predictions about the organisms being classified and is therefore the best approach.

To better understand the differences between these two methods. Let's forget about fishes for a moment and take a look at the famous crocodile-bird controversy.

The branching diagram in Figure 4 shows how the major groups of tetrapods diverged from one another through evolutionary time (the tetrapods comprise the first four-limbed vertebrates and their descendants, including the living and extinct amphibians, reptiles, mammals and birds). Everyone agrees, cladists as well as evolutionary systematists, that this is the way tetrapods evolved. What remains in question is how a classification should be derived from this sequence of branching.

The classification that cladists construct from the branching diagram in Figure 5 looks like this:

A CLADISTIC CLASSIFICATION OF TETRAPODS

Infraclass AMPHIBIA
Infraclass REPTILOMORPHA
Division SAUROPSIDA
Cohort REPTILIA
Cohort ARCHOSAURIA
Subcohort CROCODILIA
Subcohort AVES (birds)
Division MAMMALIA

Notice a couple of things. First off, the classification is a perfect reflection of the pattern of branching in the branching diagram. Everything is laid out in pairs. There are two infraclasses, two divisions, two cohorts, etc. Just as the diagram is perfectly dichotomous, so is the classification. Thus, the classification can be constructed easily by simply following the sequence of branching in the branching diagram.

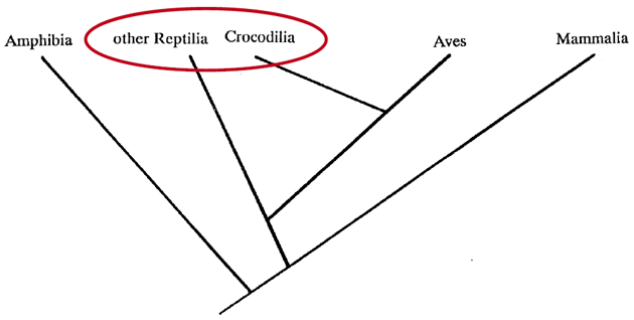

Figure 6. The branching diagram of the evolutionary systematicists.

At the same time, given the classification, it is very easy to draw the branching diagram.

Notice also, how crocodiles and birds are given equal rank. Cladists say that these two taxa are sister-groups, that is, the subcohort Crocodilia (crocodiles) is the sister group of the subcohort Aves (birds) and, vice versa, Aves is the sister-group of the Crocodilia. Cladists also say that the division Sauropsida, containing the reptiles, crocodiles and birds, constitutes the sister-group of the division Mammalia.

Let's now take a look at the other side of the controversy. Non-cladists see Figure 5 and go ballistic. They argue that this cladistic approach completely ignores the drastically different evolutionary fates of the groups in question. That is, cladists ignore genetic change that may have occurred within a group subsequent to branching away from an ancestral group. To stick with the example we started with above, non-cladists argue that birds have invaded an entirely new adaptive zone—that is, they've evolved wings and they fly—yet in the cladistic view they are given equal rank as the sister-group of the crocodiles, a group that has remained in the old ancestral adaptive zone. Of course, the problem immediately arises, how do you measure the extent to which a group of organisms has entered a new adaptive zone? How new is new? How does one quantify the differences?

Non-cladists, in constructing their classification of tetrapods, from the same pattern of evolutionary branching accepted by cladists, give birds a much higher status than crocodiles. In fact, they give birds equal rank with reptiles (reptiles now containing both "other reptiles" and crocodiles), thus emphasizing the amount of evolutionary change between branching points. Their branching diagram is shown in Figure 6.

Notice that the pattern of branching is identical to that in the diagram of the cladist, but the angles formed between the branches vary in accordance with estimates of the amount of evolutionary change (morphological divergence) between branching points.

Here is their classification—four classes of equal rank:

AN EVOLUTIONARY CLASSIFICATION OF TETRAPODS

Class AMPHIBIA
Class REPTILIA
Subclass ARCHOSAURIA
Subclass CROCODILIA
Class AVES
Class MAMMALIA

Notice a couple of things. First off, the classification is not at all a reflection of the pattern of branching in the branching diagram. Thus, the classification cannot be constructed by following the sequence of branching in the branching diagram. And, vice versa, it is impossible to draw the branching diagram based on the classification alone.

Notice also that in lumping crocodiles with "other reptiles," non-cladists violate a major premise of the cladistic approach: they violate the concept of recency of common descent.

Cladists therefore view the "Reptilia" of the non -cladist as an "unnatural assemblage."

Followers of evolutionary systematics say that their evolutionary tree and classification provide much more information than a cladogram and a cladistic classification. They say their approach provides important information about the (1) extent of radiation and the (2) amount of evolutionary divergence between groups. Cladists come right back and say, this is all well and good, but how does one go about measuring, i.e., quantifying the extent of radiation (an evolutionary radiation is an increase in taxonomic diversity or morphological disparity, due to adaptive change or their environment) and the amount of evolutionary change? Cladists argue that these values are unknowable, they can't be determined, and thus any attempt to use these concepts to order the diversity of life is not science!

THE CONCEPT OF "RELATIONSHIP"

To compare these competing methodologies and provide another example that will help to differentiate between pheneticists, cladists and evolutionary systematists, let's take a look at the word "relationship."

Phenetic approach: for the pheneticist, relationship simply means similarity. Pheneticists operate on the assumption that the total phenotype accurately reflects the genotype. They believe that an unweighted measure of overall similarity provides an accurate determination of relationship. In so doing, pheneticists ignore the possibility of evolutionary convergence.

Cladistic approach: cladists define relationship in a strictly genealogical sense—the measure of phylogenetic relationship is the relative recency of common descent.

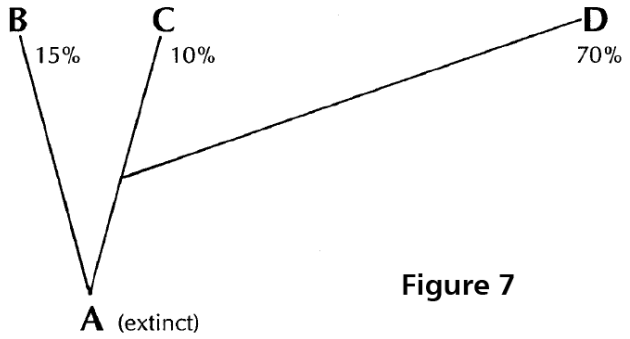

Figure 7

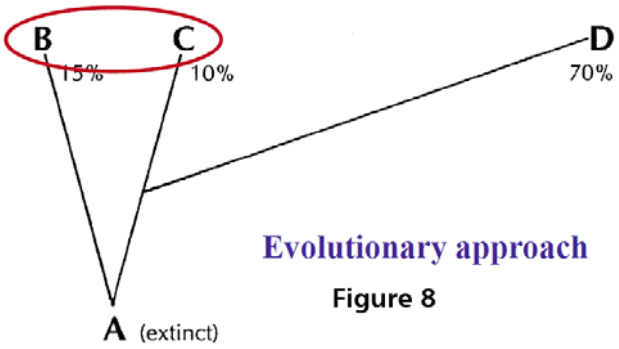
Evolutionary approach: for the evolutionary systematist, relationship means more than just kinship in a strictly genealogical sense—it also involves a measure of genetic change that may occur within a group subsequent to its divergence (branching) from an ancestral group.

Let's illustrate this with the diagram shown in Figure 7.

Imagine an ancestral species A that gives rise to three modern-day species, B, C and D.
Imagine further that
15% of the genetic content of species B differs from that of species A,
10% of the genetic content of species C differs from that of species A, and
70% of the genetic content of species D differs from that of species A.

There is, therefore a *maximum* genetic difference of 25% between the genomes of B and C, but 80% between C and D. Note: The maximum genetic difference between the genomes of B and C, for example, occurs when B's 15% is entirely different from C's 10% and so we add their genetic content to get this number; a similar calculation is made for C and D.

The evolutionist would say B and C are more closely related than either is to D, because there is much less genetic difference or genetic



Evolutionary approach

Figure 8

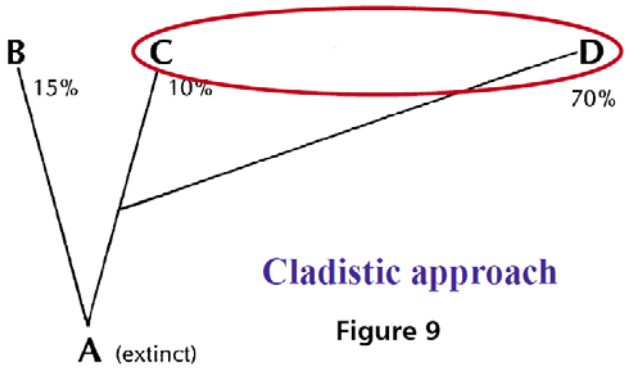
change between them, that is, they have a much greater inferred amount of shared genotype (Figure 8).

The cladist, in direct opposition to the evolutionary systematist, would conclude that C is more closely related to D than to B because of greater recency of common descent (Figure 9).

Over the years, the cladistic approach has become widely accepted over any alternative approach, so that today nearly everyone in the field of biosystematics is a cladist!

WHAT'S IT ALL MEAN TO AQUARISTS?

The answer is, "very little." At times, an aquarist will find it more useful to adopt Aristotle's binary classification, as when a key to a group of fishes is consulted. Generally speaking, however, aquarists are more interested in similarities than in phylogeny so it might seem that phenetics



Cladistic approach

Figure 9

got us into the millennia-old error in the first place of confusing a porpoise with a fish. And, philosophically and practically speaking, cladistics is not going to be much of a help to an aquarist when it insists that there is no such thing as a fish.

Aquarists are not picky when it comes to nomenclature (and here they are in good company since Linnaeus didn't much care, either, although he did prefer that it be in that pesky Latin), nor are aquarists picky about classification.

In addition to these the methods of classification discussed in this essay, differences may also exist among classification systems depending on whether the worker is a "lumper" or a "splitter." A lumper constructs a classification with categories containing more groups than that of a splitter. There are no rules for the amount of difference necessary to designate various categories. A lumper recognizes one family for salmon, whitefish and grayling; a splitter, 2 or 3 families. Aquarists often get the urge to gather up feathers and heat up tar when an ichthyologist moves half of his favorite species to a dozen or so newly-minted genera, most of which are impossible to pronounce. Finally, an interesting classification of fishes based upon ecological factors is shown in Figure 10 (from Allen, 2006).

Some ichthyologists see classification as an expression of theories about the relationships between taxa and others see it as an information storage and retrieval system. Aquarists see it mostly as the latter since it benefits them more. This view imposes limits on both the number of taxa a higher taxon can sensibly contain, and on the number of levels appropriate in a hierarchy. Cladistics, with its deep hierarchies, can be seen as a move towards greater scientific accuracy at

the expense of efficient information retrieval. This inefficiency with regard to information retrieval helps explain why many authors - including aquarists - continue to organize their material using Linnaean ranks rather than hierarchies of clades.

In any event, with regard to aquarists involving themselves in the quarrel between cladists and evolutionary systematists, I end with this quote from the bible: "Whoever meddles in a quarrel not his own is like one who takes a passing dog by the ears."

SEX AND THE SINGLE BOTANIST

by Albert J. Klee, Ph.D

(Aquarium Hobby Historical Society of America, Facebook Files, August 29, 2015)

The fame of Carl Linnaeus (1707-1778) - ennobled Carl von Linné in 1757 - rests upon his reform of natural history. Among other things, by introducing binominal nomenclature in *Systema naturae* (1735) and finally adopted in *Species plantarum* (1753), he created order in a period when there was great confusion in naming animals and plants. No uniform system existed. Every biologist gave names according to his own method. Linnaeus shared the frustration of many of his contemporaries at some nomenclature experiments, once remarking, "The names bestowed on plants by the ancient Greeks and Romans I commend, but I shudder at the sight of most of those given by modern authorities." He had good reason to shudder; one "formal" name for the tomato was *Solanum caule inerme herbaceo, foliis pinnatis incisis, racemis simplicibus*. Linnaeus standardized the terminology for 8,000 plants and 6,000 animals. His reform consists essentially of giving a one-word name such as *Acipenser* or *Cyprinus* to a genus and a two-word name such as *Perca fluviatilis* or *Malapterurus niloticus* to an individual species within this genus.

The Swiss philosopher Jean-Jacques Rousseau sent Carl Linnaeus the message: "Tell him I know no greater man on earth." The German writer Johann Wolfgang von Goethe wrote: "With the exception of Shakespeare and Spinoza, I know no one among the no longer living who has influenced me more strongly." Swedish author August Strindberg wrote: "Linnaeus was in reality a poet who happened to become a naturalist." Among other compliments, Linnaeus has been called Princeps botanicorum (Prince of Botanists), "The Pliny of the North," and "The Second Adam." *Time Magazine* named Linnaeus the 31st most influential person in human history and the 5th most influential scientist. According to the German biologist, Ernst Haeckel, the question of man's origin began with Linnaeus, as he helped future research in the natural history of man by describing humans just as he described any other plant or animal.

From the time it was introduced, the Linnaean system had both competition and detractors. Michel Adanson of France proposed a different system that organized plants globally and incorporated indigenous terms to name them. (Linnaeus scoffed that many of those terms "can scarcely be pronounced by our tongues.") Buffon, meanwhile, argued that nature "advances by imperceptible nuances" that no naming system could capture.

Encyclopedist Denis Diderot took offense at Linnaeus's classification of man as a quadruped. Diderot - no fundamentalist - thought Linnaeus had given short shrift to the human mind. Further, he repeated the Linnaean classification system for man to show its absurdity: Man is not a rock or a plant, so he must be an animal. Man has more than one foot, so he's not a worm. Man has no antennae, so he's not

Carl Linnaeus (1707-1778)

an insect. Man has no fins so he's not a fish. Man has no feathers, so he's not a bird. Man must be a quadruped.

As for man, Linnaeus concluded there were four types of *Homo sapiens: europaeus, asiaticus, americanus* and *afer*. And that was not including people in "a state of nature" (*Homo sapiens ferus*) and pathological types (*Homo sapiens monstrosus*). In all fairness to Linnaeus, belief in separate human species and even separate human origins for different races persisted long after he died. However, this business of including man along with plants and animals caused a religious uproar in some quarters and is the subject of this essay.

AN EARLY FRIENDSHIP

Linnaeus and Johann Georg Siegesbeck (1686-1755), initially had had a friendly relationship. Siegesbeck was born at Seehausen, near Magdeburg, and took his doctor of medicine degree in Wittenberg in 1716. After this he practiced as a physician in his hometown, then at Helmstedt, from 1730-1735 meanwhile studying botany under Lorenz Heister. Botany eventually took over from medicine for Siegesbeck and he was appointed a demonstrator at the Botanical Garden of St Petersburg in 1735 (a demonstrator's job was to explain to his pupils, i.e., the apprentices of the Garden, the names, classes, and medicinal uses of the plants, according to the order in which they are placed in the garden). He went on to take up the post of Professor of Botany at the Russian Academy of Sciences and director of the Botanical Gardens, where he remained until 1747. Afterwards he returned to Seehausen, again working as a physician, until his death in 1755.

Between November 14, 1735 and April 12, Siegesbeck wrote four very ingratiating letters to Linnaeus when Linnaeus lived on Hartecamp in the Netherlands, the estate of his Dutch benefactor, George Clifford (1685-1760). Siegesbeck also sent Russian plants to Clifford for his collection. On May 24, 1736, Siegesbeck informed Linnaeus that by order of the Russian Empress Anna, medical gardens had been founded the year before in both St. Petersburg and Moscow. Siegesbeck was in charge

George Clifford (1685-1760), Linnaeus's Dutch benefactor

of the former and another German botanist, Traugott Gerber, of the latter. It was their task not only to examine domestic plants, especially those that were rare and not yet described, but also to start a botanical correspondence so as to collect exotic plants for their medical gardens.

The common opinion of Siegesbeck is that he was a poor botanist. In fact he is mentioned in the history of botany only for having criticized the famous Linnæus and, because of which, he has been considered something of a fool.

THE BACKGROUND OF THE QUARREL

In *Systema naturae* Linnæus gave a full account of his sexual system for the classification of plants, which was founded on the organs of reproduction, i.e., the stamens and pistils. These ideas were refined in *Fundamenta botanica* (1736), *Genera plantarum* (1737) and *Critica botanica* (1737). Linnaeus was very sensitive to criticism all his life and his new system for the classification of plants met with much

resistance. If Linnaeus's critics chafed at his naming system, they were truly disgusted by something else he publicized: Plants reproduce sexually. Up to that time, the gentle study of botany had been sufficiently delicate to serve as a pastime for well-bred ladies. Then Linnaeus ruined everything with his new classification system and the Pope forbade the introduction of his works to the Vatican. It was not until 1774 that a botany professor was appointed in Rome to lecture the Pope on the basis of Linnaeus's work.

However, another objection to the system was that it was repugnant and immoral. One of those critics was Siegesbeck. In December 1737 Siegesbeck published a work in which he tried to refute Linnaeus's sexual system, but the scholarly argumentation was poor, to say the least.

Linnæus asserted that the species are constant and serve God's purposes. According to him, there is an order in Nature, which goes back to God. God is present everywhere. The Creation is the glory of God and nothing has therefore been created at random. It is up to botanists to show this divine order and the Creator's hand behind it all. Linnæus says himself in *Systema naturae* that he saw the eternal, omniscient and almighty God "on his back" and he was amazed. He saw the footsteps of God in nature and noticed everywhere an eternal wisdom, an incredible perfection. Linnæus believed that he was guided by God himself and that he had a mission to reveal

God's plan for the Creation. Everything comes from the egg (omne vivum ex ovo). As a consequence of this, plants too were thought to come from the egg, i.e., the seed.

Hartecamp, in the Netherlands, the estate of Linnaeus's Dutch benefactor, George Clifford.

In this regard Siegesbeck strongly questioned Linnæus's new system: According to the Bible, God created all plants on the third day. God did not think of seeds, but created complete plants with flowers and fruits. Animals have different sexes, but from this fact we cannot conclude that the same

can be applied to the vegetable kingdom. Siegesbeck admits that the research of John Ray (1627-1705) and others showed that it is true that plants do have some sort of sex, but all the same we cannot talk of stamens and pistils as male and female organs respectively by which the plants can reproduce themselves. What really made Siegesbeck so upset was, as he put it, "the immorality" of the Linnaean system.

Siegesbeck openly mocked Linnæus asking whether God would allow twenty men or more (i.e., the stamens) to have one wife in common (i.e., the pistil) or the wedded man, apart from his legitimate wife, to have adjacent flowers as concubines. It seems fair to say that what Siegesbeck did is only to draw certain conclusions from Linnæus's own statements. Siegesbeck tried to see God's plan behind the sexual system, but failed totally when he saw its strange moral consequences. Thus Siegesbeck concluded that God would never allow such an abominable lack of chastity among his innocent plants, his dearest little creations. He called Linnaeus's ideas "loathsome harlotry" and wondered "who would have thought that bluebells, lilies and onions could be up to such immorality?" Such a method could never be proposed to young, innocent students!

LINNAEUS GETS IN A DIG

One of Linnaeus's ideas in *Critica botanica* (Critique of botany) was that there should be a link between the flower and the botanist whom it was named after. For example, *Magnolia,* Linnaeus said, has very handsome leaves and flowers, which recall the splendid botanist Magnol. But *Dorstenia* has insignificant flowers, faded and past their prime, like the works of Dorsten. According to Linnaeus there was such a "charm" in these associations of his that they would never fade from memory. Following this philosophy and being warned of Siegesbeck's attack, in *Hortus Cliffortianus,* a work of early botanical literature as a collaboration between Linnaeus and Georg Dionysius printed during the summer of 1737, Linnaeus had named a smelly little weed, *Siegesbeckia orientalis.*

***Siegesbeckia orientalis*, a low-growing plant.**

Today, although naming an unsavory organism after someone you want to insult is considered bad form, it sometimes happens. Quentin Wheeler, for example, a self-described life-long Republican and admirer of beetles that ingest slime molds, named three slime beetle species, *Agathidium bushi, Agathidium rumsfeldi* and *Agathidium cheneyi*!

LINNAEUS IN TROUBLE

Linnaeus realized that Siegesbeck's criticism had had serious consequences. When he came back to Sweden in 1738 after four years obtaining his

***Critica botanica*, 1737. In this publication Linnaeus recommended that there should be a link between the flower and the botanist whom it was named after.**

doctorate and visiting with eminent botanists, he found that the whole of Stockholm was in fact laughing at him - not at Siegesbeck. This tells us something about how Linnæus's new ideas were received. From a theological point of view people seemed to strongly favor Siegesbeck. The situation was so bad that Linnaeus could not even find one servant to work for him. Actually in one of his biographies he states that nobody even dared to send him his dog to be cured, a pretty state of affairs for a medical doctor. And he, Linnaeus, who had been honored everywhere abroad as a Princeps botanicorum, was in Sweden like a Klimius returned from the Underworld (a reference to the Norwegian-Danish author Ludvig Holberg's Niels Klim's *Underground Travels*, originally published in Latin as *Nicolai Klimii Iter Subterraneum* (1741), one of the first science fiction novels in history, along with Johannes Kepler's *Somnium* (Dream) of 1634).

Hermann Boerhaave (1668-1738) was the foremost professor of medicine of the time. Linnaeus, who was his student, promised never to partake in any scientific quarrels, and he kept that promise.

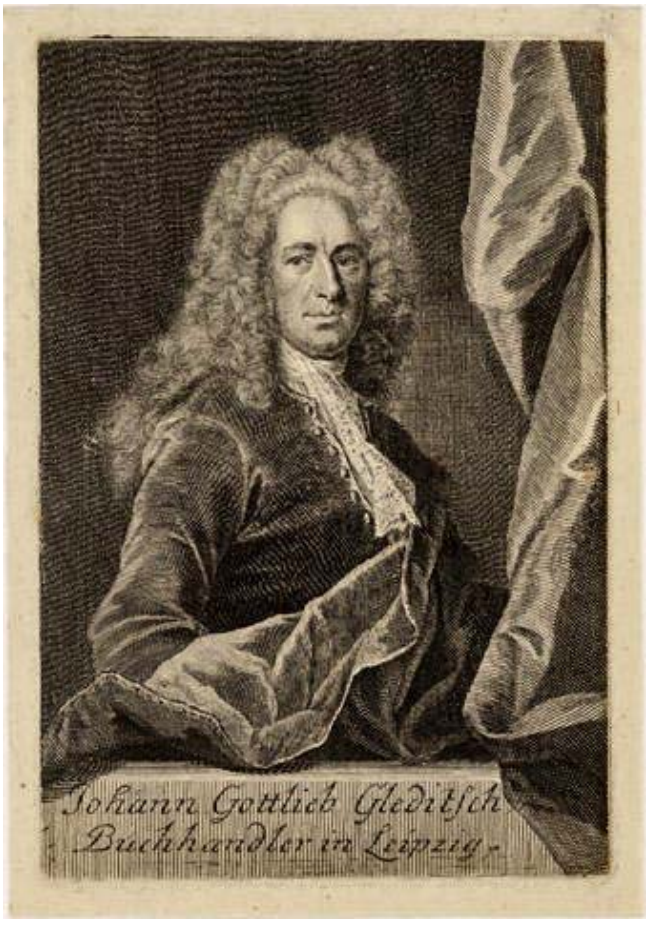
Johan Browall (1707-1775).

LINNAEUS MOUNTS A DEFENSE

Linnaeus was finally forced to defend himself against Siegesbeck's attack. In a letter on September 13, 1748, he confided to a friend that in Leiden he had promised his teacher, Hermann Boerhaave (1668 -1738), the foremost professor of medicine in those days, never to partake in any scientific quarrels. He had kept his promise in so far as he had not attacked Siegesbeck's thesis in his own name. It was Linnaeus's old friend, Johan Browall, who undertook the defense. Browall (1707-1775) was a Finnish and Swedish Lutheran theologian, physicist and botanist (Finland was part of Sweden for almost 700 years from around 1150 until the Finnish War of 1809 that saw Finland becoming an autonomous part of Russia as the Grand Duchy of Finland). He was a Professor of Physics from 1737–46, Professor of Theology 1746–49 and was the Bishop of Turku (a town on the southwest coat of Finland; its Swedish name is Åbo), then a diocese of the Church of Sweden, and Vice-

Chancellor of The Royal Academy of Turku from 1749 until his death in 1755.

In 1737 Browall published his *Examen epicriseos in Systema plantarum sexuale* (The examination of the Epicriseos system in sexual plants), where Siegesbeck's opinions were raked over the coals and shown to have no merit whatsoever. Browall asserted that the criticism that could be made against Linnaeus's sexual system is that widely different plants are brought together within the same class. But this criticism can be attributed to every artificial system and cannot be avoided until a true natural system is discovered. Linnaeus's system still contained more natural classes than any other previous system. In one of his autobiographies Linnaeus says himself that he supported Browall when he wrote the thesis, *Multa communicavit* (many things shared).



Johann Gottlieb Gleditsch (1714-1786), another of Linnaeus's German correspondents who came to his defense.

Another attempt aimed to refute Siegesbeck was published in 1741 by Johann Gottlieb Gleditsch (1714-1786), another of Linnaeus's German correspondents, under the title *Vaniloquentiae botanicae specimen* (*Idle talk about botanical specimens*). Siegesbeck's replies to these defenses of Linnaeus, however, in no way improved his own reputation. He remarked, for example, that he did not know whether Linnaeus was competing with botanists, poets or orators since he calls the seeds ovaries and talks of matrimony, happiness and love of the plants. He concludes by saying that Linnaeus's sexual method should be called the lascivious method and that there was a great difference between polygamy and associations with prostitutes. The one is sanctioned in the Old Testament, the other not!

THE ST. PETERSBURG OOPS!

The hostility between Linnaeus and Siegesbeck was intensified in the 1740's through a series of coincidences. Linnaeus found a seed packet with some fruits of *Siegesbeckia orientalis* in the University Botanical Garden at Uppsala and he could not restrain himself. All his bitterness towards Siegesbeck burst out anew. He relabeled the packet with the name *Cuculus ingratus* ("the ungrateful cuckoo"). This would not have caused such embarrassment if the packet had not ended up at St. Petersburg and finally found its way to Siegesbeck himself.

These were the unfortunate circumstances. In 1744, Count Sten Carl Bielke (1709-1753) - a private student of Linnaeus - together with Linnaeus's future disciple Pehr Kalm, made a journey to Russia to collect plants. A rich collection of dried plants, seeds and more than 200 sorts of herbs, all Siberian, was brought back to Uppsala. However, at St. Petersburg Bielke happened to trade the packet by chance for Russian seeds. Thus it eventually came into Siegesbeck's own hands. He sowed the seeds with great curiosity and harvested - a *Siegesbeckia.* Naturally enough Siegesbeck was absolutely furious. Linnaeus's little mischief was to have damaging

effects on the botanical interchange as Siegesbeck now stopped all exchange of herbs with Uppsala.

This was a severe blow to Linnaeus, who was very interested in the Siberian flora, as its plants were ideal for the barren soil of Uppsala. Bielke repeatedly tried to put things right by urging Linnaeus to send a letter of apology to Siegesbeck saying the fault was that of the gardener who had written the label, not he. As a last resort Bielke tried to persuade Linnaeus by offering all the Siberian plants that he could have in return, reminding Linnaeus that Georg Wilhelm Steller (1709-1746), who sailed with Vitus Bering (1681-1741), would soon return with great collections from Kamchatka (in those days this comprised the whole of the Russian far East). However Linnaeus replied:

With regards to your last letter I must say with Pilate, 'What is written is written.' Siegesbeck shows himself to be cruel; death and cruelty will always have some cause. Nobody has ever been able to give me a rarer gift than the one you, dear Count, gave me of Siberian herbs, but if someone told me, 'apologize to Siegesbeck, and I will give you an equally big and rare collection,' I must admit that this would be impossible for me, because of a public malice without reason. He then tried to escape, but it is an idiot and fool, under which I have suffered, such a thing cannot be eradicated from a mortal heart. The more he writes, the more he rages, the better it is. If you, dear Count, writes to him, you had better pray him right away to open all his sources of evilness and rush forward as an example to posterity, an *ingratissimus cuculus et nebulo* (ungrateful cuckoo and blockhead). Let him also know that I will never forgive him his roguery, but also that I do not meet wickedness with wickedness, but smile at the idiot and fool, who pretends to be a botanicus, something that he will never become.

THE COUP DE GRAS

Linnæus had many critics. But in the 1760's his works had long been accepted and he allowed himself to make an assessment of contemporary botanists by listing all the "officers of Flora." No less

Albrecht von Haller (1708-1777. Like Linnaeus, he was a pupil of Herman Boerhaave. Haller was a stubborn critic of Linnaeus but was on friendly terms with him. They corresponded frequently and Linnaeus often provided intimate details of his family life and when Haller published these letters he was severely criticized for doing so.

than thirty-three contemporary botanists were listed and given various ranks. Although Albrecht von Haller (1708-1777, a Swiss anatomist, physiologist, naturalist and poet; he is often referred to as "the father of modern physiology" and like Linnaeus, he was a pupil of Herman Boerhaave) was a stubborn critic. To Linnaeus's credit, however, he lists him as the third botanist in rank and thus places him among the colonels ("öfwerstar"). Not surprisingly Siegesbeck was listed at the absolute bottom of the list with the grade of sergeant major ("fältväbel"). In accordance with his title of omnium seculi sui botanicorum princeps (the worlds' prince of botany), Linnæus placed himself at the top of the list as the general.

CONCLUSION

In his *Nemesis Divina*, a work with edifying and moralizing stories for the education of his son, also

called Carl, Linnaeus reveals a rather primitive sort of religion, i.e., if you suffer, it is God's punishment for something that you have done yourself; there always seems to be a just connection between guilt and punishment. "Wicked" Siegesbeck was to prove himself an excellent example of Linnaeus's interpretation of divine revenge, especially as he was to live to see his only son commit suicide, which meant the end of his family line.

Finally, as I have already suggested, humility was not one of Linnaeus's virtues. In his autobiography Linnaeus concludes, writing in the third person.

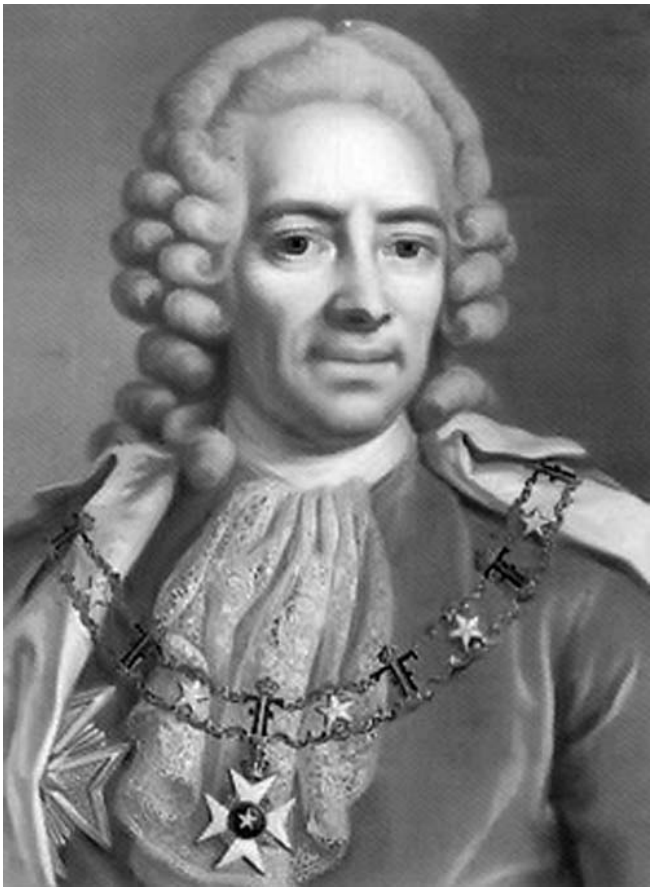
God has been with him [i.e., Linnaeus], wherever he has gone, and has eradicated all his enemies for him and made him a great name, as great as those of the greatest men on earth… Nobody has been a greater botanist or zoologist. No one has written more books, more correctly, more methodically, from personal experience. No one has more completely changed a whole science and started a new epoch.

In Linnaeus's defense, in classical literature there are a number of examples of writing an autobiography in the third person. Caesar's Wars is a very obvious example, written in the third person by Julius Caesar, e.g., "Caesar did this, Caesar did that, The Helvitiae having been thrown into confusion Caesar advanced with his cohorts to the river…" etc. Pope Pius II (1405-1464) wrote his account of his life in the third person too, in imitation of these classical exemplars. Third person autobiographies can be useful even in this day and age. For example, I wouldn't consider writing a resume today in anything but the third person.

ADDENDUM: A BROKEN FRIENDSHIP

Linnaeus and Browall ultimately had a falling out. In 1732, Linnaeus paid a visit to Claes Sohlberg (1711-1773, his friend and fellow student, in Falun, the capital of the copper-mining region of Dalarna, in central Sweden. At the time, it was necessary for Swedish medical students to complete their doctoral degrees abroad in order to open a successful medical practice in their homeland. In an agreement with Sohlberg's father, who was the royal inspector of the Falun copper mine and impressed with Linnaeus's botanical and mineralogical abilities, Linnaeus received an annual stipend to offset medical school expenses in the Netherlands. In return, Linnaeus promised to take young Sohlberg with him on the trip and serve as his academic mentor. Linnaeus, of course, accepted the offer. While in Farun, Linnaeus was introduced to Baron Nils Esbjörnsson von Reuterholm, governor of the province, who was fond of natural history. There he became fast friends with Johan Browall, the tutor of the baron's children

In James Smith's *A Selection of the Correspondence of Linnaeus, and other Naturalists, from the Original Manuscripts*, London, 1821, we have the following letter in September 1739 from Linnaeus to Haller:



Baron Nils Esbjörnsson von Reuterholm (1676-1758).
Browall tutored Reuterholm's children in Farun and it was there that Linnaeus met Browall.

In the year 1730 I taught botany in the garden at Upsal (i.e., the old name for Uppsala). Our common friend Dr. Rosen returned thither the same year. I, then a student of medicine, was Professor Rudbeck's deputy in botany, as Rosen was in anatomy, he being likewise the adjunctus, or coadjutor, in medicine. In 1732 I went to Lapland, and returned; after which I read lectures on botany and metallurgy for a whole year. I then quitted Upsal, and, as Providence ordained, went into Dalecarlia. Having accomplished my journey, I returned to Fahlun, the principal town of that province. Here I lectured on mineralogy, and followed the practice of physick. I stayed a month at Fahlun, where I was received with universal kindness.

A physician named Moraeus resided there, who was esteemed rich by the common people. Indeed he was one of the richest persons in that very poor country. With regard to learning, he might undoubtedly claim the first rank among the medical men of Sweden. I have heard him say, a thousand times, that there was no line of life less eligible than the practice of physick. Nevertheless, he was much attached to me. I found myself frequently a welcome visitor under his roof. He had a handsome daughter, besides a younger one, the former of whom was courted, but in vain, by a gentleman of rank and title. I was struck when I first saw her, and felt my heart assailed by new sensations and anxieties. I loved her, and she at length, won by my attentions, listened to my proposals and returned my passion. I became an accepted lover. I addressed myself to her father, avowing, not without much confusion, my total want of fortune. He was favorable on some accounts, but had many objections. He approved of me, but not of my circumstances; and desired that things might remain as they were for three years, after which he would tell me his determination.

A young Linnaeus. He in the traditional dress of the Sami people of Lapland, holding the twinflower, later known as *Linnaea borealis*, that became his personal emblem.

Having arranged my affairs, and made the necessary preparations for a journey, I quitted my native country with 36 gold ducats in my pocket (Linnaeus left in 1735**). I immediately took my medical degree (at Hardewick in Holland), but was not in circumstances to return home with much comfort. I remained, as you know, in Holland. In the meantime my most intimate friend B ... regularly forwarded the letters of my mistress by the post. She continued faithful. In the course of last year, 1738, which I passed at Dr. Van Royen's, with the approbation of the young lady, though it was the fourth year of my absence, and her father had required but three, B…thought he had himself made considerable progress in her favor. By my recommendation he was made a Professor; and he took upon him to persuade my betrothed that I should never return to my own country. He courted her assiduously, and was very near obtaining her, had it not been for another friend, who laid open his treachery. He has since paid dearly for his conduct, by innumerable misfortunes.**

The "B" was, of course, Browall. The recommendation Linnaeus mentioned was for the position of Professor of Physics at the Academy in Turku, Finland, a position Browall held from 1737 to 1746.

When Linnaeus returned to Falun after a four year's absence he was, as we have seen, in pitiful circumstances due to Siegesbeck's attack. A year later, however, things improved, as Linnaeus relates in his letter to Haller:

Soon afterwards I was appointed first physician to the navy. The magistracy immediately conferred upon me the regius professorship, that I might teach botany in the seat of government at Stockholm, with the addition of an annual stipend. Then my fondness for plants revived. I was also enabled to present myself to the bride to whom I had been for five years engaged, and was honorably received as her husband. My father-in-law, rather fond of his money, proved not very liberal to his son-in-law; but I can do without it, and those who come after me will enjoy it.

After a five-year engagement, Linnaeus and Sara Lisa were finally married in 1739.

The following is an interesting attempt that appeared in many accounts of the life of Linnaeus to weave together a story of three *Browallius* species that purported to explain the chronology of events of the break between Browall and Linnaeus. The entry under *Browallia grandiflora* in *Curtis's Botanical Magazine* of 1831, for example, reports:

The intimacy and subsequent rupture between Browall and Linnaeus were commemorated by the latter in the specific appellations which he bestowed on the only three individuals of the genus then known. *Browallia elata* expresses the degree of their union; *Browallia demissa* its cessation; while the ambiguous name of a third species, *Browallia alienata*, while it intimates the uncertain characteristics of the plant, implies the subsequent difference between the two parties.

This story was repeated in similar form many times over the years. However, Linnaeus first described *Browellia* before the rift in his *Hortus Cliffortianus* in 1737, but he described it without designating any species. The only time all three species appeared was in the 10th edition of *Systema Naturae* of 1759. This was after the original rift and after Browall became a bishop. However, these three species can be viewed in an entirely different way.

"*Demissa*" also means low and the plant is low-growing. Linnaeus observed that *alienata* differed slightly from the original outline of the genus (it actually is another plant, *Ruellia paniculata*) and in Latin *alienata* can also be translated as "strange." Finally, "*elata*" is also Latin for "arrogant," thus describing Browall's behavior after he was made a bishop. It is doubtful that Linnaeus would have played this kind of three-species name game, especially when two of their Latin translations are not necessarily pejorative at all. This, however, is not the whole story about *Browallia elata.*

Sara Elisabeth Linné (1716-1806), painted in 1739.

Anders Celsius (1701-1744).

A MATTER OF WATER LEVELS

To maintain in the seventeenth century that the sea had had any role in shaping the contours of the earth, other than through the catastrophe of the Flood, was to enter dangerous theological waters. Coastal erosion was explained as a phenomenon of decay: the sea was seen as the maleficent and unpredictable agent of such destruction of God's creation. In 1743, by inviting hunters in northern Sweden to inform him about the elevation of stones used as resting-places by seals, Anders Celsius calculated that there had been a drop in the water-level of more than a meter every hundred years. He also had marks engraved on the rocks recording the water level, for future research.

Celsius' result caused a considerable scientific interest. Support for the water decrease came from two of his compatriots, Linnaeus in 1745 and the physicist and medical officer Nils Gissler in 1747. On the island of Gotland in the Baltic Sea, Linnaeus had come across a sequence of ridges, all parallel to the coast, which he interpreted as old shore-lines having successively lost contact with the sea because of the water decrease. Further north Gissler studied similar sequences of shorelines, supposing, quite correctly, that they might be formed by severe storms occurring with intervals of many decades. They agreed reasonably with Celsius' value of the rate of the water decrease.

Linnaeus added to Celsius's conclusions as a kind of supplement, the following:

The Lord did not create many individuals nor were they scattered over the whole world - to what end the creation of many when the same object may be attained by means of one pair or even one individual? Year by year the sea recedes, and the outlines of the mainland are correspondingly extended. Originally the mainland was only a little inland containing everything which the Creator had appointed for the use of the human race. This island, that is to say Paradise, we may imagine as a lofty mountain under the equator; over the slopes, from foot to snow-covered summit, every species of plant found the climate suited to it. As the mainland increased in size the seeds of these plants, often of peculiar and specially adapted structure, were distributed by winds, rivers, and birds.

The conclusions of Linnaeus were on all sides favorably received, owing to their conformity with biblical tradition, whereas those of Celsius, although the outcome of the same general view, culled forth the most violent opposition, particularly his reference to the approaching destruction of all living things. Affairs reached such a point, that when the historiographer, Olof Dalin, attempted to reconstruct the earliest shape of Sweden according to Celsian principles and concluded that the country had consisted of scattered islands until shortly before Christ when the water began to withdraw, he was accused in the Swedish parliament of offending the dignity of the realm and expressed its disapproval of his theory by a special decree.

Among those who attacked the theorists of the diminution of the waters was Bishop Browallius who tried to explain Celsius' observations as what we today call systematic and random errors (thereby also defending the biblical view of the history of the Earth). Since Celsius was a friend of Linnaeus and because the latter as I have pointed out had promised his teacher, Hermann Boerhaave, never to partake in any scientific quarrels, Linnaeus was reduced to expressing his opprobrium by naming a species of *Browallia* as *elata*, thus poking fun of the Bishop on three counts; his attempt to win over Sara Lisa in 1738, his attack on his friend Anders Celsius and the bishop's propensity for pomp and pageantry. At this apparent reference to his own exalted bearing, Browall became furious and vented his anger in vindictive pamphlets against his former friend. It is the greatest of ironies to observe that only a decade earlier, Browall was defending Linnaeus against theological attacks and now Browall was attacking Linnaeus on the same grounds.

Olof von Dalin (1708-1763). Espousing Celsius's theory, Dalin was accused in the Swedish parliament of offending the dignity of the realm and the parliament expressed its disapproval of his theory by a special decree.

HOT AND COLD HAS ITS UPS AND DOWNS

Finally, a bit of trivia. Celsius used the boiling and freezing points of water to obtain his temperature scale. Celsius' own instrument with its linear scale was of glass and designed for more experimental purposes starting with 0° at the boiling-point and 100° at the freezing-point, thus creating a reversed scale with increasing numbers for decreasing temperatures and avoiding negative numbers. Linnaeus however, had the original Celsius scale turned so that 0 was marked for the freezing-point and 100 for the boiling-point of water for his instrument. By that, Linnaeus got a thermometer better suited for biological conditions. Plants are at risk to die at 0° C. The Celsius-scale, altered in this way, gives the reading below zero for minus-degrees and above zero for plus-degrees. But it also gives a much wider use, as one can even measure extreme temperatures as, e.g., the melting point of iron (+1535°C). With Celsius' original thermometer-scale this would have been quite difficult. Linnaeus realized that it would be more useful if these values were reversed and persuaded the rest of the scientific world to follow his example.

A thermometer made for Linnaeus at the end of the 1770's in the workshop of the Royal Swedish Academy of Sciences by Johan Gustav Hasselström .

Robert Warington—A Biography

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, October 4, 2015)

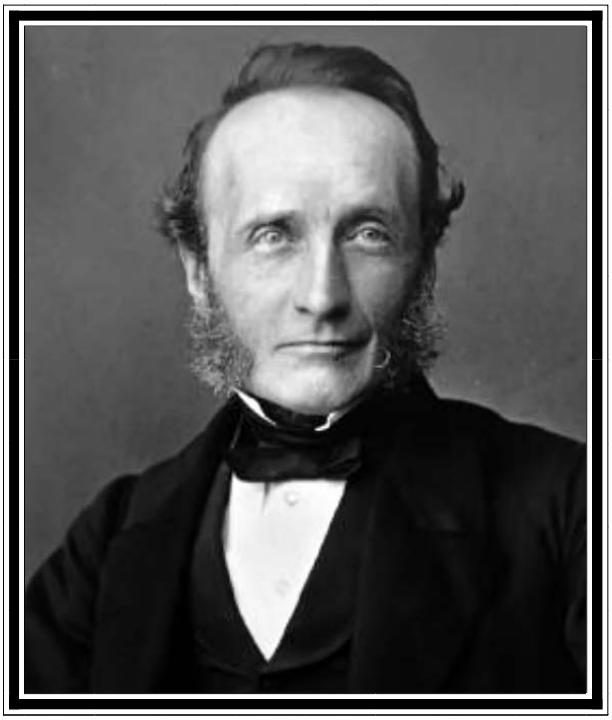
THE EARLY YEARS

Robert Warington was born in 1807 at Sheerness, a town located on the north-west corner of the Isle of Sheppey in north Kent, England. He was the son of Thomas Warington, a victualler, a person providing or selling food or other provisions, of ships. After an early childhood spent in Portsmouth, Boulogne and other places, in 1818 he entered Merchant Taylors' school (one of the most prestigious boys' schools in England; Edmund Spenser as well as Boris Karloff were educated here!). The school at that time was located in Suffolk House in London, and although it was intended he would be a land surveyor, within a few months of leaving in 1821 he became the house pupil to John Thomas Cooper to study chemistry, Cooper being both a drug manufacturer of potassium, sodium, iodine and other then rare chemical substances, and a lecturer in chemistry in a number of medical educational establishments.

With the opening of the London University (later University College) in 1828 and by now having gained his articles, Warington took up the post of assistant to Professor Edward Turner (1796-1837), a chemist known for his work on atomic weights, a popularizer of the atomic theory of Dalton and the author of a popular chemistry textbook that was the first to incorporate chemical symbols and formulae as well as organic chemistry. Holding the Chair of Chemistry at the newly opened university, Turner appointed Warington to take charge of the practical chemistry classes, which he continued for the three years of his tenure. In 1831 he published his first research - on a native sulfide of bismuth. In the same year, on Turner's recommendation, he was appointed chemist to Messrs. Truman, Hanbury & Buxton, the brewers, with whom he remained until midsummer 1839.

A FORTUITOUS MARRIAGE

In 1836 in Spitalfields, an area of London, he married Elizabeth Jackson, the daughter of surgeon George Jackson F.R.S. (1792-1860), a keen microscopist of repute. It was around this time that Warington joined the Mathematical Society of Spitalfields, which he attempted to regenerate by organizing a number of lectures at their meeting place in Crispin Street, but with little success. It was here that he was introduced to his father-in-law's close associate, James Scott Bowerbank. Bowerbank had created what appears to have been the first ordinary-sized aquarium, complete with a piece of glass on top to make it closely glazed. It was this jar of Bowerbank's that attracted the attention of the Secretary of the Zoological Society, David Mitchell, and gave him the idea for the public aquarium that was opened in 1853 in the Zoological Gardens in Regent's Park.



Robert Warington (1807-1867).

By the midsummer of 1839, having sufficient funds to support his family, Warington was able to leave Truman's brewery to concentrate his attention on other interests. By associating with the friends of his father-in-law, Warington was able to join them in supporting Edwin J.Quekett, an early worker in botany and histology, and a microscopist, to eventually form the Microscopical Society of London. Warington's experience and close connection with Jackson were enough to ensure that at the inaugural meeting of the Society, both would be offered seats on its Council.

A FOUNDER OF THE ROYAL SOCIETY OF CHEMISTRY

In 1839 Warington, occupying then no official position and having the necessary leisure, started a movement to found the Chemical Society of London (from 1848 on the Royal Society of Chemistry), the first meeting being convened by him at the Royal Society of Arts on February 23, 1841. The account of the first meeting stands thus in the first minute book of the Society:

1841, Feb. 23rd, Society of Arts, John Street, Adelphi. A meeting of gentlemen, convened by Robert Warington, was held in the rooms of this Society for the purpose of taking into consideration the formation of a Chemical Society. Present: A. Aikin, Esq., Dr. Thos. Clark, [W.] J. Cock, Esq., J. T. Cooper, Esq., D. Cooper. Esq., Thos., Everitt, Esq., Win, Ferguson, Esq., J. P. Gassiott, Esq., Professor T. Graham, W. R. Grove, Esq., Henry Hennell, Esq., T. U. Henry, Esq., C. Heisch, Esq., G. Lowe, Esq., [W. H.] Miller, Esq., Apsley Pellatt, Esq., Richard Phillips, Esq., Dr. Lyon Playfair, Robert Porrett, Esq., Dr. G. O. Rees, E. Solly, Esq., J. Tennant, Esq., E. K. Teschenacher, Esq., Dr. R. D. Thomson, Robert Warington, Esq.

Mr. R. Phillips moved that Professor Graham do take the chair.

On the motion of Mr. J. T. Cooper, Robert Warington was requested to act as Hon. Secretary pro tem.

It was then put from the chair, and carried unanimously - that it is expedient that a Chemical Society be formed.

Moved by Dr. Thos. Clark, and seconded by Dr. R. D. Thomson - That the following gentlemen constitute a Provisional Committee for carrying this resolution into effect: Messrs. A. Aikin, W. T. Brande, H. J. Brooke, J. T. Cooper, J. Gumming, J. F. Daniell, Thos. Everitt, Thos. Graham, W. R. Grove, H. Hennell, G. Lowe, R. Phillips, R. Porrett, R. Warington.

Proposed by Robt. Warington, and duly seconded - that the thanks of the meeting he given to the Society of Arts for the very liberal and handsome manner in which they had allowed Mr. Warington the use of their rooms for the purposes of the meeting.

The thanks of the meeting were moved by [Mr.] J. P. Gassiott to Professor Graham for his kindness in taking the chair.

It is important to note that William Thomas Brande (1788-1866) was a founding member.

Brande deserves the honor for the first elucidation - in his 1819 Manual of Chemistry - of the principle of the balanced aquarium, and Warington for reintroducing it to a much wider audience. Warington later said that it was Brande's book that had incited him to set up his experimental tank with goldfish and *Vallisneria.*

The formal foundation took place on March 30, 1841. Warington was elected honorary secretary, and retained the post till March 1851. In acknowledgment of his services he was presented with a service of plate by the fellows of the society in December 1851.

THE SOCIETY OF APOTHECARIES

Henry Hennel was the chemical operator at Apothecaries' Hall. The Society of Apothecaries was both a City livery company and an examining authority for the medical profession. Founded in 1617 by the royal apothecary Gideon de Laune leading a breakaway group from the Grocers' Company, the Society was instrumental in raising the status of apothecaries as general practitioners. A year after the formation of the Chemical Society of London, Hennel was killed in an explosion. The following is from *Notes & Queries, A Medium of Intercommunication for Literary Men, General Readers, Etc.*, June 7, 1842:

Henry Hennell, 1842: Henry Hennel, F.R.S., the talented and much respected chemical operator at Apothecaries' Hall, had been literally blown to pieces that morning by an explosion of fulminating mercury. He was mixing in a china bowl several portions of the powder, so as to render the whole, which was required for a large military order, of a uniform colour, when the contents of the basin exploded, and he was instantly killed. At the inquest, which was held on the 6th of June, it was stated that all the upper part of Mr. Hennell's body was shattered, and the fragments cast to a distance. One arm was found on the roof of the Apothecaries' Hall, and a finger was picked up in Union Street, more than a hundred yards distant.

It has recently come to my knowledge that in the year 1859, that is, seventeen years after this sad accident, when some repairs were made to the roof of No. 3, Crescent, Block friars - which was then in the occupation of the Engle Insurance Company, and was shortly afterwards swept away to make room for the London, Chatham, and Dover Railway - there was found in one of the leaden gutters a human arm, or rather the bones of one, which had evidently been there many years. From the few facts which I have been able to gather, I think it very probable that these bones were part of the remains of the lamented Mr. Hennell; and if this were so, we have a yet further evidence of the terrific force of the explosion which killed him, as the place where the bones were found was about 130 yards distant from, and nearly forty feet above the level of, the site of the explosion. *Edward Solly.*

In the 1840s it appeared that written accounts were not quite as squeamish as they are today! On the death of Hennell, Warington was appointed chemical operator to the Society of Apothecaries, a position which he held to within a year of his death and where he was responsible for dispensing operations, managing at the same time to do some research on organic chemistry.

CHEMISTRY UNDER THE AEGIS OF PHARMICISTS?

Warington had been disillusioned with the state of chemistry at the time. Improving chemistry professionally, by bringing science and practice into closer communication, was certainly one of his aims in promoting the establishment of the Chemical Society in 1841. Warington, however, viewed the rising professional aspirations of chemists and druggists as likely to subsume the practice of chemistry under pharmacy. Disapproving of the training then available, Warington undertook the education of his sons himself, introducing them to the laboratory at a very early age. It may also have been in deference to his views that the Chemical Society's original plans included the establishment of a research laboratory. Warington even advised the young Frederick Augustus Abel, subsequently one of the Royal College of Chemistry's most illustrious alumni (one of the most important of his investigations had to do with the manufacture of guncotton, and he developed a process, consisting essentially of reducing the nitrated cotton to fine pulp, which enabled it to be safely manufactured and at the same time yielded the product in a form that increased its usefulness; this work to an important extent prepared the way for the "smokeless powders" which came into general use towards the end of the 19th century), not to study chemistry because the professional prospects were so poor.

WARINGTON'S CAREER MARCHES ON

In 1846 he took part in the formation of the Cavendish Society - a chemical printing society named after Henry Cavendish, the outstanding British scientist after Newton - of which he was secretary for three years - and from this time onwards he had many engagements as a chemical expert in legal cases.

In the year 1844 he began a series of investigations into the adulteration of tea and gave evidence at the parliamentary inquiry on adulteration in 1855. In 1851 he revised the Translation of the Pharmacopœia of the Royal College of Physicians into English, left unfinished by Richard Phillips; he was also engaged in the construction of the British Pharmacopœia in 1864, and was joint editor of the second edition in 1867. In 1854 Warington was appointed chemical referee by four of the metropolitan gas companies, and held this post for seven years. In 1864 he was elected a fellow of the Royal Society. The Royal Society's catalogue contains a list of forty-seven papers written by Warington alone, and one written in conjunction with William Francis.

WARINGTON AND THE AQUARIUM

In 1849 he began his investigation on aquaria and the means necessary to prevent the water therein from becoming stagnant. He wrote several papers, and in 1857 delivered a lecture at the Royal Institution on this subject, his work being the origin of our modern aquaria. In my 2012 essay "Who Invented the Aquarium?" I have provided

the details of Warington's work and will not repeat this information here.

Some have asserted (correctly) that Warington was not a biologist, but he definitely knew enough about aquarium biology to afford him some distinction in this area. The following two articles are examples. The first is from the *Annals and Magazine of Natural History*, Vol. XVI, Second Series, pp. 313-315, Taylor and Francis, London, 1885:

XXVII -On the Injurious Effects of an excess or want of Heat and Light on the Aquarium. By Robert Warington, Esq.

Temperature is a point requiring great attention in carrying out successfully the principles of a permanent aquarium. The mean temperature of the ocean is estimated to be about 56° Fahr., and this, under ordinary circumstances, does not vary more than about 12° throughout the different seasons of the year. The causes of this equilibrium will be readily understood when we take into consideration the effects that must be produced by the continued flux and reflux of the tides, and by the enormous streams of water which must be flowing from the Arctic regions from year's end to year's end in one constant current, and which, by their movement, must necessarily cause other currents to flow in and take their place, thus forcing, as it were, the heated surface-water of the tropical seas towards the colder regions of the globe. Again, the whole surface of the earth, submersed below the ocean, is protected by this fluid coating from the effects of the cooling influences of radiation on the one hand, and from contact with the currents of the atmosphere on the other; and hence we perceive an always existent cause for the maintenance of a steady, equable temperature by the waters of the ocean throughout the year.

Many of the inhabitants of the sea are very sensitive to changes of temperature, and we find that a few degrees of variation will cause them rapidly to move their position and seek some cooler or warmer spot as the case may be. In the ocean it will be evident that the creatures have the power readily to effect this under ordinary circumstances, by seeking deeper water not liable to be affected by atmospheric influences, by partially or entirely burying themselves in the sand or shingle, or by shielding their bodies under the protecting shadow of the rocks or growing vegetation. In arranging the rock-work in the interior of the aquarium, therefore, great care should be taken to keep these points in view, and to afford as much protection as possible to the creatures from the cooling influences of radiation on the one hand, and from the heat of the sun's rays on the other.

From my own experience I find that the range of temperature should not be below 50° Fahr., nor above 70°; within these limits all appears to progress healthily, but beyond these points many of the creatures are rapid-

ly affected. During the last long-continued and severe winter, it was found very difficult, in an ordinary sitting-room having a south aspect and a good fire maintained throughout the day—the tanks being also screened at night by a blind,—to prevent the powerful cooling effects from radiation on a clear frosty night; and on three several occasions, marking exactly the three severest frosts that we experienced during the winter, the thermometer, immersed in an aquarium containing about thirty gallons of water, fell as low as 45° Fahr. The Shrimp and Crab tribes, and the Crustaceans generally, are especially affected by these changes, and on each of the three occasions alluded to, one or two individuals perished; the larger-sized Prawns, as *Palaemon serratus*, appeared to suffer more readily than the *P. squilla*, although this might arise from the smaller ones being able to find a shelter from the radiation by concealing themselves more completely among the rock-work or vegetation. *Anthea cersus* is also very sensitive to considerable variations of temperature, falling from its foot-hold to the bottom of the tank apparently dead.

Excess of heat and also strong sunlight are likewise to be as carefully guarded against, and I may state as an evidence of this, that on a particularly hot day during the summer of 1854, being absent from home, the servant omitted to screen a small case from the sun's rays during the hottest period of the day, and on my return I found every creature dead. It contained an *Anthea cereus, Actinia dianthus*, two specimens of *Athanas nitescens*, and several others.

Too much light has also the effect of rapidly propagating several of the minute animalcules of a green colour, as the *Euglena* and its congeners, which under this influence multiply so rapidly as to render the whole water of a grass-green hue; this will at times subside to the lower part of the tank as evening approaches and disappear in the shingle bottom, but immediately the morning light shines strong upon the aquarium . it will rise like a thin green cloud and diffuse itself throughout the whole of the water. Although this animalcular growth is not unhealthy, yet it causes the aquarium to present a very unsightly appearance, and prevents all observation on the habits •of the inmates. The want of light, I need hardly observe, causes the rapid decay of the vegetation, and the products arising from this change are highly poisonous to animal life, the whole contents of the aquarium becoming of a black colour, and very soon of an offensive odour.
Apothecaries' Hall, Sept. 11, 1855.

The second is from the *Annals and Magazine of Natural History*, Vol. XVI, Second Series, pp. 330 -332, Taylor and Francis, London, 1885:

XXXI.— Observations on the Habits of the Stickleback (being a continuation of a previous paper). By Robert Warington, Esq.

During the early part of the last summer I had the good fortune to observe the whole progress of the various stages in the breeding of the Three-spined Stickleback, *Gasterosteus leiurus*, which will therefore enable me to complete the notice already published on this subject in the 'Annals and Magazine of Natural History' for October 1852.

In the account there given, the observations extended |to the completion of the nest by the male fish, and it is my intention in the present communication to carry on the details of the progress from that point, premising that the water was the same which had been employed for the original experiments of 1849, and that the fish contained in the aquarium consisted of three Stickleback, one male and two females, two Tench, and a Goldfish.

The position selected by the male fish for the construction of the nest was between two plants of *Vallisneria spiralis*, at the point where the leaves spring from the root, and directly in front of a fragment of limestone which rose behind the plants and acted as a protecting background to the position. The nest being all prepared, exactly as before described, although by another individual, the eggs were deposited, I presume, during the night of May 8th: this was judged of, not from observance of the act of spawning, but from the altered appearance of the female fish evidencing that she had shed her spawn, from the immediate change made by the male fish in the arrangement of the materials forming the nest, and, likewise, the violent repulsion of the female from the neighbourhood of its position, to which previously he had been as assiduous in driving her.

From this period the nest was opened more to the action of the water, and the vibratory motion of the body of the male fish while hovering over its surface, caused, as before described, a current of water to be propelled across the surface of the ova; this action was repeated almost continuously. The apparent luminosity of the body, if I may so term it, also decreased, and in this state all continued without change until the 18th of May, making a period of ten days. After this date the whole nest was destroyed, and the materials of which it had been composed thrown aside, with the exception of a few wiry stems of a decayed water moss, and a space cleared around the spot of about 3 inches in diameter; the mud or sand at the bottom being carefully removed with its mouth and carried in this manner to some distance, leaving the rounded stones of the gravel clean and free from any obstruction around them.

Watching carefully for a short time, to understand what all this busy alteration indicated, I at last had the pleasure of observing, by the aid of a long-focused pocket-lens, some of the young fry,—of course most minute creatures, fluttering upwards here and there, by a movement half swimming, half leaping, and then falling rapidly again upon or between

the clean pebbles of the shingle bottom. This arose from their having the remainder of the yolk still attached to their body, which, acting as a weight, caused them to sink the moment the swimming effort had ceased.

Around all this space above mentioned, and across it in every direction, the male fish, as the guardian, continually moved. And now his labours became still more arduous than they had been before, and his vigilance was taxed to the utmost extreme, for the other fish, three of them some twenty times larger than himself, as soon as they perceived that the young fry were in motion, used their utmost endeavours, continuously, to pounce upon the nest and snap them up. The courage of this little creature was certainly now put to its severest test, but nothing daunted he drove them all off, seizing their fins, and striking with all his strength at their heads and at their eyes most furiously. All the assistance that could possibly be afforded him was of course rendered, short of actual interference, by keeping them pretty well fed, in order to allay, if possible, their voracity. Another circumstance, which appeared to add greatly to the excitement that he was constantly subjected to, arose from the second female fish, being in spawn, endeavouring most pertinaciously to deposit her ova in the same locality, and hence rushing frequently down towards the spot; but the male fish was ever on the alert, and although he did not strike at her in the furious way he attacked the larger ones, yet, he kept continually under her, with the formidable back spines all raised erect, so that it was impossible for her to effect her apparent object.

The care of the young brood, while encumbered with the yolk, was very extraordinary, and as this was gradually absorbed and they gained strength, their attempts to swim carried them to a greater distance from the parent fish; his vigilance, however, seemed everywhere, and if they rose by the action of their fins above a certain height from the shingle bottom, or flitted beyond a certain distance from the nest, they were immediately seized in his mouth, brought back, and gently puffed or jetted into their place again. This was constantly occurring, the other fish being continually on the watch to devour these stragglers, and make a savoury morsel of these Lilliputian truants. Indeed, the greater number of the whole brood must have fallen a prey to their voracity, as it was only some three or four that reached a size to place them beyond the power of these destroyers.

As soon as the young fry could swim strongly the parent fish gradually relinquished his duties, although a constant watch appeared to be still quietly maintained on their motions as they swam about near the surface of the water and among the floating leaves of the *Vallisneria* and *Lemna*. It is a curious circumstance, that, very soon after these young Stickleback were left unmolested by their companions, both the parent fish disappeared, and I presume have died in some hid-

ing-place among the rock-work; as though, their allotted functions, namely the propagation of their species, having been completed, their period of existence must terminate.
Apothecaries' Hall, Sept. 11, 1855.

In his "The Aquavivarium, Fresh and Marine being an account of the principles and objects involved in domestic culture of water plants and animals," published in 1856, Edwin Lankester wrote:

If there has been no open controversy, there has been a good deal of latent feeling on the subject of the invention of collections of plants and animals in water.

Lankester might well have been referring to the disputes between Warington and Philip Henry Gosse that I mentioned in my 2012 essay, "Who Invented the Aquarium?" This, however, is a complicated and long story so I have added it as a complementary essay that follows this one, titled "The Warington-Gosse Aquarium Controversy Revisted."

Finally, the following is an excerpt from *Notices of the Proceedings at the Meetings of the Members of the Royal Institution of Great Britain*, Vol. II, pp. 403-408, 1857.

WEEKLY EVENING MEETING,
Friday, March 27.
THE DUKE OP NORTHUMBERLAND, K.G. F.R.S. President, in the Chair.
ROBERT WARINGTON, ESQ., On the Aquarium.
The speaker opened the evening's demonstration, by stating that he had immediately responded to the invitation of the Managers of the Royal Institution to deliver this discourse, on what they had been pleased to call his "own subject," from the feeling, that as the originator of the aquarium, he was in duty bound to afford, to all those who had taken up this "new pleasure," every assistance, from the results of his own experience, that lay in his power, in order to render the undertaking more easy and pleasurable; and for this purpose, he proposed to lay before his audience, as far as was practicable, a demonstration of the principles on which it was founded, particularly as very erroneous ideas had been promulgated on the subject, and instructions given in several most engaging publications, which might tend materially to mislead and disappoint those inclined to recreate themselves with this interesting subject.

With regard to the last part of this excerpt, when Warington was pressed to give to the world a little manual of instructions for amateurs, he always stated as a reason for non-compliance with the request, that the book market was overcrowded already with the worthless compilations of many scribblers on the subject. He was a really scientific man, and he did not wish to be associated with authors who wrote about things which they had never seen or done.

ADDENDUM: WARINGTON'S SON

Warington died at Budleigh Salterton, Devonshire in 1867. He left three children, of whom his eldest son - also named Robert (1838-1907) - was to outdo the fame of his father. As a boy he learned chemistry from his father and from the lectures of Faraday, Brande and Hofmann. When twenty years of age, he worked at Rothamsted, located at Harpenden in the English county of

Robert Warington Junior (1838-1907).

Hertfordshire. It is one of the oldest agricultural research institutions in the world, having been founded in 1843. Later he returned to London and went to the Royal Agricultural College in Cirencester - a market town 93 miles from London. It was here that he commenced lecturing on the Rothamsted experiments. Between 1843 and 1856, nine field experiments were started at Rothamsted Research to study the nutrient requirements of the principle arable crops and a hay meadow. These experiments have continued, with appropriate modifications, until today and are the oldest, continuous agronomic experiments in the world.

In Harpenden, where he remained until 1891, he published many memoirs on the nitrification of the soil. Leaving the Rothamsted laboratory, he lectured in America, and after his return home was an examiner in agriculture to the Science and Art Department and Sibthorpian professor of rural economy at Oxford, a post he held for three years. But he was most widely known and his name will be longest remembered for his admirable text books on agricultural chemistry, and most especially for that standard work, “Chemistry of the Farm,” which was translated into several foreign languages and reached its nineteenth edition while he was still alive.

The WARINGTON-GOSSE CONTROVERSY REVISITED

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, May 21, 2016)

In *The Toy Fish* (Klee, 2003), I described the falling out between Robert Warington and Philip Gosse over a matter involving the preparation of artificial sea water. The material was based on William H. Brock's article, "The Warington-Gosse aquarium controversy: two unrecorded letters" (Brock 1991). However, I was never satisfied with Brock's description of the sequence of events that led up to the controversy nor was I with his views of who was at fault. Indeed, with regard to the latter, I disagreed so strongly that I did not include them in *The Toy Fish*, leaving this to my essay titled, "Who Invented the Aquarium?" (Klee, 2012), in which I went into the controversy in greater detail. Recently, however, I re-examined all the evidence and also gathered new information; this essay is intended to examine why and how they fell out, and who was at fault.

At first glance the controversy boiled down to the matter of which gentleman was to be believed, and in such matters opinion and/or emotions usually decide the outcome. However, Utilizing Ockham's Razor, I decided to take an entirely different tack. Both Warington and Gosse were honorable men, so could the controversy between them be explained by assuming that both were telling the truth? Once I did this, everything became clear.

GOSSE'S SEAWATER ARTICLE

In Gosse's article, "On keeping Marine Animals and Plants alive in unchanged Sea-water" (Gosse, 1852), in the following he refers to an article - no author was named - that appeared in *Chamber's Edinburgh Journal* (Anon., 1852):

In a recent Number of 'Chambers' Edinburgh Journal' (July 1852) a paper has just been pointed out to me, on maintaining the balance between animal and vegetable life in an aquarium. Mr. Warington, whose experiments are there alluded to, has succeeded in keeping living plants and animals together in fresh water, and announces that he is "attempting a similar arrangement with a confined portion of sea-water, employing some of the green sea-weeds as the vegetable members of the circle, and the common winkle or whelk to represent the Limneæ," which in the former case he had found useful in consuming the slime produced by the decay of the vegetable matter.

Priority of publication is universally acknowledged to give a title to whatever honour attaches to a new discovery, and this I shall not dispute with Mr. Warington.' I may be permitted to state, however, that I have for some considerable time been pursuing experiments on the same subject.

At another point he states:

The possibility of similar results being obtained with sea-water had suggested itself to my own mind, as it has to that of Mr. Waring-

ton; and the subject of growing the marine Algæ had become a favourite musing, though my residence in London precluded any opportunity of carrying out my project.

And lastly:

Mr. Warington's suggestion of employing the phytophagous Mollusca to get rid of the accumulating vegetable matter, had not occurred to me; it is ingenious, and might perhaps obviate this inconvenience.

I cite the second and third quotes to show that it must have disappointed Gosse to always come in last behind Warington. It was Warington who got the credit for the proof of principle for both the freshwater and marine aquarium, and it was Warington who got the credit for introducing the term "aquarium" as it pertains to the keeping of fish in containers. I cite the fourth quote to show that Gosse was an honorable man and gave credit where credit was due. But then, so was Warington. In 1819, William Thomas Brande first elucidated the principle of the balanced aquarium, and then some 31 years later, Warington demonstrated the principle and, in the process, popularized it. Warington later said that it was Brande's statement that had incited him to set up his experimental tank with goldfish and *Vallisneria.*

Before leaving Gosse's 1852 article, I should mention Brock's interpretation of its significance on Warington. In his paper Brock writes:

As Warington's surviving jottings demonstrate, he became obsessed with the demonstration of his own priority. Gosse's claim in July 1854 to have "invented" an artificial seawater at a time when the newly-published The Aquarium was receiving adulatory reviews, only seemed to confirm what Thompson had suggested the year before.

As we shall see shortly, Gosse claimed no such thing, but for now it is necessary to explain the reference to Thompson. The first of the two unrecorded letters in the title of Brock's article was from Gosse to Warington (October 1, 1852), in which he stated,

Far as be any thoughts of jealousy on the subject of common interest; I rejoice to see that your success has far exceeded mine, as you have kept sea-water pure for six months.

In the remainder of the letter Gosse offers to provide the red algae of several species, as well as many species of zoophytes. It is clear that at this time, Gosse and Warington were on very friendly terms.

The other letter was from William Thompson (1822-1879), a Weymouth naturalist who carried out what many consider the first recorded attempt to use a photographic camera underwater. Although a friend of Philip Gosse, he wrote to Warington on May 9, 1853 informing him that, in his view, Gosse's work was unoriginal and that Warington was undoubtedly the real creator of the marine vivarium, i.e., the term used at that time for the saltwater aquarium:

I need not apologise for sending this as I consider you the first projector and originator of the Marine Vivarium. After reading the Chemistry of Creation by Robert Ellis 1850 in reference to the Chemistry of the Oceans and your papers in the *Gardeners Chronicle, Chambers Journal* and the *Annals*, I hesitate very much as to the propriety of according to Mr. Gosse any honour for the originality of his paper in the *Annals* for October 1852.

In short, Thompson praised Warington's work and derogated Gosse's. For some reason, Brock chose this to mean that Gosse's article would increase Warington's resentment of him. However, this was directly opposite to what Warington really thought. The following is from Warington's tour de force paper on the marine aquarium, "On Preserving the Balance Between the Animal and Vegetable Organisms in Sea-water" (Warington, 1853):

For a considerable period, after commencing these experiments, I was much troubled to obtain living subjects in a healthy condition, but having alluded to this, and the success of my investigations, in a short notice appended to a paper published in the '*Annals of Natural History*' for October 1852, my friend Mr. P. H. Gosse, who was then sojourning at Ilfracombe for his health, offered in the kindest manner possible to supply me with materials, and from that period he **has always most heartily responded to my wants.**

How Block could have missed this is puzzling, since the reference in listed in his bibliography.

GOSSE'S ARTIFICAL SEAWATER ARTICLE

Sometime during 1854 Gosse became interested in artificial seawater and to this end, familiarized himself with Edward Schweitzer's paper, "Analysis of Seawater as it exists in the English Channel near Brighton" (Schweitzer, 1839). In April of 1854 he conducted experiments using a modification of Schweitzer's formula, using both marine plants and animals (anemones and snails, but not fishes) as test animals. After six weeks they had survived and he wrote a paper about his research titled, "On Manufactured Sea-water for

the Aquarium." The paper was submitted to the *Annals* on June 9, 1854. In it he did not state that he had "invented" an artificial seawater. The credit was given to Schweitzer although August Laurent's analysis of the seawater of the Mediterranean was mentioned as well.

Gosse visited Warington in 1854 on two occasions at Apothecaries Hall, on January 16th and again on January 21st. Among other things, the feasibility of using artificial seawater was discussed. *Gosse, however, did not tell Warington that he already knew about Edward Schweitzer's analysis of the water of the English Channel taken off Brighton.* He did, however, learn that Warington had experimented with artificial seawater the previous year. Perhaps he feared that Warington would write a paper and get it published first, or perhaps he was just interested in what Warington thought about the matter, but whatever the reason, it turned out to be a monumental mistake, compounded by what Gosse said in his article that was published later in the July 1854 issue of the *Annals*. The following is an excerpt (Gosse,1854):

Several scientific friends to whom I mentioned my thoughts, expressed their doubts of the possi-bility of the manufacture; and one or two went so far as to say that it had been tried, but that it had been found not to answer; that though it looked like sea-water, tasted, smelt, like the right thing, yet it would not support animal life. Still, I could not help saying, with the lawyers, " If not, why not ?" - *Experientia docet*. I determined to try the matter for myself.

This was probably the most colossal blunder in the history of the aquarium hobby, since Warington was one of his "scientific friends" and he recalled Gosse discussing the matter with him in face-to-face meetings six months earlier. Warington responded in the *Annals* in December (Warington, 1854):

In the 'Annals and Magazine of Natural History' for July last, you published a short communication from Mr. Gosse, on the artificial formation of sea water, and having lately had my attention especially directed to this paper by a friend who wished to put the formula given into practice, I was surprised at the difference in the proportions of the ingredients as compared with what I had myself employed in the course of 1853, more particularly from the circumstance, that when Mr. Gosse called upon me in January last, and consulted me on the feasibility of the plan, I told him that there could be no difficulty in the matter, as I had made and had then in use several small quan-tities artificially produced, and that all that was required was that a good analysis should be taken as the basis for deducing the proportions, and at the same time referred him to the source from which I myself had worked, namely Dr. E. Schweitzer's analysis of the water of the English Channel taken off Brighton.

Warington then began the process of correcting Gosse's errors. Block, by the way, referred to Warington's comments as a "bitter note," clearly showing his bias against Warington since, as readers can see, Warington's reply was reasonable, gentlemanly and temperate. In fact, the strongest language he used was, "I was surprised." In any event, the editor speeded matters up and Gosse responded in the January 1855 issue of the *Annals* (Gosse, 1855):

If Mr. Warington supposes that I obtained from him one atom of information previously unknown to me, on the subject of making sea -water from its constituent salts, he is most thoroughly mistaken. He is no less wrong in saying that I "consulted" him; since I merely mentioned what was on my mind in familiar conversation.

I believe that Gosse knew about Schweitzer's seawater formulation and perhaps even had an idea about writing an article about it before he and Warington met in January of 1854. *However, a damning question is, if Gosse had previously known this information, why didn't he stop Warington and tell him so?* Not doing so could be considered as unethical behavior; certainly it is something one does not do to a friend. The result was that after Warington mentioned his meeting with Gosse in January and provided the correct details for the formula for seawater, Warington was the one more frequently believed. The following is from *The Leisure Hour* (Anon., 1855):

It is now some months ago that Mr. Gosse, the gentleman on whom the care of the marine vivarium belonging to the Zoological Society devolves, and to whom the public are indebted for some most interesting works on natural philosophy, pub-lished a formula for the generation of sea-water artificially, and having supplied some marine pets with the liquid, found that they thrived in it well. The analysis of sea-water chosen by Mr. Gosse was that made by Dr. Schweitzer, the formula of which it appears was suggested to that gentleman by Mr. Warington of Apothecaries Hall.

The article then goes on to present Warington's correct formula and also his recommendation to obtain the dried extract of seawater and regenerate it by the addition of water. A source for the extract was also provided in this article.

ADDITIONAL ARGUMENTS BY BROCK

Brock presented the following three points in his attempt to show that it Warington who was at fault:

It was Gosse, whose livelihood depended upon literary, activities, who had the time and the literary ability to write the best-selling A Naturalist's Rambles on the Devonshire Coast (1853) and The Aquarium (1854a); it was Gosse, not Warington, whom D. W. Mitchell contracted to supply the Zoological Gardens with an aquarium in 1853; and it was Gosse, not Warington, whose work formed the focus of Charles Kingsley's *Glaucus* in 1855.

With regard to Gosse's literary ability to write best -sellers, Warington was never in competition with Gosse. As Brock himself points out, Warington was a busy chemist with heavy day-to-day responsibilities for the standardization and prevention of adulteration of drugs; his aquarium research was only a leisure time activity.

With regard to the Zoological Gardens at Regent's Park, the aquariums - based upon Warington's new concept of the aquarium (Anon., 1852A) - were ordered from Sanders & Woolcott by David W. Mitchell, Secretary of the Zoological Society of London. Warington was associated with the freshwater exhibits and Gosse with the marine tanks. The freshwater tanks were a success but because of the design of the marine system, the seawater had to be replenished often and at appreciable expense.

Unfortunately, Gosse ceased his association with the Zoological Gardens somewhat under a cloud. Gosse's main contribution to the aquarium at the zoo was to provide marine plants and animals, including fish, for which he was to be paid. When he submitted his bill, Mitchell presented it to the Society's Council who directed him to try and persuade Gosse to reduce it. Gosse, replied, however, that if he wasn't paid then all collections would stop. Ironically, William Thompson offered to supply the animals.

Gosse requested that the matter go to independent arbitration with Thomas bell, a friend and fellow of the Zoological Society, representing his interests. The Council agreed and appointed James Scott Bowerbank - the man who inspired Mitchell to install a "vivarium" at the Zoological Gardens at Regent's Park - to represent the Society. However, the arbiters soon found that the reason the Council had disputed the payment was that the Council had discovered that Gosse had also collected and sent specimens to the Surrey Zoological Gardens during his time in Weymouth but charged the Zoological Society for this time. Understandably, the Council were only willing to remunerate Gosse for the animals he sent to the Zoo. The arbitrators found in favor of the Society, awarding Gosse only £150, which he quietly accepted. In view of all of the above, when comparing Warington's and Gosse's associations with the Zoological Gardens at Regent's Park, Warington's looks much the better.

Finally, Kingsley's *Glaucus* had little or nothing to do with the aquarium hobby. Kingsley, uncommon among clerics battling with the religious and moral problems introduced by Darwinian theories, saw no conflict between the teachings of science and the teachings of religion. Indeed, like Gosse, he consistently emphasized that by studying science one was in effect studying the work of God and getting to know him better. How much he knew about natural history, however, is in doubt. The following is a review of the book (Anon., 1856)

It is a very difficult thing to write a good review, more especially on subjects of a scientific nature: the review must not be too learned, or it will have too few readers; it must not betray ignorance of the subject by the writer, or it is simply useless. "Glaucus," if considered as a review, shares both these faults; it is much too learned, and at the same time reveals to us an alarming extent of ignorance in the writer on the subject of natural history.

Yet, few works published during the past year have been more read than "Glaucus"; go where you will, talk to whom you will, every one has seen "Glaucus," and speaks approvingly of it; some, indeed, suggest, that it would have been better "if so and so had been omitted," or object to a passage in this page or a sentence in that; but, taken as a whole, it is very seldom that a work receives so cordial a welcome.

Now, what is the secret of this success? Mr. Kingsley had acquired fame as a writer on other topics before he touched upon natural history; and though apparently very ignorant of this latter subject, still he brought all the trained skill of the author, and all the weight of a pen of no mean calibre, to bear upon the topic he chose to advocate. Imagine the excitement that would be caused if Macaulay or Dickens were to bring out a book on natural history; all the world would read it, to see what they could have to say on the subject; and we presume it has been with much the same motive that all the world has read Kingsley's "Glaucus."

GOSSE'S SEAWATER FORMULA

In Brock's article he writes:

In fact, the differences between Warington's and Gosse's formulae for artificial sea-water were not all that significant; Warington used slightly greater amounts of sodium, potassium and magnesium chlorides and magnesium sulphate, and also included the magnesium bromide and calcium carbonate and sulphate which Gosse had considered too insignificant to include. Because the major factors in the preparation of sea-water for aquaria are the total salinity and hence specific gravity, it is scarcely surprising that Gosse's much simpler recipe worked. He was writing for "practical people, to whom minute accuracy was impossible", Gosse (1855) informed readers of the Annals in reply to Warington's challenge. The fact that Gosse's formula was scientifically incorrect did not convict him of being a poor scientist. On the contrary, he declared, he had proved his hypothesis before publishing it, for the sea-water he had prepared on 21 April 1854, and written about in June, was still supporting life.

Actually, the differences were significant, ranging from 24 to 47 percent (see table). Furthermore, Gosse did not eliminate the calcium sulphate because he considered it was too small to be of significance, *but because he had difficulty in dissolving it and because Laurens found it in "excessively minute quantity."* However, Laurens found the potassium chloride in his Mediterranean seawater analysis to be even lower than his calcium sulphate - 0.001 versus 0.045 - so why didn't Gosse eliminate the potassium chloride also? Indeed, why did Gosse even bother with Laurens' analyses, since the Mediterranean sea is far from the English Channel where the most of the readers of his sea-water article lived and where Schweitzer's samples were taken?

Gosse was criticized for his decisions made when he modified Schweitzer's formula. The following was written by George Wilson (1818-1859), a Scottish chemist and physician, succes-

sively appointed chemical lecturer in the School of Arts, director of the Industrial Museum of Scotland and regius professor of technology in the university of his native city (Wilson, 1854):

The paper was a criticism on a communication made by Mr. Gosse, and contained in the 'Annals of Natural History.' Guiding himself by Schweitzer's analysis, Gosse employed chloride of sodium, sulphate of magnesia, chloride of magnesium and chloride of potassium. Into a mixed aqueous solution of these salts, Gosse introduced various species of marine plants and animals; and for six weeks they throve and flourished. Dr. Wilson considers, however, that the less abundant, but still essential, constituents of sea-water—such as carbonate of lime, sulphate of lime, phosphate of lime, fluoride of calcium, silica, iodine, and bromine—should not be absent, as these latter sub-stances are found in marine plants and animals; and it is therefore plainly evident that the medium in which they live ought to contain the same substances.

As for the early glowing recommendations for Gosse's formulation, none of them, including Gosse's own experiments and those of William Alford Lloyd involved keeping fish; the highest invertebrates studied were marine snails and anemones. In any event, Gosse's seawater formulation was not a success. From Hibberd, 1856: **"But artificial water is quite unsuited for animal life of any kind, until it has been brought into condition by means of growing weeds for eight or ten days, and for Crustaceans, Starfishes, and Fishes proper, it is not suitable till it has been in use for many months, and even then some species lose their health in it, and at last perish…"** and from Hughes, 1874: **"Much has been said about artificial seawater, but my experience is not very favourable to it - I found it crude and harsh in its effects on the anemones, they refused to expand, and shrank up and died."**

EPILOGUE

In his desire to be the first to write about artificial seawater - and especially in his desire to beat Warington to it - things turned out badly for Gosse. He admitted discussing the subject in his meeting with Warington in January 1854, but he did not explain why he failed to tell Warington about what he knew about the subject during these discussions. Added to this, Warington's rejoinder (Warington, 1854) clearly showed that Gosse's grasp of chemistry was woefully inade-

TABLE I
THE SCHWEITZER, GOSSE AND LAURENS FORMULAS COMPARED
The numbers are lbs./ 100 lbs. of water (= 10 Imperial gallons).

COMPONENT	(1) SCHWEITZER	(2) GOSSE	% INCREASE (1) OVER (2)	(3) LAURENS
Sodium chloride	2.7060	2.1875	24%	2.722
Potassium chloride	0.0766	0.0563	36%	0.001
Magnesium chloride	0.3666	0.2813	30%	0.614
Magnesium bromide	0.0029	-	-	-
Calcium sulphate	0.1407	-	-	0.015
Magnesium sulphate	0.2296	0.1563	47%	0.702
Calcium carbonate	0.0030	-	-	0.009
Magnesium carbonate	-	-	-	0.011

quate in this matter and so the scientific community regarded him as the one who should be credited with the idea, not Gosse.

It is a shame that these two friends parted ways over what should have never happened in the first place. Ironically, Warington was never seriously interested in seawater formulae; he much preferred to obtain the dried extract of seawater and regenerate it by the simple addition of water.

William Thomas Brande and the Balanced Aquarium Principle

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, October 10, 2015)

William Thomas Brande (1788–1866) was born in 1788 at Arlington Street in southwest London, the youngest of the six children of Augustus Everard Brande (1746–1834), an apothecary (an apothecary was a medical professional who formulated and dispensed materia medica to physicians, surgeons and patients; the modern pharmacist in American English - or chemist in British English - has taken over this role). Brande was a scion of a wealthy family of apothecaries with appointments to the Hanoverian and London courts stretching back to near the beginning of the eighteenth century. Brande's father, born in Hanover (naturalized 1784), was apothecary to Queen Charlotte between 1783 and 1801.

FAMILY PROBLEMS

From about 1794 until 1797 Brande received a rudimentary classical education at a private school in Kensington. Between 1797 and 1801 he attended Westminster School, where he made fair progress in classical and general knowledge. In the latter year Brande's father retired from the court and moved to Chiswick, a district of West London. As a consequence Brande met the chemist Charles Hatchett, who had a small chemical manufacturing business there and who was to exercise an immense influence over Brande's choice of career and its course. Hatchett had a private laboratory in Roehampton, southwest London, where he allowed Brande both to assist him and to undertake his own chemical experiments. This inculcated in Brande a taste for chemistry which never left him. Although his father wished him to enter the church, Brande decided to study medicine - then the only route to a career in chemistry. His decision may explain the rather strained relationship which Brande had with his family; his father's will made much less provision for him than for his siblings.

CAUGHT UP IN THE WAR

From 1802 until 1810, Brande was indentured to his elder brother, Everard Brande (1776–1868), who was then running the family business in Arlington Street. During his apprenticeship he visited Hanover where he pursued scientific and linguistic studies at Göttingen and Brunswick following the Treaty of Amiens in 1802 that temporarily ended hostilities between the French Republic and Great Britain during the French Revolutionary Wars. When the war recommenced in April 1803, Brande had difficulty returning to London but he finally escaped via Hamburg on a Dutch ship. By 1804 he had resumed working with his brother and in the same year he also commenced studying at the Great Windmill Street School of Medicine and at St. George”s Hospital, where he studied chemistry. According to Brande, at this time his brother “threw every

William Thomas Brande (1788-1866).

obstacle in the way of my chemical progress that was decently in his power." Nevertheless, he "found time … to read and often to experiment in my bedroom late in the evening."

BRANDE MEETS HUMPHRY DAVY

In 1801 Brande, still at Westminster School, was introduced to Humphry Davy who had then just been appointed professor of chemistry at the newly founded *Royal Institution*. Davy (1778–1829), the son of an impoverished Cornish woodcarver, rose meteorically to become a leader in the reformed chemistry movement initiated by Antoine -Laurent Lavoisier - albeit a critic of some of its basic premises - and a pioneer in the new field of electrochemistry.

On his return from Hanover, Brande renewed his acquaintance and "as a result, his zeal in the pursuit of chemistry was greatly augmented." From 1805 he started to attend Davy's lectures at the Royal Institution and occasionally absented himself from Arlington Street or Great Windmill Street in order to do so. In 1808 Brande and Davy were among the founders of the Animal Chemistry Club.

Despite his youth and family opposition Brande was able to conduct original chemical research, some of which was published in the *Philosophical Transactions of the Royal Society*. Such was his ability that in 1808, four years after he started studying there, Brande was lecturing at Great Windmill Street. This gave him membership of the London lecturing circle and in the next few years he delivered lectures on pharmaceutical chemistry at the medical school in Cork Street and on materia medica. In 1809, at the age of twenty-one, he was elected a fellow of the *Royal Society*.

In 1812 Davy resigned his professorship of chemistry at the *Royal Institution*. Brande moved into the Royal Institution and later in the year was also appointed superintendent of the house. Brande also replaced Davy in giving lectures on agricultural chemistry to the board of agriculture, but gave only one series before the board was dissolved the following year. In 1813 he was also appointed professor of chemistry to the *Society of Apothecaries*.

Brande's appointment to the *Royal Institution* marked an important change in his career. Unlike most other lecturers in the period, who earned their living by giving itinerant lectures, Brande was now permanently in an institution made famous by Davy and possessing the best-equipped laboratory in Britain. This did not mean, however, that he ceased giving lectures elsewhere. For instance, in 1819 he delivered the first lecture and course at the newly built London Institution, which had been founded in imitation of the *Royal Institution*, and he gave other courses there in later years.

BRANDE'S REPUTATION SPREADS

Brande's meteoric rise within the London scientific community was confirmed during 1813 by

Humphrey Davy (1778–1829)

his election to membership of the *Royal Society Club* and by the award of the society's Copley medal for a paper on experiments dealing with the alcoholic content of wine and other drinks. In 1816 he succeeded W. H. Wollaston, at the latter's suggestion, as one of the two secretaries of the society, a position he held for the following ten years. By 1818 he was sufficiently financially secure to marry the younger daughter of his patron, Anna Frederica Hatchett (1797–1881). His marriage on July 4th entailed his moving out of the *Royal Institution*. They had two sons and three daughters.

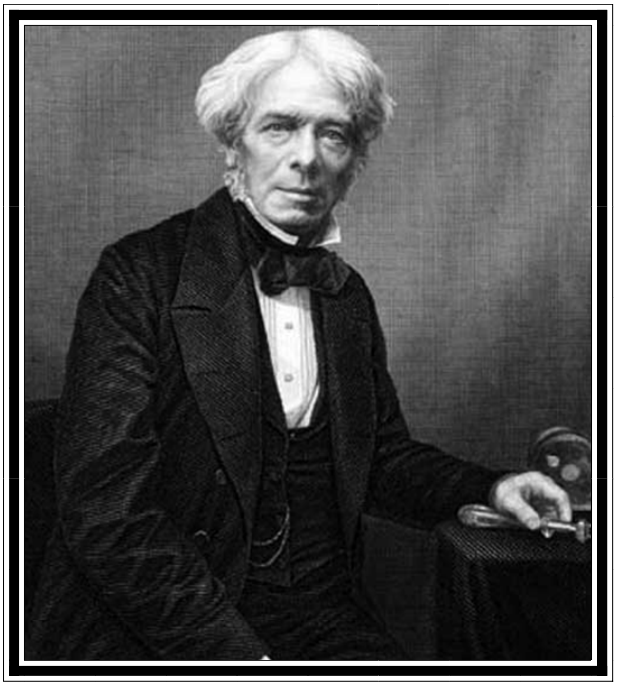
According to Brande's later recollection:

From 1815 to 1848, I also delivered a series of lectures and demonstrations on theoretical and practical chemistry in the Laboratory below [the main lecture theatre of the Royal Institution]. They were intended for all denominations of students, and were given thrice weekly, from October to May. They were the first lectures in London in which so extended a view of chemistry, and of its applications, including technical, mineralogical, geological and medical chemistry, was attempted.

These lectures were mainly attended by students from Great Windmill Street and, from 1828, from St George's Hospital. Initially he delivered these courses alone with the help of Michael Faraday, who as the assistant chemist at the Royal Institution was responsible, until 1825, for preparing and executing lecture demonstrations for Brande. Michael Faraday (1791-1867), who like Davy came from a very poor family, became one of the greatest scientists in history. His achievement was remarkable in a time when science was the preserve of people born into privileged families. The unit of electrical capacitance is named the farad in his honor. In 1824 Faraday gave some of the lectures and from the following year the course was given jointly. In 1846 Brande tried to drop them but was persuaded to continue, though at a reduced level. Brande also gave many courses of Saturday lectures on specific topics at the *Royal Institution*, delivered twenty-eight Friday Evening discourses between 1826 and 1852, and gave seven series of Christmas lectures between 1834 and 1851.

BRANDE'S PUBLISHING CAREER

Brande's lectures at the *Royal Institution* served, at least initially, as the basis for his major publications. In 1817 he published "Outlines of Geology" (2nd edition, 1829) while in 1819 his "Manual of Chemistry" appeared; both were based on his lectures. The "Manual of Chemistry" became a hugely successful and influential textbook and formed the model for many subsequent chemical textbooks by other authors. It went through six English editions by 1848 and was translated into several languages. He repeated the formula with his "Manual of Pharmacy," which, published in 1825, had reached its third edition by 1833. Then followed his "Dictionary of Materia medica" (1839) and the highly successful "Dictionary of Science, Literature, and Art," published in 1842. This latter went through many



Michael Faraday (1791-1867

editions and was still being published posthumously in 1875.

His last major publication, "Organic Chemistry" (1854), was based on his last course of lectures at the *Royal Institution*, in 1852. The link between Brande's publications and the institution also extended to his editing, between 1816 and 1830, of the *Quarterly Journal of Science* which, although not an official publication of the *Royal Institution*, was nevertheless closely connected with it. It contained original papers, details of lectures given at the institution, summaries of papers published in overseas journals, and book reviews, and provided a quick route to publication for those associated with the *Royal Institution*. Faraday helped Brande with the work, preparing summaries of papers, and when Brande was away was completely in charge. The *Quarterly Journal* was a valuable general science journal at a time when there were very few such.

BRANDE AND THE ROYAL MINT

Brande was active in promoting the study of chemistry. In 1836 he was one of the original members of the senate of the University of London and in 1846 was appointed an examiner in chemistry, a post he retained until 1858. He was one of the founders of the *Chemical Society* in 1841 and was among its first vice-presidents, a post he held from 1841 to 1846. He was president from 1847 to 1849, during which period he oversaw the incorporation of the society and commencement of publication of its *Quarterly Journal*.

In 1823 the government consulted Brande on the manufacture of iron and steel to be used as dies for coins at the Royal Mint. This was the start of his long association with the mint in which, once again, Hatchett played some initiating role. Two years later Brande was appointed clerk of the irons and superintendent of machines. Though these posts involved much administrative work they provided an annual income of £700 and accommodation at the mint which the Brande occupied after leaving Grafton Street. Following the royal commission of 1848, the organization of the mint was reformed and in early 1852 Brande was appointed at an annual salary of £900 to the newly created post of Superintendent of the Coining and Die department, a post he held until death. One of the requirements of the reformed mint was that employees must have no other paid employment so Brande had to resign his professorships at the *Society of Apothecaries* (of which he was master for the year 1851–2) and the *Royal Institution*, though he was made an honorary professor there. He also had to cease consultancy work for the various London water companies. He had undertaken this kind of work for many years and in the preceding three had played a major role in the extremely controversial issue of how to provide a new water supply for London.

"It's murder during these power cuts."

A DISAPPOINTING CAREER

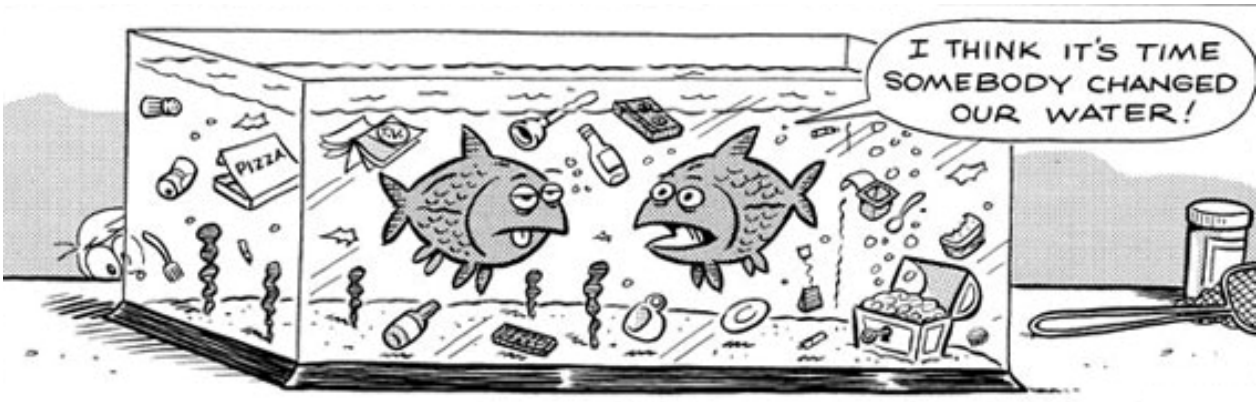
Brande's contribution to science and its practical application was recognized by the award of a Doctor of Civil Law by the University of Oxford in 1853. Nevertheless, most of his contemporaries believed that he had not fulfilled his early promise. According to John Davy, Davy became "very much disappointed" with Brande, whom he believed to be "mercenary and had no lofty views." Brande was not a brilliant lecturer when compared with his predecessor at the Royal Institution, Davy, or with his successor, Faraday, but these are hardly fair comparisons and the fact that he was able to sustain his lectures to medical students and others for more than thirty years certainly helped keep the institution in a reasonable financial state. A contemporary noted that Brande was "distinguished for the clearness of his [lecturing] style, for the methodical arrangement of his matter, as well as for the admirable selection and performance of his experimental illustrations." Nor, unlike Davy and Faraday, did Brande make any scientific discovery of major importance. Yet in the application of science to medicine, to water analysis, and to coining, Brande made a significant contribution to bringing science and technology together in the nineteenth century. He died on his seventy-eighth birthday at his country house in
Tunbridge Wells in 1866 and was survived by his wife and children.

THE BALANCED AQUARIUM PRINCIPLE

The first edition of Brande's "Manual of Chemistry" appeared in 1819 and was in one volume containing 699 pages. Subsequent editions tripled this. Although Brande's book had chapters, Brande numbered sections with each chapter consecutively over all chapters. This has caused some confusion since a section in the first edition numbered 1000 might be numbered 2000 in another edition even though the material is identical.

The Manual contains a chapter "Of vegetal substances" and another "Of animal substances." The following appeared in the vegetal chapter:

As the plant advances to perfection, it becomes dependent upon the air and soil for its nutriment: the roots absorb moisture and other materials; and the leaves, while they exhale moisture, frequently absorb carbon from the carbonic acid present in the atmosphere, and evolve oxygen. This evolution of oxygen takes place while plauta are exposed to the solar rays, and appears one of the most efficient causes hitherto suggested of the purification and renovation of the air. In the night-time, the leaves of plants always exhale carbonic acid, and at all times if the leaves be dying or unhealthy. There are also certain plants which appear under all circumstances rather to deteriorate than renovate the air; to the whole, however, the balance is in favour of amelioration (Davy's *Agricultural Chem. 4to.* p. 195) though the disappearance of the enormous quantities of carbonic acid gas continually pouring into our atmosphere,



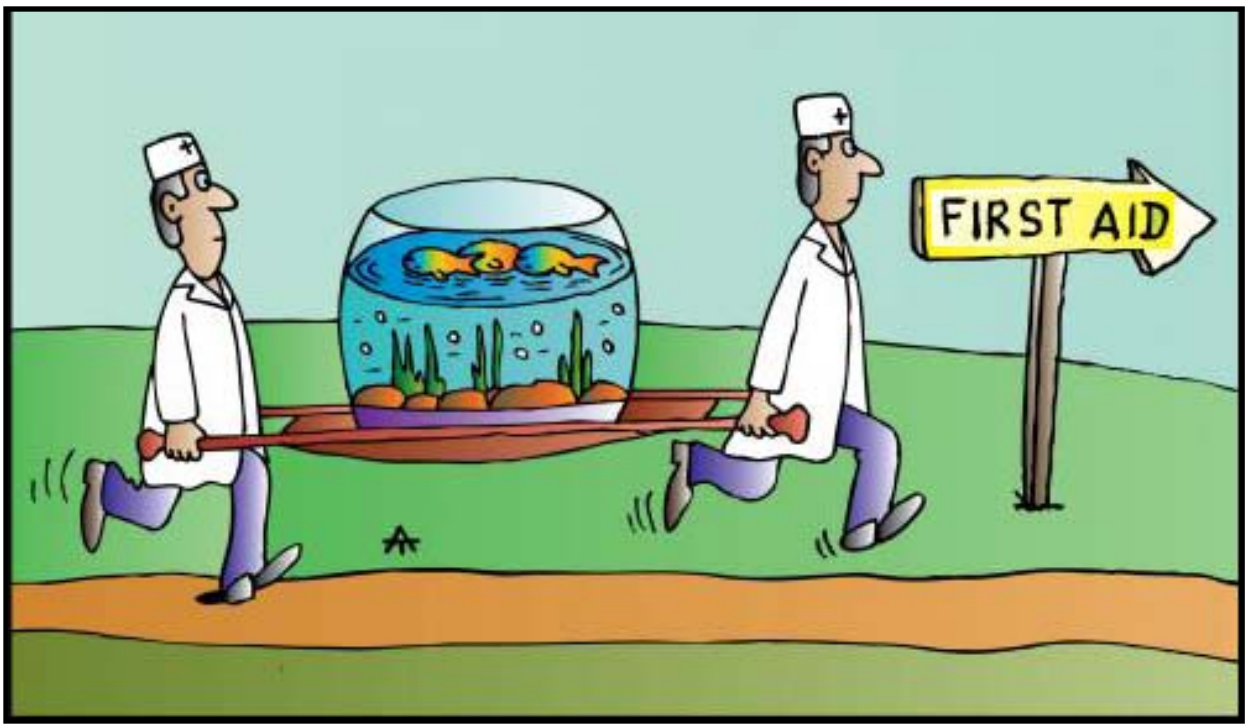
can, I think, scarcely be referred to the purifying action of vegetables alone.

Under certain circumstances, the leaves of plants also absorb a considerable portion of aqueous vapour and water, as is shown by the resuscitation of a drooping plant, on sprinkling it with water, or exposing it to a humid atmosphere. It is probable that, in healthy vegetation, the absorption of water by the leaves takes place in the night season chiefly, and that their principal function in the day is that of transpiration. Upon these subjects the reader may consult Saussure's *Richerches Chimiques sur la Végétation.*

The following appeared in the animal chapter:

Different animals require very different quantities of oxygen for the purposes of respiration. Man, and warm-blooded animals, consume the largest quantity; the amphibious tribes not only require less, but can breathe in an atmosphere which will not support the life of the former; and many insects take such small quantity, as sometimes to have been supposed capable of living without air, which is not the case. In the production of carbonic acid all animals agree, and consequently the nature of the deterioration suffered by the air is similar throughout the animal creation.

Fishes breathe the air which is dissolved in water; they therefore soon deprive it of its oxygen, the place of which is supplied by carbonic acid; this is in many instances decomposed by aquatic vegetables, which restore oxygen, and absorb the carbon [here Brande refers to the section in the vegetal chapter quoted above**]; hence the advantage of cultivating growing vegetables in artificial fish-ponds. It has been ascertained by Biot, and verified by others, that the air- bladders of fish that live in very deep water are filled with a mixture of oxygen and nitrogen, in which the former greatly preponderates: but in fish that are taken near the surface, the nitrogen is most abundant. In the *trygla lyra* [**actually *Trigla lyra*, the Piper gurnard**], always caught in very deep water, the air bladder contained 87 *per cent,* of oxygen: in the carp and roach, according to Fourcroy and Priestley, the air-bladder con-**



tains little else than nitrogen.—BIOT, *Memoires d' Arcueil,* i. & ii.

It is in the foregoing paragraph that Brande made the first elucidation of the principle of the balanced aquarium to appear in print. In other words, Brande first elucidated the principle, and then some 31 years later, Warington demonstrated the principle and, in the process, popularized it. Warington later said that it was Brande's statement that had incited him to set up his experimental tank with goldfish and *Vallisneria.*

Note: Antoine François, comte de Fourcroy (1755-1809) was a French chemist and a contemporary of Antoine Lavoisier. Fourcroy collaborated with Lavoisier, Guyton de Morveau, and Claude Berthollet on the *Méthode de nomenclature chimique*, a work that helped standardize chemical nomenclature.

With regard to Biot, the *Society of Arcueil* was a circle of French scientists who met regularly on summer weekends between 1806 and 1822 at the country houses of Claude Louis Berthollet and Pierre Simon Laplace at Arcueil, then a village 3 miles south of Paris. Other famous members of the group included Alexander von Humboldt and Jean-Baptiste Biot. Biot (1774-1862) was a French physicist, astronomer and mathematician who made many contributions to the scientific community in his lifetime – most notably in optics, magnetism and astronomy. He established the reality of meteorites, made an early balloon flight (he reached a height of 23,000 feet, quite dangerous without supplementary oxygen) and studied the polarization of light. Biot also discovered the mineral biotite, a name used for a large group of black mica minerals that are commonly found in igneous and metamorphic rocks.

A HISTORY OF THE AQUARIUM HOBBY IN THE NETHERLANDS

By Albert J. Klee, Ph.D.
(Aquarium Hobby Historical Society of America,
Facebook Files, November 28, 2015)

WHAT'S IN A NAME?

Holland? Or the Netherlands? And what's the difference between the two? The Netherlands is often referred to as Holland, nevertheless, the official name of the country is the (Kingdom of the) Netherlands. The Netherlands consists of twelve provinces. Two of them, North and South Holland, are the two provinces that together make up "Holland." Due to the maritime and economic power of these provinces in the 17th century, the Netherlands became known worldwide as "Holland." To make matters even more confusing, the inhabitants of the Netherlands are called Dutch, except in the two provinces of North Holland and South Holland where they are called Hollanders! You pays yer money and takes yer choice!

THE FIRST INTRODUCTION OF THE GOLDFISH INTO EUROPE

In their 1968 book, *The Goldfish*, by George F. Hervey and Jack Hems, the authors state:

Bloch [i.e., Marcus Elieser Bloch (1723-1799), a German medical doctor and naturalist generally considered one of the most important ichthyologists of the 18th century], in his *Oeconomische Naturgeschichte der Fische Deutschlands* (1784), records that goldfish were introduced into England in 1611, and he cites Pennant's *British Zoology* as his authority. But, as Pennant gives the year as 1691 it is clear the Bloch's 1611 is a misprint, even if we did not know that misprints were very common in eighteenth-century books.

It is too much of a coincidence in the date to suspect otherwise than that this error in Bloch's book might also be the source of a claim regarding Portugal. It is widely asserted that goldfish were introduced to Portugal in 1611 and from there introduced to other parts of Europe. The wording of these assertions follows each other so closely that it is obvious that they have been copied over and over from a single source. Zhang Zhong-ge (1984) suggested that the goldfish may have arrived in Portugal in 1611, were introduced into England about 1705, in Scandinavia before 1740, in France about 1750 and in Holland between 1753 and 1754.

In the zoological literature, the goldfish is first referred to Portugal by Vandelli (1797) under the scientific name *Cyprinus auratus* and the common name "Peixe da China" (this suggests a probable introduction into Portugal from China). However, the goldfish is not mentioned in Baptista's account in 1789, suggesting that the introduction of the goldfish to Portugal occurred sometime between 1789 and 1797, not 1611. That Zhang Zhong-ge's dates are either not credible or else suspect is shown by the following.

SO WHO GOT THE GOLDFISH FIRST?

Towards the end of the Ming Dynasty (1644 A.D.) every Chinese household had a small (or large) goldfish basin. This was the centerpiece of the dwelling and brought people much pleasure, acting as a source of interest and entertainment, and already the first cultivated forms were appearing, such as the bubble-eye, the celestial and the twin-tailed Lionhead. In 1643 the Jesuits arrived in Hangzhou where they proceeded to construct their churches. Some of the priests, however, became interested in a local farm where goldfish were being bred. From these ponds the Jesuit, Martinus Martini, brought 10 goldfish to Holland in 1643 and thus this date is the first documented introduction of goldfish into Europe (Martini, 1663).

A bronze statue of Dr. Job Baster (1711-1775) in the town of Zierikzee. The statue represents Baster in 18th century costume with a goldfish in his right hand.

JOB BASTER

Job Baster, sometimes written Hiob Baster (1711-1775) was a Dutch physician and naturalist who devoted himself almost entirely to the study of medicine and natural history. He studied and took his degree of doctor of medicine at Leiden in 1731. Albrecht von Haller (1708-1777), a Swiss anatomist, physiologist, naturalist and poet, often referred to as "the father of modern physiology, thought his thesis, *De Osteogenia* [the study of the formation of bones], worthy of a place in his collection. Professors like Herman Boerhaave, a Dutch botanist and physician of European fame (1668-1738), regarded as the founder of clinical teaching and of the modern academic hospital and sometimes referred to along with his pupil von Haller as "the father of physiology." trained him in scientific methods and how to study natural phenomena. After his studies he visited the hospitals and botanical gardens in Paris and London where he became friends with Philip Miller (an English botanist) and Hans Sloane (an Irish physician and collector of natural history objects). Afterwards he settled as a physician in his native town of Zierikzee, a small city located in the Dutch province of Zeeland.

In 1738 he became a Fellow of the Royal Society in London on recommendation of Boerhaave and Willem Jacob's Gravesande (1688-1742), the latter a Dutch mathematician and natural philosopher, chiefly remembered for developing experimental demonstrations of the laws of classical mechanics. Baster was a versatile scientist; in addition to his work as a physician he contributed papers about medicine, horticulture and marine biology to the *Philosophical Transactions* and the V*erhandelingen der Hollandsche Maatschappij der Wetenschappen*. He was well-known for his translation of Philip Miller's work on horticulture and also maintained a vast correspondence with the leading biologists of his time.

In 1758 he came into possession of some farmland in Zierikzee called Zonnehof that had trees and two ponds. Baster used it to grow plants for his research and in the ponds he managed to cultivate Chinese goldfish. That was unique in the eighteenth century in the Netherlands. Thanks to his (corresponding) memberships in many learned societies, through a contact in England he came into possession of twelve gold fish. The following is translated from his book, "Physical Amusements, with the purport of some observations about some sea plants and sea insects, and in addition, seed houses and egg nests" (Baster, 1762-1765):

A shipment of young goldfish were sent by the British from China in 1728 via St. Helena Island on the East Indian ship, *The Houghton*, captained by Philip Worth, a man held in high regard by the famous Merchant, Sir Mathew Dekker. From that moment on they

came over on several ships to England, put in ponds and bred. From there they were sent along into Europe where they have become well-known.

In the month of November 1758, I received the first twelve of these fingerlings from England. I put eight in one pond and four in another of my garden. Except for about four, which I saw floating on the water after they died, I never saw any of them again. I have heard that this accident has happened to many other people who have put these fingerlings in their ponds. Perhaps this happens when the fish are poured into the water from a bucket and, becoming fearful, quickly shoot to the bottom and are so deeply embedded there that they cannot get out of the mud and thus smother. Therefore I have found it advisable using cords to suspend a net under the water and to keep the fish there until they are at ease and swimming.

In the month of October in 1759, I again received another twelve and put them all in the pond I had put the first four in. During that winter which was quite severe I had, because the water was unusually clear, sometimes seen the fish amusing themselves in the bright sunshine, even though deep under the ice. In February of 1790 I received six more, two of which died within a few days. Sixteen now remained and from them I obtained all of my offspring.

In the last of April and during the month of May 1790, they could be seen playing, and sometimes six or eight males chased a female, swimming behind her. When she had chosen one of her suitors, they swam pairwise for a while. They took special positions in the water and, lying on her side, she rubbed her belly on him and expelled her roe. They made no distinction regarding color, some sporting gold, silver and black, all one with one another, and treated as one kind of fish.

During the month of June, and therefore four or five weeks after spawning, one began to see the small fish, in which then only three or four lines had any length, and the grayish green of their coloration. Six weeks after they started to fatten up there were some shimmering silver or white patches between the dorsal fin and tail that, as the fish grew older, developed into one run and a stripe of half a line width. The fish now are grown up to an inch and a half long, and started eating little crumbs of bread, having up to this time been feeding on the water-insects that travel in the vegetation and along the lining and edges of the pond.

In Holland he became famous for this introduction of this common goldfish (Kin-Yu or Chin-yu) to the Netherlands and breeding it on Dutch soil. From his ponds in Zierikzee he handed them out to many acquaintances and thus began the march of goldfish across the country and beyond. In a letter (in Latin) to Carl Linnaeus in 1763,

A pair of Kin-Yu by the French artist, Edme Billardon-Sauvigne.

Jac. P. Thijsse (1865-1945). Interest in aquatic animals in Holland was first aroused by Heimans and Thijsse with the publication in their book, "In Pond and Stream," 1895.

Baster mentioned that he had a lot of goldfish in his ponds, and that they had withstood the winter cold. He even offered to send some to Linnaeus if some means could be found to send them quickly and safely.

HEIMANS AND THIJSSE

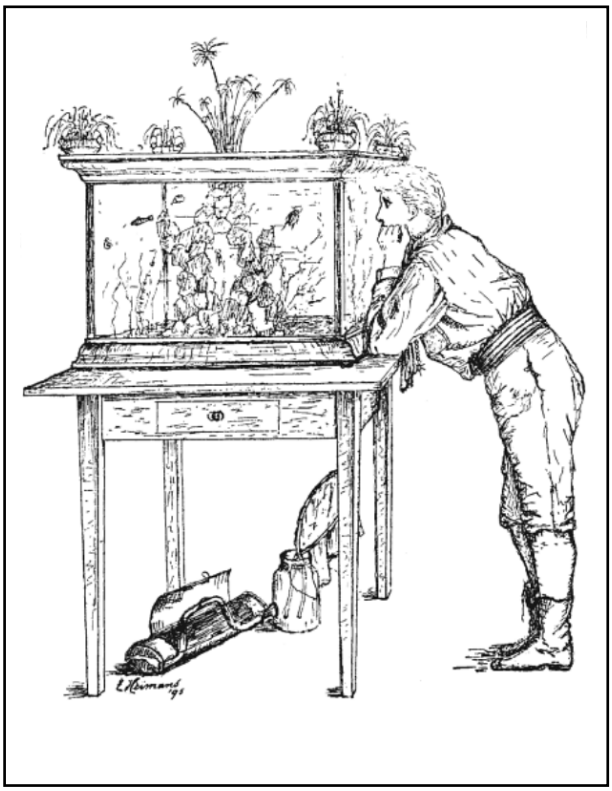
In the Netherlands, interest in aquatic animals was first aroused by Heimans and Thijsse with the publication in their book, "In Pond and Stream" (Heimans and Thijsse, 1895).

Jacobus Pieter Thijsse (1865-1945) was born in Maastricht, a town in the southeast of the Netherlands, his father serving as a sergeant in the second infantry regiment. Three years later the family moved to the small fortified town of Grave, and in 1873 his father left the service and found work in the larger town of Woerden. In those years both towns were enclaves in a vast, agricultural and sparsely populated landscape, which was hardly affected by industry and major infrastructure projects.

Both in Grave and in Woerden, Thijsse lived on the edge of town and he loved to go out into the fields and hang out along the waterfront. With friends from Woerden he liked mucking about in nature, where "We would eat huge meals of potatoes roasted under the ashes, wild strawberries, prepared eel which we caught and also a lot of 'Goats Beard,' a kind of chicory." But nature was not only a great place to play or get out of mischief. The young Thijsse wandered around alone to marvel at all that lived and grew there. He found it endlessly delightful to walk and revel in nature. He would call himself later by the Afrikaans word, "alleenloper" because loner in Dutch sounded too negative.

On these trips he tried to learn as much as possible about plants and animals and to study their characteristics. In plants it was easier than in birds, because how could you see what a tree-creeper looked like exactly? Thirty years later he wrote how he did it in his youth: "In the old days

Jac. P. Thijsse (far left) and other members of the Association for the Preservation of Nature (which he founded) during an excursion on the island of Textel (1908).



Boy with aquarium and vasculum, in *In sloot en plas* (Pond and Stream). A vasculum was a container, usually made of tin, used by botanists to transport plants without crushing them and by maintaining a cool, humid environment.

you took a rifle or a blowpipe or a catapult and shot the bird dead; then you could see everything at your leisure." This patriarch of Dutch nature conservation had a long way to go!

Of course the young Thijsse could not always study nature. As a clerk at a notary's office, Thijsse's father earned a reasonable salary so at age twelve he did not have to go to work. On his fourteenth year he enrolled in the Municipal Training College where his favorite subject was the History of Nature.

In 1883, at the age of eighteen, Thijsse obtained his teacher's certificate and after a few unsuccessful applications he received an appointment at the end of the year at a Second Class C school. (A Class C school was intended for school children of "limited means" and the school was poor. The poorest children went to a free "grade" school.)

Like most of his colleagues, Thijsse wanted to move higher up in the hierarchy of comprehensive education and therefore looked to the achievement awards. He took them in French, English and German, plus the main one by which he could teach in a primary school. In 1887 he was rewarded for these efforts with a promotion to teacher "second class."

Two years later he was hired at the teacher training college called Leerschool. However, his ambitions went far beyond that and in this period he applied to several better paying institutions, including even a position at the Eglise Hollandaise in St. Petersburg, a Dutch school for children of the elite who lived there. But before he received an answer from Russia, he had already found a job on the island of Textel, a municipality and an island in the province of North Holland.

In the so-called "French School" of Texel, Thijsse carried on all kinds of educational reforms. He took his students out of the classroom and he also became the first lifeguard in the Texel pool. He also introduced them to the then elite game of soccer. Thijsse took a deep interest in birds. Before that he was mainly occupied with plants and landscapes, but here he became fascinated by the many birds that he had never seen in Amsterdam, such as silver plovers, ducks and Stone Mountain runners. Here he first wrote about nature. After he had come into contact with English birders who had discovered Texel as particularly rich bird island, he wrote for the British popular science magazine, *Science Gossip*, his first article being about the breeding birds of the island.

Thijsse married in 1891 and the couple returned a year later returned to the capital. He was appointed head of a primary school on the outskirts of the Jordan area and as he no longer had his own classes was reasonably free to experiment on his

own time. He introduced the "walking school" where students left the classroom for an object lesson. The goal here was that students become familiar with nature, but history and cultural subjects were also given plenty of attention.

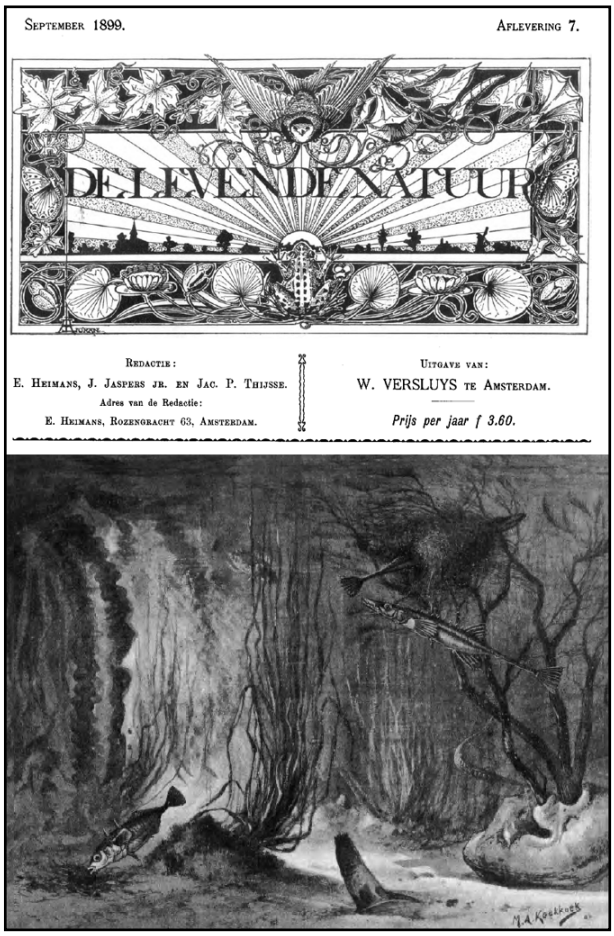
Numerous educational reformers also propagated the phenomenon of a school walk. They felt that the old education techniques where only dry book knowledge was taught were insufficiently suited to the interests and experiences of children. One of the innovation-minded teachers of the time, Eli Heimans, published a book in in 1893 called, "The Living Nature." This textbook was not, as was usual at the time, written by a professional biologist, but the material - based upon the flora and fauna of the Amsterdam Sarphatipark - was described in an attractive and lively way. (The park is named after the Jewish doctor and philanthropist, Samuel Sarphati (1813-1866). This small - it stretches for only two blocks - rectangle of green in the middle of the trendy De Pijp area is one of the nicest in Amsterdam. Shortly thereafter Thijsse and Heimans met, they quickly hit it off well and planned to write books together.

Eli Heimans (1861-1914) grew up with four brothers and two sisters in an Orthodox Jewish family in Zwolle, the capital city of the province of Overijssel, where his father had a silk-dying factory. When the company ran into financial difficulties, Eli had to leave the fourth class of the State higher secondary school to help his father. As a 'traveler' he had to pick up paint on the farm as well. During these hikes, his love of nature - instilled in him by his mother - grew stronger and he made his first sketches. Heimans went to the evening secondary school and there he revealed himself as a great writer. One of his essays resulted in a school prize in the form of Willem Frederik Reiner Suringars 1876 book, "Zakflora," a manual for identifying the plants growing wild in the Netherlands, which henceforth he would always carry with him on his trips. Along with his developing knowledge of the indigenous flora he had a chance encounter with "Herbal-Marie." Through this woman, who collected herbs for local pharmacists, the young Heimans came to know many wild plants.

Besides a great interest in living nature, Heimans developed an equally strong interest in the geology and genesis of the earth. The germ for this was already awakened in his early childhood. At home, he had to hear about the biblical creation story many times. "It was like God created the world over and over again in my presence," he wrote later. Doubt began to grow and he was carried by the waves of a movement that Darwin put in motion and in the years 1860 to 1880 brought the scientific world into great turmoil. Fossils, which bore the title of monstrosities before Darwin's time, taught him and many others that the earth must be much older than that assumed in the Bible.

In 1879 Heimans won the achievement award for mathematics, followed a year later by the award

Eli Heimans (1861-1914).



De Levende Natuur **(Living Nature), with the subtitle** ***Tijdschrift voor de Natuursport*** **(*Magazine of Nature Sport),* published by Thijsse, Heimans [and Jaspers, Jr.] in 1896.**

of assistant teacher. In 1882 he was appointed as the third teacher at a public elementary school in a poor inner city of Amsterdam. After obtaining the certificate of headmaster one year later, Heimans was appointed second teacher at a newly erected school that soon gained a reputation for its talented teachers. This privileged position certainly helped the teacher in Heimans to develop fully, because he was a dedicated educator at heart.

In Amsterdam Heimans was member of the *Netherlands Teachers Association of the Pedagogical Study Club*. Later, in 1897 with other members of the Association, he started the educational journal *New Year*, which thousands of teachers counted as subscribers. Heimans also wrote children's books, and in 1889 he published the popular boy's book, *Willem Roda.* As an author, he had a gift of writing for "ordinary people"; an elitist position was alien to him. Heimans' business sense was not strong, however; an Amsterdam publisher offered him one-hundred guilders for the rights to the book and, after some hesitation, he accepted and waived all rights to future publication. The book, to Heimans' dismay, was reprinted many times.

The innovations in education at the end of the 19th century were based on learning how to understand one's own familiar environment. The education in natural history in those years was barren and dry; a book reading or a look at a wall-chart was typical. No living material was present or used in the classroom. Heimans made a difference by taking animals and plants to school. He also went as far as possible with his pupils to Amsterdam's Sarphatipark, his favorite excursion site. He restrained during these lessons and the school walks from mentioning the names of plants and animals, and mostly tried to teach his students to see the connection between life and form. Heimans' ideas about a new form of science education were brought together in his book, *De levende natuur. Handleiding bij het onderwijs in de kennis van planten en dieren op de lagere school, in het bijzonder voor groote steden* (Living nature, a manual of education in the knowledge of plants and animals in elementary schools, especially for large cities) which appeared in 1893.

In 1894 Heimans and Thijsse published *Langs dijken en wegen* (Along dikes and roads) the first of a series on butterflies, flowers and birds. The booklet, designed for schools, was initially received lukewarmly, and the reviewer of an education magazine suggested that boys preferred to read about "…Indians and dark murder novels and girls were mostly interested in romance: What are butterflies and beetles and birds to our

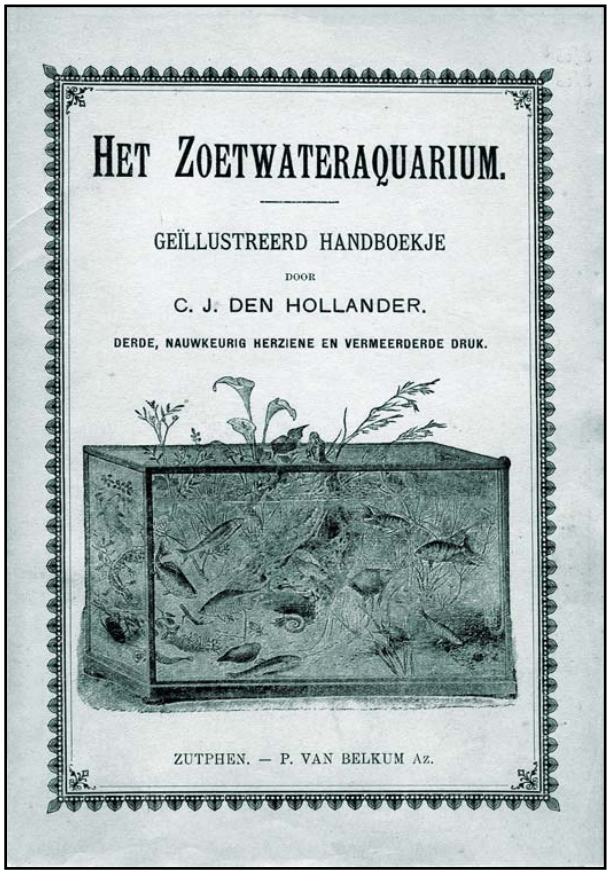
12-13 year-old youngsters?" In spite of this, the book and the others that followed were commercially successful.

The next to be published was *In sloot en plas* (In pond and stream, 1895). This was significant since in the Netherlands interest in aquatic animals was first aroused by this book. The accompanying figure shows a drawing from the book made by Heimans of a young boy observing the catch in a freshwater aquarium. Below the tank are a net and a vasculum. A vasculum or botanical box was a stiff container in the form of a cylinder and typically made from tinned and sometime lacquered iron, used by botanists to keep field samples viable for transportation. The main purpose of the vasculum was to transport plants without crushing them and to keep them in a cool, humid environment.

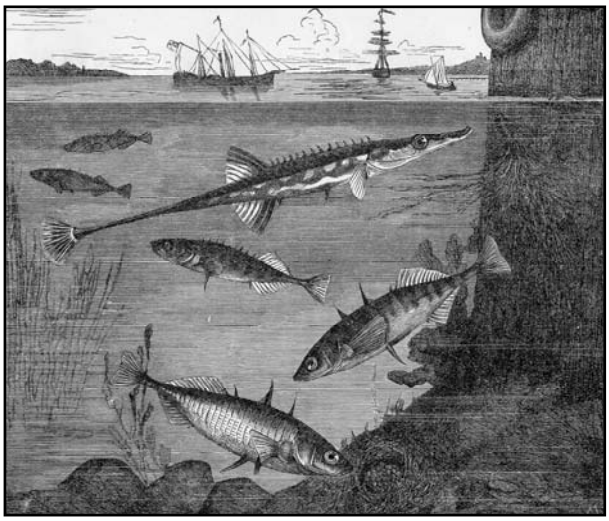
This book was followed by Door *het rietland* (By the reeds, 1896), *Hei en dennen* (Heath and pine, 1897), *In de duinen* (In the Dunes, 1899) and *In het bosch* (In the Forest, 1901). These publications had a pleasant and popular writing style and featured colorful illustrations drawn by the authors. Their readily understandable and catchy way of writing about nature was new and spoke to a wide audience. The authors took the reader, as it were, on their walks to a park or a ditch. The booklets challenged the reader to follow the authors, to go and see for themselves, and thus encouraged the study of nature as a hobby, sometimes called a "natural sport."

The response to this series of books was enormous, and in 1896 the idea was conceived to publish a magazine for amateur naturalists. For this venture they co-opted another teacher, J. Jaspers, Jr., and their magazine was christened *De Levende Natuur* (Living Nature) with the subtitle, *Tijdschrift voor de Natuursport* (Magazine of Nature Sport), implying that the study of nature was not just for gathering and spreading knowledge, but was also fun and exciting.

The success of the magazine in gaining a substantial readership was immediate, and the editors made it one of their aims to engage readers in different projects, encouraging them to submit articles and questions that would be answered by the editors or other specialists. From an early period, assistance from readers was requested on research on the distribution of plant species, and when this became a success the Governmental Herbarium in Leiden used the same method in preparing distribution maps for Dutch flora. Within a relatively short period, *De Levende Natuur* became well established and a source of encouragement and inspiration from which new initiatives were being taken, such as the foundation of several natural history societies, with Heimans and Thijsse elected to their boards.



***Het Zoetwateraquarium*, the first aquarium book written in the Dutch language (1900).**



Various types of sticklebacks pictured in *Het Zoetwateraquarium.*

THE FIRST DUTCH AQUARIUM BOOK

The first aquarium book written in the Dutch language was *Het Zoetwateraquarium* (The Freshwater Aquarium) written by C. J. den Hollander (i.e., Carol Jacob den Hollander) in 1900. Hollander lived in Nieuwaal, a village on the De Waal River in the Dutch province of Gelderland - part of the municipality of Zaltbommel - located about 46 miles west of Rotterdam. The school was in existence from 1886 to 1953 and Hollander was its headmaster from its inception to 1917.

Hollander was a keen student of nature and took his students on field trips to the surrounding area. He was especially interested in keeping fishes in aquariums (in those days it was primarily native fishes) and he contributed to various journals, including *De Levende Natuur.* As a result, he was constantly receiving letters from other interested parties asking for advice and information on keeping fishes. Hollander responded as best he could but was limited in his replies as he had to be succinct in letters. He observed that there were numerous books on the subject, both small and large, but none in Dutch. After years of observation, searching in ponds and streams and examining freshwater fishes and plants up close, he decided to write this book. In doing so he sought and found help from others, as well as consulting well-known works such as Alfred Edmund Brehem's *Tierleben* and Anton Kerner Ritter von Marilaun's *Pflanzenleben*. It was highly thought of and praised, and went through many editions over the years with the last edition being published in 1928.

Hollander had planned to write a second book dealing with amphibians, crustaceans, mollusks, worms, infusoria and the like. This, however, did not come to fruition. *Het Zoetwateraquarium* described the establishment and maintenance of an aquarium, aquatic plants and fishes. He liked to refer to aquariums as "water palaces" and maintained that a glass container with some duckweed and some midge-larvae is as good an aquarium as under that name as the famous grand public establishments in Naples, Amsterdam, Paris or London.

FURNISHING AND MAINTENANCE

He was not as sanguine about the typical goldfish bowl, however, noting that they necked down to a circular opening at the top, restricting oxygenation of the water. He also remarked that they were difficult to clean and dangerous to move. When filled three quarters with water it was heavy and usually wet so it was slippery; if one lost one's grip the result would be disastrous. As Hollander remarked, "It is too bad that the gorgeous goldfish, so easy to keep clean and stay healthy, is given a most inefficient house." He recommended the larger cylindrical containers used for preserving food as a much better solution.

Hollander also experimented with the sulfuric acid bottles suggested by Rossmässler, which were of large size and thick glass (although the green color predominated, clear was also available). Hollander's aquarium supplier sent a bottle to a famous glass factory for the removal of the top of the jar but the bottle had burst under the operation. The procedure was to wrap a piece of knitted cotton soaked with turpentine around the bottle and set fire to it. If one was lucky, the bot-

tle would crack along this line. Hollander, of course, was skeptical.

Hollander provided a list of fourteen suppliers of aquariums in Holland and Germany, seven of which also provided fish and aquarium equipment. He also listed the sizes and prices for a variety of aquariums from one supplier including all-glass rectangular and round tanks, and framed tanks. Also included was a brand of German heatable aquariums called "Thermecon," fitted with a metal mantel cemented in the bottom where a heating lamp fueled by alcohol or kerosene could be placed underneath the mantel. For his own use, he had a zinc worker build a number of containers, 80x50x40 cm (32x20x16 inches) - about 42 gallons, glazed with a heavy plate glass.

In those days aquariums were not heated - especially those containing native fishes - and in those not drained for the winter and not kept in a heated room ice would form and the glass would break. The problem with drained tanks, however, was that the aquarium cement would dry and when next filled they would leak.

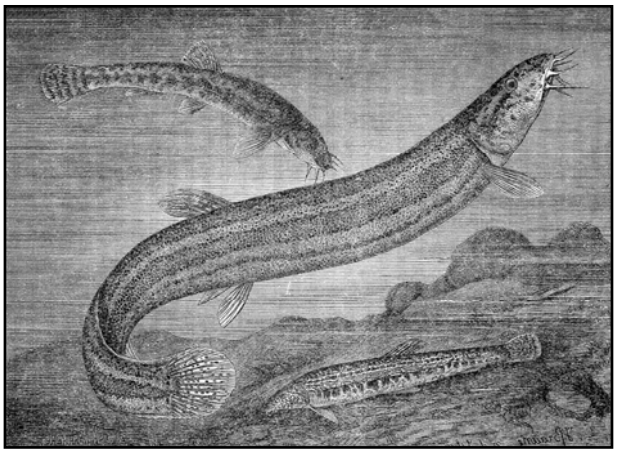
One of his aquariums was located in his living room but was relatively close to the stove and so was unevenly heated. During one winter an unexpected bang like a gunshot startled Hollander; the glass had cracked and he ran to the kitchen for some buckets to avoid the expected deluge in his living room. Wonder of wonders and to everyone's astonishment, the cracked glass did not leak, even over a span of 20 years when the tank was never filled less than half with water. Hollander finally replaced the glass and had the tank re-glazed. However, in the middle of summer the same glass side cracked again from top to bottom. Once again the tank did not leak and remained so for the next five years.

Hollander provided instructions for preparing aquarium cements. He recommended one devised by a French industrial chemical firm, Serbat, located in Saint-Saulve. Composed of a well-worked mixture of 72 parts annealed and rubbed lead sulfate, 24 parts magnesium peroxide and 13 parts linseed oil, it could be kept for a long time; one could knead easily with the hands and without any addition of oil.

He also had a very flat aquarium constructed, one meter square by 5.9 inches high (about 40 gallons), indispensable for the temporary observation of animals that required oxygen-rich water or lived at a shallow depth.

Hollander discussed the placing of aquariums with regard to light, aquarium stand requirements, cemented rockwork and cooling the water during hot days. He was not a fan of expensive systems so the one he devised was the gravity fountain aeration system. A water container was located above the aquarium, clamps controlling the water flow from it through a rubber hose that ended in a U-shaped lead tube capped by a brass cap provided with fine holes. The excess water was removed by an overflow.

Hollander warned about water that contained excess iron and groundwater with an excessive iron or calcium content as it was very detrimental to plant and animal life. He deemed the city water in Amsterdam and Haarlem ideally suited for the



Various loaches and weatherfish pictured in *Het Zoetwateraquarium.* From top to bottom: *Cobitis barbulata, Misgurnus fossilis* and *Cobitis taenia*.

aquarium. Rainwater that had been first boiled, then cooled and reaerated was also recommended.

Cleanliness was emphasized. Rotten leaves were to be cut with a pair of scissors and removed, and the detritus at the bottom was to be siphoned off. Hollander provided much practical advice, such as never cleaning the algae off the glass with sand as it would scratch and mar the surface. The only fault I found with this section on setting up and maintaining an aquarium was the lack of diagrams or illustrations. There is only a single engraving (i.e., his "Water Palace) in the whole chapter.

THE GREEN IN OUR GLASS PALACE

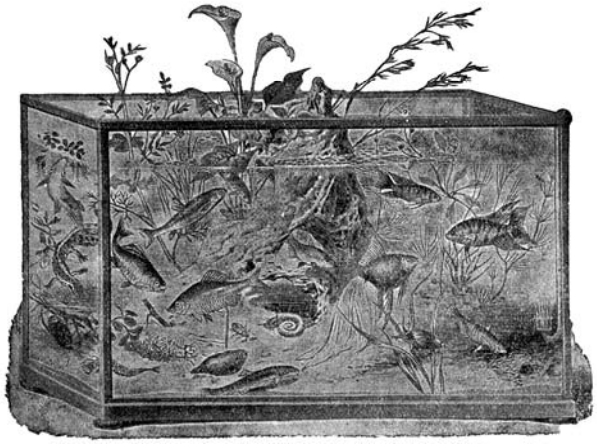
The section on plants - dubbed "The Green in Our Glass Palace" by Hollander - is profusely illustrated, the illustrations being taken from a number of different botanical texts. Most of them will be recognized by American aquarists, e.g., *Ceratophyllum, Hydrocharis, Elodea, Utricularia, Azolla, Lemna, Myriophyllum, Potamogeton, Sagittaria, Nuphar, Fontinalis, Chara* and *Vallisneria*. All of these plant descriptions are quite detailed. It is the introductory material that is of greater interest, however.

Hollander describes where aquatic plants are found and how to collect them. At one point he comments:

Since ditches, puddles, ponds, kills, ponds, streams, and even the rivers offer us a wealth of aquatic plants, we will not have much trouble in obtaining a puny amount of the needed green for the puddle in our room. Free-floating aquatic plants are easily scooped up; rooted plants on the other hand, are more difficult to come by. Thus we ask one of the farmers along the way if we can borrow a rake or ditch hook (a few cents handed out to the local preschoolers works miracles here!) Then it's possible for us to pull out the deepest rooting plants.

Hollander explains how different plants require different substrates for nourishment. Water Mint and the great Water Plantain are able to make do with a nutrient-poor soil layer: they grow and prosper against all odds. However, a vigorous growth and flowering of most aquatic plants can only be expected if the sand layer rests on a mixture of peat, sand and clayish soil, or finely divided earth into which peat is stirred.

He also advises on how to plant a tank, depending upon whether it is the plants, fish, aquatic insects or invertebrates that are to be featured. Cleaning and trimming of the plants, transportation, lighting considerations, algae and snails with relation to plants are also discussed. What I find interesting is that although - including Hollander's book - individual species of plants are described in detail in aquarium books published throughout the following one hundred and thirty years, none of them talk about many of the issues dwelt with in *Het Zoetwateraquarium*, especially in the collecting of plants and installing them for particular effects.



Hollander described how rockwork, using rocks, stones, brick and cement could be used to construct a fountain. However, here he shows an artificial rock containing niches for sand or soil that extends out of the water. In it are planted marsh plants that thrive with their roots in water and the bulk of their leaves out of water.

Hollander (arrow) with a group of his students in 1903.

THE SCALY FOLK

The section on fishes - dubbed "The Scaly Folk" by Hollander - is similar in that it is profusely illustrated, the illustrations being taken mainly from Alfred Edmund Brehem's *Tierleben*. As Hollander states:

In this chapter we want to investigate which of our native fishes fare best in captivity. Nothing will be said about ornamental fish from other countries and continents, which in many richly planted salon aquariums display an uncommon beauty, because it is our intention in this work of limited scope only to deal with our own fishes to the exclusion of everything alien. The only exception is the widely admired goldfish, since it is a completely naturalized foreigner and cannot be ignored.

Hollander points out that aquarists will have little trouble keeping native fishes from small ponds or ditches; however, with river or stream dwellers the transition from running to stagnant water will be more of a challenge. For sturgeons, flatfishes or lampreys one will want to wait for a few days or weeks and keep them under close observation in the special flat or low aquarium he devised since such fish need a spacious, well aerated home.

After explaining the oxygen/carbon dioxide relationship of plants to fishes and the necessity of providing rockwork where fish can get out of direct sunlight during hot summers, Hollander turns to the task of feeding. Here he favors earthworms. For smaller fish he boils them in hot water, minces them up in small pieces and adds some Piscidin - a commercial fish food of the time - resulting in a sort of paste. Bass, pike, eels and other predators were fed on small fish, easily obtained during the summer time. Carp and goldfish got stale bread crumbs but also occasionally lean meat cut up with a pair of scissors. Hollander lived near a butcher shop that supplied him with ground beef heart, calf brains and a variety of blutwurst.

The majority of the fishes that Hollander described are really large. The following are the only reasonable small species in his list: *Cobitis taenia* (Spined loach), *Misgurnus fossilis* (Weatherfish), *Gasterosteus aculeatus aculeatus* (Three-spined stickleback), *Rhodeus amarus* (Bitterling) and *Barbus barbus* (Barbel). For some reason, he overlooked describing two more of the smaller native fishes, i.e., *Leuciscus leuciscus* (Common dace) and *Phoxinus phoxinus* (Eurasian minnow).

Hollander also refers to his low or flat aquarium he described in his first chapter.

If we want a closer look for a few days or weeks at a sturgeon or a lamprey, then we use a flat aquarium (already described earlier) placed on our observation table. Said fish then have the spacious and well-aerated home that they need.

I can't see that a one meter square tank, 6 inches high is all that spacious for fish of this size but most likely Hollander was referring to juvenile specimens. He remarks that on occasion a lamprey will slither over the side and drop to the floor, but this fish can lie there for some time, reviving with unharmed since it can stand being out of the water better than it can take high water temperatures. Hollander used sand and soil on the bottom, small hills of gravel and stones (and he kept these far from the walls of this low tank to minimize the possibility of a fish crawling out). Floating water plants helped shield the tank from the sun, and aeration and cooling was provided by sending water from an elevated basin through a tube ending in fine nozzles. He also mentions that he placed crayfish and bullheads in this tank. This tank is an oddity I have not come across before in an aquarium book.

AN OVERGROWN ROCK

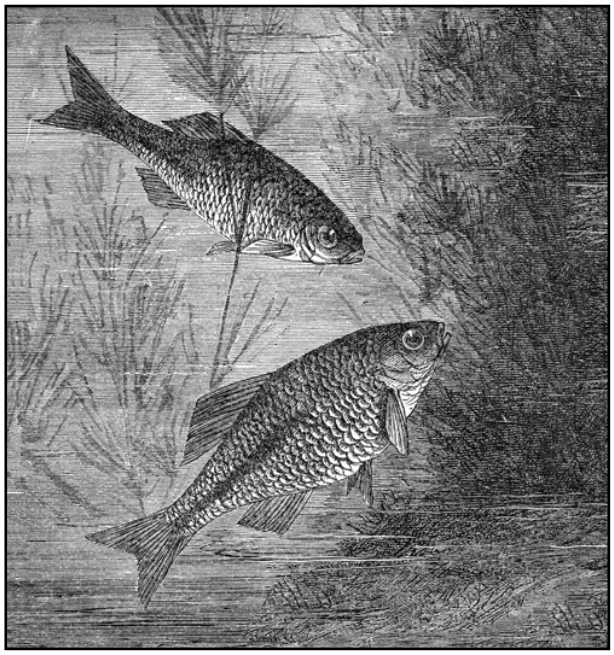
The last section - dubbed "An Overgrown Rock" by Hollander - deals with rockwork in the aquarium. In those days, display tanks were usually not covered with glass but were left open and not filled to the top with water. In the first chapter Hollander described how rockwork, using rocks, stones, brick and cement could be used to construct a fountain. Here he describes an artificial rock containing niches for sand or soil that extends out of the water. In it are planted marsh plants that thrive with their roots in the water and the bulk of their leaves out of water. (A good example is the one shown that is the only aquarium pictured in Hollander's book.) The sort of plants discussed in this section include: *Hydrocotyl, Viola, Samolus, Chrysosplendium, Oxalis, Drosera, Pinguicula* and *Veronica*.

All in all, the book is well-written and based upon the experiences of the author. It was thought well enough of that quite a few editions were published in the 29 years of its lifetime. By 1902, for example, it had been re-printed five times.

THE STIRRINGS OF THE HOBBY IN HOLLAND

The origin of the hobby in the Netherlands goes back to the early 19th century, although there certainly had been in the years before people who had been dealing with keeping fish and other aquatic animals. As we have seen, this mainly involved its native fishes, which served as an object for scientific study, education or enjoyment. The number of tropical or subtropical fish, which were not available in the Netherlands, could be counted on the fingers of two hands.

There were hardly any retailers who sold these fish, and if there were any, they were located mainly in the major port cities of Rotterdam and Amsterdam. Some fish were brought in by sailors who supplemented their modest wages in this way. The prices that each dealer charged for these exotic fish were astronomically high if one compares them with the then prevailing wages; a laborer's earnings usually did not exceed ƒ10 to ƒ15 per week (the florin, f, or guilder was worth about $15 today). Thus, for example, in 1911 a pair imported guppies was ƒ1.50, a few *Barbus*



European Bitterlings (*Rhodeus amarus*) from *Het Zoetwateraquarium*

conchonius ƒ2.25 and a few red fighting fish ƒ2.50. It is no wonder that in those time fish hobbyists regularly exchanged their home-bred fish with each other.

As far as other sources were concerned, fish were brought in directly from the east from Germany - where the aquarium hobby already had many followers - and were sold by local merchants. Famous commercial names at that time were Hanselman in Rotterdam, and Holgen and Voorwalt in Amsterdam.

Aquariums, often fully glazed containers (such as battery containers) but sometimes made of cement or wood, later of angle iron, and equipment such as thermometers, oil heaters, glass capture bells and nets, and siphons were included among the wares of the retailers. Those who could not pay the prices asked had to roll up their sleeves and make their own equipment. Some aquarists devised inexpensive solutions that were very inventive.

There were established aquarium clubs in the Netherlands before the First World War and that they were found in the two major ports of Rotterdam and Amsterdam is not surprising. In the year 1908 and almost simultaneously, the *Triton* was founded in Amsterdam and the *Anthony van Leeuwenhoek* in Rotterdam. In the heyday of its existence, the latter had 40 club members; not all lived in Rotterdam - others were spread across the country. One year after its establishment, the *Anthony van Leeuwenhoek* split up (this, by the way, was typical of Dutch aquarium societies). Under the leadership of F. Groeneveld, a number of its members formed a group under the name *De Exotische Club* (The Exotic Club). Smaller aquarium clubs, often with no more than a handful of members, were also established in Amersfootse, Tilburg, Sittard and in Vlaardingen.

A TONGUE-TWISTER FIRST UNION

Because the only magazines that were available to Dutch aquarists were the German *Blätter* and *Wochenschrift*, it was thought that the time was right to establish a bond among the existing aquarium societies scattered here and there and to establish a union (the name used by the Dutch; it is what we generally call a federation or an association) and to publish a Dutch magazine. Thus was founded in 1909 as a union with the tongue-twisting name A.A.B.B.C.C. for *Algemeene Aquarium Bezitters Bond Cyprinus Carpio* (Universal Aquarium Owners Union Cyprinus Carpio). It is amusing to note that in these early days, the Dutch referred to an aquarist as an "aquarium owner."

In 1910 the A.A.B.B.C.C. had 169 members and published a magazine called *Ons Eigen Blad* (Our Own Journal). It had about 200 subscribers and cost ƒ1.50 per year. Its Editor was J.H.M. Gadiot, who fulfilled this task in an extremely professional manner. Gadiot however, was in poor health and died in 1913. His death marked the end of *Ons Eigen Blad* and the A.A.B.B.C.C. One Dutch aquarist remarked that it was fortunate that this union disappeared from the scene since merely pronouncing its name would tie up the speaker for the rest of the day!

On the initiative of A. van Essen, president of *Natuurgenot* (Natural Pleasures) in Rotterdam, a

Comical or offensive Dutch surnames were a practical joke on their French occupiers during the Napoleonic wars.
Some quirky Dutch surnames: Gekkehuis (Madhouse), Naaktgeboren (Born naked), Uittenbroek (out of his pants) and Spring in 't Veld (Jump in the Field)

new union was established in 1916 with the name *Bond van Aquariumhouders in Nederland* (Federal Aquarium holders in the Netherlands) or B.A.N. However, it did not last long and after the end of World War I - in 1922 - it went bankrupt. Note that the term used by the B.A.N. for an aquarist was an "aquarium holder." The Dutch also referred to aquarium societies as associations, but I will use aquarium societies (and clubs) in this essay in order to avoid confusion.

A BEVY OF FIRST NAMES

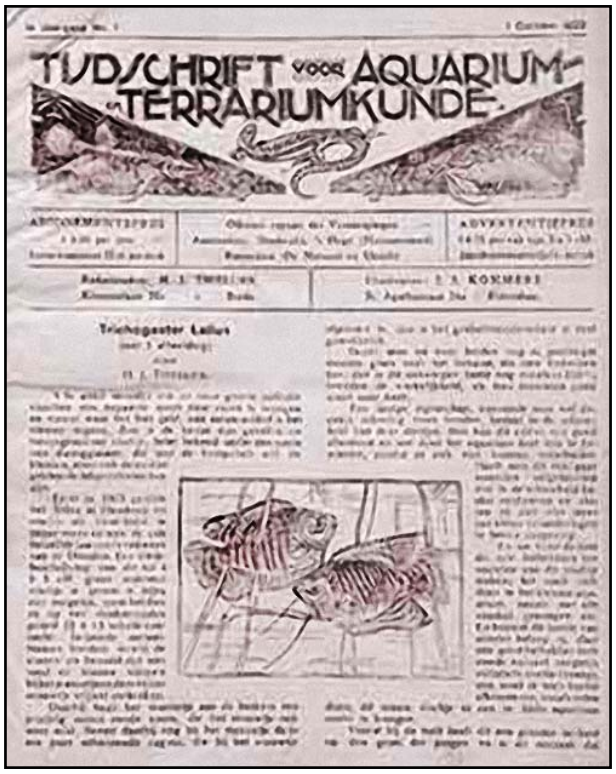
Note the name, "J.H.M. Gadiot" and later in this essay, "J.H.J.M. Oosterhuis." In early times the Dutch frequently had three, four or more first names and no middle names (nearly half of Dutch children today receive one name, over 30% are given two names, 17% have three names, 2.5% get four names and only very few children have five or more first names). This why initials are used in names; writing all the first names is a chore. In fact, the names recorded by banks in The Netherlands are usually written using initials for first names in order to simplify their records. Unfortunately, this makes research involving biographical data much more difficult.

Another oddity is that even with all these first names, a family may decide on an additional name used only by family and friends. For example, a Dutch politician was named Henricus Antonius Franciscus Maria Oliva van Mierlo (yep, five first names). The announcement of his birth (the one parents send to family and friends) probably said "We are glad to announce the birth of Henricus Antonius Franciscus Maria Oliva van Mierlo; we call him Hans." Until his death he was indeed known as "Hans van Mierlo." Note that Hans had no resemblance to any of his actual first names. Fortunately, Hans van Mierlo didn't have to write his full name very often since if "Hans" was not enough, his initials would usually be okay.

POST WORLD WAR I

The number of aquarium societies now increased. In 1919 there were *Danio rerio* in Delft, De *Natuurvriend* (The Nature Friend) in The Hague, *De Natuur* (The Nature) in Dordrecht, *Natuurgenot* (Natural Pleasures) in Utrecht, and in 1921 *Natura* in Arnhem followed. *Danio rerio* still exists and *Natuurvriend* also still exists, albeit merged with the related *Scalare* in The Hague.

The aquarium society *De Natuur*, now incorporated into *De Bijlzalm* (The Hatchetfish), organized a successful aquarium exhibition in Rotterdam in the first year of its existence, which produced a significant amount of money for the club. *De Natuur* elected not to join B.A.N. since it feared the that by joining the Union the club's board would be liable for its debts; it also disagreed with how its business was conducted (including its poorly executed magazine). In October 1922 *De Natuur* took a big step. With the money from the exhibition as seed, the club took



TIJDSCHRIFT voor AQUARIUM- en TERRARIUMKUNDE

The first issue of Tijdschrift voor Aquarium- en Terrariumkunde Flora en Fauna **(Flora and Fauna, the Journal of Aquarium and Terrarium Science), October 1, 1922. Its first editors were W.J.M. Deutz, M. den Outer and H.J. Thiellier.**

W.J.M. Deutz, an important figure in the history of the aquarium hobby in the Netherlands.

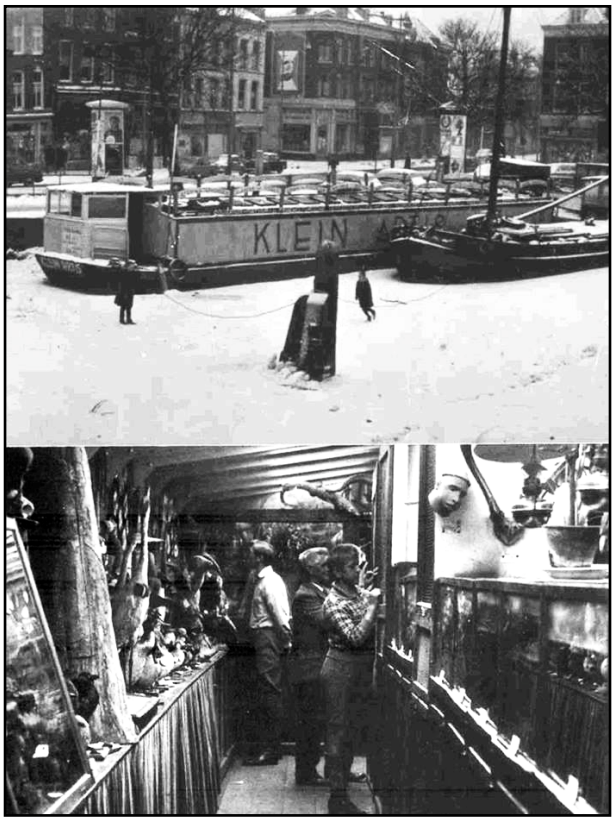
a risk and started publication of the *Tijdschrift voor Aquarium- en Terrariumkunde Flora en Fauna* (Flora and Fauna, the Journal of Aquarium and Terrarium Science). Its first editors were W.J.M. Deutz, M. den Outer and H.J. Thiellier. The subscription price amounted to ƒ3.50 per year. Quite soon afterwards a number of clubs used the journal as their own official newsletter and published information about their meetings and activities (sometimes in too detailed a manner!).

In 1924, saltwater aquarists were organized in The Hague under the name, *Zeeclub Biologia Maritima* (Maritime Biological Seaclub). The co-founder and board member of the club at the time was L. Athos who had joined *Flora and fauna* at the start of its second issue as an employee. Athos wrote countless articles about the aquarium which, slightly modified and adapted to the knowledge of that time, could just as well be published today.

A FLOATING AQUARIUM

Founded in 1838, the Artis Royal Zoo in Amsterdam (artis is short for *natura artis magistra*, Latin for "Nature is the teacher of art and science") is a haven for some 700 animal species and 200 tree varieties, many on the verge of extinction. Artis is also one of the few zoos in Europe to have as many listed buildings within its grounds, namely the Large Museum (1855), the unique Library building (1867) and the Aquarium (1882).

In June of 1924 Deutz started taking what he named the *Klein Artis* (Little Artis), a sort of floating zoo in a small river barge, all along the Dutch waterways and, when docked, asked for a few cents entrance fee. At this time Deutz was succeeded as editor of *Flora and fauna* by C. Cherries. The *Klein Artis* mostly traveled in the provinces of Friesland and Limburg, the people there showing much interest in nature. Rotterdam was the boat's winter mooring. The vessel was



Top: The Klein Artis anchored at its wintertime moorings. Bottom: The interior of the Klein Artis.

equipped with dozens of aquariums, iron-framed with puttied glass and heated by means of oil burners under the bottom tray.

As you can see from the accompanying photograph, strolling through the *Klein Artis* was a very tight squeeze. If you entered the boat during the winter you were covered in smoke from the burners. One Dutch aquarist remarked that when returning home from a visit to *Klein Artis* without him saying where he had been, his wife would welcome him home by saying, "How was the *Klein Artis*?" On his travels throughout the country, Deutz would target aquarium societies along his route and thus increased the interest in the aquarium hobby in the Netherlands. The business later passed on to his son, but after 32 years in existence the *Klein Artis* was no more.

On November 2, 1926, the *Klein Artis* was moored in the Kolk River in Assen, a city in the northeastern Netherlands. A.H. Mulder paid a visit to the boat and he and Deutz discussed the possibility of setting up an aquarium society in Assen. That conversation led to a meeting of six aquarists - along with Deutz and his son - on November 9th who decided to set up a club called *Antoni Leeuwenhoek*. The first executive board consisted of A.H. Mulder (chairman), Mr. Tjepkema (secretary), H. Heringa (treasurer) and Mr. Kwerreveld (general). The club stands as the oldest aquarium society of the Northern provinces and also one of the oldest aquarium societies in The Netherlands.

Deutz was a passionate man, had a tremendous work ethic and often had really good ideas. During the first year of the existence of *Aqua-Terra*, he gave dozens of talks and devised a number of principles for maintaining an aquarium; in addition, he still wrote many articles for his magazine. In the second and subsequent editions of *Aqua-Terra*, the first color images appeared, something that until then had not been featured in a Dutch aquarium magazine.

A CHOCOLATE FACTORY GETS INTO THE ACT

Koninklijke Verkade is a Dutch manufacturing company headquartered in Zaandam and at one time was one of the oldest existing family companies in the Netherlands. Originally founded in 1886 by Ericus Verkade to make mostly bread and rusk, it expanded to produce cookies, sweets and especially chocolates. Starting in 1906, the company began issuing cards (much like our baseball cards but also with writing) with pictures of its products, which could be collected in albums. It started with three Fairytale albums with illustrations purchased in Germany. This was a great success and Verkade decided to issue other

The Klein Artis.

books about various aspects of nature and landscapes in the Netherlands. The albums, most of them written by Jacobus P. Thijsse, were very popular. They generated a kind of collection mania among the Dutch population before World War II; about 30 albums and 360 million cards were made and distributed over a span of 30 years. A huge boost for the aquarium hobby occurred in 1925 when Verkade published an album edited and written by A.F.J. Portielje called *Mijn aquarium* (My Aquarium).

ANTON JOHAN FREDERIK PORTIELJE

Anton Johan Frederik (Frits) Portielje (1886-1965) spent 46 years in the service of the Artis Zoo in Amsterdam. Many thought he was the director of the zoo, but that was not the case. He was for all those years the figurehead of Artis and wrote many books. He was the son of Gerrit and Johanna Portielje Hassels who had a printing business. After his school years he worked at the Nieuwsblad where in addition to writing about court records for his job he also wrote a number of articles about animals. Because of his interest and love for animals he became an assistant in 1906 to the director of Artis who later appointed him later as Inspecteur van de Levende (Superintendent of Livestock).

Anton Johan Frederik (Frits) Portielje (1886-1965).

Portielje was the first specialist in the world to conducted behavioral experiments involving animal instincts. In 1939 he performed experiments on monkeys and the crowning achievement of his investigations into animal behavior was seeing his book, *Dieren* (Animals) published in 1938 and receiving widespread recognition in the academic world. For his contribution to the knowledge of the life and his passion in developing the instinct concept, he received an honorary doctorate in 1946 in mathematics and physics from the University of Amsterdam.

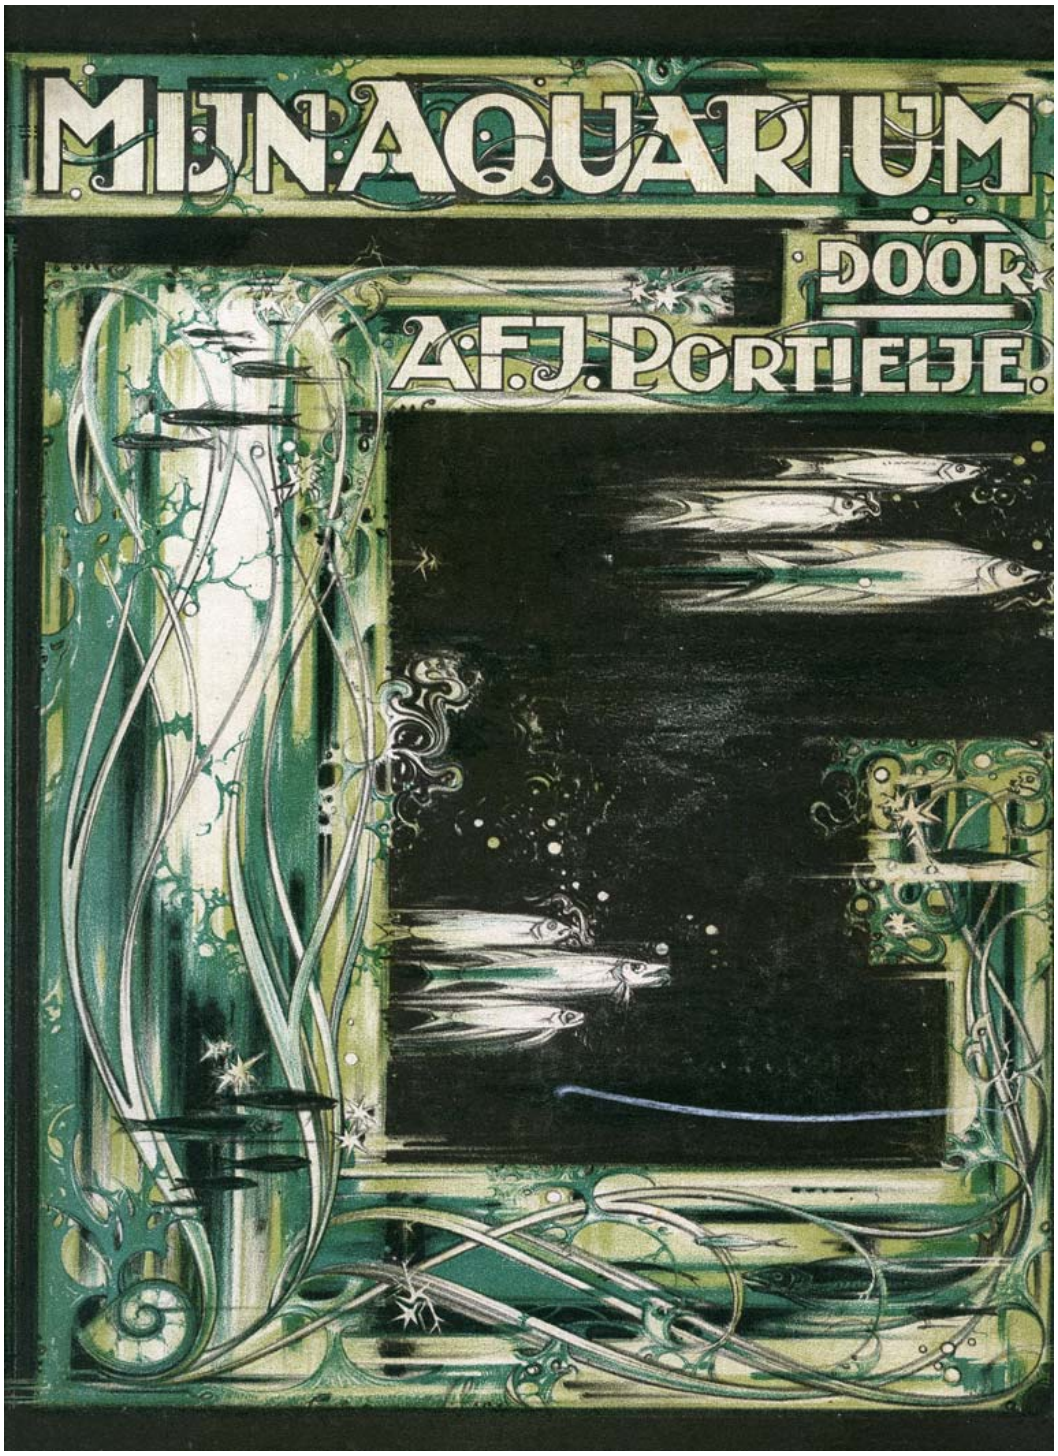
He made many presentations on animal behavior and for a number of years hosted a program on animals at the Dutch radio station, AVRO. His Verkade albums, which were illustrated with the pictures of packaged biscuits and other Verkade products, were very popular: *Wandelingen door Natura Artis Magistra* (Walks through Natura Artis Magistra) in 1922, Mijn *aquarium* (My Aquarium) in 1925, *Dierenleven in Artis* (Lives of animals in Artis) in 1939 and *Apen en hoefdieren* (Monkeys and ungulates) in 1940; they all were printed and distributed in large numbers.

In 1946 he was appointed head of the information department of Artis. In 1952 he retired, the big celebration in Dutch cinemas at that time being a documentary entitled "De dieren van Artis nemen afscheid van Dr. Portielje" (The Artis animal's farewell to Dr. Portielje). For his research, writings and lectures he was awarded the Visser-Neerlandia Prize in 1960.

MIJN AQUARIUM

Verkade's business model for their albums was simple. They sold each album for 50 cents, available from any dealer in

their goods. If desired, the album could also be delivered by mail upon receipt of 70 cents (Note: there were 100 cents in a guilder and the guilder was worth about $15 in today's money). The albums were very large - 12" high x 9-1/2" wide x 3/4" thick - and resembled the photo albums in use today except that the pictures were pasted in rather than using triangular corner holders. The covers were of a thick, hard material and well-bound.

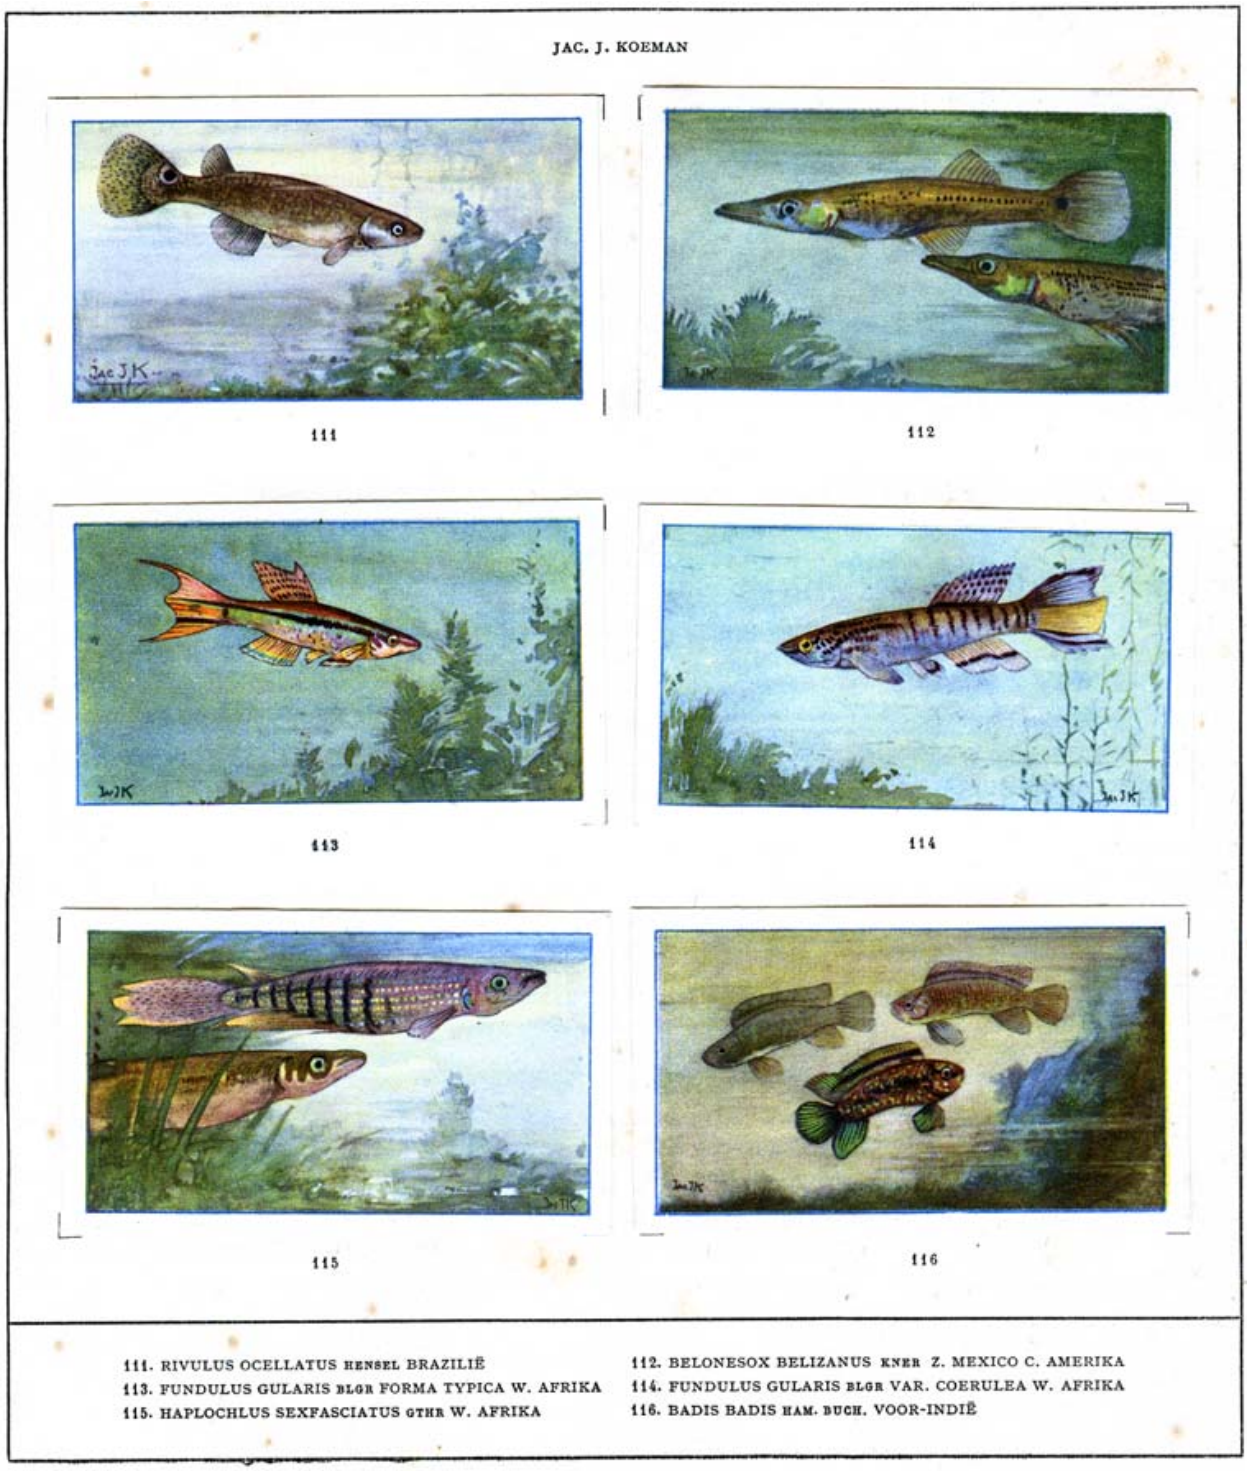


Cover of Mijn Aquarium.

The albums came with the text and the black and white images already on the bound pages; all that the owner had to do was to collect the colored paintings and paste them in. The *Mijn Aquarium* album contained 126 small paintings, each 3-1/2" x 2", printed on a light card stock. On the back of each card were the instructions as to where to paste the card. These cards were packed with Verkade's goods (bread, cookies, chocolates, etc.) and, of course, were free if you bought the

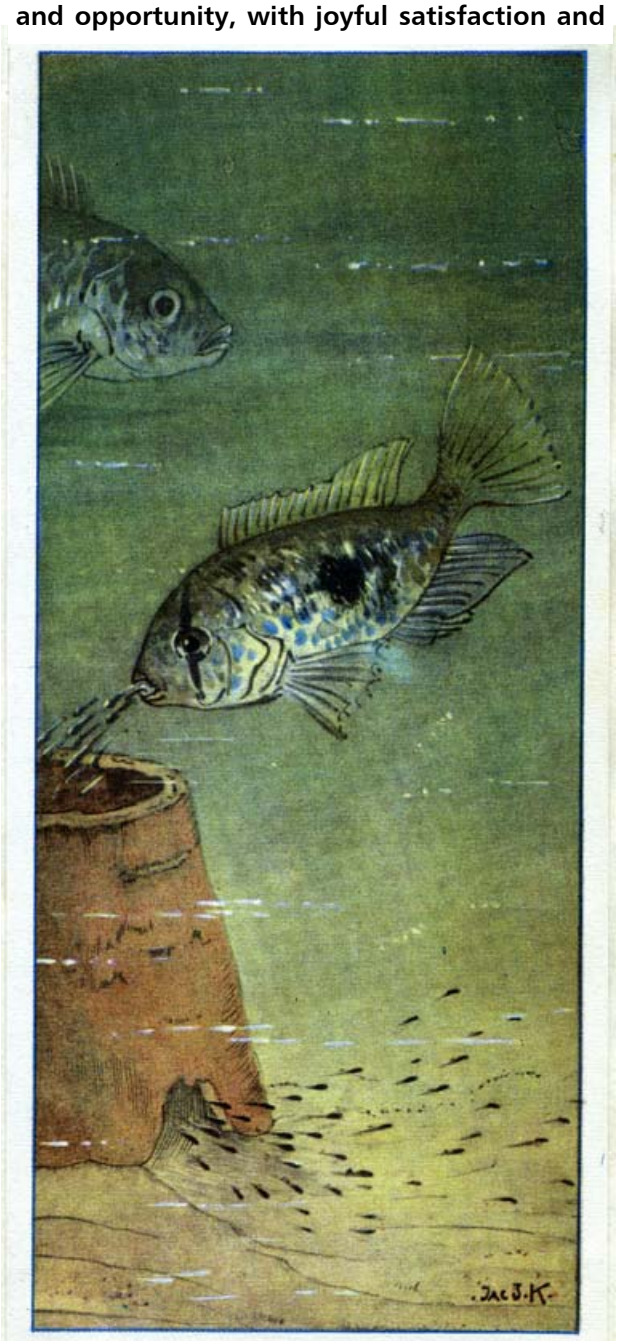
Frontispiece from Mijn Aquarium.

item. Verkade made sure that you would be able to complete the album and one could exchange duplicate cards or buy needed cards directly from the Verkade factory. In addition to the 126 small paintings, the *Mijn Aquarium* album contained about a dozen plates that ranged from a full size page (8-1/2" H x 7-1/2" wide - absolutely gorgeous!) to tall paintings 8" H x 2-1/4" W. These had to be obtained directly from the Verkade factory.



The black and white drawings - and there were many strewed throughout the album - were by J. Voerman Jr. but the colored painting were done by Jac. J. Koeman. The following is how Verkade explained how this all came about:

Having failed to take advantage of both time and opportunity, with joyful satisfaction and after a nearly ten-year period of dormancy we now resume the issue of our albums. Outsiders can hardly imagine how much time and how many headaches there are in the preparation of such an album. A happy coincidence brought us to this new edition. At an exhibition of the work of his pupils held here in Zaandam, we met the young painter, Jac. J.

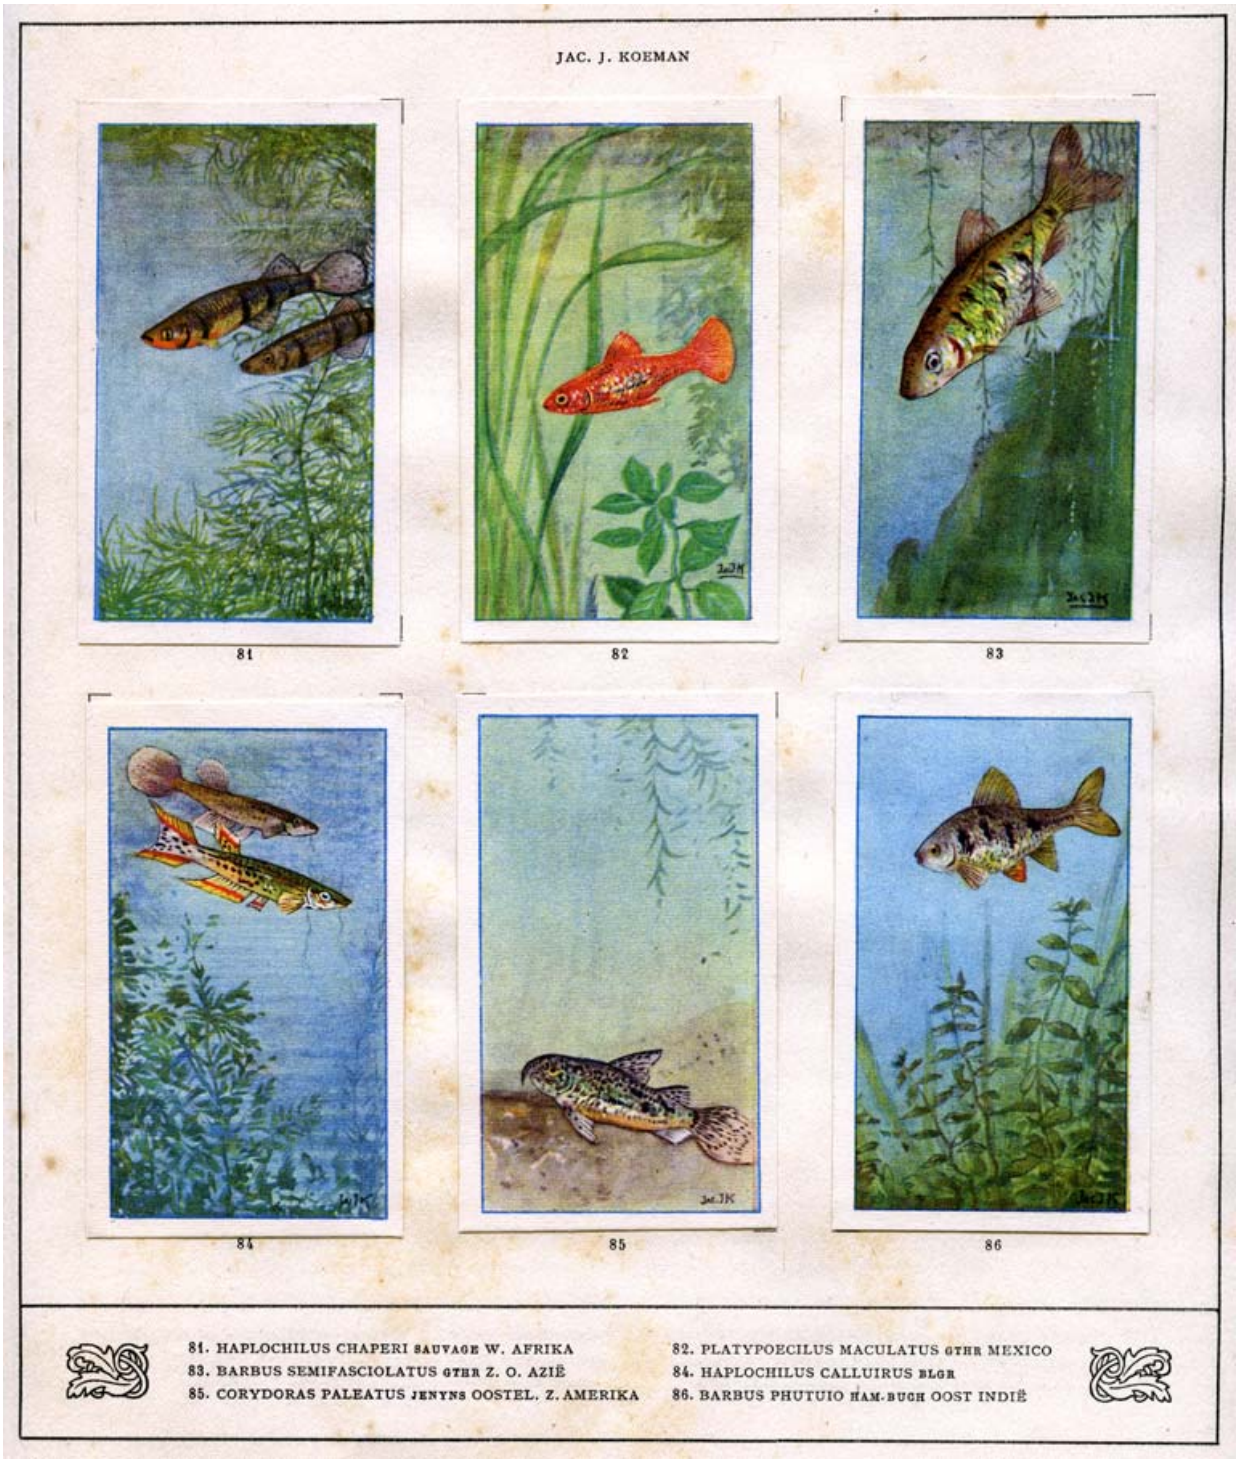


GEOPHAGUS GIJMNOGENYS HECKEL
MET LARVEN

(CARASSIUS LANGSDORFI CUV. ET VAL. VAR JAPONICUS BICAUDATUS.) (JAPANSCH KWEEKPRODUCT) MET CABOMBA CAROLINIANA A. GRAY UIT NOORD-AMERIKA

Koeman. From conversations we had with him it turned out that he was an enthusiastic admirer of our previous albums. He was able to allay our objections to an eventual new edition by being willing not only to take on the whole preparation itself, but also to co-operate in the design and implementation of the graphics and leaf embellishments. As a result, we provisionally commissioned him to create an album, possibly followed by others. What, however, would be the subject?

Firstly, we wanted to take into account our previous workers on the albums, Thijsse,



Carter and Wenckebach, with whom Koeman then held his first talks. That they offered their cooperation willingly is the reason for us to give here our expression of gratitude. The subject matter was resolved by Koeman himself. He wrote to us: "In a quiet corner of my studio is my home aquarium. The many hours that I have enjoyed this wonderful world, have convinced me that this would be a splendid subject for the new album." We were in complete agreement with his choice.

So we now here present this new album, *Mijn Aquarium*. We wanted it to be not only a feast for the eyes, but also a reliable guide for the owners of aquariums, so we asked Mr. A.F.J. Portielje, Superintendent of Livestock at Artis, to write the text. We have no doubt that in him we found "the right man in the right place."

The accompanying illustrations from the book show that Verkade was right! Finally, it is important to note that the publication of *Mijn Aquarium* was an important boost for the hobby in The Netherlands.

THE 1920s MARCH ON

In 1927 an aquarium society called *Vivarium* was established in the "City of Light, a name for the city of Eindhoven, having established a light bulb factory there some six months later. The president of the club, R.W. Dahmen von Buchholz, wrote an article in the April issue of *Flora and fauna* about illuminating aquariums with artificial light. Until then, the lighting of the aquarium consisted exclusively of daylight. Aquariums were either placed near or in front of a window. Daylight, however, is a variable and uncertain factor, so that plant growth during the dark winter seasons left much to be desired. Dahmen von Buchholz illuminated his 100 x 50 x 50 cm-sized aquarium (40x20x20 inches) with two parabolic reflectors, each with a 75-watt bulb (one silver and one semi-matte), burned for 7-2/3 hours each day. In this way he achieved remarkable results, and he described the growth of his plants in detail.

The NBA IS FORMED

By now the aquarium hobby had wind in its sails. New clubs were founded, some of which adopted *Flora and fauna* as its official organ. This increase meant that the demand in 1929 for this umbrella publication was great. It was *Natuurvriend* that took the initiative. It sent a letter to the clubs, asking for cooperation in the establishment of a union. Many clubs had absolutely no interest, the B.A.N. adventure being still fresh in their memory. However, a dozen clubs convened in The Hague to discuss the creation of a union. The majority were convinced of the value of such since together they could achieve more. The stumbling block, however, was the magazine. Should they go on with *Flora and fauna*, or publish their own magazine? Some clubs opted for *Flora en Fauna* further only if they were assured of greater participation and were given more information on its operating costs and revenue. *De Natuur*, which had published the magazine for years at its own risk and expense refused and withdrew.

On August 18, 1929 a commission was appointed and met to prepare for the establishment of a un-

"I lost my appetite!"

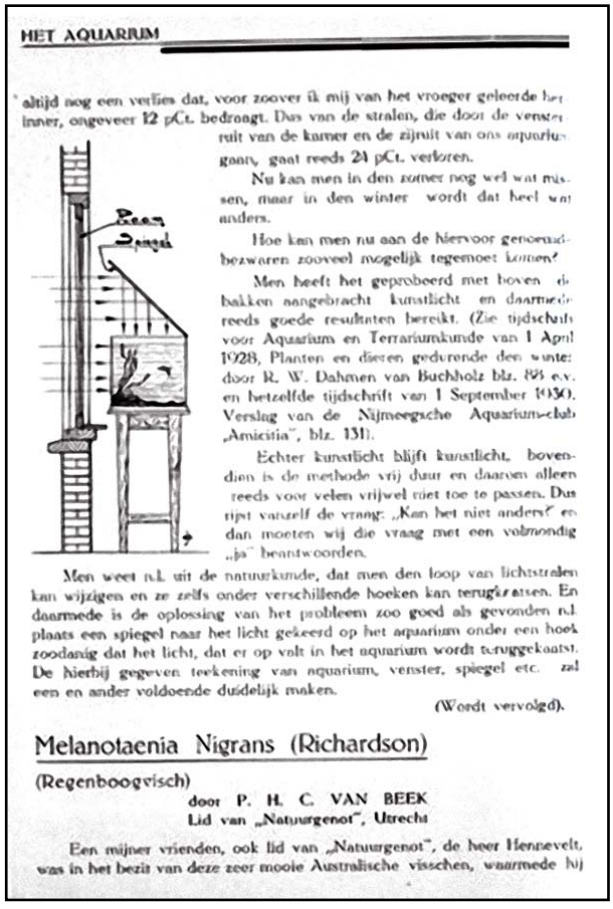
ion. This committee consisted of H. Gijswijt, C.G. Kwint, A. de Ruyter, F.J.C. Zaalberg and J.H.J.M. Oosterhuis. Considering his position in his club, the latter gentleman, although a member of *De Natuur*, was placed on the committee. On March 16, 1930 it finally happened. The inaugural meeting was held in Utrecht, and the *Nederlandsche Bond van Aquariumhouders* or NBA (the Dutch Union of Aquarium owners) was a fact. The core of this third union were the aquarium societies *De Natuurvriend* (Nature Friend) in The Hague, *De Natuur* (Nature) in Haarlem, Dordrecht and Zutphen, the *EUAC* in Utrecht, *Natuurgenot* (Nature Indulgence) in Utrecht, *Danio rerio* in Amsterdam, and *Vivarium* in Eindhoven; a total of eight clubs together consisting of 275 aquarists. The first Board members were: H. Gijswijt, chairman, F.J.C. Zaalberg, secretary, W. Schrameijer, treasurer, L. Prooijen, Commissioner and A. de Ruyter, librarian. Since the NBA had no funds, they issued shares in the amounts of ƒ1.00, f5.00 and ƒ 10.00 to establish an initial capital fund.

THE 1930's

In June 1930 the first issue of *Het Aquarium* (The Aquarium) appeared. It had 16 pages, the subscription price was ƒ3 per year and its first editor was J.R. van der Void of Eindhoven. Only 500 copies of the first edition were printed but after six months this had risen to 800. Yet not all was going well. A few months after the establishment of the NBA, *De Natuurvriend* went back to the *Flora and Fauna Group*. A number of members who disagreed with this decision split off and founded the *Vereniging van Aquariumhouders Scalare* (Association of Aquarium Owners Scalare). Afterwards *De Natuurvriend* and *Scalare* merged once again.

It is remarkable that a subject covered in the first issue of *Het Aquarium* is still topical, viz. how to combat blue-green algae. The second issue led off describing a remarkable novelty electric heater. Up to then heating was with oil lamps, and this would continue for years as the main fuel for heating the aquarium. Mr. Leeuwenberg, a member of *Amicitia* - Nijmegen, wrote an article in August 1931 about heating aquariums using a brine heater. Electric lighting of the aquarium again was described. The author of the article used a reflector with a 75 watt Philips Argalamp for an aquarium of 80 x 30 x 45 cm (32x12x18 inches) and had good results. C.G. Kwint, a staff member of *Het Aquarium*, responded. He opined that this kind of lighting amounted to nothing. Artificial light had no effect on plant growth, he wrote; an aquarium belonged by a window where it could receive daylight.

However, matters with the NBA generally went well and more and more clubs joined the union. In October 1931 there was a change in the editori-



HET AQUARIUM

altijd nog een verlies dat, voor zoover ik mij van het vroeger geleerde her inner, ongeveer 12 pCt. bedraagt. Dus van de stralen, die door de venster ruit van de kamer en de zijruit van ons aquarium gaan, gaat reeds 24 pCt. verloren.

Nu kan men in den zomer nog wel wat missen, maar in den winter wordt dat heel wat anders.

Hoe kan men nu aan de hiervoor genoemde bezwaren zooveel mogelijk tegemoet komen?

Men heeft het geprobeerd met boven de bakken aangebracht kunstlicht en daarmede reeds goede resultaten bereikt. (Zie tijdschrift voor Aquarium en Terrariumkunde van 1 April 1928, Planten en dieren gedurende den winter door R. W. Dahmen van Buchholz blz. 895 e.v. en hetzelfde tijdschrift van 1 September 1930, Verslag van de Nijmeegsche Aquarium-club „Amicitia", blz. 1311.

Echter kunstlicht blijft kunstlicht, bovendien is de methode vrij duur en daarom alleen reeds voor velen vrijwel niet toe te passen. Dus rijst vanzelf de vraag: „Kan het niet anders?" en dan mooten wij die vraag met een volmondig „ja" beantwoorden.

Men weet n.l. uit de natuurkunde, dat men den loop van lichtstralen kan wijzigen en ze zelfs onder verschillende hoeken kan terugkaatsen. En daarmede is de oplossing van het probleem zoo goed als gevonden nl. plaats een spiegel naar het licht gekeerd op het aquarium onder een hoek zoodanig dat het licht, dat er op valt in het aquarium wordt teruggekaatst. De hierbij gegeven teekening van aquarium, venster, spiegel etc. zal een en ander voldoende duidelijk maken.

(Wordt vervolgd).

Lid van „Natuurgenot", Utrecht

Een mijner vrienden, ook lid van „Natuurgenot", de heer Hennevelt, was in het bezit van deze zeer mooie Australische visschen, waarmede hij

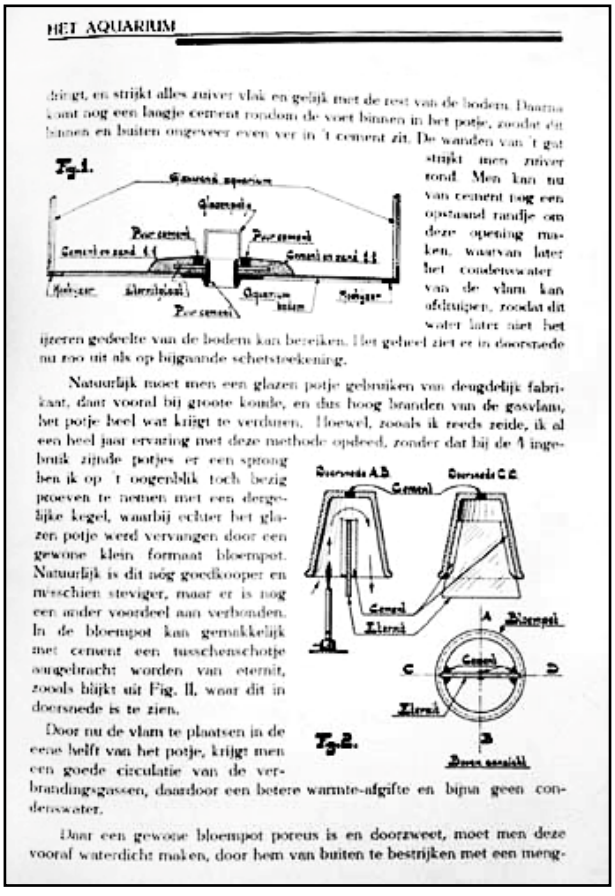
***Het Aquarium*, 1st year, No. 6, February 1930. This was an example of how one could get daylight for plants in an aquarium using a mirror.**

al staff. Van der Void dropped out and was replaced by J. Sybrandi who would perform this function until his death in 1940. During this period Sybrandi, who was an extremely able man and who wrote numerous articles for the magazine, made his mark on *Het Aquarium*. His death was an irreparable loss to the NBA, but even more so for *Het Aquarium*.

The third year began with pep talk from the Union president, H. Gijswijt. The circulation of the *Het Aquarium* had risen to 1,500 copies and the number of employees had increased, he noted, and it was enjoyable to work jointly towards a common goal. If the increase in readers kept up this way we may reach the second thousand at the end of the year. Grow, bloom, bear fruit - that is our watchword, as he ended his speech. Ironically, however, in 1933 Gijswijt got into trouble with his club and had to resign as chairman of *Scalare*. It also meant his end as president of the Union.

After a short interim period, during which Mr. Kranenburg acted as temporary President of the NBA, Dr. L. van der Perk was elected President. The economic crisis in the Netherlands (as in other countries in the world), accompanied by high unemployment, began to be felt in the thirties and the growth of the NBA came to a standstill. The Union now had 26 clubs with a total of 1200 members. Because of the poor financial state of the Union in September 1934, it was decided to issue a loan in the amount of ƒ1000.00. *Flora and Fauna* also suffered the effects of the crisis and the magazine had to reduce the number of its pages. Finally, in September 1934, De *Natuur* in Rotterdam, *De Natuurvriend* in The Hague, *Danio rerio* in Delft and *Natura* in Arnhem joined the NBA and unity was finally restored.

In 1935 the economic crisis reached its peak. Many people were forced to examine every penny twice before spending it. The Union dues amounted to ƒ0.30 per month, an amount which one now laughs at, but then it represented an insurmountable obstacle for many aquarists. For this reason, many newly established clubs decided not to join the Union. Meanwhile, after traveling for 10 years throughout the country with the museum ship *Klein Artis*, W.J.M. Deutz turned the helm over to his son H. Deutz and started living ashore. Soon afterwards old friends with whom he had worked with on *Flora and Fauna* urged him to start a new aquarium magazine. After some hesitation, Deutz agreed. In June 1935 the magazine *Aqua-Terra* appeared on the market with Deutz as its owner and editor. His fellow editors were L. Athos and E. Saathoff. The first issue of *Aqua-Terra* had only eight pages, but within a year the number had doubled to 16. The price of the magazine was only ƒ2 per year and for groups the price was



HET AQUARIUM

dringt, en strijkt alles zuiver vlak en gelijk met de rest van de bodem. Daarna komt nog een langje cement rondom de voet binnen in het potje, zoodat dit binnen en buiten ongeveer even ver in 't cement zit. De wanden van 't gat strijkt men zuiver rond. Men kan nu van cement nog een opstaand randje om deze opening maken, waarvan later het condenswater van de vlam kan afdruipen, zoodat dit water later niet het ijzeren gedeelte van de bodem kan bereiken. Het geheel ziet er in doorsnede nu zoo uit als op bijgaande schetsteekening.

Fig. 1.

Natuurlijk moet men een glazen potje gebruiken van deugdelijk fabrikaat, dan vooral bij groote koude, en dus hoog branden van de gasvlam, het potje heel wat krijgt te verduren. Hoewel, zooals ik reeds zeide, ik al een heel jaar ervaring met deze methode opdeed, zonder dat bij de 4 ingebruik zijnde potjes er een sprong, ben ik op 't oogenblik toch bezig proeven te nemen met een dergelijke kegel, waarbij echter het glazen potje werd vervangen door een gewone klein formaat bloempot. Natuurlijk is dit nóg goedkooper en misschien steviger, maar er is nog een ander voordeel aan verbonden. In de bloempot kan gemakkelijk met cement een tusschenschotje aangebracht worden van eternit, zooals blijkt uit Fig. II, waar dit in doorsnede is te zien.

Door nu de vlam te plaatsen in de eene helft van het potje, krijgt men een goede circulatie van de verbrandingsgassen, daardoor een betere warmte-afgifte en bijna geen condenswater.

Fig. 2.

Daar een gewone bloempot poreus is en doorzweet, moet men deze vooraf waterdicht maken, door hem van buiten te bestrijken met een meng-

***Het Aquarium*, 2nd year, No. 8, January 1932. Not only was light but heat was a problem. This article concerned a discussion on using gas or oil to heat the aquarium.**

even lower. It is no wonder that in its first year of existence 16 clubs, some of which like *Natura* in Arnhem previously affiliated with the Union, chose *Aqua-Terra* as their official organ.

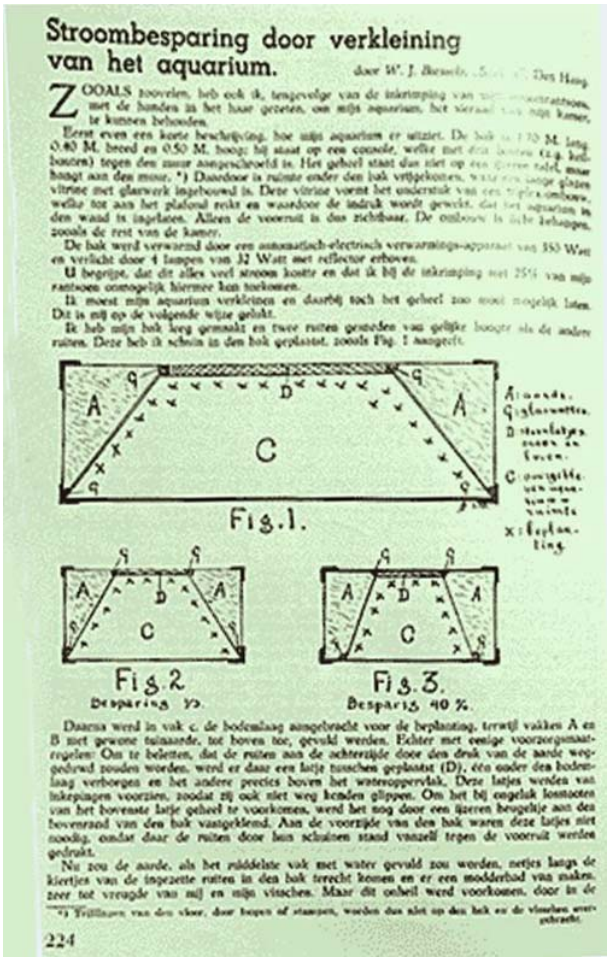
WORLD WAR II

Although in 1939 the Netherlands was not yet involved in the war, it did feel some consequences, especially in the distribution of petroleum products. It is true that petroleum as a fuel for heating the aquarium was already partially replaced by gas and electricity, but many aquariums were still heated with a kerosene burner. In January 1940 the Members Council of the NBA took an important step, one that would have far-reaching consequences. Due to the improved financial situation of the Union its dues, which amounted to over ƒ0.30, were reduced to ƒ 0.20 per month. Thus the main stumbling block for the recruitment of clubs was removed and the results exceeded all expectations. Existing clubs returned to the fold and newly established clubs joined. A few months after the decision, the Union's membership rose by a whopping 50%.

The war affected many cities. The following months demonstrated how important it was to have an umbrella body for aquarium societies. The NBA's board held talks with the National Office for Petroleum Products and achieved limited success. Homes not equipped with gas or electricity were given an allocation of 6 liters of petrol per month. Unfortunately, this joy was short-lived, for in July 1940 a message came from the National Bureau that there might be no further allocations. Also changed were the conditions to be able to petition the Board; clubs or private aquarists were not going to be heard by the authorities.

The heating of tanks and everything connected with it was difficult. It was striking how many aquarium owners trying to solve this urgent problem came up with inventive solutions. In the Volume 13, 1942-1943 issue of *Het Aquarium* there was an article showing how power requirements could be reduced by filling the corners of the aquarium with sand and so reducing the amount of water in the tank to be heated (see the accompany image). The magazine also, with tongue in cheek, advised the members of the NBA to *Slaap zelf met koude voeten en hang de warme kruik in Uw aquarium!* (Sleep with cold feet and hang the hot water bottle in your aquarium!).

The first years of the war had little influence on the paper quality and size of the *Het Aquarium* or *Aqua-Terra*. In late 1941, however, the paper



Stroombesparing door verkleining van het aquarium.

door W. J. Berends, ... Den Haag

ZOOALS toovelen, heb ook ik, tengevolge van de inkrimping van ... met de honden in het haar gezeten, om mijn aquarium, het ... te kunnen behouden.

Eerst even een korte beschrijving, hoe mijn aquarium er uitziet. De bak is 120 M. lang, 0.40 M. breed en 0.50 M. hoog; hij staat op een *console*, welke met ... (e.g. hoekbouten) tegen den muur aangeschroefd is. Het geheel staat dus niet op een ... tafel, maar hangt aan den muur. *) Daardoor is *ruimte onder* den bak vrijgekomen, ... een soort glazen vitrine met glazenwerk ingebouwd is. Deze vitrine vormt het onderstuk van een ... welke tot aan het plafond reikt en waardoor de indruk wordt gewekt, dat het aquarium in den wand is ingelaten. Alleen de voorruit is dus zichtbaar. De ... zoowels de rest van de kamer.

De bak werd verwarmd door een automatisch-electrisch verwarmings-apparaat van 180 Watt en verlicht door 4 lampen van 32 Watt met reflector erboven.

U begrijpt, dat dit alles veel stroom kostte en dat ik bij de inkrimping met 25% van mijn rantsoen onmogelijk hiermee kan toekomen.

Ik moest mijn aquarium verkleinen en daarbij toch het geheel zoo mooi mogelijk laten. Dit is mij op de volgende wijze gelukt.

Ik heb mijn bak lang gemaakt en twee ruiten gemeden van gelijke hoogte als de andere ruiten. Deze heb ik schuin in den bak geplaatst, zooals Fig. 1 aangeeft.

Fig. 1.

Fig. 2
Besparing 33.

Fig. 3.
Besparing 40 %.

Daarna werd in vak c. de bodemlaag aangebracht voor de beplanting, terwijl vakken A en B met gewone tuinaarde, tot boven toe, gevuld werden. Echter met enige voorzorgsmaatregelen! Om te beletten, dat de ruiten aan de achterzijde door den druk van de aarde weggedrukt zouden worden, werd er daar een latje tusschen geplaatst (D), één onder den bodemlaag verborgen en het andere precies boven het wateroppervlak. Deze latjes werden van inkepingen voorzien, zoodat zij ook niet weg konden glippen. Om het bij ongeluk loostoten van het bovenste latje geheel te voorkomen, werd het nog door een ijzeren beugeltje aan den bovenrand van den bak vastgeklemd. Aan de voorzijde van den bak waren deze latjes niet noodig, omdat daar de ruiten door hun schuinen stand vanzelf tegen de voorruit werden gedrukt.

Nu zou de aarde, als het middelste vak met water gevuld zou worden, netjes langs de kiertjes van de ingezette ruiten in den bak terecht komen en er een modderbad van maken, zeer tot vreugde van mij en mijn vischjes. Maar dit onheil werd voorkomen, door in de

*) Trillingen van den vloer, door loopen of stampen, worden dus niet op den bak en de vischjes overgebracht.

224

This article in Volume 13, 1942-1943 issue of *Het Aquarium* showed how power requirements could be reduced by filling the corners of the aquarium with sand and so reducing the amount of water in the tank to be heated. At this point Dutch aquarists were grasping at straws.

shortage was exacerbated; the number of pages of the magazines was reduced and the quality of the paper deteriorated.

August 1943 spelled curtains for *Het Aquarium* and *Aqua-Terra*; both journals were closed by orders from on high. The months that followed were extremely difficult for the Dutch population, especially in the west of the country, which included The Hague, Amsterdam and Utrecht. Hunger, cold and war ravaged the people. Who could think at that time about aquariums? Aquarists had only one goal: to survive! Although the end of the war brought true freedom, there was no immediate improvement in the economic situation. There was an enormous shortage in every field and this included paper, which was available only on allocation. It would be late in 1945 before *Het Aquarium* and *Aqua-Terra* would reappear.

UNION IS FINALLY ACHIEVED, SORT OF

The personal feuds that for many years stood in the way of cooperation between the NBA and Aqua-Terra, started to fade with the idea of unity that prevailed after the war. Although in the 10th edition of *Aqua-Terra* Deutz still fiercely disagreed with the government of the NBA, there was already in another area talk of reconciliation. Shortly after the end of the war, NBA's management managed to get an extra petroleum allocation for the members of the clubs affiliated with the Union. When shortly thereafter Aqua-Terra also made a similar attempt, it was told by the National Agency for Petroleum that they wanted to deal with only one central body since one phone call between the secretary of the Petroleum Contact Committee and the Secretary of the NBA was sufficient to resolve any issue. The Union presented the application of the Aqua-Terra Group to the Contact Committee and obtained for it the requested extra allocation.

Unity finally came on May 12, 1946. With tempers sometimes running high, after preliminary discussions the merger agreement was signed in Utrecht by the NBA and the Aqua-Terra Group. All 62 clubs with a total of 3140 members were now united in a single union, which from that time bore the name Nederlandse Bond Aqua Terra (NBAT). Publication of *Aqua-Terra* was suspended and two of its editors joined the editorial staff of the *Het Aquarium*. The first executive committee of the NBAT consisted of J.M. Lodewijks, Chairman; Mr. Bot, Secretary; and J.A. de Rot, treasurer. W.J.M. Deutz also was elected to the Board and assumed the role of Publicity Chairman. The years that followed were dominated by the reconstruction period in the Netherlands but slowly, economic stagnation came to an end and the aquarium hobby crawled out of the mire.

In the cold winter of 1944/45, when fuel was mostly unattainable, not many aquarium fish had survived. The fish population was now severely depleted, and the prices of aquarium fish soared. Glass also was scarce and only available upon allocation. Despite all these handicaps, the hobby flourished. New clubs were established and within a short time the membership of the Union rose to more than 5000 in 1949; later it would even exceed 10,000. The work associated with this increased membership was too large for a single

"You can't blame it on the dog, Hans; I can see the bubbles."

board member to do in his spare time. Therefore, in September 1948 Mr. P. de Bruijn was appointed as administrator and NBAT finally had a Union office.

After four years of peace and progress in the Union, the first cracks became visible in the hitherto closely united NBAT. Deutz became more and more in conflict with his fellow members of the Board and the arguments came to a head in 1950. Deutz threatened to leave the NBAT, remarking, "Torn as it [the NBAT] is, I'll tear it with me."

From October 21-29, 1950 eight clubs held a large aquarium exhibition in the Rivièrahal building of the Blijdorp Zoo in Rotterdam that attracted a record number of over 40,000 visitors. Despite this success, the tension remained, especially since it was known that Deutz had many followers in Rotterdam. During the exhibition, the bomb burst. Together with a few former loyalists he founded the *Unie van Aquariumverenignen* or UvA (Union of Aquarium Associations). Three of the Rotterdam clubs and some in other parts of the country rallied behind Deutz and joined the new Union. As if nothing had happened in the past four years, the first issue of the 11th volume of *Aqua-Terra* was published in January 1951. The NBAT responded almost immediately. With the merger in 1946, Deutz had ceded all rights to the name so the NBAT filed a lawsuit against Deutz, demanding that he stop using it. The NBAT won the case and Deutz was forced to change the name of his magazine to *Waterweelde* (Water Riches).

Not only did the NBAT prosper by the economic boom in the aquarium hobby, UvA also benefited, albeit to a lesser extent. In June 1951 the Union had 25 member clubs; in March of 1952 there were 50. In subsequent years, however, the growth of UvA stagnated and the first of its problems came in 1955. UvA wanted to take over the management of *Waterweelde*, hitherto owned by Deutz and his co-editor Jeremy Lever. Liver agreed and reluctantly Deutz abided by the decision taken by the Council of Members of the UvA. Defeat, however, was unacceptable for Deutz. In September 1956 he left the UvA and reported back to the NBAT, some clubs following him and also joining the NBAT. It was the beginning of a veritable exodus of UvA clubs. In 1962 it threw in the sponge and disbanded. Meanwhile, television posed a much greater competitor to the NBAT. In many households aquarium viewing gave way to the tube and, as a result, membership in the Union dropped for the first time in 10 years.

EPILOGUE

De Nederlandse Bond Aquaterra or NBAT today is the umbrella organization for nearly 90 aquarium clubs. *Het Aquarium* is still its official organ and the magazine is published - in full color - eight times a year for aquarium, terrarium and pond lovers. I have subscribed to this magazine for many years and consider it one of the finest aquarium magazines ever published. Publication in a digital format is planned for next year.

In 1943, 31 clubs with 1,357 members were affiliated with the NBAT. By 1946 this had grown to

"Don't tap on the glass dear; those are fish, not apps."

Okay, here's the glass cutter you asked for. Now don't go doing anything stupid!

62 clubs with 6,140 members and by 1955 to 232 clubs with 16,112 members. In 1972 nearly 35,000 members were associated with the NBAT although this had decreased to around 9000 by 1992. The latter figure probably represented something less than 10% of the total number of people in the Netherlands with one or more aquaria, a number believed to be between 100,000 and 150,000 and having stayed fairly stable over the last few years. According to a recent estimate, in the Netherlands there are as many as 220 fish clubs and (including people with a pond) 450,000 fish hobbyists in the country.

As the hobby developed in the Netherlands, competitive aspects became of increasing importance with local and national competitions arising in which aquaria are judged in situ. Originally fish only played a minor role in these aquaria, with aquatic plants being of major importance. However, as more and more specialist aquarist associations arose, themed aquaria - for example, those for East African cichlids with rocky habitats, or marine aquaria - were also allowed to enter the competitions. Fish and other animals were of much greater importance in these more specialized aquaria. Nowadays the competition is further extended with the participation of riparia (i.e. shoreline aquaria) and aqua-terraria.

Finally, two major aquascaping styles dominate the world of freshwater aquariums today: the Nature style and the Dutch style. Of these two, the Dutch aquascape style is the oldest. The Dutch aquarium employs a lush arrangement in which multiple types of plants having diverse leaf colors, sizes and textures are displayed much as terrestrial plants are shown in a flower garden. This style was developed in the Netherlands starting in the 1930s as freshwater aquarium equipment became more commercially available. It emphasizes

Example #1 of the Dutch Aquarium.

plants located on terraces of different heights and frequently omits rocks and driftwood. More than 80% of the aquarium floor is covered with plants, and little or no substrate is left visible. Tall growing plants that cover the back glass originally served the purpose of hiding bulky equipment behind the tank.

A CASE of AQUARIUM PIRACY and PLAGIARISM

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, December 5, 2015)

In my essay, "Emil Adolf Rossmässler, Father of the Aquarium Hobby in Germany," I described a book, *Aquarium. Belehrung und Anleitung, solche anzulegen und zu unterhalten* (Aquarium. Instruction and Guidance for its Creation and Maintenance) written by a "Dr. L. Müller" in 1856 and published in Leipzig by Ernst Schäfer. The author was somewhat of a mystery since he could not be identified with any certainty. However, some bibliographic references identified him as Dr. Ludwig Müller, a subrector (i.e., an assistant to a rector, the highest academic official of a school) at a school in Kiel. Müller was born in 1801 and studied theology at the University of Kiel. His doctorate was an Honorary Doctor of Philosophy, given to him in 1847 by the University of Kiel for his 25 years of outstanding service to his school. In 1864 he died of cancer. However, I was unwilling to naming him as the author since the book was not mentioned in his obituary.

After I published my Rossmässler essay I came into possession of the book, *Plain instructions for the Management of the Aquarium, or, tank for Gold and Other Fish, Water Plants, Insects, etc.*, written by F.S. Leach, a "manufacturer and fitter up aquariums." The editor was James Bishop and the illustrations were done by R.C. West. It was a small book, 46 pages, published in London by Dean & Son ("three doors west of Old Bailey').

Figure 1 shows the covers of the Leach and Müller books and Figures 2 and 3 each show a similar

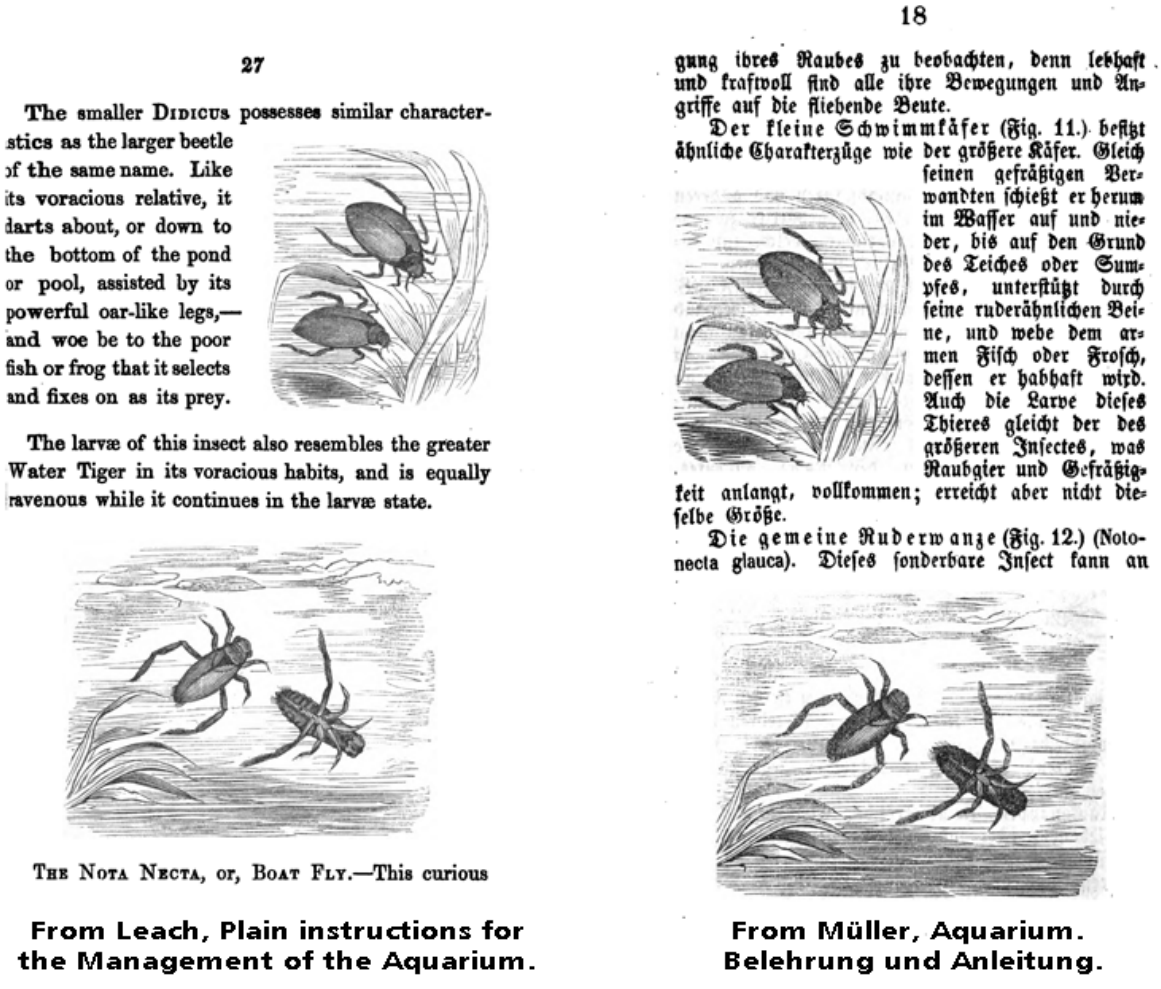
page from each book. Incidentally, in describing the "*Didicus"* beetle in both books, the name of the beetle is misspelled as it should be "*Dyticus*" if you accept Etienne Geoffrey Saint-Hilaire's name for the genus or "*Dytiscus*" is you accept Linneaus' name. Linneaus first wrote *Dyliscus* in 1735, and he never altered it. The word *Dyticus* first appeared in Geoffroy's "Histoire Abrégée des Insectes" which was published anonymously twenty-seven years later. Therefore, in accordance with the law of priority, the spelling must be *Dytiscus*. In any event, the point is that Müller's book is a word-for-word translation of the Leach book. There parts of the latter that were not translated, of course, since they were relevant to the British hobby or to Leach himself; for example, pages 42-43 where Leach talks about a young friend's experiences. Of the 46 pages of the Leach book, 32 pages were identical to that of the German translation.

The publisher did not include a date for the Leach book. However, the *Publisher's Circular* included the book in its edition of June 2, 1856 and the *American Publisher's Circular and Literary Gazette* included it in its edition of June 28, 1856. Finally, although the British Museum Library Catalogue notes the date as 1856, my copy has a library date stamp that reads "21 MY 56" so I am accepting May 1856 as the latest publication date.

The modern concept of copyright originated in England in the year 1710 with the Statute of Anne, with the copyright term lasting for 14 years plus an optional renewal of 14 additional years. Under the



27

The smaller DIDICUS possesses similar characterstics as the larger beetle of the same name. Like its voracious relative, it darts about, or down to the bottom of the pond or pool, assisted by its powerful oar-like legs,—and woe be to the poor fish or frog that it selects and fixes on as its prey.

The larvæ of this insect also resembles the greater Water Tiger in its voracious habits, and is equally ravenous while it continues in the larvæ state.

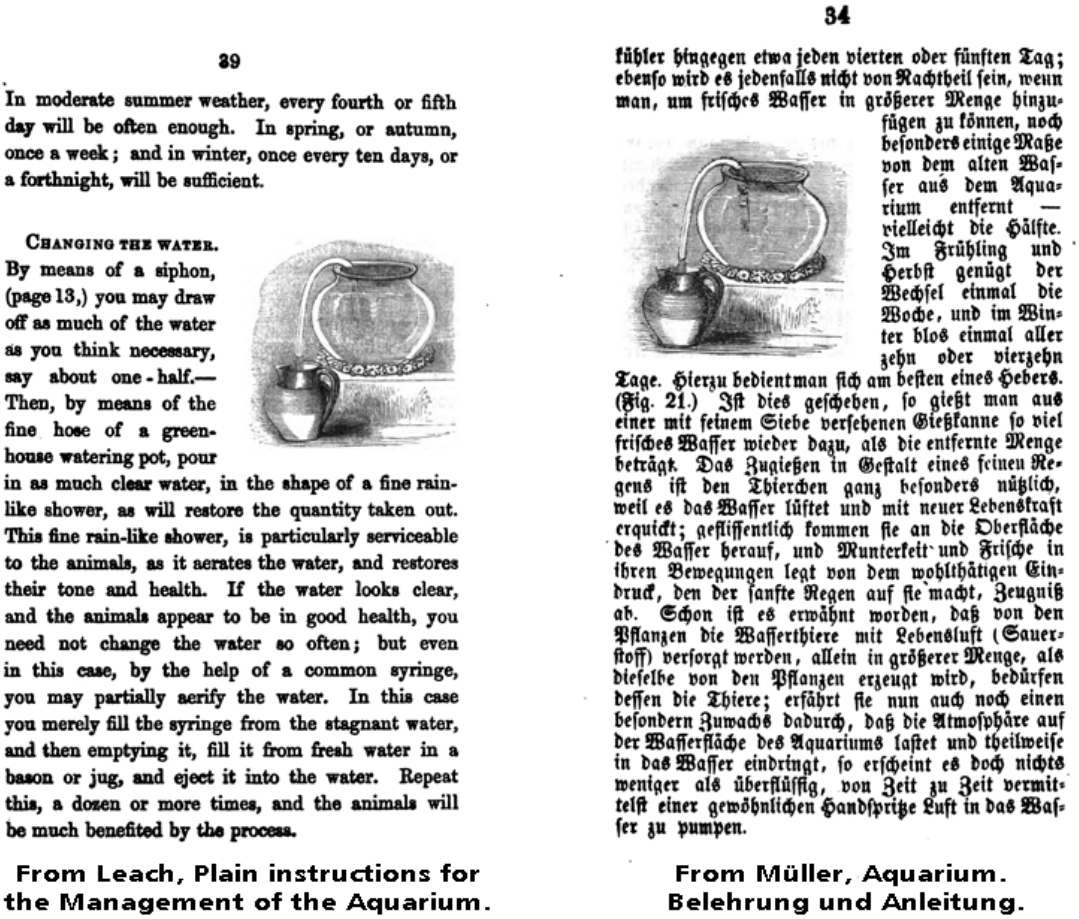
FIGURE 2

Copyright Act of 1842 - covering the period in which I am comparing these two books - the copyright period lasted for the lifetime of the author plus 7 years, or for 42 years from first publication, whichever was longer. However, the Act only applied to the copying of books and nothing was said in the Act about translations. It was only until the Convention of Berne in 1886 when authors were specifically protected against unauthorized translations. The fact that the British law had no provision for translations, explains why the publisher of the Leach book, Dean & Son of London, did not do anything about it.

Germany, on the other hand, didn't bother with the concept of copyright for a long time. Prussia, then by far Germany's biggest state, introduced a copyright law in 1837, but the division into small states meant that it was hardly possible to enforce the law throughout the empire since authors and publishers just had to go to another German state to circumvent its ruling. In Germany, therefore, publishers had plagiarizers who could reprint each new publication and sell it cheaply without fear of punishment breathing down their necks. Copyright laws in German were not enforceable until the unification of Germany in 1871. Thus the publisher of the Müller book, Ernst Schäfer of Leipzig (which was not a part of Prussia at the time), could easily get away with plagiarism.

There is no mystery as to who published first and who pirated from whom, however. The artist's signature appears on the cover art of the Leach book as well as the "Fresh-water Wilk" on page 16, the "Diving Water Spider" on page 17, the "Hydris"



39

In moderate summer weather, every fourth or fifth day will be often enough. In spring, or autumn, once a week; and in winter, once every ten days, or a forthnight, will be sufficient.

CHANGING THE WATER.

By means of a siphon, (page 13,) you may draw off as much of the water as you think necessary, say about one-half.—Then, by means of the fine hose of a green-house watering pot, pour in as much clear water, in the shape of a fine rain-like shower, as will restore the quantity taken out. This fine rain-like shower, is particularly serviceable to the animals, as it aerates the water, and restores their tone and health. If the water looks clear, and the animals appear to be in good health, you need not change the water so often; but even in this case, by the help of a common syringe, you may partially aerify the water. In this case you merely fill the syringe from the stagnant water, and then emptying it, fill it from fresh water in a bason or jug, and eject it into the water. Repeat this, a dozen or more times, and the animals will be much benefited by the process.

From Leach, Plain instructions for the Management of the Aquarium.

34

kühler hingegen etwa jeden vierten oder fünften Tag; ebenso wird es jedenfalls nicht von Nachtheil sein, wenn man, um frisches Wasser in größerer Menge hinzufügen zu können, noch besonders einige Maße von dem alten Wasser aus dem Aquarium entfernt — vielleicht die Hälfte. Im Frühling und Herbst genügt der Wechsel einmal die Woche, und im Winter blos einmal aller zehn oder vierzehn Tage. Hierzu bedient man sich am besten eines Hebers. (Fig. 21.) Ist dies geschehen, so gießt man aus einer mit feinem Siebe versehenen Gießkanne so viel frisches Wasser wieder dazu, als die entfernte Menge beträgt. Das Zugießen in Gestalt eines feinen Regens ist den Thierchen ganz besonders nützlich, weil es das Wasser lüftet und mit neuer Lebenskraft erquickt; gestissentlich kommen sie an die Oberfläche des Wasser herauf, und Munterkeit und Frische in ihren Bewegungen legt von dem wohlthätigen Eindruck, den der sanfte Regen auf sie macht, Zeugniß ab. Schon ist es erwähnt worden, daß von den Pflanzen die Wasserthiere mit Lebensluft (Sauerstoff) versorgt werden, allein in größerer Menge, als dieselbe von den Pflanzen erzeugt wird, bedürfen dessen die Thiere; erfährt sie nun auch noch einen besondern Zuwachs dadurch, daß die Atmosphäre auf der Wasserfläche des Aquariums lastet und theilweise in das Wasser eindringt, so erscheint es doch nichts weniger als überflüssig, von Zeit zu Zeit vermittelst einer gewöhnlichen Handspritze Luft in das Wasser zu pumpen.

From Müller, Aquarium. Belehrung und Anleitung.

FIGURE 3

on page 21, the Triton on page 23, the "Didicus" on page 25, "The Anachrus" on page 33 and "The Valisneria Spiralis" on page 34. Although a good magnifying glass is a help in determining the signature, on the rather large Valisneria on page 34 the artist's name is quite easily seen without squinting. The artist is R.C. West and this name has been deliberately erased in all of these instances in the Müller book!

This, and the fact that the British law had no provision for translations, explains why the publisher of the Müller book, Ernst Schäfer of Leipzig (which was not a part of Prussia at the time), was able to get away with this piracy (for the copying) and plagiarism. And, purely and simply, it was plagiarism since no one has the right to claim authorship when all one has done is to simply translate a work like Müller did. In this, both Müller (whoever he was) and the firm of Ernst Schäfer are to be condemned.

In any event, it is not true that Müller's book was the first German book, as it is nothing more than a translated British book. The first German book was Rossmässler's *Das Süsswasser-Aquarium*, published in 1857.

Lastly, it should be noted that the Leach book was, to say the least, held in some contempt. In an anonymous article titled "The Literature of the Aquarium" that appeared in the *National Magazine*, Vol. III, pp. 46-48, 1858, the author states:

We have before us eight of the many works that have been published on the aquarium; and strange to say, with but one exception, each has merits of its own, and no two come into actual competition. We give the titles of these below, and shall glean from them a few particulars which may prove both interesting and useful to our readers.

The following is the list of the books the author consulted:

(1) **Shirley Hibberd**: *Rustic Adornments far Homes of Taste, and Recreations for Town-folk in the Study and Imitation of Nature*.

(2) **Shirley Hibberd**: *The Book of the Aquarium and Water-Cabinet; or Instructions on the Formation and Management of Collections of Freshwater and Marine Life.*

(3) **H. Noel Humphreys**: *Ocean and River Gardens: a History of the Marine and Fresh-water Aquaria*.

(4) **G. B. Sowerby**: *Popular History of the Aquarium*.

(5) **E. Lancaster**: *The Aquavivarium, Fresh and Marine*.

(6) **Rev. J. G. Wood**: *The Common Objects of the Seashore, including Hints for an Aquarium.*

(7) **H. G. Adams**: *The Seaside Lesson-Book: designed to convey to the youthful Mind a Knowledge of the Common Things of the Seacoast*.

(8) **F. S. Leach**: *Plain Instructions for the Management of the Aquarium*.

The commentaries for each of these books were in my opinion well-done, but the omission of any of Gosse's books is strange. In any event, the following is the last paragraph of the article:

We have only one word for the last book on our list, and it is this: How Messrs. Dean could attach their respectable name to it we cannot imagine. It is by attempting to follow such a work as this that we hear of so many "aquarians in difficulties."

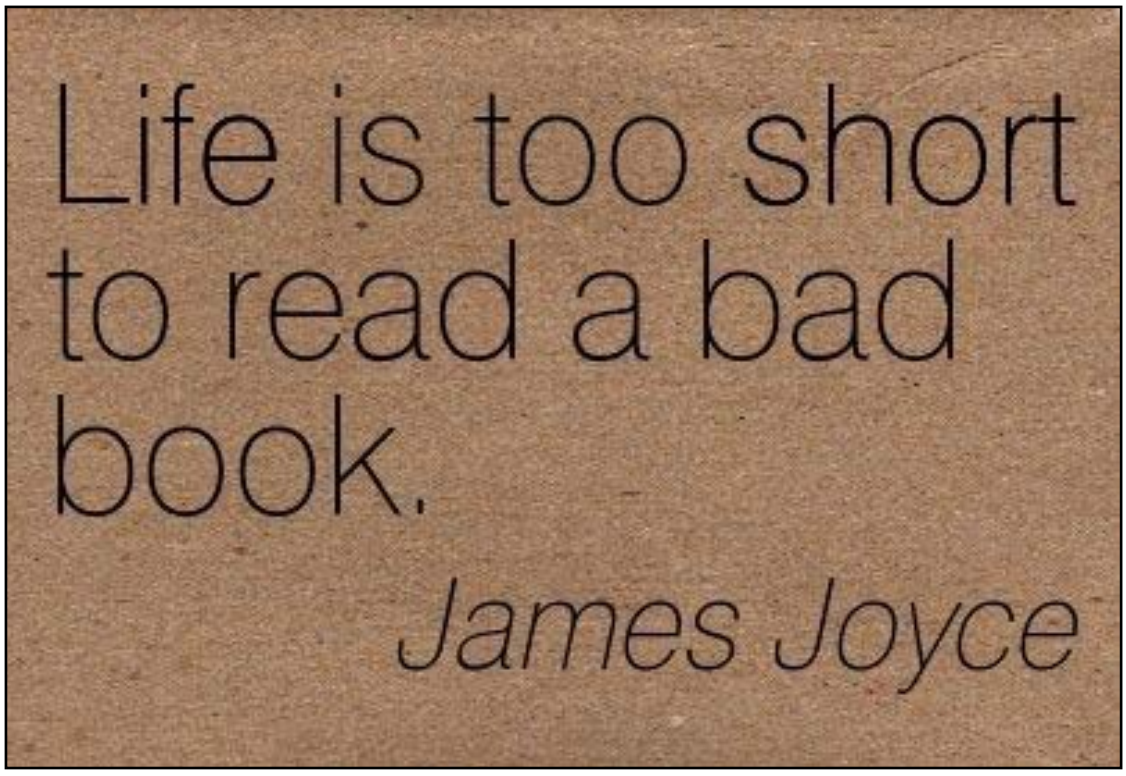
If I have ever read a more severe condemnation of a book, I cannot recall one. However, I cannot disagree with the reviewer. There were much better books for the "Management of the Aquarium."

However, the anonymous reviewer did not provide any details of what he found wrong with it. The following review, however, provides the missing details (Reference: **Anon.**, "Instructions for the Management of the Aquarium, by F. S. Leach. Edited by J. Bishop," *The Governess: A Repertory of Female Education*, Vol II, pp. 283, Darton & Co, Holborn Hill, London, June 1856.):

When a shilling pamphlet occupies the pens of two persons in its production, we have a right to expect something good for our money; but this work would be unacceptable, even as a gift. Instead of teaching us how to stock and maintain an aquarium, the book is replete with small twaddle about spiders, beetles, flies, and worms; two or three pages only being devoted to the fishes. When we find that the few remarks respecting the latter are worse than commonplace—in fact, miserably erroneous, we can do no more than pronounce the work as worthless. It is a most illiterate production; the names of animals and plants are in nearly every case incorrectly spelt, and the diction throughout is of the lowest class. Do our scientific readers know anything of the *Anachrus* or the *Diditcus*, or, above all, the plant to which the author, in ignorance of its true name, designates the Anna Comfry. We know what the plants are that he refers to, and we could tell him how to spell their names; but that may not be the case with the young people for whom the book professes to be written.

The whole thing is an evidence of how little knowledge it requires now-a-days to produce books. If this is intended by Mr. Leach as a mere trade advertisement, we should advise him and his editor to go to school, or the literary partnership may cause the breaking up of what little trade Mr. Leach may have already acquired in this very new and to him strange employment, of dealing in aquarian stock. A good book on the subject is still wanting.

This review, by the way, is evidence of a real contribution to the aquarium world by women in the nineteenth century, namely in the world of education. *The Governess* reviewed all sort of books but without exception they all had something to do with education. Ergo, these female educators believed that the aquarium had a place in the classroom as an educational tool and used it as such. Chalk up another first for women in the aquarium hobby!



The FISHES and FISHPONDS of ANCIENT EGYPT

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, January 9, 2016)

In the 4th edition of THE TOY FISH, I wrote:

"Although it might seem that the Romans should be given credit for being the first Stage I aquarists to construct vertical-walled tanks, (the figure) shows an ornamental fish pond at the Temple of Amon in Luxor, constructed about 1350 B.C. Since the amphorae embedded in the walls show that the Egyptians not only knew how to build fishponds but also were knowledgeable about the requirements for keeping fish, the credit, therefore clearly goes to the Egyptians."

Fish were enjoyed by all classes of Egyptian society, both the poor and the wealthy, and were part of most Egyptians' daily diet. Like in Rome much later, Mullet were particularly favored, and the roe was considered to be a delicacy. The Israelites, who had become accustomed to the standard Egyptian diet of bread, fish and vegetables, complained when they were wandering in the desert: "We remember the fish, which we did eat freely in Egypt…"

Certain species of fish were associated with various deities and therefore considered to be sacred. The symbol of the patron goddess of fishermen, Hat-Mehit, was the Lepidotus Fish (*Barbus bynni*). The goddess Neith was associated with the Nile Perch (*Lates niloticus*; the Greeks named the city of Esna "Latopolis" for the prominence that the Nile perch held in the city's religious practices), the Nile Carp (*Labeo niloticus*) was associated with Osiris, and the gods Ra and Atum with the eel. The Nile Mormyrid was a symbol of the evil god Set, and therefore reviled (in some instances, however, it was held as sacred because it was thought to carry some of Osiris' own flesh). The Chromis (*Chromis niloticus*) acted as a pilot for Ra's solar bark and warned him of the approach of the serpent Apophis as the bark traveled through the Duat, the realm of the dead in Egyptian mythology.

Khabekhnet lived during the 19th dynasty when Ramesses II (1279-1212 BC) was on the throne. He worked in the royal tombs at the Valley of the Kings in Deir el-Medina, his title being "Servant in the Place of Truth." In his tomb there is a wall painting of a mummy depicted as a fish (Figure 1). The fish has been identified as the Nile perch (*Lates niloticus*) and was explained as a symbol of the deceased awaiting rebirth. The precise meaning of this fish mummy is uncertain, but it probably represents the deceased, who associated himself with the god Osiris. The Nile perch has been interpreted as symbolizing the turbulent stage of the journey of the deceased; the Nile tilapia the calmer. Why Khabekhnet chose the Nile perch in this case and not the usual tilapia, we probably will never know.

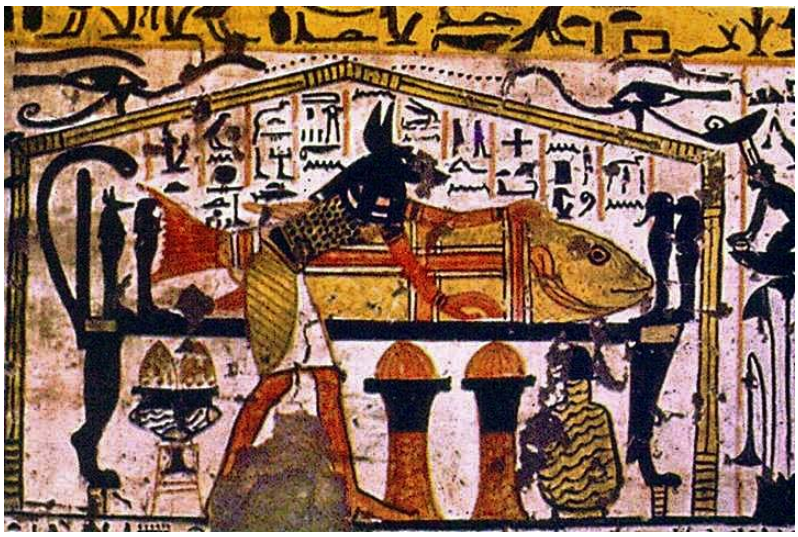


Figure 1: The fish mummy in the tomb of Khabekhnet, 19th Dynasty.

Tilapias - *Tilapia nilotica* or *galilaea* (see my essay, "Our First Aquarium Cichlid") - were regarded as a symbol of rebirth because it carries its eggs in its mouth. They were believed to have multiple lives, and to be self-created. The image of a Tilapia with lotus flowers issuing from its mouth was a symbol of resurrection. Amulets of both were buried with the dead. The heart was likened to a "red fish swimming in a pond." During the harrowing journey through the Duat, the deceased at one point changed into a fish and the possession of a fish amulet was believed to help with this transformation. Sometimes an actual mummified fish (often a *Lates*) was included in the mummy wrappings.

Figure 2 Shows a painting of fish offerings (tilapia) from the Tomb of Benia, supervisor of construction work at the foot of the south-eastern hills of Sheikh Abd el-Qurna in Thebes. The offering of fish is rarely seen, probably because it was not considered prestigious enough. A representation of a tilapia is noteworthy, however, since as I have mentioned previously this fish is also a symbol of rebirth. Dating the tomb precisely is a difficult task and is still debated, because there are no names of rulers mentioned anywhere in the tomb.

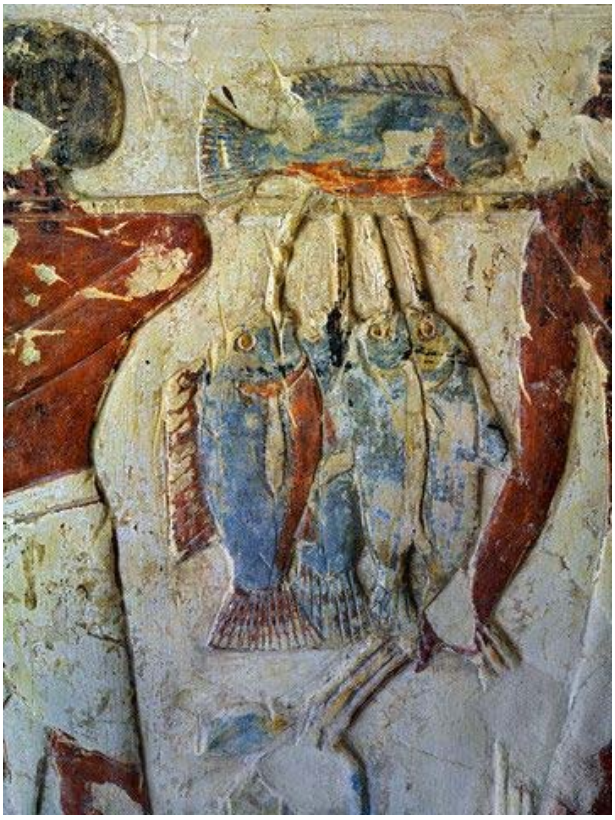

Figure 2: Fish offerings (tilapia) from the Tomb of Benia,

My interest in this essay, however, is not with the culinary or religious aspects of ancient Egyptian society, but with its ornamental ponds and its fishes. A notable example is that found at the end of the Avenue of Ram-headed Sphinxes at the Temple of Amun in Luxor (Figure 3) where ceramic vessels were incorporated into the walls to protect the fish from predacious neighbors and to provide shade under the hot Egyptian sun. Although it has been suggested that ponds like these equipped with such ceramic niches were probably deigned for the raising of eels - since some of the vessels are close below the surface of the water and eels are not

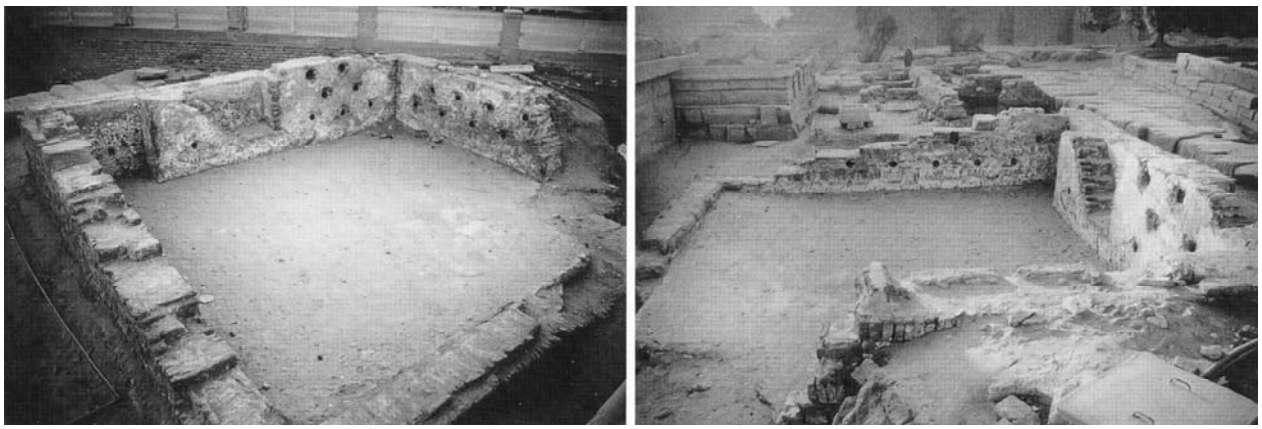

Figure 3: The pond at the end of the Avenue of Sphinxes at the Temple of Amun in Luxor.

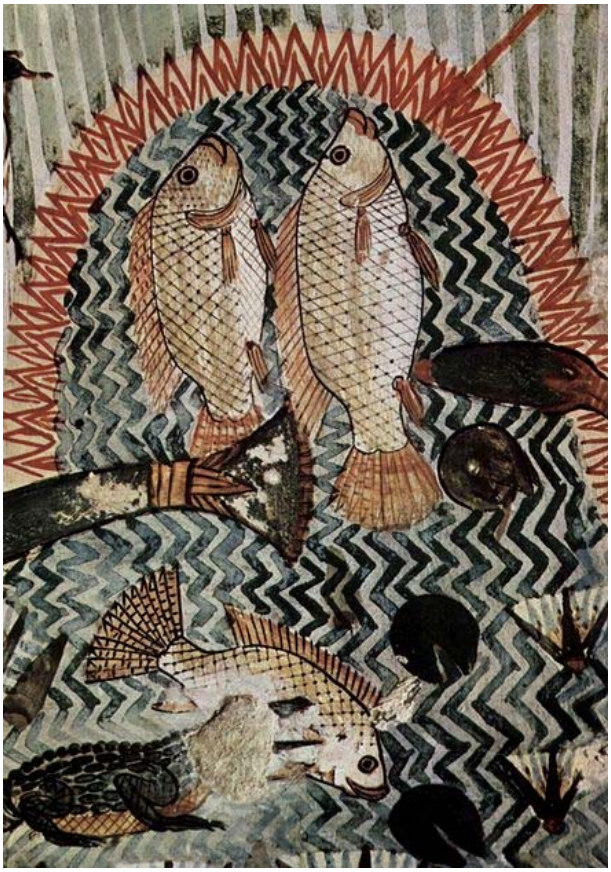

Figure 4: A detail from Menna's tomb showing tilapia swimming into his spear.

known to be jumpers - other species of fish could take advantage of them and eels could live in ponds without them. Note the built-in staircase that facilitated the cleaning of the tank after it had been emptied.

Illustrations of tilapia were very common in Egyptian wall paintings. The one in Figure 4 is a detail from Menna's tomb of three tilapia swimming into his spear. Menna held the title, "Scribe of the Fields of the Lord of the Two Lands of Upper and Lower Egypt," as well as field overseer of Amun. However, these were probably not two separate positions. He probably supervised temple owned agricultural lands which were dependencies of state granaries. He is thought to have worked for the Temple of Amun at Karnak, supervising the measuring of fields, inspecting the work on the land, prosecuting defaulters and recording the crop yield. He lived during the 18th Dynasty and probably worked under both Tuthmosis IV and Amenhotep III.

Ponds and pools were a common feature of the residential gardens of the wealthy and powerful of Ancient Egypt, and are shown in a number of tomb paintings. Beginning with the New Kingdom, pleasure gardens became a common feature of luxury residences in Egypt. According to paintings in tombs in Thebes from the 18th Dynasty (1552-1296 BC), the gardens of that time had a standard design. They had a pond, usually rectangular and in the center, filled with colorful fish, lotus blossoms in the water and flowers around the edges. Around the pond were successive rows of trees, including sycamores, palms, and grenadiers, alternating with flower beds. The edges of the water basins were sloping, with a stairway down one side so gardeners could collect water for irrigation.

The pond was often surrounded by walls or columns supporting grapevines. The walls and columns were decorated with colorful paintings of people, animals and plants such as the poppy and rose. Sometimes, as in the garden of Hatshepsut's temple at Deir el-Bahri, the pond was in the shape of a T, with one part of the T connected to a river or canal. The water was usually hoisted into the pond from the river by hand, or using a shadouf (Figure 5). Fish for food and ornament were raised in the ponds. They also were the home of migrating water birds.

Figure 5: Ancient Egypt—Shadouf.

The example in Figure 6 comes from the tomb of Rekhmire. Rekhmire was an ancient Egyptian noble and official of the 18th dynasty who served as Governor of the Town (Thebes) and Vizier during the reigns of Thutmosis III and Amenhotep II. He is noted for constructing a lavishly decorated tomb for himself in Sheikh Abd el-Qurna, part of the Theban Necropolis, containing lively, well preserved scenes of daily life during the Egyptian New Kingdom.

Like all very senior officials, Rekhmire had for his pleasure a pool in his large garden. This pool was also used for ritual practices upon the statue of the deceased, as here. Opinion is divided as to when such ceremonies were held; in any case it was not during the funeral. It is likely that the ceremony was repeated every year; the deceased could thus benefit from the new pool, drink from it, fish in it and gain sustenance from the products of its trees and gardens.

In this bird's eye view of the garden composed of four rectangles, the water in the central pool is rippled by the wind and full of flowers and fish; on either side shady Powering plants; around it an embankment lined by a row of fruit trees, and then another strip of green, bounded by other shade trees alternating with flowering shrubs. The facade of the house crowned by a cornice and with a large portal that is set amidst the greenery overlooks the short end.

The pool, surrounded by walls, is rectangular, lined with three rows of trees, sycamores on the outside (the 4th rectangle) and then alternately

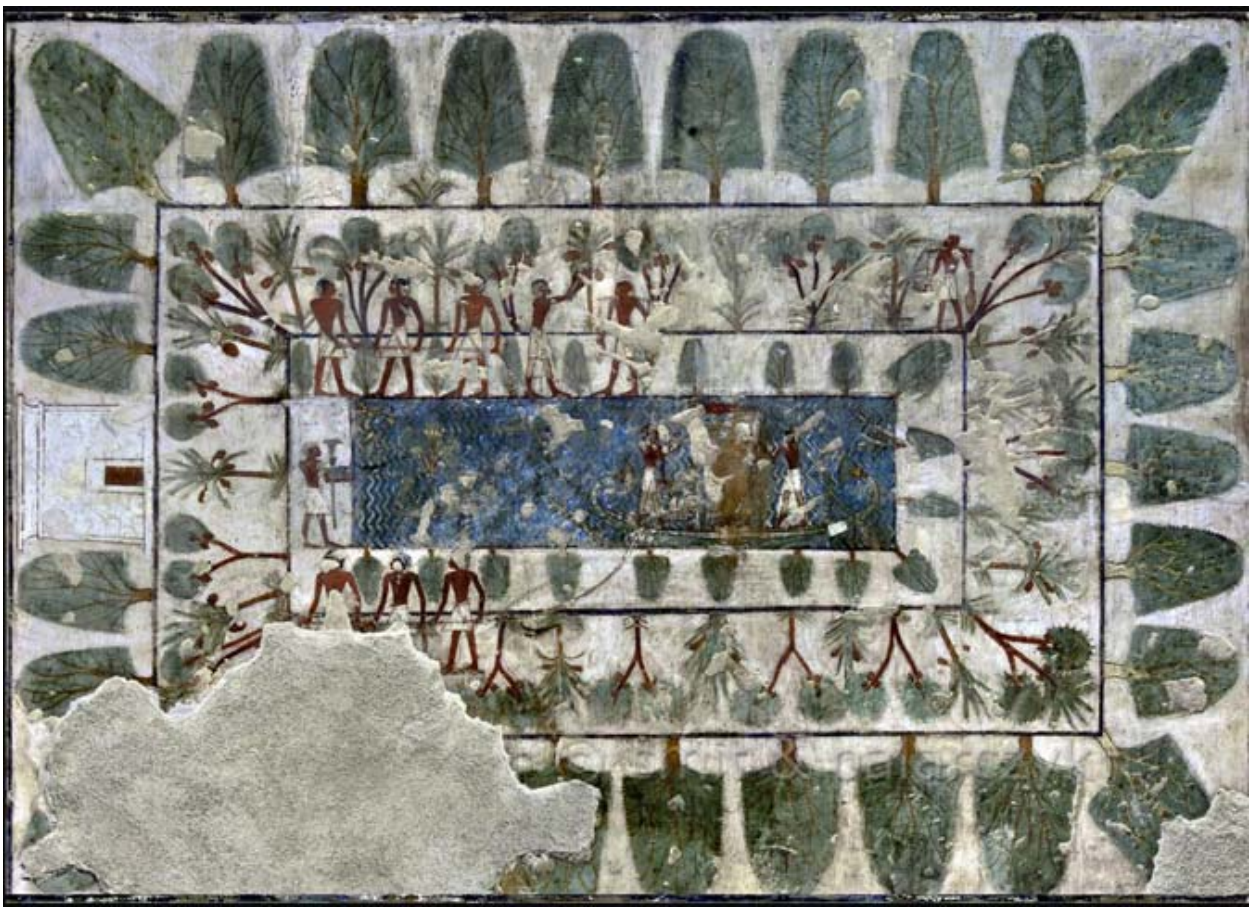

Figure 6: The garden of Rekhmire, an official of the 18th dynasty who served as Governor of the Town (Thebes) and Vizier during the reigns of Thutmosis III and Amenhotep II.

Figure 7: Henry Salt (1780–1827) was an English artist, traveler, collector of antiquities, diplomat and Egyptologist.

date palms and dom palms (3rd rectangle), then in the second rectangle other smaller sycamores. On the basis of aspective (as opposed to perspective), trees have been shown lying outwards. In the pool, covered with water plants, fish swim. A gardener is picking dates and two others bring water to irrigate trees. A boat is towed on the water by two groups of three haulers. Upon its middle stands the statue of the Vizier in an open chapel (this representation has been effaced). In front of the shrine, a priest makes a libation and censes, while behind, a priest laments with arms raised. On the left, on the bank, a man awaits the statue with a papyrus stem and bunches of onions.

Nebamun was a middle-ranking official scribe and grain accountant during the period of the New Kingdom in ancient Egypt. He is thought to have lived circa 1350 BC and worked at the vast temple complex near Thebes (now Luxor) where the state-god Amun was worshipped. His name was translated as “My Lord is Amun.”, and his association with the temple, coupled with the importance of grain supplies to Egypt, meant that he was a person of considerable practical importance, though not of the highest rank. He is known today because of the 1820 discovery of the richly-decorated Tomb of Nebamun on the west bank of the Nile at Thebes.

Henry Salt, the British Consul-General (Figure 7), had been encouraged to collect Egyptian relics by Sir Joseph Banks, a trustee of the British Museum at the time. From 1819, Salt’s agent was a young Greek, Giovanni (Yanni) d’Athanasi. It was during his excavations on Salt’s behalf that d’Athanasi would make his momentous discovery. D’Athanasi removed what he wanted from the Nebamun tomb simply by hacking and gouging fragments from the walls of the tomb. D’Athanasi’s workmen probably cut into the plaster surface of the walls with knives and saws, outlining rectangular pieces which they then pried off the walls with implements such as crowbars. Sometimes they removed the full depth of the mud plaster, but sometimes they carried away only a very thin layer and the edges inevitably suffered cracking and disintegration.”

Ten of the fragments taken by d’Athanasi were included in the first huge, batch of collections that Henry Salt sent back to the British Museum. After much haggling, the Museum settled for what Salt described as the “miserable sum” of £2,000, apparently not enough to even cover his expenditure s. After Salt died in 1827, d’Athanasi offered his services to the Museum in 1835 but fell out with the curators over his finder's fee and he refused to divulge the precise position of the tomb. After a failed venture as a picture dealer in London, d’Athanasi died in poverty in 1854, taking with him his knowledge of the site of the tomb.

Although the exact location of that tomb is now lost, a number of wall paintings from the tomb were acquired by the British Museum where they

Figure 8: Left - Nebamun hunting wild fowl from a skiff in marshland along the Nile. Right - a detail of the painting showing a pufferfish in the middle and one tilapia swimming into the scene and another swimming out.

are now on display. They are considered to be one of that museum's greatest treasures. These are works of art of the highest aesthetic quality. They were painted not by jobbing artisans but by true artists who made conscious aesthetic decisions, and were sometimes willing to break with the pictorial conventions of Egyptian art to achieve a surprising degree of naturalism. Archaeologists have no idea about the identity of the artist swho created them and are equally puzzled why painters of such talent were involved with a relatively minor clerk like Nebamun.

And so, in the scene where Nebamun is shown hunting wild fowl from a skiff in marshland along the Nile (Figure 8), the artist adheres to the conventions of Egyptian art by showing the accountant in profile and making him much bigger than the figures of his wife and young daughter who accompany him. But this artist goes further – he makes sure that Nebamun stands out by painting his flesh using impastoed (impasto is a technique used in painting, where paint is laid on an area of the surface very thickly, usually thickly enough that the brush or painting-knife strokes are visible) white under paint covered with a layer of red. Seen within the dark interior of the chapel, the figure would have appeared to glow.

The paintings were intended to provide a link between Nebamun's life and the way in which he would have wished to be commemorated by his family in death (the afterlife). Friends and family would have visited the painted upper part of the tomb, contemplate the paintings, leave gifts and hold feasts to commemorate his life.

Figure 9: A detail of the pond in Nebamun's garden, showing a number of tilapia swimming about.

Nebamun's garden (Figure 10) in the afterlife is not unlike the earthly gardens of wealthy Egyptians. The pool is full of birds and fish, and surrounded by borders of flowers and shady rows of trees. The fruit trees include sycamore-figs (*Ficus sycomorus*) , date-palms and dom-palms - the dates are shown with different degrees of ripeness.

On the right of the pool a goddess leans out of a tree and offers fruit and drinks to Nebamun (now lost). The artists accidentally painted her skin red at first but then repainted it yellow, the correct color for a goddess' skin. On the left, a sycamore-fig tree speaks and greets Nebamun as the owner of the garden, its words are recorded in the hieroglyphs. The pool is shown from above, with three rows of trees arranged around its edges. The waves of the pool were painted with a darker blue pigment; much of this has been lost, like the green on the trees and bushes.

Artificially-constructed fishponds were known to the Egyptians long before the Romans and the piscatorial heyday of the First Century AD. Although they were not hobbyists (my definition of the hobby is "A subject or pursuit involving fishes, undertaken primarily for pleasure during one's leisure time and to which a person is notably devoted"), they were THE aquarists of Stage I of the hobby.

THE MAKING OF AN HISTORIAN

By Albert J. Klee, Ph.D.

(Aquarium Hobby Historical Society of America, Facebook Files, January 23, 2016)

My interest in aquarium hobby history started in the 1960's when I wondered why the only such history almost always involved goldfish. The goldfish is not the earliest known aquarium fish nor was it of paramount importance in the hobby except in its very early years. Thus I set out to do something to rectify the situation. One starts any historical research with documents (or so I thought at the time) and in the 1960's this consisted primarily of aquarium books and magazines. I also started to expand the collection of books and magazines that I already had. Back in those days there was little interest in collecting, so the acquisition of these materials was cheap, compared to what some of these items bring today.

Two publications were of great help to me in this regard: for books it was Bashford Dean's *A Bibliography of Fishes*, and for magazines it was the *Union List of Serials*, both rather weighty tomes (the latter must weigh somewhere between 10 and 15 pounds!). Although a small number of facsimile editions of books were available at the time, like Smith's *The Fishes of Siam*, in general I had to purchase them and since this is history we are talking about here these were used books. Local libraries were of limited use except for the Lloyd Library (sundry old aquarium books and *Aquatic Life*) and the one in the Cincinnati Historical Society (the *Cincinnati Gazette* and the *Deutscher Pioneer*, mostly for information about Hugo Mulertt).

The acquisition of aquarium magazines was a slow and expensive process, involving mostly microfilm from those libraries that offered this service. Although a few books were available on microfiche, these were expensive and I did not have a microfiche reader. However, microfilm was not a problem since I was also a photographer.

I started the history series in *Aquarium Illustrated* and it ran for ten issues, from January/February 1966 to July/August 1967, ending when I took over the editorship of *The Aquarium* magazine. In the December 1967 issue of *The Aquarium* I re-started the history again from scratch, and it continued for a total of 22 installments, ending in the September 1969 issue. The series has been cited many times over the years. In the late 1980's Ross Socolof approached me with a view to having the series published as a single volume to help fund the American Cichlid Association's Guy D. Jordan Endowment Fund. This I did, pro bono, and the book appeared in 1987, Lee and Aline Finley doing most of the hard work of putting it together for publication. Its subsequent sales of over $3,000 were a significant addition to the Jordan Fund.

However, I was extremely dissatisfied with the history. Historians study the past by interpreting evidence. They work by examining primary sources - texts, artifacts and other materials from the time period. From comparing these sources and evaluating them in context, the historian develops interpretations, often in light of the interpretations of other historians although the interpretative writings of historians - books, journal articles, encyclopedia entries - are considered useful secondary sources. However, if what I had done was historical scholarship, then

so was the gossip columns of the *National Enquirer*. All I did essentially was to compile material from books and magazines. There was no proper bibliography nor was there any attempt to comment on the significance of developments as the hobby progressed from its development in England - the point at which I started the history - to the start of World War II - the point at which I ended it.

The process of historical analysis involves investigation and analysis of competing ideas, facts and purported facts to create coherent narratives that explain "what happened" and "why or how it happened." Thus I decided to rectify the situation by doing a lot of reading on what constituted historical research and starting over once again. One of the most interesting of the books I read was *The Historian as Detective, Essays on Evidence* (Winks, 1968).

This time, technology helped a great deal. In 1979 I built my first digital computer, a Heathkit H89 (from that year onward I have never bought a desktop computer; I build them myself), and in 1992 I had the first version of Photoshop (version 2.5) running on my home PC. Shortly afterwards I had added both a flatbed and a slide scanner to my equipment. Of course the biggest advance was the beginning of the World Wide Web, which made searches for material an order of magnitude easier, as well as providing digital copies of material otherwise difficult for me to obtain. Thus, with these technological advances in hand was born *The Toy Fish*.

The title I used, "The Toy Fish," was a term introduced into the hobby by Ida May Mellen in 1931. Some years before I started writing the book, Dr. James W. Atz, a good friend and distinguished former Curator and Dean Bibliographer in the Department of Ichthyology at the American Museum of Natural History, planned to write such an account himself. However, "The best laid schemes o' mice and men…" and Jim never did get around to it. Unknown to me at the time, he also had intended to use the title. Two minds with the thought!

By the year 2000, what I thought of as the Second Edition of *The Toy Fish* (I thought of the First Edition as being the series in *The Aquarium*) was almost completed but I had no publisher in mind. While attending the American Killifish Association Convention that year, several people asked me whether I was going to publish a new edition of my history. After thinking about it, I decided I would offer this Second Edition to the AKA in the way the First Edition was offered to the American Cichlid Association. However, there was a big difference between the First and Second editions as many more pages of text as well as illustrations had been added, making the publication cost much higher this time around. Lee Finley approached me and asked if I would be interested in writing a new edition. Lee had just published Jerry Ryan's *The Forgotten Aquariums of Boston* and was looking for his next book to publish. This was the perfect solution and since the Chairman of the AKA had not yet presented my proposal before the AKA Board of Trustees, the discussion with the AKA was closed on an amiable basis.

One of the pieces of software I thought I never would get involved with was desktop publishing. However, my wife was on the Board of Trustees of the Home Owner's Association of Lake Lorelei, Ohio and she wanted to publish an independent newsletter. She enlisted the help of a friend who had Microsoft Publisher, which she used for publishing fliers, but the requirements of the program for a bimonthly 36-page publication with many photos exceeded the capacity of her computer (it was painfully slow). My and my wife's computers were, on the other hand, state of the art and so I reluctantly agreed to get involved.

Mastering Publisher quickly turned out to be no problem. The text was prepared in Word (Publisher is a formatting program, not a text editor) and the illustrations in Photoshop. My wife did some of the photography and I did the rest. I am a fair graphics artist so I did the artwork and prepared all the advertising layouts.

The output was be printed by offset lithography, so I had to install a Postscript printer driver in Publisher to rasterize the images and produce the hardcopy on a laser printer. Photographs in Publisher cannot be printed out on a laser printer using the normal printer driver. They must rasterized or made into halftones - i.e., made up of black dots. This hardcopy was then photographed by the printer to make the negative plates for printing.

There always was a problem in getting the hardcopy right because of technical hurdles such as "dot gain," the spreading of the black ink dots that reduced the resolution and contrast of the images. I prepared the Second Edition of *The Toy Fish* in the same way and we ran into the same problems in producing acceptable halftones for Lee's lithographer. I can't remember the number of times the printer ran off galley sheets of the halftones for my and Lee's inspection, but it was many. Lee, by the way, wanted it named the "Revised and expanded Edition," and I had no problem with that at the time since it suggested correctly that more significant improvements were in store than just a version upgrade.

Lee and I have had discussions over the years about whether offset printing was the best way to go and we feel now that we should have investigated in more detail the POD (Print on Demand. i.e., a Xerox copy) process. The cost would have been almost double, but the process is easier and produces better output since the images are not halftones. Also, one produces only that number of books that you can sell; there are no remanded copies. To go POD one produces a pdf copy, which any office supply store can print (or you can print it at home). It is constructed from a Publisher file but does not involve a Postscript (ugh!) driver. This is the way Lee and I produced the smaller books he published later such as *The Guppy* and *The History of Aquarium Inventions*. All I had to do was to print the Publisher file to a pdf file (I used Adobe Acrobat) and turn it over to him. Later on I did the same for the Third Edition of *The Toy Fish* and sundry smaller books I wrote and published about the hobby.

One of the major problems I had in writing aquarium hobby history was in the matter of definitions. In the Second Edition of *The Toy Fish* I stated:

There is also, alas, a problem with precisely what is meant by the word, "hobby." Consider the following dictionary definitions: "A subject or pursuit of absorbing interest, undertaken primarily for pleasure during one's leisure time," "An individual pursuit to which a person is unduly devoted," and "A favorite occupation or topic, pursued for amusement." The first two definitions require a stricter criterion, i.e., absorbing interest or undue devotion; the third is much less demanding. None, however, specify the number or kind of tanks a person must maintain before it becomes a hobby, nor is there any standard scale available to us by which we can measure the degree of "absorbing interest" or "undue devotion." Even if such a scale existed, it would be hopeless to attempt to apply it to aquarists who lived a century or two ago. We may ask ourselves whether Anna Thynne was a hobbyist, or A.A. Ma-

conochie, or some unknown American who maintained several jars of native fishes during the Presidency of Andrew Jackson, but the answers are in no way clear.

I stewed over the definition and finally found a way out when I observed that the hobby had progressed in four clearly different stages. I gave each a name and the result was that I had sidestepped the knotty problem of a succinct definition. This made much more sense since the hobby was clearly a different hobby in each of the four stages. To this day, the paradigm still works. The four stages concept was presented to the *Aquarium Hobby Historical Society of America* in 2005 and was included in the Third Edition of *The Toy Fish* published in 2009.

However, at certain times a formal definition is needed. One instance is when deciding who or what was "first," such as when I stated in the Fourth Edition of *The Toy Fish* that the Romans were the first hobbyists. The definition I used for the aquarium hobby there was: "A subject or pursuit involving fishes, undertaken primarily for pleasure during one's leisure time and to which a person is notably devoted." When you define something, one may not always agree with you but at least they know exactly what the elements in dispute are.

Not all definitions are that easy, however. I wrote about the problem of determining who was first in my 2012 essay, "Who Invented the Aquarium?" In Great Britain in the early 1850's the de facto definition of an aquarium was a vessel containing water and plants, plus aquatic animals (excluding, of course, mammals and water fowl) in which the water was not aerated or changed. Note that fish were not necessarily included. Implicit in this definition was that the basis for the aquarium was the relationship that the plants absorbed the carbon dioxide that the aquatic animals generated whilst the animals absorbed the oxygen that the plants generated.

With these requirements as part of the set of criteria, I then added one additional criterion, that of priority of publication. Next, since fish were never a strict requirement, I decided to define four "firsts," not just one: (1) the freshwater aquarium sans fishes, (2) the freshwater aquarium with fishes, (3) the marine aquarium without fishes and (4) the marine aquarium with fishes. If, however, I added another criterion, that of the impact on the aquarium hobby in the Nineteenth Century, then the firsts for the freshwater aquarium and the marine aquarium change. The point here is that naming firsts is not always an easy endeavor and definitions are absolutely required to avoid misunderstandings.

The definition of "aquarium" was the subject of detailed analyses through the years by such renowned and respected figures as William Alford Lloyd (1876), Philip F. Rehbock (1980) and Stephen Jay Gould (1998). Both Rehbock and Gould relied greatly upon the so-called principle of the balanced aquarium for their definition of the word. Rehbock argued that the true aquarium is one that remains in a healthy state without requiring any renewal of the water, fresh or salt. Gould argued that the fish bowl is not an aquarium because it lacks the following defining feature: a *stable community* of aquatic organisms. Lloyd did not use the balanced aquarium principle for his definition since he argued that when one changed the water in an aquarium the polluted water went into the sewers and ultimately returned to the ocean where it was purified by natural means. In other words, keeping fish in a container devoid of plants is part of a cycle that did keep the oxygen and carbon dioxide in balance; it just didn't require that the purification took place in the aquarium.

However, trying to find a definition for the word "aquarium" is tantamount to an exercise in reinventing the wheel. An aquarium is a Latin word for a something that holds water, regardless of what is in it. Cato was the first author of record to use the word aquarium. Examples from his *De Agricultura*, written about 160 BC, include the following: situlum aquarium ("water bucket"), urceum aquarium ("water vessel") and bonumque aquarium ("well-watered"). Note, however, that aquarium here did NOT mean a container of water but water used as a modifier. Over the years, from Pliny the Elder, 77-79 AD, to Reisinger, 1830 and beyond, the word aquarium was used simply as a synonym for "water," as in *aquarium dulcium*, a phrase that meant fresh water.

I was unable to find any examples where the Romans used aquarium or its orthographic cousins in the sense of a container; however, it was frequently used to mean a watering place for cattle. Some have suggested that the Romans used the term to mean a water trough for cattle but this idea most likely came about through a mistranslation of the original Latin texts. (A detailed account of how the Romans used the word and its relatives can be found in my 2015 essay "A Few Words on the Origin of the Word 'Aquarium'.")

The word aquarium came to the aquarium hobby via the botanical community; John Loudon used the term in his 1824 *Encyclopaedia of Gardening* for various artificial ponds and greenhouses and suggested that fish might be added to them. However, the term goes back to Carl Linnaeus. Linnaeus was a big fan of the Latin language and was quite familiar with the term used by the Romans to describe a cattle watering place. Perhaps he thought that by analogy it was perfectly logical to use the term for a place to water aquatic plants. In any event, in his 1742 prologue to his *Hortus Upsaliensis*, Linnaeus defined the following terms under the heading of "Aquaria:" (1) Aquarium fluviatile, (2) Aquarium lacustre and (3) Aquarium palustre), denoting respectively a river pond aquarium, lake pond aquarium and marsh pond aquarium. Later horticulturists broadened the term to include the troughs in greenhouses that contained water for the growth of aquatic plants. Linnaeus did not have tanks in mind when he used the term, just small ponds. Future horticulturists modified the meaning of aquarium to include artificial vessels as well.

When Gosse introduced the term in 1854 for the container that housed fish and aquatic plants he referred to this use by horticulturists:

I have adopted the word Aquarium, as being free from the objections which lie against the other two [i.e., Vivarium and Aqua-Vivarium], while it possesses the neatness of the former, and the definiteness of the latter. The term had already been in use among the botanists, to designate the tanks in which aquatic plants were reared; and the employment of the same term for our tanks is not forbidden by the character of the service to which they are put, since this is not an alteration, but only an extension.

Thus, an aquarium is simply the container in which we keep our fishes. Thus, the Egyptians were our first aquarists (but not our first hobbyists). In fact, anyone who keeps even a single goldfish in jar whose water is changed at intervals is an aquarist.

Having solved the hurdle of definitions, after five years of additional research and writing I finally completed the third edition of *The Toy Fish*. That this was a significant expansion is shown by the following table:

	SECOND EDITION	THIRD EDITION
WORDS	75,062	163,248
ILLUSTRATIONS	242	514
BIBLIOGRAPHIC ENTRIES	119	319
PAGES	204	391
CHAPTERS	24	27
ADDENDA ENTRIES	5	9
INDEX ENTRIES	463	618

As can be seen, the number of words and illustrations had more than doubled, the increases being almost entirely due to additions and not merely changes or alterations. Many of the new illustrations were of noted figures in the history such as Henry Dennison Butler, William Emerson Damon, Shirley Hibberd, Joseph Winn Fiske, Henry Bishop, Gustav Armbruster, Otto Gneiding, Raymond Potts and many others.

New chapters had been added and others expanded. Much new material relating to Dr. Robert Wilson Shufeldt, Ida Mellen, Christopher Coates and William Alford Lloyd were also added, as well as that relating to other major personalities. Additionally, many aspects of the hobby that were mentioned only in passing in the Second Edition were expanded in this one.

A significant new inclusion was a lengthy preface that placed the early development of the aquarium hobby in this country in a new perspective, including women's issues, how and by whom aquarium fishes and equipment were marketed, the effect of changing technologies, and the impact upon the hobby of varying economic factors between 1870 and 1938.

A major addition was a detailed history of aquarium glass from the Romans to the present day, a history for which curators at the major glass museums were unable to provide any significant input and for which I had to seek help elsewhere. Another major addition dealt in detail with a rigorous scientific method, based upon mass transfer and absorption coefficients and previously unknown to the aquarium hobby, for determining the number of fish that populate an aquarium of given dimensions, various aeration conditions and different types of fish. Although the sample calculations I showed provided new evidence for the reasons behind the success of Victorian aquarists, the formulas, tables, and graphs provided enabled aquarists to do their own calculations for present-day purposes. In 2009 I decided to produce a very limited number of copies of this Third Edition via POD and offered them at cost to members of the *Aquarium Hobby Historical Society of America*; about 60 were sold.

I had intended that the Third Edition of *The Toy Fish* would be the last edition but certain assertions had been made in print and on the Internet concerning the Romans that had to be refuted. It was necessary to remove the material on the Romans from the history of glass - excepting the Roman glass history - and devise a new section devoted to them. Except for this, only minor additions were made in this edition and my resolve to do no more editions finally was put into effect. The Fourth Edition was offered to the *Aquarium Hobby Historical Society of America* in digital form (pdf) only and there will be no further editions.

During my time with the Yahoo *Aquarium Hobby Historical Society of America* group I started to worry about the loss of important historical material in some of my posts and in my uploaded files (for others, that is, since all my materials are well backed-up) should Yahoo fail. Thus I collected what I had written to date and started a new book called *A Compendium of Aquarium Hobby History Society Articles* (although it contained a few that had not been published there) and in 2012, when it stood at

223 pages, I offered it on digital form (pdf) to members of the Society. In 2015 I changed the name to *Essays on Aquarium Hobby History*, following Steven Jay Gould's lead in referring to his monographs as essays. Adding material to books already published without redoing their format is difficult; writing an essay where one doesn't have to worry about where it is placed it in a book takes a great load off an author if he is also the publisher. The essays book has allowed me to write about aquarium hobby history as the spirit moves me, without worrying about how it gets published.

I prefer my work to appear in the pdf format (although I occasionally just use Word) for two reasons (1) Anyone can read them since pdf readers are free and easily available, and (2) the format has a search function enabling one to find anything quickly, including even text in captions to images. With services like DropBox, even large volumes such as the essay book can be distributed quickly and easily to select audiences. Some people still prefer hard copy, but there is no restriction on anyone printing their own by going with the POD process; with a pdf copy then, one gets the best of both worlds.

ADDENDUM

Several times over the years my friends have tried to persuade me to write something about the history of the aquarium hobby after the end of World War II. However, it should be noted that I had dropped out of the aquarium hobby - publically, not privately - after my tenure as Editor of *The Aquarium* ended in December 1971 in order to pursue my doctorate and I did not resume my public persona until I joined the *Aquarium Hobby Historical Society of America* Yahoo group in 2003.

The problem for me in writing about aquarium history after World War II but prior to 1972 is that I was part of that history and my objectivity could easily be challenged. It doesn't make any sense for me to write about aquarium history after 1972 either - especially with history that deals with personages of that time - since there are many people alive who are better equipped to write about it. Because I live in the Cincinnati area, which is not noted as being a significant aquarium hobby center, the number of face-to-face acquaintances I had during this time period was limited. Finally, as this essay has shown, my interest in the history of the aquarium hobby has lain primarily elsewhere, not in the period after World War II, although I have written sundry history that did include material after that date.

SUMER: THE HOME OF THE FIRST AQUARIUM?

by Albert J. Klee, Ph.D.

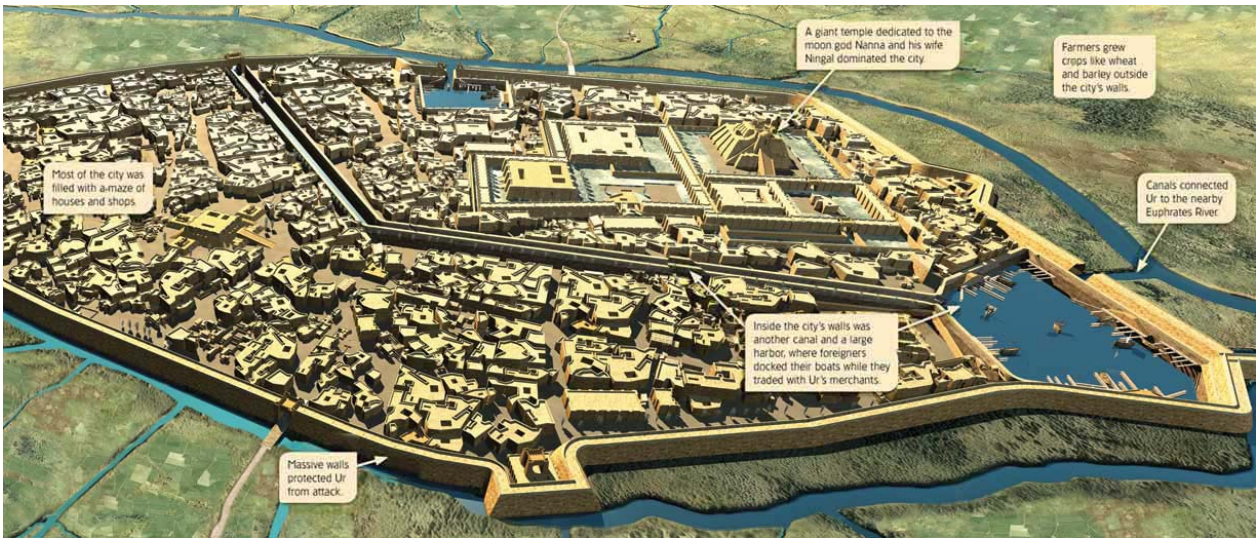
(Aquarium Hobby Historical Society of America, Facebook Files, March 13, 2016)

Sumer was the southernmost region of ancient Mesopotamia (modern-day Iraq and Kuwait) which is generally considered the cradle of civilization. In the biblical Book of Genesis Sumer is known as Shinar. According to the Sumerian King List, when the gods first gave human beings the gifts necessary for cultivating society, they did so by establishing the city of Eridu in the region of Sumer. While the Sumerian city of Uruk is held to be the oldest city in the world, the ancient Mesopotamians believed that it was Eridu and that it was here that order was established and civilization began.

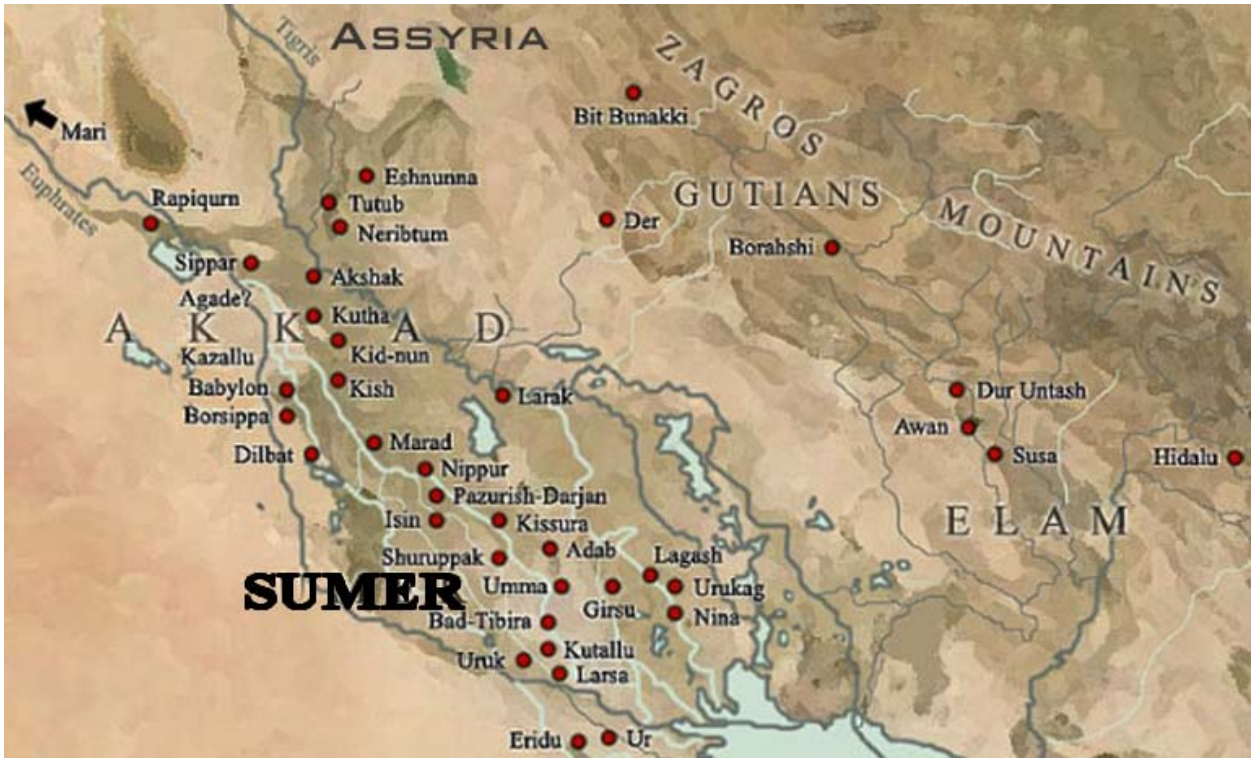
The region of Sumer was long thought to have been first inhabited around 4500 BCE. This date has been contested in recent years, however, and it now thought that human activity in the area began much earlier. The first settlers were not Sumerians but a people of unknown origin. Whoever these people were, they had already moved from a hunter-gatherer society to an agrarian one prior to 5000 BC.

Whenever the Sumerian civilization was first established in the region, by 3600 BCE they had invented the wheel, writing, the sailboat, agricultural processes such as irrigation and the concept of the city (though China and India also lay claim to `the first cities' in the world). It is generally accepted that the first cities in the world rose in Sumer and, among the most important, were Eridu, Uruk, Ur, Larsa, Isin, Adab, Kullah, Lagash, Nippur and Kish. The city of Uruk is held to be the first true city in the world. It has been noted that these places were founded, at least as villages, much earlier than c. 5000 BCE.

The last period in Sumerian history - 2047-1750 BC - is known as The Sumerian Renaissance due to the remarkable advances in culture – touching upon virtually every single aspect of civilized human life – which were made. The kings of Ur, Ur-Nammu and Shulgi, set cultural advancement as the goal of their administrations and maintained a peace which allowed for art and technology to flourish. Whether invented before or during this period, the tools, concepts, and technological innovations in place during that time solidified the Sumerian's place in history as the creators of civilization as we know it. Among the 'firsts' in history from the region are the first schools, the first proverbs and sayings, the first messiahs, the first Noah and the Flood stories, the first love song, the first legal precedents in court cases, the first tale of a dying and resurrected god,



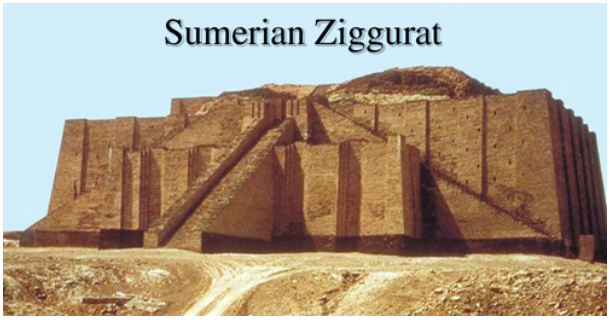
A schematic of the Sumarian city of Ur.



the first funeral chants, first biblical parallels, the first moral ideas and, of greatest interest to us here, the first aquarium.

Although a wall was constructed 155 miles long to keep those they called `the barbarians' out of Sumer proper, the barrier proved ineffective. The wall could not be properly manned or maintained and, further, was not anchored to any solid barrier at the end points and so invaders could simply follow the wall on the one side to either end point and then walk around it. The forces of neighboring Elam breached the wall and marched on Ur, sacking it and carrying away the king c. 1750 BC. With the fall of Ur a severe famine resulting from climate change and the over-use of the land caused many to migrate for points south. Among these, it is thought, was Abraham, who left Ur to settle in the land of Canaan. Abraham was the first of the three biblical patriarchs and his story, told in chapters 11 through 25 of the Book of Genesis, plays a prominent role as an example of faith in Judaism, Christianity, and Islam.

Cuneiform Sumarian script



Zigguratu, an Assyrian word, means "height."

In the animal world, the Sumerians had a deep, tender, affection for the fish, the helpless creature that often evoked tragic images in the minds of the poets, especially those who composed lamentation liturgies. Miguel Civil (Miquel Civil i Desveus) is an expert in Sumerian and Ancient Mesopotamian studies and is widely considered the world expert in the use of the cuneiform script to write down the Sumerian language. In a poem translated by Civil (1961) and designated by him as "The Home of the Fish," the anonymous author depicts the construction of a home for the fish, a kind of well-furnished and abundantly provided aquarium, where all sorts of fish could live in undisturbed peace, safe from preying birds and predator sharks.

The text consists of an address purported to be uttered by some individual who for one reason or another was an ardent lover of fish. It begins with a reassuring announcement that the speaker has built a house for the fish, large, spacious, and unapproachable, and provided it with fine food and drink, especially beer and sweet cookies.

"My Fish, a house…..
My Fish I have built a house for you, I have built a granary for you,
In the house an extra court, an extended sheepfold, I have built for you,
Its center I have covered with incense, I have dug (?) a well of jubilation, a place that rejoices the heart,
No one can approach your closely threaded (?) house, I have bedecked (?) it with plants,
In the house there is food, food of top quality,
In the house there is drink, drink of well being,
In your house, no flies swarm (?) about the liquor bar,

The Abgal are seven Sumerian demigods said to have been created by the god Enki to give civilization to mankind. They served as priests of Enki and as advisors or sages to the earliest "kings" or rulers of Sumeria before the flood. They are credited with giving mankind the moral code, the crafts, and the arts. They were seen as fish-like men who emerged from the sweet water Apsu. In the form called the puradu-fish (carp?) they are commonly represented as having the lower torso of a fish, or dressed as a fish, . They have also been depicted with wings, having either a human head or an eagle's head. All three forms are shown here.

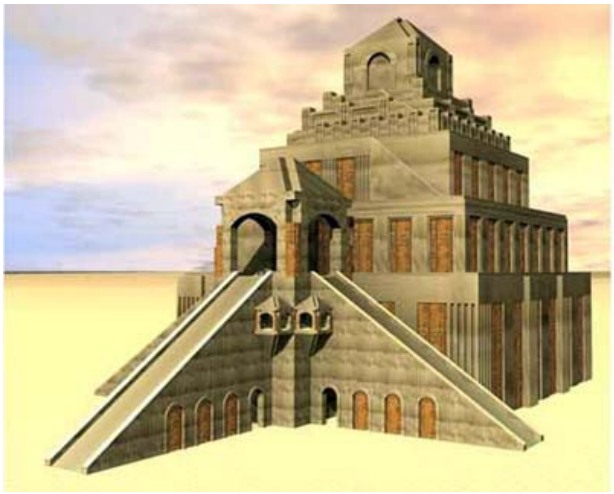
In your entrance (?) no complainer sets an inimical foot.
At its threshold and bolt where flour is sprinkled, I have set up the censer,
The house smells sweet like a forest of sweet smelling cedar,
By the house I have placed beer, I have placed fine quality beer,
I have placed there honeybeer and sweet cookies as…"

The speaker now urges the Fish to let all his friends, acquaintances, companions, relatives, in fact anyone who so wishes, come into his house.

"Let your acquaintances come,
Let your dear ones come,
Let your father and grandfather come,
Let your son of the elder brother and son of your younger brother come,
Let your little ones and your big ones come,
Let your wife and your children come,
Let your friends and your companions come,
Let your brother-in-law and your father-in-law come,
Let your crowd (whoever says) I, too, would enter, come,
Let none of your neighbors be left out."

But it is his *Fish*, his "beloved son," that the speaker is primarily concerned with, and so he addresses him saying,

"Enter my beloved son,
Enter my goodly son,
Day is passing, night is coming,
Enter by the light of the moon.
When the day will have passed, the night will have come,
Having entered, you will be at rest there, I have fitted out a place for you there,
In its midst I have arranged a 'seat' for you,
My Fish, when lying no one will disturb you,
When sitting, no one will start a quarrel with you.
Enter my beloved son,
Enter my goodly son.
Like (in?) a brackish canal you will not 'know' agitation (?),
Like (in?) river silt you will not 'know' disturbance,
Like (in?) flowing water do not spread, do not (yet) spread your bed,
Although the moonlight has entered, do not (yet) spread your bed,
I would come with you that I might gaze in wonder,
Like a . . I would come with you that I might gaze in wonder,
Like a dog I would come with you to your sniffing place that I might gaze in wonder,
Like a . . I would come to where you 'stand,' that I might gaze in wonder.
Lo! Like an ox to your stall, like a sheep to your fold!
When you enter like an ox to your stall,
My Fish, Ashimbabbar (the god of the New Moon) will rejoice with you.
When you enter like a sheep to your fold,
My Fish, Dumuzi will rejoice with you."



Another Sumarian Ziggurat.

Following a lacuna of about fifteen lines we find the speaker saying,

"My Fish, may all kinds of fish enter with you," a statement that introduces an itemized listing of some sixteen different fish, each described with a brief, pithy, riddle-like comment; those that can be identified with some degree of certainty are the barbel, large and small, the carp, the sturgeon, the catfish and the eel. The speaker now makes an urgent plea to the Fish to come quickly to his newly built home, for the day has passed and danger is lurking all about him from the fish-eating birds and the sharks, concluding with these words:

**"My Fish, the day has passed, come to me,
The day (?) has passed, come to me,
The queen of the fishermen, the goddess Nanše, will rejoice with you."**

According to Civil,

"The poem is a monologue by a deity, in all probability Nanše who, as "mother of the fish," has built a new house for them, and invites all of them to come and spend the night there, where they will find a comfortable place of rest and will be safe and secure from all the animals which usually prey on them. It is always difficult to place works of Mesopotamian literature in the categories devised by classical rhetoricians. The anthropomorphic descriptions place our composition close to the fable, but it cannot be considered as such, because the classical definition of a fable always includes some kind of action, and no action at all is involved in our text. In some other respects we may consider our poem as lyrical: it is based on the author's sentiments evoked by the multiple aspects of aquatic life, and on the emotional appeal of a "sweet home." Other secondary themes interwoven with this are the "naming of the fish"—to be compared perhaps with Adam naming all living creatures in the Garden of Eden or, more probably, it is simply a display of erudition—and the attempt to explain how water birds prey on fish, in spite of the fact that both of them are under Nanše's protection."

It should be noted that Fishing and the fishing industry were a major source of Sumer's food supply, especially in the earlier millennia of its history. Close to a hundred different types of fish are mentioned in the Sumerian economic and lexical texts, of which some thirty-odd can now be tentatively identified according to the Finnish Orientalist, Armas Salonen (Salonen, 1970). In the extant text of the "Home of the Fish," sixteen are named and described in terse, pithy phraseology, and of these a half dozen or so can be roughly identified. Marie-Louis Thomsen, the author of *The Sumerian Language, An Introduction to*

Ancient Lagash in Sumer.

Its History and Grammatical Structure (it has become the standard grammar of Sumerian) provided a different interpretation of the poem (Thomsen, 1975):

"In brief, we may summarize the whole text as an address to the fish, inviting them to spend the night in a certain house. So far we may take it at face value, but certain questions have to be raised. First, who is the speaker of this monologue? In view of the fact that Nanše is mentioned in the third person in the concluding line, she would seem to be excluded. We could then suggest that it is a fisherman, and this would explain, too, the explicit mention of Nanše as the queen of the fishermen here.
